Part I

User’s Guide
CHAPTER ONE

INSTALLING

Note: If you wish to contribute to the project, it’s recommended you install the latest development version.

Contents

• Installing
  • Installing an official release
    * Test data
  • Third-party distributions of Matplotlib
    * Scientific Python Distributions
    * Linux: using your package manager
  • Installing from source
    * Dependencies
    * Building on Linux
    * Building on macOS
    * Building on Windows
      • Wheel builds using conda packages
      • Conda packages

1.1 Installing an official release

Matplotlib and its dependencies are available as wheel packages for macOS, Windows and Linux distributions:

```
python -m pip install -U pip
python -m pip install -U matplotlib
```

Note: The following backends work out of the box: Agg, ps, pdf, svg and TkAgg.
For support of other GUI frameworks, LaTeX rendering, saving animations and a larger selection of file formats, you may need to install additional dependencies.

Although not required, we suggest also installing IPython for interactive use. To easily install a complete Scientific Python stack, see Scientific Python Distributions below.

1.1.1 Test data

The wheels (*.whl) on the PyPI download page do not contain test data or example code.

If you want to try the many demos that come in the Matplotlib source distribution, download the *.tar.gz file and look in the examples subdirectory.

To run the test suite:

- extract the lib/matplotlib/tests or lib/mpl_toolkits/tests directories from the source distribution;
- install test dependencies: pytest, Pillow, MiKTeX, GhostScript, ffmpeg, avconv, ImageMagick, and Inkscape;
- run python -mpytest.

1.2 Third-party distributions of Matplotlib

1.2.1 Scientific Python Distributions

Anaconda and Canopy and ActiveState are excellent choices that “just work” out of the box for Windows, macOS and common Linux platforms. WinPython is an option for Windows users. All of these distributions include Matplotlib and lots of other useful (data) science tools.

1.2.2 Linux: using your package manager

If you are on Linux, you might prefer to use your package manager. Matplotlib is packaged for almost every major Linux distribution.

- Debian / Ubuntu: sudo apt-get install python3-matplotlib
- Fedora: sudo dnf install python3-matplotlib
- Red Hat: sudo yum install python3-matplotlib
- Arch: sudo pacman -S python-matplotlib

1.3 Installing from source

If you are interested in contributing to Matplotlib development, running the latest source code, or just like to build everything yourself, it is not difficult to build Matplotlib from source. Grab the latest tar.gz release file from the PyPI files page, or if you want to develop Matplotlib or just need the latest bugfixed version, grab the latest git version, and see Install from source.
The standard environment variables `CC`, `CXX`, `PKG_CONFIG` are respected. This means you can set them if your toolchain is prefixed. This may be used for cross compiling.

```bash
export CC=x86_64-pc-linux-gnu-gcc
export CXX=x86_64-pc-linux-gnu-g++
export PKG_CONFIG=x86_64-pc-linux-gnu-pkg-config
```

Once you have satisfied the requirements detailed below (mainly Python, NumPy, libpng and FreeType), you can build Matplotlib.

```bash
cd matplotlib
python -mpip install .
```

We provide a `setup.cfg` file which you can use to customize the build process. For example, which default backend to use, whether some of the optional libraries that Matplotlib ships with are installed, and so on. This file will be particularly useful to those packaging Matplotlib.

If you have installed prerequisites to nonstandard places and need to inform Matplotlib where they are, edit `setupext.py` and add the base dirs to the `basedir` dictionary entry for your `sys.platform`; e.g., if the header of some required library is in `/some/path/include/someheader.h`, put `/some/path` in the `basedir` list for your platform.

### 1.3.1 Dependencies

Matplotlib requires the following dependencies:

- **Python** (>= 3.6)
- **FreeType** (>= 2.3)
- **libpng** (>= 1.2)
- **NumPy** (>= 1.11)
- **setuptools**
- **cycler** (>= 0.10.0)
- **dateutil** (>= 2.1)
- **kiwisolver** (>= 1.0.0)
- **pyparsing**

Optionally, you can also install a number of packages to enable better user interface toolkits. See *What is a backend?* for more details on the optional Matplotlib backends and the capabilities they provide.

- **tk** (>= 8.3, != 8.6.0 or 8.6.1): for the Tk-based backends;
- **PyQt4** (>= 4.6) or **PySide** (>= 1.0.3): for the Qt4-based backends;
- **PyQt5**: for the Qt5-based backends;
- **PyGObject**: for the GTK3-based backends;
- **wxpython** (>= 4): for the WX-based backends;
- **cairocffi** (>= 0.8) or **pycairo**: for the cairo-based backends;
- **Tornado**: for the WebAgg backend;
For better support of animation output format and image file formats, LaTeX, etc., you can install the following:

- **ffmpeg/avconv**: for saving movies;
- **ImageMagick**: for saving animated gifs;
- **Pillow** (>= 3.4): for a larger selection of image file formats: JPEG, BMP, and TIFF image files;
- **LaTeX** and **GhostScript** (>=9.0): for rendering text with LaTeX.

**Note:** Matplotlib depends on non-Python libraries.

On Linux and OSX, **pkg-config** can be used to find required non-Python libraries and thus make the install go more smoothly if the libraries and headers are not in the expected locations.

If not using pkg-config (in particular on Windows), you may need to set the include path (to the FreeType, libpng, and zlib headers) and link path (to the FreeType, libpng, and zlib libraries) explicitly, if they are not in standard locations. This can be done using standard environment variables – on Linux and OSX:

```bash
export CFLAGS='-I/directory/containing/ft2build.h ...'
export LDFLAGS='-L/directory/containing/libfreetype.so ...'
```

and on Windows:

```bash
set CL=/IC:\directory\containing\ft2build.h 
set LINK=/LIBPATH:C:\directory\containing\freetype.lib 
```

where ... means “also give, in the same format, the directories containing `png.h` and `zlib.h` for the include path, and for `libpng.so`/`png.lib` and `libz.so`/`z.lib` for the link path.”

**Note:** The following libraries are shipped with Matplotlib:

- **Agg**: the Anti-Grain Geometry C++ rendering engine;
- **qhull**: to compute Delaunay triangulation;
- **ttconv**: a TrueType font utility.

### 1.3.2 Building on Linux

It is easiest to use your system package manager to install the dependencies.

If you are on Debian/Ubuntu, you can get all the dependencies required to build Matplotlib with:

```bash
sudo apt-get build-dep python-matplotlib
```

If you are on Fedora, you can get all the dependencies required to build Matplotlib with:

```bash
sudo dnf builddep python-matplotlib
```

If you are on RedHat, you can get all the dependencies required to build Matplotlib by first installing `yum-builddep` and then running:
These commands do not build Matplotlib, but instead get and install the build dependencies, which will make building from source easier.

### 1.3.3 Building on macOS

The build situation on macOS is complicated by the various places one can get the libpng and FreeType requirements (MacPorts, Fink, /usr/X11R6), the different architectures (e.g., x86, ppc, universal), and the different macOS versions (e.g., 10.4 and 10.5). We recommend that you build the way we do for the macOS release: get the source from the tarball or the git repository and install the required dependencies through a third-party package manager. Two widely used package managers are Homebrew, and MacPorts. The following example illustrates how to install libpng and FreeType using brew:

```bash
brew install libpng freetype pkg-config
```

If you are using MacPorts, execute the following instead:

```bash
port install libpng freetype pkgconfig
```

After installing the above requirements, install Matplotlib from source by executing:

```bash
python -m pip install .
```

Note that your environment is somewhat important. Some conda users have found that, to run the tests, their PYTHONPATH must include /path/to/anaconda/.../site-packages and their DYLD_FALLBACK_LIBRARY_PATH must include /path/to/anaconda/lib.

### 1.3.4 Building on Windows

The Python shipped from [https://www.python.org](https://www.python.org) is compiled with Visual Studio 2015 for 3.5+. Python extensions should be compiled with the same compiler, see e.g. [https://packaging.python.org/guides/packaging-binary-extensions/#setting-up-a-build-environment-on-windows](https://packaging.python.org/guides/packaging-binary-extensions/#setting-up-a-build-environment-on-windows) for how to set up a build environment.

Since there is no canonical Windows package manager, the methods for building FreeType, zlib, and libpng from source code are documented as a build script at [matplotlib-winbuild](https://matplotlib-winbuild).

There are a few possibilities to build Matplotlib on Windows:

- Wheels via [matplotlib-winbuild](https://matplotlib-winbuild)
- Wheels by using conda packages (see below)
- Conda packages (see below)

**Wheel builds using conda packages**

This is a wheel build, but we use conda packages to get all the requirements. The binary requirements (png, FreeType,...) are statically linked and therefore not needed during the wheel install.
Set up the conda environment. Note, if you want a qt backend, add `pyqt` to the list of conda packages.

```
conda create -n "matplotlib_build" python=3.7 numpy python-dateutil pyparsing tornado
cycler tk libpng zlib freetype msinttypes
conda activate matplotlib_build
```

For building, call the script `build_alllocal.cmd` in the root folder of the repository:

```
build_alllocal.cmd
```

**Cconda packages**

The conda packaging scripts for Matplotlib are available at https://github.com/conda-forge/matplotlib-feedstock.
This page contains more in-depth guides for using Matplotlib. It is broken up into beginner, intermediate, and advanced sections, as well as sections covering specific topics.

For shorter examples, see our examples page. You can also find external resources and a FAQ in our user guide.

### 2.1 Introductory

These tutorials cover the basics of creating visualizations with Matplotlib, as well as some best-practices in using the package effectively.

**Note:** Click *here* to download the full example code

#### 2.1.1 Usage Guide

This tutorial covers some basic usage patterns and best-practices to help you get started with Matplotlib.

**General Concepts**

Matplotlib has an extensive codebase that can be daunting to many new users. However, most of matplotlib can be understood with a fairly simple conceptual framework and knowledge of a few important points.

Plotting requires action on a range of levels, from the most general (e.g., ‘contour this 2-D array’) to the most specific (e.g., ‘color this screen pixel red’). The purpose of a plotting package is to assist you in visualizing your data as easily as possible, with all the necessary control – that is, by using relatively high-level commands most of the time, and still have the ability to use the low-level commands when needed.

Therefore, everything in matplotlib is organized in a hierarchy. At the top of the hierarchy is the matplotlib “state-machine environment” which is provided by the `matplotlib.pyplot` module. At this level, simple functions are used to add plot elements (lines, images, text, etc.) to the current axes in the current figure.
Note: Pyplot’s state-machine environment behaves similarly to MATLAB and should be most familiar to users with MATLAB experience.

The next level down in the hierarchy is the first level of the object-oriented interface, in which pyplot is used only for a few functions such as figure creation, and the user explicitly creates and keeps track of the figure and axes objects. At this level, the user uses pyplot to create figures, and through those figures, one or more axes objects can be created. These axes objects are then used for most plotting actions.

For even more control – which is essential for things like embedding matplotlib plots in GUI applications – the pyplot level may be dropped completely, leaving a purely object-oriented approach.

```python
# sphinx_gallery_thumbnail_number = 3
import matplotlib.pyplot as plt
import numpy as np
```
Parts of a Figure

**Figure**

The **whole** figure. The figure keeps track of all the child *Axes*, a smattering of ‘special’ artists (titles, figure legends, etc), and the **canvas**. (Don’t worry too much about the canvas, it is crucial as it is the object that actually does the drawing to get you your plot, but as the user it is more-or-less invisible to you). A figure can have any number of *Axes*, but to be useful should have at least one.

The easiest way to create a new figure is with pyplot:
fig = plt.figure()  # an empty figure with no axes
fig.suptitle('No axes on this figure')  # Add a title so we know which it is

fig, ax_lst = plt.subplots(2, 2)  # a figure with a 2x2 grid of Axes

No axes on this figure
Axes

This is what you think of as ‘a plot’, it is the region of the image with the data space. A given figure can contain many Axes, but a given Axes object can only be in one Figure. The Axes contains two (or three in the case of 3D) Axis objects (be aware of the difference between Axes and Axis) which take care of the data limits (the data limits can also be controlled via set via the set_xlim() and set_ylim() Axes methods). Each Axes has a title (set via set_title()), an x-label (set via set_xlabel()), and a y-label set via set_ylabel()).

The Axes class and it’s member functions are the primary entry point to working with the OO interface.

Axis

These are the number-line-like objects. They take care of setting the graph limits and generating the ticks (the marks on the axis) and ticklabels (strings labeling the ticks). The location of the ticks is determined by a Locator object and the ticklabel strings are formatted by a Formatter. The combination of the correct Locator and Formatter gives very fine control over the tick locations and labels.
Artist

Basically everything you can see on the figure is an artist (even the Figure, Axes, and Axis objects). This includes Text objects, Line2D objects, collection objects, Patch objects ... (you get the idea). When the figure is rendered, all of the artists are drawn to the canvas. Most Artists are tied to an Axes; such an Artist cannot be shared by multiple Axes, or moved from one to another.

Types of inputs to plotting functions

All of plotting functions expect np.array or np.ma.masked_array as input. Classes that are ‘array-like’ such as pandas data objects and np.matrix may or may not work as intended. It is best to convert these to np.array objects prior to plotting.

For example, to convert a pandas.DataFrame

```python
a = pandas.DataFrame(np.random.rand(4,5), columns = list('abcde'))
a_asarray = a.values
```

and to convert a np.matrix

```python
b = np.matrix([[1,2],[3,4]])
b_asarray = np.asarray(b)
```

Matplotlib, pyplot and pylab: how are they related?

Matplotlib is the whole package and matplotlib.pyplot is a module in Matplotlib.

For functions in the pyplot module, there is always a “current” figure and axes (which is created automatically on request). For example, in the following example, the first call to plt.plot creates the axes, then subsequent calls to plt.plot add additional lines on the same axes, and plt.xlabel, plt.ylabel, plt.title and plt.legend set the axes labels and title and add a legend.

```python
x = np.linspace(0, 2, 100)
plt.plot(x, x, label='linear')
plt.plot(x, x**2, label='quadratic')
plt.plot(x, x**3, label='cubic')
plt.xlabel('x label')
plt.ylabel('y label')
plt.title("Simple Plot")
plt.legend()
plt.show()
```
**pylab** is a convenience module that bulk imports *matplotlib.pyplot* (for plotting) and *numpy* (for mathematics and working with arrays) in a single namespace. *pylab* is deprecated and its use is strongly discouraged because of namespace pollution. Use *pyplot* instead.

For non-interactive plotting it is suggested to use *pyplot* to create the figures and then the OO interface for plotting.

**Coding Styles**

When viewing this documentation and examples, you will find different coding styles and usage patterns. These styles are perfectly valid and have their pros and cons. Just about all of the examples can be converted into another style and achieve the same results. The only caveat is to avoid mixing the coding styles for your own code.

**Note:** Developers for matplotlib have to follow a specific style and guidelines. See *The Matplotlib Developers’ Guide*.

Of the different styles, there are two that are officially supported. Therefore, these are the preferred ways to use matplotlib.

For the *pyplot* style, the imports at the top of your scripts will typically be:
import matplotlib.pyplot as plt
import numpy as np

Then one calls, for example, np.arange, np.zeros, np.pi, plt.figure, plt.plot, plt.show, etc. Use the pyplot interface for creating figures, and then use the object methods for the rest:

```python
x = np.arange(0, 10, 0.2)
y = np.sin(x)
fig, ax = plt.subplots()
ax.plot(x, y)
plt.show()
```

So, why all the extra typing instead of the MATLAB-style (which relies on global state and a flat namespace)? For very simple things like this example, the only advantage is academic: the wordier styles are more explicit, more clear as to where things come from and what is going on. For more complicated applications, this explicitness and clarity becomes increasingly valuable, and the richer and more complete object-oriented interface will likely make the program easier to write and maintain.

Typically one finds oneself making the same plots over and over again, but with different data sets, which leads to needing to write specialized functions to do the plotting. The recommended function signature is something like:
def my_plotter(ax, data1, data2, param_dict):
    """
    A helper function to make a graph

    Parameters
    ----------
    ax : Axes
        The axes to draw to

    data1 : array
        The x data

    data2 : array
        The y data

    param_dict : dict
        Dictionary of kwargs to pass to ax.plot

    Returns
    -------
    out : list
        list of artists added
    """
    out = ax.plot(data1, data2, **param_dict)
    return out

# which you would then use as:

data1, data2, data3, data4 = np.random.randn(4, 100)
fig, ax = plt.subplots(1, 1)
my_plotter(ax, data1, data2, {'marker': 'x'})
or if you wanted to have 2 sub-plots:

```python
fig, (ax1, ax2) = plt.subplots(1, 2)
my_plotter(ax1, data1, data2, {'marker': 'x'})
my_plotter(ax2, data3, data4, {'marker': 'o'})
```
Again, for these simple examples this style seems like overkill, however once the graphs get slightly more complex it pays off.

**Backends**

**What is a backend?**

A lot of documentation on the website and in the mailing lists refers to the “backend” and many new users are confused by this term. matplotlib targets many different use cases and output formats. Some people use matplotlib interactively from the python shell and have plotting windows pop up when they type commands. Some people run Jupyter notebooks and draw inline plots for quick data analysis. Others embed matplotlib into graphical user interfaces like wxpython or pygtk to build rich applications. Some people use matplotlib in batch scripts to generate postscript images from numerical simulations, and still others run web application servers to dynamically serve up graphs.

To support all of these use cases, matplotlib can target different outputs, and each of these capabilities is called a backend; the “frontend” is the user facing code, i.e., the plotting code, whereas the “backend” does all the hard work behind-the-scenes to make the figure. There are two types of backends: user interface backends (for use in pygtk, wxpython, tkinter; qt4, or macosx; also referred to as “interactive backends”) and hardcopy backends to make image files (PNG, SVG, PDF, PS; also referred to as “non-interactive backends”).

There are four ways to configure your backend. If they conflict each other, the method men-
tioned last in the following list will be used, e.g. calling use() will override the setting in your `matplotlibrc`.

1. The `backend` parameter in your `matplotlibrc` file (see Customizing Matplotlib with style sheets and rcParams):

   ```python
   backend : WXAgg  # use wxpython with antigrain (agg) rendering
   ``

2. Setting the `MPLBACKEND` environment variable, either for your current shell or for a single script. On Unix:

   ```
   > export MPLBACKEND=module://my_backend
   > python simple_plot.py
   > MPLBACKEND="module://my_backend" python simple_plot.py
   ```

   On Windows, only the former is possible:

   ```
   > set MPLBACKEND=module://my_backend
   > python simple_plot.py
   ```

   Setting this environment variable will override the `backend` parameter in any `matplotlibrc`, even if there is a `matplotlibrc` in your current working directory. Therefore setting `MPLBACKEND` globally, e.g. in your `.bashrc` or `.profile`, is discouraged as it might lead to counter-intuitive behavior.

3. If your script depends on a specific backend you can use the `use()` function:

   ```python
   import matplotlib
   matplotlib.use('PS')  # generate postscript output by default
   ```

   If you use the `use()` function, this must be done before importing `matplotlib.pyplot`. Calling `use()` after `pyplot` has been imported will have no effect. Using `use()` will require changes in your code if users want to use a different backend. Therefore, you should avoid explicitly calling `use()` unless absolutely necessary.

**Note:** Backend name specifications are not case-sensitive; e.g., ‘GTK3Agg’ and ‘gtk3agg’ are equivalent.

With a typical installation of matplotlib, such as from a binary installer or a linux distribution package, a good default backend will already be set, allowing both interactive work and plotting from scripts, with output to the screen and/or to a file, so at least initially you will not need to use any of the methods given above.

If, however, you want to write graphical user interfaces, or a web application server (Matplotlib in a web application server), or need a better understanding of what is going on, read on. To make things a little more customizable for graphical user interfaces, matplotlib separates the concept of the renderer (the thing that actually does the drawing) from the canvas (the place where the drawing goes). The canonical renderer for user interfaces is `Agg` which uses the Anti-Grain Geometry C++ library to make a raster (pixel) image of the figure. All of the user interfaces except macosx can be used with `agg` rendering, e.g., `WXAgg`, `GTK3Agg`, `QT4Agg`, `QT5Agg`, `TkAgg`. In addition, some of the user interfaces support other rendering engines. For example, with GTK+ 3, you can also select Cairo rendering (backend `GTK3Cairo`).

For the rendering engines, one can also distinguish between `vector` or `raster` renderers. Vector graphics languages issue drawing commands like “draw a line from this point to this...
point” and hence are scale free, and raster backends generate a pixel representation of the line whose accuracy depends on a DPI setting.

Here is a summary of the matplotlib renderers (there is an eponymous backend for each; these are non-interactive backends, capable of writing to a file):

<table>
<thead>
<tr>
<th>Renderer</th>
<th>Filetypes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGG</td>
<td>png</td>
<td>raster graphics – high quality images using the Anti-Grain Geometry engine</td>
</tr>
<tr>
<td>PS</td>
<td>ps eps</td>
<td>vector graphics – Postscript output</td>
</tr>
<tr>
<td>PDF</td>
<td>pdf</td>
<td>vector graphics – Portable Document Format</td>
</tr>
<tr>
<td>SVG</td>
<td>svg</td>
<td>vector graphics – Scalable Vector Graphics</td>
</tr>
<tr>
<td>Cairo</td>
<td>png ps pdf</td>
<td>raster graphics and vector graphics – using the Cairo graphics library</td>
</tr>
</tbody>
</table>

And here are the user interfaces and renderer combinations supported; these are interactive backends, capable of displaying to the screen and of using appropriate renderers from the table above to write to a file:

<table>
<thead>
<tr>
<th>Backend</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Qt5Agg</td>
<td>Agg rendering in a Qt5 canvas (requires PyQt5). This backend can be activated in IPython with <code>%matplotlib qt5</code>.</td>
</tr>
<tr>
<td>ipympl</td>
<td>Agg rendering embedded in a Jupyter widget. (requires ipympl). This backend can be enabled in a Jupyter notebook with <code>%matplotlib ipympl</code>.</td>
</tr>
<tr>
<td>GTK3Agg</td>
<td>Agg rendering to a GTK 3.x canvas (requires PyGObject, and pycairo or cairocffi). This backend can be activated in IPython with <code>%matplotlib gtk3</code>.</td>
</tr>
<tr>
<td>macOSx</td>
<td>Agg rendering into a Cocoa canvas in OSX. This backend can be activated in IPython with <code>%matplotlib osx</code>.</td>
</tr>
<tr>
<td>TkAgg</td>
<td>Agg rendering to a Tk canvas (requires TkInter). This backend can be activated in IPython with <code>%matplotlib tk</code>.</td>
</tr>
<tr>
<td>nbAgg</td>
<td>Embed an interactive figure in a Jupyter classic notebook. This backend can be enabled in Jupyter notebooks via <code>%matplotlib notebook</code>.</td>
</tr>
<tr>
<td>WebAgg</td>
<td>On show() will start a tornado server with an interactive figure.</td>
</tr>
<tr>
<td>GTK3Cairo</td>
<td>Cairo rendering to a GTK 3.x canvas (requires PyGObject, and pycairo or cairocffi).</td>
</tr>
<tr>
<td>Qt4Agg</td>
<td>Agg rendering to a Qt4 canvas (requires PyQt4 or pyside). This backend can be activated in IPython with <code>%matplotlib qt4</code>.</td>
</tr>
<tr>
<td>WXAgg</td>
<td>Agg rendering to a wxWidgets canvas (requires wxPython 4). This backend can be activated in IPython with <code>%matplotlib wx</code>.</td>
</tr>
</tbody>
</table>

**ipympl**

The Jupyter widget ecosystem is moving too fast to support directly in Matplotlib. To install ipympl

```
pip install ipympl
jupyter nbextension enable --py --sys-prefix ipympl
```

or
conda install ipympl -c conda-forge

See jupyter-matplotlib for more details.

GTK and Cairo

GTK3 backends (both GTK3Agg and GTK3Cairo) depend on Cairo (pycairo>=1.11.0 or cairocffi).

How do I select PyQt4 or PySide?

The QT_API environment variable can be set to either pyqt or pyside to use PyQt4 or PySide, respectively.

Since the default value for the bindings to be used is PyQt4, matplotlib first tries to import it, if the import fails, it tries to import PySide.

What is interactive mode?

Use of an interactive backend (see What is a backend?) permits—but does not by itself require or ensure—plotting to the screen. Whether and when plotting to the screen occurs, and whether a script or shell session continues after a plot is drawn on the screen, depends on the functions and methods that are called, and on a state variable that determines whether matplotlib is in “interactive mode”. The default Boolean value is set by the matplotlibrc file, and may be customized like any other configuration parameter (see Customizing Matplotlib with style sheets and rcParams). It may also be set via matplotlib.pyplot.ion(), and its value may be queried via matplotlib.pyplot.is_interactive(). Turning interactive mode on and off in the middle of a stream of plotting commands, whether in a script or in a shell, is rarely needed and potentially confusing, so in the following we will assume all plotting is done with interactive mode either on or off.

**Note:** Major changes related to interactivity, and in particular the role and behavior of show(), were made in the transition to matplotlib version 1.0, and bugs were fixed in 1.0.1. Here we describe the version 1.0.1 behavior for the primary interactive backends, with the partial exception of macosx.

Interactive mode may also be turned on via matplotlib.pyplot.ion(), and turned off via matplotlib.pyplot.ioff().

**Note:** Interactive mode works with suitable backends in ipython and in the ordinary python shell, but it does not work in the IDLE IDE. If the default backend does not support interactivity, an interactive backend can be explicitly activated using any of the methods discussed in What is a backend?.

Interactive example

From an ordinary python prompt, or after invoking ipython with no options, try this:
import matplotlib.pyplot as plt
plt.ion()
plt.plot([1.6, 2.7])

Assuming you are running version 1.0.1 or higher, and you have an interactive backend installed and selected by default, you should see a plot, and your terminal prompt should also be active; you can type additional commands such as:

plt.title("interactive test")
plt.xlabel("index")

and you will see the plot being updated after each line. Since version 1.5, modifying the plot by other means should also automatically update the display on most backends. Get a reference to the Axes instance, and call a method of that instance:

ax = plt.gca()
ax.plot([3.1, 2.2])

If you are using certain backends (like macosx), or an older version of matplotlib, you may not see the new line added to the plot immediately. In this case, you need to explicitly call draw() in order to update the plot:

plt.draw()

Non-interactive example

Start a fresh session as in the previous example, but now turn interactive mode off:

import matplotlib.pyplot as plt
plt.ioff()
plt.plot([1.6, 2.7])

Nothing happened—or at least nothing has shown up on the screen (unless you are using macosx backend, which is anomalous). To make the plot appear, you need to do this:

plt.show()

Now you see the plot, but your terminal command line is unresponsive; the show() command blocks the input of additional commands until you manually kill the plot window.

What good is this—being forced to use a blocking function? Suppose you need a script that plots the contents of a file to the screen. You want to look at that plot, and then end the script. Without some blocking command such as show(), the script would flash up the plot and then end immediately, leaving nothing on the screen.

In addition, non-interactive mode delays all drawing until show() is called; this is more efficient than redrawing the plot each time a line in the script adds a new feature.

Prior to version 1.0, show() generally could not be called more than once in a single script (although sometimes one could get away with it); for version 1.0.1 and above, this restriction is lifted, so one can write a script like this:
which makes three plots, one at a time. I.e. the second plot will show up, once the first plot is closed.

Summary

In interactive mode, pyplot functions automatically draw to the screen.

When plotting interactively, if using object method calls in addition to pyplot functions, then call `draw()` whenever you want to refresh the plot.

Use non-interactive mode in scripts in which you want to generate one or more figures and display them before ending or generating a new set of figures. In that case, use `show()` to display the figure(s) and to block execution until you have manually destroyed them.

Performance

Whether exploring data in interactive mode or programmatically saving lots of plots, rendering performance can be a painful bottleneck in your pipeline. Matplotlib provides a couple ways to greatly reduce rendering time at the cost of a slight change (to a settable tolerance) in your plot’s appearance. The methods available to reduce rendering time depend on the type of plot that is being created.

Line segment simplification

For plots that have line segments (e.g. typical line plots, outlines of polygons, etc.), rendering performance can be controlled by the `path.simplify` and `path.simplify_threshold` parameters in your `matplotlibrc` file (see `Customizing Matplotlib with style sheets and rcParams` for more information about the `matplotlibrc` file). The `path.simplify` parameter is a boolean indicating whether or not line segments are simplified at all. The `path.simplify_threshold` parameter controls how much line segments are simplified; higher thresholds result in quicker rendering.

The following script will first display the data without any simplification, and then display the same data with simplification. Try interacting with both of them:

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib as mpl

# Setup, and create the data to plot
y = np.random.rand(100000)
y[50000:] *= 2
y[np.logspace(1, np.log10(50000), 400).astype(int)] = -1
```
Matplotlib currently defaults to a conservative simplification threshold of $1/9$. If you want to change your default settings to use a different value, you can change your `matplotlibrc` file. Alternatively, you could create a new style for interactive plotting (with maximal simplification) and another style for publication quality plotting (with minimal simplification) and activate them as necessary. See *Customizing Matplotlib with style sheets and rcParams* for instructions on how to perform these actions.

The simplification works by iteratively merging line segments into a single vector until the next line segment’s perpendicular distance to the vector (measured in display-coordinate space) is greater than the `path.simplify_threshold` parameter.

**Note:** Changes related to how line segments are simplified were made in version 2.1. Rendering time will still be improved by these parameters prior to 2.1, but rendering time for some kinds of data will be vastly improved in versions 2.1 and greater.

### Marker simplification

Markers can also be simplified, albeit less robustly than line segments. Marker simplification is only available to `Line2D` objects (through the `markevery` property). Wherever `Line2D` construction parameter are passed through, such as `matplotlib.pyplot.plot()` and `matplotlib.axes.Axes.plot()`, the `markevery` parameter can be used:

```python
plt.plot(x, y, markevery=10)
```

The `markevery` argument allows for naive subsampling, or an attempt at evenly spaced (along the x axis) sampling. See the `/gallery/lines_bars_and_markers/markevery_demo` for more information.

### Splitting lines into smaller chunks

If you are using the Agg backend (see *What is a backend?*), then you can make use of the `agg.path.chunksize` rc parameter. This allows you to specify a chunk size, and any lines with greater than that many vertices will be split into multiple lines, each of which have no more than `agg.path.chunksize` many vertices. (Unless `agg.path.chunksize` is zero, in which case there is no chunking.) For some kind of data, chunking the line up into reasonable sizes can greatly decrease rendering time.

The following script will first display the data without any chunk size restriction, and then display the same data with a chunk size of 10,000. The difference can best be seen when the figures are large, try maximizing the GUI and then interacting with them:
import numpy as np
import matplotlib.pyplot as plt
import matplotlib as mpl
mpl.rcParams['path.simplify_threshold'] = 1.0

# Setup, and create the data to plot
y = np.random.rand(100000)
y[50000:] **= 2
y[np.logspace(1, np.log10(50000), 400).astype(int)] = -1
mpl.rcParams['path.simplify'] = True

mpl.rcParams['agg.path.chunksize'] = 0
plt.plot(y)
plt.show()

mpl.rcParams['agg.path.chunksize'] = 10000
plt.plot(y)
plt.show()

Legends

The default legend behavior for axes attempts to find the location that covers the fewest data points (loc='best'). This can be a very expensive computation if there are lots of data points. In this case, you may want to provide a specific location.

Using the fast style

The fast style can be used to automatically set simplification and chunking parameters to reasonable settings to speed up plotting large amounts of data. It can be used simply by running:

```
import matplotlib.style as mplstyle
mplstyle.use('fast')
```

It is very light weight, so it plays nicely with other styles, just make sure the fast style is applied last so that other styles do not overwrite the settings:

```
mplstyle.use(['dark_background', 'ggplot', 'fast'])
```

Note: Click here to download the full example code

2.1.2 Pyplot tutorial

An introduction to the pyplot interface.
Intro to pyplot

`matplotlib.pyplot` is a collection of command style functions that make matplotlib work like MATLAB. Each `pyplot` function makes some change to a figure: e.g., creates a figure, creates a plotting area in a figure, plots some lines in a plotting area, decorates the plot with labels, etc.

In `matplotlib.pyplot` various states are preserved across function calls, so that it keeps track of things like the current figure and plotting area, and the plotting functions are directed to the current axes (please note that “axes” here and in most places in the documentation refers to the *axes part of a figure* and not the strict mathematical term for more than one axis).

Note: the pyplot API is generally less-flexible than the object-oriented API. Most of the function calls you see here can also be called as methods from an `Axes` object. We recommend browsing the tutorials and examples to see how this works.

Generating visualizations with `pyplot` is very quick:

```python
import matplotlib.pyplot as plt
plt.plot([1, 2, 3, 4])
plt.ylabel('some numbers')
plt.show()
```

You may be wondering why the x-axis ranges from 0-3 and the y-axis from 1-4. If you provide a
single list or array to the *plot()* command, matplotlib assumes it is a sequence of y values, and automatically generates the x values for you. Since python ranges start with 0, the default x vector has the same length as y but starts with 0. Hence the x data are [0,1,2,3].

*plot()* is a versatile command, and will take an arbitrary number of arguments. For example, to plot x versus y, you can issue the command:

```python
plt.plot([1, 2, 3, 4], [1, 4, 9, 16])
```

![Graph](image)

**Formatting the style of your plot**

For every x, y pair of arguments, there is an optional third argument which is the format string that indicates the color and line type of the plot. The letters and symbols of the format string are from MATLAB, and you concatenate a color string with a line style string. The default format string is 'b-', which is a solid blue line. For example, to plot the above with red circles, you would issue

```python
plt.plot([1, 2, 3, 4], [1, 4, 9, 16], 'ro')
plt.axis([0, 6, 0, 20])
plt.show()
```
See the `plot()` documentation for a complete list of line styles and format strings. The `axis()` command in the example above takes a list of `[xmin, xmax, ymin, ymax]` and specifies the viewport of the axes.

If matplotlib were limited to working with lists, it would be fairly useless for numeric processing. Generally, you will use `numpy` arrays. In fact, all sequences are converted to numpy arrays internally. The example below illustrates a plotting several lines with different format styles in one command using arrays.

```python
import numpy as np

# evenly sampled time at 200ms intervals
r = np.arange(0., 5., 0.2)

# red dashes, blue squares and green triangles
plt.plot(t, t, 'r--', t, t**2, 'bs', t, t**3, 'g^')
plt.show()
```
Plotting with keyword strings

There are some instances where you have data in a format that lets you access particular variables with strings. For example, with `numpy.recarray` or `pandas.DataFrame`.

Matplotlib allows you to provide such an object with the `data` keyword argument. If provided, then you may generate plots with the strings corresponding to these variables.

```python
data = {'a': np.arange(50),
        'c': np.random.randint(0, 50, 50),
        'd': np.random.randn(50)}
data['b'] = data['a'] + 10 * np.random.randn(50)
data['d'] = np.abs(data['d']) * 100
plt.scatter('a', 'b', c='c', s='d', data=data)
plt.xlabel('entry a')
plt.ylabel('entry b')
plt.show()
```
Plotting with categorical variables

It is also possible to create a plot using categorical variables. Matplotlib allows you to pass categorical variables directly to many plotting functions. For example:

```python
names = ['group_a', 'group_b', 'group_c']
values = [1, 10, 100]

plt.figure(figsize=(9, 3))
plt.subplot(131)
plt.bar(names, values)
plt.subplot(132)
plt.scatter(names, values)
plt.subplot(133)
plt.plot(names, values)
plt.suptitle('Categorical Plotting')
plt.show()
```
Controlling line properties

Lines have many attributes that you can set: linewidth, dash style, antialiased, etc; see `matplotlib.lines.Line2D`. There are several ways to set line properties

- Use keyword args:

  ```python
  plt.plot(x, y, linewidth=2.0)
  ```

- Use the setter methods of a `Line2D` instance. `plot` returns a list of `Line2D` objects; e.g., `line1, line2 = plot(x1, y1, x2, y2)`. In the code below we will suppose that we have only one line so that the list returned is of length 1. We use tuple unpacking with `line`, to get the first element of that list:

  ```python
  line, = plt.plot(x, y, '-')
  line.set_antialiased(False)  # turn off antialiasing
  ```

- Use the `setp()` command. The example below uses a MATLAB-style command to set multiple properties on a list of lines. `setp` works transparently with a list of objects or a single object. You can either use python keyword arguments or MATLAB-style string/value pairs:

  ```python
  lines = plt.plot(x1, y1, x2, y2)
  # use keyword args
  plt.setp(lines, color='r', linewidth=2.0)
  # or MATLAB style string value pairs
  plt.setp(lines, 'color', 'r', 'linewidth', 2.0)
  ```

Here are the available `Line2D` properties.

</tbody>
</table>

To get a list of settable line properties, call the `setp()` function with a line or lines as argument

```python
In [69]: lines = plt.plot([1, 2, 3])
In [70]: plt.setp(lines)
    alpha: float
    animated: [True | False]
    antialiased or aa: [True | False]
    ...snip
```

Working with multiple figures and axes

MATLAB, and `pyplot`, have the concept of the current figure and the current axes. All plotting commands apply to the current axes. The function `gca()` returns the current axes (a `matplotlib.axes.Axes` instance), and `gcf()` returns the current figure (`matplotlib.figure.Figure` instance). Normally, you don’t have to worry about this, because it is all taken care of behind the scenes. Below is a script to create two subplots.

```python
def f(t):
    return np.exp(-t) * np.cos(2*np.pi*t)

t1 = np.arange(0.0, 5.0, 0.1)
t2 = np.arange(0.0, 5.0, 0.02)
```

(continues on next page)
plt.figure()
plt.subplot(211)
plt.plot(t1, f(t1), 'bo', t2, f(t2), 'k')

plt.subplot(212)
plt.plot(t2, np.cos(2*np.pi*t2), 'r--')
plt.show()

The figure() command here is optional because figure(1) will be created by default, just as a subplot(111) will be created by default if you don’t manually specify any axes. The subplot() command specifies numrows, numcols, plot_number where plot_number ranges from 1 to numrows*numcols. The commas in the subplot command are optional if numrows*numcols<10. So subplot(211) is identical to subplot(2, 1, 1).

You can create an arbitrary number of subplots and axes. If you want to place an axes manually, i.e., not on a rectangular grid, use the axes() command, which allows you to specify the location as axes([left, bottom, width, height]) where all values are in fractional (0 to 1) coordinates. See /gallery/subplots_axes_and_figures/axes_demo for an example of placing axes manually and /gallery/subplots_axes_and_figures/subplot_demo for an example with lots of subplots.

You can create multiple figures by using multiple figure() calls with an increasing figure number. Of course, each figure can contain as many axes and subplots as your heart desires:
Matplotlib, Release 3.1.1

import matplotlib.pyplot as plt
plt.figure(1)
# the first figure
plt.subplot(211)
# the first subplot in the first figure
plt.plot([1, 2, 3])
plt.subplot(212)
# the second subplot in the first figure
plt.plot([4, 5, 6])

plt.figure(2)
plt.plot([4, 5, 6])

# a second figure
# creates a subplot(111) by default

plt.figure(1)
# figure 1 current; subplot(212) still current
plt.subplot(211)
# make subplot(211) in figure1 current
plt.title('Easy as 1, 2, 3') # subplot 211 title
You can clear the current ﬁgure with clf() and the current axes with cla(). If you ﬁnd it
annoying that states (speciﬁcally the current image, ﬁgure and axes) are being maintained
for you behind the scenes, don’t despair: this is just a thin stateful wrapper around an object
oriented API, which you can use instead (see Artist tutorial)
If you are making lots of ﬁgures, you need to be aware of one more thing: the memory required
for a ﬁgure is not completely released until the ﬁgure is explicitly closed with close(). Deleting
all references to the ﬁgure, and/or using the window manager to kill the window in which the
ﬁgure appears on the screen, is not enough, because pyplot maintains internal references
until close() is called.
Working with text
The text() command can be used to add text in an arbitrary location, and the xlabel(),
ylabel() and title() are used to add text in the indicated locations (see Text in Matplotlib
Plots for a more detailed example)
mu, sigma = 100, 15
x = mu + sigma * np.random.randn(10000)
# the histogram of the data
n, bins, patches = plt.hist(x, 50, density=1, facecolor='g', alpha=0.75)

plt.xlabel('Smarts')
plt.ylabel('Probability')
plt.title('Histogram of IQ')
plt.text(60, .025, r'$\mu=100,\ \sigma=15$')
plt.axis([40, 160, 0, 0.03])
plt.grid(True)
plt.show()

2.1. Introductory

35


All of the `text()` commands return an `matplotlib.text.Text` instance. Just as with lines above, you can customize the properties by passing keyword arguments into the text functions or using `setp()`:

```python
t = plt.xlabel('my data', fontsize=14, color='red')
```

These properties are covered in more detail in *Text properties and layout*.

**Using mathematical expressions in text**

`matplotlib` accepts TeX equation expressions in any text expression. For example to write the expression $\sigma_i = 15$ in the title, you can write a TeX expression surrounded by dollar signs:

```python
plt.title(r'\$\sigma_i=15\$')
```

The `r` preceding the title string is important – it signifies that the string is a raw string and not to treat backslashes as python escapes. `matplotlib` has a built-in TeX expression parser and layout engine, and ships its own math fonts – for details see *Writing mathematical expressions*. Thus you can use mathematical text across platforms without requiring a TeX installation. For those who have LaTeX and dvipng installed, you can also use LaTeX to format your text and incorporate the output directly into your display figures or saved postscript – see *Text rendering With LaTeX*. 
### Annotating text

The uses of the basic `text()` command above place text at an arbitrary position on the Axes. A common use for text is to annotate some feature of the plot, and the `annotate()` method provides helper functionality to make annotations easy. In an annotation, there are two points to consider: the location being annotated represented by the argument `xy` and the location of the text `xytext`. Both of these arguments are \((x,y)\) tuples.

```python
ax = plt.subplot(111)

t = np.arange(0.0, 5.0, 0.01)
s = np.cos(2*np.pi*t)
line, = plt.plot(t, s, lw=2)

plt.annotate('local max', xy=(2, 1), xytext=(3, 1.5),
             arrowprops=dict(facecolor='black', shrink=0.05),
            )

plt.ylim(-2, 2)
plt.show()
```

In this basic example, both the `xy` (arrow tip) and `xytext` locations (text location) are in data coordinates. There are a variety of other coordinate systems one can choose – see Basic annotation and Advanced Annotation for details. More examples can be found in 2.1 Introductory.
Logarithmic and other nonlinear axes

`matplotlib.pyplot` supports not only linear axis scales, but also logarithmic and logit scales. This is commonly used if data spans many orders of magnitude. Changing the scale of an axis is easy:

```python
plt.xscale('log')
```

An example of four plots with the same data and different scales for the y axis is shown below.

```python
from matplotlib.ticker import NullFormatter  # useful for 'logit' scale

# Fixing random state for reproducibility
np.random.seed(19680801)

# make up some data in the interval ]0, 1[
y = np.random.normal(loc=0.5, scale=0.4, size=1000)
y = y[(y > 0) & (y < 1)]
y.sort()
x = np.arange(len(y))

# plot with various axes scales
plt.figure()

# linear
plt.subplot(221)
plt.plot(x, y)
plt.yscale('linear')
plt.title('linear')
plt.grid(True)

# log
plt.subplot(222)
plt.plot(x, y)
plt.yscale('log')
plt.title('log')
plt.grid(True)

# symmetric log
plt.subplot(223)
plt.plot(x, y - y.mean())
plt.yscale('symlog', linthreshy=0.01)
plt.title('symlog')
plt.grid(True)

# logit
plt.subplot(224)
plt.plot(x, y)
plt.yscale('logit')
```

(continues on next page)
plt.title('logit')
plt.grid(True)

# Format the minor tick labels of the y-axis into empty strings with
# `NullFormatter`, to avoid cumbering the axis with too many labels.
plt.gca().yaxis.set_minor_formatter(NullFormatter())

# Adjust the subplot layout, because the logit one may take more space
# than usual, due to y-tick labels like "1 - 10^{-3}".
plt.subplots_adjust(top=0.92, bottom=0.08, left=0.10, right=0.95, hspace=0.25, wspace=0.35)

plt.show()

It is also possible to add your own scale, see *Developer’s guide for creating scales and transformations* for details.

**Note:** Click here to download the full example code

### 2.1.3 Sample plots in Matplotlib

Here you’ll find a host of example plots with the code that generated them.
Line Plot

Here’s how to create a line plot with text labels using `plot()`.

![Simple Plot](image1)

**Fig. 1: Simple Plot**

**Multiple subplots in one figure**

Multiple axes (i.e. subplots) are created with the `subplot()` function:

![Subplot](image2)

**Fig. 2: Subplot**

**Images**

Matplotlib can display images (assuming equally spaced horizontal dimensions) using the `imshow()` function.
Contouring and pseudocolor

The `pcolormesh()` function can make a colored representation of a two-dimensional array, even if the horizontal dimensions are unevenly spaced. The `contour()` function is another way to represent the same data:

![pcolormesh example](image)

![contour example](image)

Fig. 4: Example comparing `pcolormesh()` and `contour()` for plotting two-dimensional data

Histograms

The `hist()` function automatically generates histograms and returns the bin counts or probabilities:

Paths

You can add arbitrary paths in Matplotlib using the `matplotlib.path` module:
Fig. 5: Histogram Features

Fig. 6: Path Patch
Three-dimensional plotting

The mplot3d toolkit (see Getting started and mplot3d-examples-index) has support for simple 3d graphs including surface, wireframe, scatter, and bar charts.

![Surface3d](image)

Fig. 7: Surface3d

Thanks to John Porter, Jonathon Taylor, Reinier Heeres, and Ben Root for the mplot3d toolkit. This toolkit is included with all standard Matplotlib installs.

Streamplot

The streamplot() function plots the streamlines of a vector field. In addition to simply plotting the streamlines, it allows you to map the colors and/or line widths of streamlines to a separate parameter, such as the speed or local intensity of the vector field.

This feature complements the quiver() function for plotting vector fields. Thanks to Tom Flannaghan and Tony Yu for adding the streamplot function.

Ellipses

In support of the Phoenix mission to Mars (which used Matplotlib to display ground tracking of spacecraft), Michael Droettboom built on work by Charlie Moad to provide an extremely accurate 8-spline approximation to elliptical arcs (see Arc), which are insensitive to zoom level.

Bar charts

Use the bar() function to make bar charts, which includes customizations such as error bars: You can also create stacked bars (bar_stacked.py), or horizontal bar charts (barh.py).

Pie charts

The pie() function allows you to create pie charts. Optional features include auto-labeling the percentage of area, exploding one or more wedges from the center of the pie, and a shadow
Fig. 8: Streamplot with various plotting options.

Fig. 9: Ellipse Demo
Fig. 10: Barchart Demo
effect. Take a close look at the attached code, which generates this figure in just a few lines of code.

Fig. 11: Pie Features

Tables

The `table()` function adds a text table to an axes.
Scatter plots

The `scatter()` function makes a scatter plot with (optional) size and color arguments. This example plots changes in Google’s stock price, with marker sizes reflecting the trading volume and colors varying with time. Here, the alpha attribute is used to make semitransparent circle markers.

![Scatter Demo](image)

GUI widgets

Matplotlib has basic GUI widgets that are independent of the graphical user interface you are using, allowing you to write cross GUI figures and widgets. See `matplotlib.widgets` and the widget examples.

Filled curves

The `fill()` function lets you plot filled curves and polygons:
Fig. 14: Slider and radio-button GUI.

Fig. 15: Fill
Thanks to Andrew Straw for adding this function.

**Date handling**

You can plot timeseries data with major and minor ticks and custom tick formatters for both.

**Fig. 16: Date**

See `matplotlib.ticker` and `matplotlib.dates` for details and usage.

**Log plots**

The `semilogx()`, `semilogy()` and `loglog()` functions simplify the creation of logarithmic plots.

**Fig. 17: Log Demo**

Thanks to Andrew Straw, Darren Dale and Gregory Lielens for contributions log-scaling infrastructure.
Polar plots

The $polar()$ function generates polar plots.

Fig. 18: Polar Demo

Legends

The $legend()$ function automatically generates figure legends, with MATLAB-compatible legend-placement functions.

Fig. 19: Legend

Thanks to Charles Twardy for input on the legend function.

TeX-notation for text objects

Below is a sampling of the many TeX expressions now supported by Matplotlib’s internal mathtext engine. The mathtext module provides TeX style mathematical expressions using FreeType and the DejaVu, BaKoMa computer modern, or STIX fonts. See the $matplotlib$ mathtext module for additional details.
Matplotlib’s mathtext infrastructure is an independent implementation and does not require TeX or any external packages installed on your computer. See the tutorial at Writing mathematical expressions.

**Native TeX rendering**

Although Matplotlib’s internal math rendering engine is quite powerful, sometimes you need TeX. Matplotlib supports external TeX rendering of strings with the `usetex` option.
**EEG GUI**

You can embed Matplotlib into pygtk, wx, Tk, or Qt applications. Here is a screenshot of an EEG viewer called *pbrain*.

![EEG Viewer and Analyzer](image)

The lower axes uses *specgram()* to plot the spectrogram of one of the EEG channels.

For examples of how to embed Matplotlib in different toolkits, see:

- /gallery/user_interfaces/embedding_in_gtk3
- /gallery/user_interfaces/embedding_in_wx2
- /gallery/user_interfaces/mpl_with_glade3
- /gallery/user_interfaces/embedding_in_qt
- /gallery/user_interfaces/embedding_in_tk
XKCD-style sketch plots

Just for fun, Matplotlib supports plotting in the style of xkcd.

![Subplot example](image)

Fig. 22: xkcd

Subplot example

Many plot types can be combined in one figure to create powerful and flexible representations of data.
```python
import matplotlib.pyplot as plt
import numpy as np

np.random.seed(19680801)
data = np.random.randn(2, 100)

fig, axs = plt.subplots(2, 2, figsize=(5, 5))
axs[0, 0].hist(data[0])
axs[1, 0].scatter(data[0], data[1])
axs[0, 1].plot(data[0], data[1])
axs[1, 1].hist2d(data[0], data[1])

plt.show()
```

**Note:** Click here to download the full example code

### 2.1.4 Image tutorial

A short tutorial on plotting images with Matplotlib.
**Startup commands**

First, let’s start IPython. It is a most excellent enhancement to the standard Python prompt, and it ties in especially well with Matplotlib. Start IPython either at a shell, or the IPython Notebook now.

With IPython started, we now need to connect to a GUI event loop. This tells IPython where (and how) to display plots. To connect to a GUI loop, execute the `%matplotlib` magic at your IPython prompt. There’s more detail on exactly what this does at IPython’s documentation on GUI event loops.

If you’re using IPython Notebook, the same commands are available, but people commonly use a specific argument to the `%matplotlib` magic:

```
In [1]: %matplotlib inline
```

This turns on inline plotting, where plot graphics will appear in your notebook. This has important implications for interactivity. For inline plotting, commands in cells below the cell that outputs a plot will not affect the plot. For example, changing the color map is not possible from cells below the cell that creates a plot. However, for other backends, such as Qt5, that open a separate window, cells below those that create the plot will change the plot - it is a live object in memory.

This tutorial will use matplotlib’s imperative-style plotting interface, pyplot. This interface maintains global state, and is very useful for quickly and easily experimenting with various plot settings. The alternative is the object-oriented interface, which is also very powerful, and generally more suitable for large application development. If you’d like to learn about the object-oriented interface, a great place to start is our Usage guide. For now, let’s get on with the imperative-style approach:

```
import matplotlib.pyplot as plt
import matplotlib.image as mpimg
```

**Importing image data into Numpy arrays**

Loading image data is supported by the Pillow library. Natively, Matplotlib only supports PNG images. The commands shown below fall back on Pillow if the native read fails.

The image used in this example is a PNG file, but keep that Pillow requirement in mind for your own data.

Here’s the image we’re going to play with:
It’s a 24-bit RGB PNG image (8 bits for each of R, G, B). Depending on where you get your data, the other kinds of image that you’ll most likely encounter are RGBA images, which allow for transparency, or single-channel grayscale (luminosity) images. You can right click on it and choose “Save image as“ to download it to your computer for the rest of this tutorial.

And here we go...

```python
img = mpimg.imread('..../doc/_static/stinkbug.png')
print(img)
```

Out:

```
[[0.40784314 0.40784314 0.40784314]
 [0.40784314 0.40784314 0.40784314]
 [0.40784314 0.40784314 0.40784314]
...
[0.42745098 0.42745098 0.42745098]
 [0.42745098 0.42745098 0.42745098]
 [0.42745098 0.42745098 0.42745098]]

[[0.4117647  0.4117647  0.4117647 ]
 [0.4117647  0.4117647  0.4117647 ]
 [0.4117647  0.4117647  0.4117647 ]
...
```

(continues on next page)
Note the dtype there - float32. Matplotlib has rescaled the 8 bit data from each channel to floating point data between 0.0 and 1.0. As a side note, the only datatype that Pillow can work with is uint8. Matplotlib plotting can handle float32 and uint8, but image reading/writing for any format other than PNG is limited to uint8 data. Why 8 bits? Most displays can only render 8 bits per channel worth of color gradation. Why can they only render 8 bits/channel? Because that’s about all the human eye can see. More here (from a photography standpoint): Luminous Landscape bit depth tutorial.

Each inner list represents a pixel. Here, with an RGB image, there are 3 values. Since it’s a black and white image, R, G, and B are all similar. An RGBA (where A is alpha, or transparency), has 4 values per inner list, and a simple luminance image just has one value (and is thus only a 2-D array, not a 3-D array). For RGB and RGBA images, matplotlib supports float32 and uint8 data types. For grayscale, matplotlib supports only float32. If your array data does not meet one of these descriptions, you need to rescale it.
Plotting numpy arrays as images

So, you have your data in a numpy array (either by importing it, or by generating it). Let’s render it. In Matplotlib, this is performed using the `imshow()` function. Here we’ll grab the plot object. This object gives you an easy way to manipulate the plot from the prompt.

```python
imgplot = plt.imshow(img)
```

You can also plot any numpy array.

Applying pseudocolor schemes to image plots

Pseudocolor can be a useful tool for enhancing contrast and visualizing your data more easily. This is especially useful when making presentations of your data using projectors - their contrast is typically quite poor.

Pseudocolor is only relevant to single-channel, grayscale, luminosity images. We currently have an RGB image. Since R, G, and B are all similar (see for yourself above or in your data), we can just pick one channel of our data:

```python
lum_img = img[:, :, 0]

# This is array slicing. You can read more in the `Numpy tutorial`
```
Matplotlib, Release 3.1.1

(continued from previous page)

```python
plt.imshow(lum_img)
```

Now, with a luminosity (2D, no color) image, the default colormap (aka lookup table, LUT), is applied. The default is called viridis. There are plenty of others to choose from.

```python
plt.imshow(lum_img, cmap="hot")
```
Note that you can also change colormaps on existing plot objects using the `set_cmap()` method:

```python
imgplot = plt.imshow(lum_img)
imgplot.set_cmap('nipy_spectral')
```
**Note:** However, remember that in the IPython notebook with the inline backend, you can’t make changes to plots that have already been rendered. If you create imgplot here in one cell, you cannot call set_cmap() on it in a later cell and expect the earlier plot to change. Make sure that you enter these commands together in one cell. plt commands will not change plots from earlier cells.

There are many other colormap schemes available. See the list and images of the colormaps.

**Color scale reference**

It’s helpful to have an idea of what value a color represents. We can do that by adding color bars.

```python
imgplot = plt.imshow(lum_img)
plt.colorbar()
```
This adds a colorbar to your existing figure. This won't automatically change if you change you switch to a different colormap - you have to re-create your plot, and add in the colorbar again.

**Examining a specific data range**

Sometimes you want to enhance the contrast in your image, or expand the contrast in a particular region while sacrificing the detail in colors that don’t vary much, or don’t matter. A good tool to find interesting regions is the histogram. To create a histogram of our image data, we use the `hist()` function.

```python
plt.hist(lum_img.ravel(), bins=256, range=(0.0, 1.0), fc='k', ec='k')
```
Most often, the “interesting” part of the image is around the peak, and you can get extra contrast by clipping the regions above and/or below the peak. In our histogram, it looks like there’s not much useful information in the high end (not many white things in the image). Let’s adjust the upper limit, so that we effectively “zoom in” part of the histogram. We do this by passing the clim argument to imshow. You could also do this by calling the `set_clim()` method of the image plot object, but make sure that you do so in the same cell as your plot command when working with the IPython Notebook - it will not change plots from earlier cells.

You can specify the clim in the call to `plot`.

```python
imgplot = plt.imshow(lum_img, clim=(0.0, 0.7))
```
You can also specify the clim using the returned object

```python
fig = plt.figure()
a = fig.add_subplot(1, 2, 1)
imgplot = plt.imshow(lum_img)
a.set_title('Before')
plt.colorbar(ticks=[0.1, 0.3, 0.5, 0.7], orientation='horizontal')
a = fig.add_subplot(1, 2, 2)
imgplot = plt.imshow(lum_img)
imgplot.set_clim(0.0, 0.7)
a.set_title('After')
plt.colorbar(ticks=[0.1, 0.3, 0.5, 0.7], orientation='horizontal')
```
Array Interpolation schemes

Interpolation calculates what the color or value of a pixel “should” be, according to different mathematical schemes. One common place that this happens is when you resize an image. The number of pixels change, but you want the same information. Since pixels are discrete, there’s missing space. Interpolation is how you fill that space. This is why your images sometimes come out looking pixelated when you blow them up. The effect is more pronounced when the difference between the original image and the expanded image is greater. Let’s take our image and shrink it. We’re effectively discarding pixels, only keeping a select few. Now when we plot it, that data gets blown up to the size on your screen. The old pixels aren’t there anymore, and the computer has to draw in pixels to fill that space.

We’ll use the Pillow library that we used to load the image also to resize the image.

```python
from PIL import Image

img = Image.open('.../doc/_static/stinkbug.png')
img.thumbnail((64, 64), Image.ANTIALIAS)  # resizes image in-place
imgplot = plt.imshow(img)
```
Here we have the default interpolation, bilinear, since we did not give `imshow()` any interpolation argument.

Let’s try some others. Here’s “nearest”, which does no interpolation.

```python
imgplot = plt.imshow(img, interpolation="nearest")
```
and bicubic:

```python
imgplot = plt.imshow(img, interpolation="bicubic")
```
Bicubic interpolation is often used when blowing up photos - people tend to prefer blurry over pixelated.

**Total running time of the script:** ( 0 minutes 1.185 seconds)

**Note:** Click *here* to download the full example code

### 2.1.5 The Lifecycle of a Plot

This tutorial aims to show the beginning, middle, and end of a single visualization using Matplotlib. We’ll begin with some raw data and end by saving a figure of a customized visualization. Along the way we’ll try to highlight some neat features and best-practices using Matplotlib.

**Note:** This tutorial is based off of *this excellent blog post* by Chris Moffitt. It was transformed into this tutorial by Chris Holdgraf.
A note on the Object-Oriented API vs Pyplot

Matplotlib has two interfaces. The first is an object-oriented (OO) interface. In this case, we utilize an instance of `axes.Axes` in order to render visualizations on an instance of `figure.Figure`.

The second is based on MATLAB and uses a state-based interface. This is encapsulated in the `pyplot` module. See the `pyplot tutorials` for a more in-depth look at the pyplot interface.

Most of the terms are straightforward but the main thing to remember is that:

- The Figure is the final image that may contain 1 or more Axes.
- The Axes represent an individual plot (don’t confuse this with the word “axis”, which refers to the x/y axis of a plot).

We call methods that do the plotting directly from the Axes, which gives us much more flexibility and power in customizing our plot.

**Note:** In general, try to use the object-oriented interface over the pyplot interface.

Our data

We’ll use the data from the post from which this tutorial was derived. It contains sales information for a number of companies.

```python
# sphinx_gallery_thumbnail_number = 10
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.ticker import FuncFormatter

data = {'Barton LLC': 109438.50,
        'Frami, Hills and Schmidt': 103569.59,
        'Fritsch, Russel and Anderson': 112214.71,
        'Jerde-Hilpert': 112591.43,
        'Keeling LLC': 100934.30,
        'Koelp Ltd': 103660.54,
        'Kulas Inc': 137351.96,
        'Trantow-Barrows': 123381.38,
        'White-Trantow': 135841.99,
        'Will LLC': 104437.60}
group_data = list(data.values())
group_names = list(data.keys())
group_mean = np.mean(group_data)
```

Getting started

This data is naturally visualized as a barplot, with one bar per group. To do this with the object-oriented approach, we’ll first generate an instance of `figure.Figure` and `axes.Axes`. The Figure is like a canvas, and the Axes is a part of that canvas on which we will make a particular visualization.
**Note:** Figures can have multiple axes on them. For information on how to do this, see the *Tight Layout tutorial*.

```python
fig, ax = plt.subplots()
```

Now that we have an Axes instance, we can plot on top of it.

```python
fig, ax = plt.subplots()
ax.barh(group_names, group_data)
```
There are many styles available in Matplotlib in order to let you tailor your visualization to your needs. To see a list of styles, we can use `pyplot.style`.

```python
print(plt.style.available)
```

```
```

You can activate a style with the following:

```python
plt.style.use('fivethirtyeight')
```

Now let's remake the above plot to see how it looks:
The style controls many things, such as color, linewidths, backgrounds, etc.

**Customizing the plot**

Now we’ve got a plot with the general look that we want, so let’s fine-tune it so that it’s ready for print. First let’s rotate the labels on the x-axis so that they show up more clearly. We can gain access to these labels with the `axes.Axes.get_xticklabels()` method:

```python
fig, ax = plt.subplots()
ax.barh(group_names, group_data)
labels = ax.get_xticklabels()
```
If we’d like to set the property of many items at once, it’s useful to use the `pyplot.setp()` function. This will take a list (or many lists) of Matplotlib objects, and attempt to set some style element of each one.

```python
fig, ax = plt.subplots()
ax.barh(group_names, group_data)
labels = ax.get_xticklabels()
plt.setp(labels, rotation=45, horizontalalignment='right')
```
It looks like this cut off some of the labels on the bottom. We can tell Matplotlib to automatically make room for elements in the figures that we create. To do this we’ll set the `autolayout` value of our `rcParams`. For more information on controlling the style, layout, and other features of plots with `rcParams`, see *Customizing Matplotlib with style sheets and rcParams*.

```python
plt.rcParams.update({'figure.autolayout': True})

fig, ax = plt.subplots()
ax.barh(group_names, group_data)
labels = ax.get_xticklabels()
plt.setp(labels, rotation=45, horizontalalignment='right')
```
Next, we’ll add labels to the plot. To do this with the OO interface, we can use the `axes.Axes.set()` method to set properties of this Axes object.

```python
fig, ax = plt.subplots()
anx.barh(group_names, group_data)
labels = ax.get_xticklabels()
plt.setp(labels, rotation=45, horizontalalignment='right')
ax.set(xlim=[-10000, 140000], xlabel='Total Revenue', ylabel='Company',
       title='Company Revenue')
```
We can also adjust the size of this plot using the `pyplot.subplots()` function. We can do this with the `figsize` kwarg.

**Note:** While indexing in NumPy follows the form (row, column), the `figsize` kwarg follows the form (width, height). This follows conventions in visualization, which unfortunately are different from those of linear algebra.

```python
fig, ax = plt.subplots(figsize=(8, 4))
ax.barh(group_names, group_data)
labels = ax.get_xticklabels()
plt.setp(labels, rotation=45, horizontalalignment='right')
ax.set(xlim=[-10000, 140000], xlabel='Total Revenue', ylabel='Company',
       title='Company Revenue')
```
For labels, we can specify custom formatting guidelines in the form of functions by using the `ticker.FuncFormatter` class. Below we’ll define a function that takes an integer as input, and returns a string as an output.

```python
def currency(x, pos):
    """The two args are the value and tick position""
    if x >= 1e6:
        s = '${:1.1f}M'.format(x*1e-6)
    else:
        s = '${:1.0f}K'.format(x*1e-3)
    return s

formatter = FuncFormatter(currency)
```

We can then apply this formatter to the labels on our plot. To do this, we’ll use the `xaxis` attribute of our axis. This lets you perform actions on a specific axis on our plot.

```python
fig, ax = plt.subplots(figsize=(6, 8))
ax.barh(group_names, group_data)
labels = ax.get_xticklabels()
plt.setp(labels, rotation=45, horizontalalignment='right')

ax.set(xlim=[-10000, 140000], xlabel='Total Revenue', ylabel='Company',
       title='Company Revenue')
ax.xaxis.set_major_formatter(formatter)
```
Combining multiple visualizations

It is possible to draw multiple plot elements on the same instance of `axes.Axes`. To do this we simply need to call another one of the plot methods on that axes object.

2.1. Introductory
fig, ax = plt.subplots(figsize=(8, 8))
ax.barh(group_names, group_data)
labels = ax.get_xticklabels()
plt.setp(labels, rotation=45, horizontalalignment='right')

# Add a vertical line, here we set the style in the function call
ax.axvline(group_mean, ls='--', color='r')

# Annotate new companies
for group in [3, 5, 8]:
    ax.text(145000, group, "New Company", fontsize=10,
            verticalalignment="center")

# Now we'll move our title up since it's getting a little cramped
ax.title.set(y=1.05)

ax.set(xlim=[-10000, 140000], xlabel='Total Revenue', ylabel='Company',
       title='Company Revenue')
ax.xaxis.set_major_formatter(formatter)
ax.set_xticks([0, 25e3, 50e3, 75e3, 100e3, 125e3])
fig.subplots_adjust(right=.1)

plt.show()
Now that we’re happy with the outcome of our plot, we want to save it to disk. There are many file formats we can save to in Matplotlib. To see a list of available options, use:

```python
print(fig.canvas.get_supported_filetypes())
```

Out:

```python
{'ps': 'Postscript', 'eps': 'Encapsulated Postscript', 'pdf': 'Portable Document Format',
 'pgf': 'PGF code for LaTeX', 'png': 'Portable Network Graphics', 'raw': 'Raw RGBA bitmap',
 'rgba': 'Raw RGBA bitmap', 'svg': 'Scalable Vector Graphics', 'svgz': 'Scalable Vector Graphics',
 'jpg': 'Joint Photographic Experts Group', 'jpeg': 'Joint Photographic Experts Group',
 'tif': 'Tagged Image File Format', 'tiff': 'Tagged Image File Format'}
```
We can then use the `figure.Figure.savefig()` in order to save the figure to disk. Note that there are several useful flags we’ll show below:

- `transparent=True` makes the background of the saved figure transparent if the format supports it.
- `dpi=80` controls the resolution (dots per square inch) of the output.
- `bbox_inches="tight"` fits the bounds of the figure to our plot.

```python
# Uncomment this line to save the figure.
# fig.savefig('sales.png', transparent=False, dpi=80, bbox_inches="tight")
```

**Note:** Click [here](#) to download the full example code

### 2.1.6 Customizing Matplotlib with style sheets and rcParams

Tips for customizing the properties and default styles of Matplotlib.

**Using style sheets**

The `style` package adds support for easy-to-switch plotting “styles” with the same parameters as a `matplotlib rc` file (which is read at startup to configure matplotlib).

There are a number of pre-defined styles provided by Matplotlib. For example, there’s a pre-defined style called “ggplot”, which emulates the aesthetics of ggplot (a popular plotting package for R). To use this style, just add:

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib as mpl
plt.style.use('ggplot')
data = np.random.randn(50)
```

To list all available styles, use:

```python
print(plt.style.available)
```

Out:

```
['seaborn-talk', 'seaborn-darkgrid', 'seaborn-whitegrid', 'grayscale', 'seaborn-pastel',
 'seaborn', 'seaborn-muted', 'seaborn-ticks', 'fivethirtyeight', 'seaborn-dark',
 'seaborn-deep', 'seaborn-poster', 'classic', 'ggplot', 'seaborn-bright', '_classic_test',
 'seaborn-white', 'Solarize_Light2', 'bmh', 'dark_background', 'seaborn-paper',
 'seaborn-dark-palette', 'seaborn-colorblind', 'seaborn-notebook', 'tableau-colorblind10',
 'fast']
```
Defining your own style

You can create custom styles and use them by calling `style.use` with the path or URL to the style sheet. Additionally, if you add your `<style-name>.mplstyle` file to `mpl_configdir/stylelib`, you can reuse your custom style sheet with a call to `style.use(<style-name>)`. By default `mpl_configdir` should be `~/.config/matplotlib`, but you can check where yours is with `matplotlib.get_configdir()`; you may need to create this directory. You also can change the directory where matplotlib looks for the stylelib/ folder by setting the `MPLCONFIGDIR` environment variable, see `matlotlib configuration and cache directory locations`.

Note that a custom style sheet in `mpl_configdir/stylelib` will override a style sheet defined by matplotlib if the styles have the same name.

For example, you might want to create `mpl_configdir/stylelib/presentation.mplstyle` with the following:

```{.ini}
[axes]
titlesize : 24
labelsize : 20

[lines]
linewidth : 3
markersize : 10

[xtick]
labelsize : 16

[ytick]
labelsize : 16
```

Then, when you want to adapt a plot designed for a paper to one that looks good in a presentation, you can just add:

```python
>>> import matplotlib.pyplot as plt
>>> plt.style.use('presentation')
```

Composing styles

Style sheets are designed to be composed together. So you can have a style sheet that customizes colors and a separate style sheet that alters element sizes for presentations. These styles can easily be combined by passing a list of styles:

```python
>>> import matplotlib.pyplot as plt
>>> plt.style.use(['dark_background', 'presentation'])
```

Note that styles further to the right will overwrite values that are already defined by styles on the left.

Temporary styling

If you only want to use a style for a specific block of code but don’t want to change the global styling, the style package provides a context manager for limiting your changes to a specific scope. To isolate your styling changes, you can write something like the following:

```python
with plt.style.context('dark_background'):
    plt.plot(np.sin(np.linspace(0, 2 * np.pi)), 'r-o')
plt.show()
```
You can also dynamically change the default rc settings in a python script or interactively from the python shell. All of the rc settings are stored in a dictionary-like variable called `matplotlib.rcParams`, which is global to the matplotlib package. `rcParams` can be modified directly, for example:

```python
mpl.rcParams['lines.linewidth'] = 2
mpl.rcParams['lines.color'] = 'r'
plt.plot(data)
```
Matplotlib also provides a couple of convenience functions for modifying rc settings. The `matplotlib.rc()` command can be used to modify multiple settings in a single group at once, using keyword arguments:

```python
mpl.rc('lines', linewidth=4, color='g')
plt.plot(data)
```
The `matplotlib.rcdefaults()` command will restore the standard matplotlib default settings. There is some degree of validation when setting the values of rcParams, see `matplotlib.rcsetup` for details.

The `matplotlibrc` file

`matplotlib` uses `matplotlibrc` configuration files to customize all kinds of properties, which we call `rc settings` or `rc parameters`. You can control the defaults of almost every property in `matplotlib`: figure size and dpi, line width, color and style, axes, axis and grid properties, text and font properties and so on. `matplotlib` looks for `matplotlibrc` in four locations, in the following order:

1. `matplotlibrc` in the current working directory, usually used for specific customizations that you do not want to apply elsewhere.
2. `$MATPLOTLIBRC` if it is a file, else `$MATPLOTLIBRC/matplotlibrc`.
3. It next looks in a user-specific place, depending on your platform:
   - On Linux and FreeBSD, it looks in `.config/matplotlib/matplotlibrc` (or `$XDG_CONFIG_HOME/matplotlib/matplotlibrc`) if you’ve customized your environment.
   - On other platforms, it looks in `.matplotlib/matplotlibrc`.

See `matplotlib configuration and cache directory locations`. 

---

The following code snippet demonstrates how to use the `matplotlib` library for plotting data. The plot shows a random walk over 50 steps, with positive and negative values.

```python
import matplotlib.pyplot as plt
import numpy as np
import matplotlib

matplotlib.rcParams['font.size'] = 16

fig, ax = plt.subplots()
ax.plot(np.random.randn(50))

plt.show()
```
4. `INSTALL/mpl-data/matplotlibrc`, where `INSTALL` is something like `/usr/lib/python3.7/site-packages` on Linux, and maybe `C:\Python37\Lib\site-packages` on Windows. Every time you install matplotlib, this file will be overwritten, so if you want your customizations to be saved, please move this file to your user-specific matplotlib directory.

Once a `matplotlibrc` file has been found, it will not search any of the other paths.

To display where the currently active `matplotlibrc` file was loaded from, one can do the following:

```python
>>> import matplotlib
>>> matplotlib.matplotlib_fname()
'/home/foo/.config/matplotlib/matplotlibrc'
```

See below for a sample `matplotlibrc` file.

A sample `matplotlibrc` file

```python
### MATPLOTLIBRC FORMAT

## This is a sample matplotlib configuration file - you can find a copy
## of it on your system in
## site-packages/matplotlib/mpl-data/matplotlibrc. If you edit it
## there, please note that it will be overwritten in your next install.
## If you want to keep a permanent local copy that will not be
## overwritten, place it in the following location:
## unix/linux:
## $HOME/.config/matplotlib/matplotlibrc or
## $XDG_CONFIG_HOME/matplotlib/matplotlibrc (if $XDG_CONFIG_HOME is set)
## other platforms:
## $HOME/.matplotlib/matplotlibrc

## See http://matplotlib.org/users/customizing.html#the-matplotlibrc-file for
## more details on the paths which are checked for the configuration file.
##
## This file is best viewed in an editor which supports python mode
## syntax highlighting. Blank lines, or lines starting with a comment
## symbol, are ignored, as are trailing comments. Other lines must
## have the format
## key : val ## optional comment
##
## Colors: for the color values below, you can either use - a
## matplotlib color string, such as r, k, or b - an rgb tuple, such as
## (1.0, 0.5, 0.0) - a hex string, such as ff00ff - a scalar
## grayscale intensity such as 0.75 - a legal html color name, e.g., red,
## blue, darkslategray

#### CONFIGURATION BEGINS HERE

## The default backend. If you omit this parameter, the first
## working backend from the following list is used:
## MacOSX Qt5Agg Qt4Agg Gtk3Agg TkAgg WxAgg Agg

(continues on next page)
## Other choices include:
Qt5Cairo Qt4Cairo GTK3Cairo TkCairo WxCairo Cairo Wx PS PDF SVG Template.

You can also deploy your own backend outside of matplotlib by referring to the module name (which must be in the PYTHONPATH) as 'module://my_backend'.

#backend : Agg

Note that this can be overridden by the environment variable QT_API used by Enthought Tool Suite (ETS); valid values are "pyqt" and "pyside". The "pyqt" setting has the side effect of forcing the use of Version 2 API for QString and QVariant.

# The port to use for the web server in the WebAgg backend.
#webagg.port : 8988

# The address on which the WebAgg web server should be reachable
#webagg.address : 127.0.0.1

# If webagg.port is unavailable, a number of other random ports will be tried until one that is available is found.
#webagg.port_retries : 50

# When True, open the webbrowser to the plot that is shown
#webagg.open_in_browser : True

# if you are running pyplot inside a GUI and your backend choice conflicts, we will automatically try to find a compatible one for you if backend_fallback is True
#backend_fallback: True

#interactive : False
#toolbar : toolbar2 ## None | toolbar2 ("classic" is deprecated)
#timezone : UTC ## a pytz timezone string, e.g., US/Central or Europe/Paris

# Where your matplotlib data lives if you installed to a non-default location. This is where the matplotlib fonts, bitmaps, etc reside
#datapath : /home/jdhunter/mpldata

#### LINES
See http://matplotlib.org/api/artist_api.html#module-matplotlib.lines for more information on line properties.

#lines.linewidth : 1.5 ## line width in points
#lines.linestyle : - ## solid line
#lines.color : C0 ## has no affect on plot(); see axes.prop_cycle
#lines.marker : None ## the default marker
#lines.markerfacecolor : auto ## the default markerfacecolor
#lines.markeredgewidth : 1.0 ## the line width around the marker symbol
#lines.markersize : 6 ## markersize, in points

(continues on next page)
---

#lines.dash_joinstyle : round  # miter/round/bevel
#lines.dashcapstyle : butt   # butt/round/projecting
#lines.solid_joinstyle : round # miter/round/bevel
#lines.solidcapstyle : projecting # butt/round/projecting
#lines.antialiased : True    # render lines in antialiased (no jaggies)

## The three standard dash patterns. These are scaled by the linewidth.
#lines.dash_pattern : 3.7, 1.6
#lines.dashdot_pattern : 6.4, 1.6, 1, 1.6
#lines.dotted_pattern : 1, 1.65
#lines.scale_dashes : True

#markers.fillstyle: full  # full/left/right/bottom/top/none

#### PATCHES
## Patches are graphical objects that fill 2D space, like polygons or
## circles. See
## http://matplotlib.org/api/artist_api.html#module-matplotlib.patches
## information on patch properties
#patch.linewidth : 1   # edge width in points.
#patch.facecolor : C0
#patch.edgecolor : black  # if forced, or patch is not filled
#patch.force_edgecolor : False  # True to always use edgecolor
#patch.antialiased : True  # render patches in antialiased (no jaggies)

#### HATCHES
#hatch.color : black
#hatch.linewidth : 1.0

#### Boxplot
#boxplot.notch : False
#boxplot.vertical : True
#boxplot.whiskers : 1.5
#boxplot.bootstrap : None
#boxplot.patchartist : False
#boxplot.showmeans : False
#boxplot showcaps : True
#boxplot.showbox : True
#boxplot.showfliers : True
#boxplot.meanline : False

#boxplot.flierprops.color : black
#boxplot.flierprops.marker : o
#boxplot.flierprops.markercolor : none
#boxplot.flierprops.markeredgewidth : 1.0
#boxplot.flierprops.markersize : 6
#boxplot.flierprops.linestyle : none
#boxplot.flierprops.linewidth : 1.0

#boxplot.boxprops.color : black
#boxplot.boxprops.linewidth : 1.0

(continues on next page)
### FONT

# font properties used by text.Text. See
# http://matplotlib.org/api/font_manager_api.html for more
# information on font properties. The 6 font properties used for font
# matching are given below with their default values.
#
# The font.family property has five values: 'serif' (e.g., Times),
# 'sans-serif' (e.g., Helvetica), 'cursive' (e.g., Zapf-Chancery),
# 'fantasy' (e.g., Western), and 'monospace' (e.g., Courier). Each of
# these font families has a default list of font names in decreasing
# order of priority associated with them. When text.usetex is False,
# font.family may also be one or more concrete font names.
#
# The font.style property has three values: normal (or roman), italic
# or oblique. The oblique style will be used for italic, if it is not
# present.
#
# The font.variant property has two values: normal or small-caps. For
# TrueType fonts, which are scalable fonts, small-caps is equivalent
# to using a font size of 'smaller', or about 83% of the current font
# size.
#
# The font.weight property has effectively 13 values: normal, bold,
# bolder, lighter, 100, 200, 300, ..., 900. Normal is the same as
# 400, and bold is 700. bolder and lighter are relative values with
# respect to the current weight.
#
# The font.stretch property has 11 values: ultra-condensed,
## extra-condensed, condensed, semi-condensed, normal, semi-expanded, expanded, extra-expanded, ultra-expanded, wider, and narrower. This property is not currently implemented.

## The font.size property is the default font size for text, given in pts. 10 pt is the standard value.

#font.family : sans-serif
#font.style : normal
#font.variant : normal
#font.weight : normal
#font.stretch : normal
## note that font.size controls default text sizes. To configure special text sizes tick labels, axes, labels, title, etc, see the rc settings for axes and ticks. Special text sizes can be defined relative to font.size, using the following values: xx-small, x-small, small, medium, large, x-large, xx-large, larger, or smaller
#font.size : 10.0
#font.serif : DejaVu Serif, Bitstream Vera Serif, Computer Modern Roman, New Century Schoolbook, Century Schoolbook L, Utopia, ITC Bookman, Bookman, Nimbus Roman No9 L, Times New Roman, Times, Palatino, Charter, serif
#font.sans-serif : DejaVu Sans, Bitstream Vera Sans, Computer Modern Sans Serif, Lucida Grande, Verdana, Geneva, Lucid, Arial, Helvetica, Avant Garde, sans-serif
#font.cursive : Apple Chancery, Textile, Zapf Chancery, Sand, Script MT, Felipa, cursive
#font.fantasy : Comic Sans MS, Chicago, Charcoal, ImpactWestern, Humor Sans, xkcd, fantasy
#font.monospace : DejaVu Sans Mono, Bitstream Vera Sans Mono, Computer Modern Typewriter, Andale Mono, Nimbus Mono L, Courier New, Courier, Fixed, Terminal, monospace

#### TEXT
## text properties used by text.Text. See http://matplotlib.org/api/artist_api.html#module-matplotlib.text for more information on text properties
#text.color : black

#### LaTeX customizations. See http://wiki.scipy.org/Cookbook/Matplotlib/UsingTex
#text.usetex : False ## use latex for all text handling. The following fonts are supported through the usual rc parameter settings:
## new century schoolbook, bookman, times, palatino,
## zapf chancery, charter, serif, sans-serif, helvetica,
## avant garde, courier, monospace, computer modern roman,
## computer modern sans serif, computer modern typewriter
## If another font is desired which can loaded using the \usepackage command, please inquire at the matplotlib mailing list
#text.latex.preamble : ## IMPROPER USE OF THIS FEATURE WILL LEAD TO LATEX FAILURES AND IS THEREFORE UNSUPPORTED. PLEASE DO NOT ASK FOR HELP IF THIS FEATURE DOES NOT DO WHAT YOU EXPECT IT TO.
## text.latex.preamble is a single line of LaTeX code that will be passed on to the LaTeX system. It may contain

(continues on next page)
## any code that is valid for the LaTeX "preamble", i.e.
## between the \"\documentclass" and \"\begin{document}\" 
## statements.
## Note that it has to be put on a single line, which may
## become quite long.
## The following packages are always loaded with use\TeX, so
## beware of package collisions: color, geometry, graphicx,
## type1cm, textcomp.
## Adobe Postscript (PSSNFS) font packages may also be
## loaded, depending on your font settings.

#text.latex.preview : False

#text.hinting : auto  ## May be one of the following:
## none: Perform no hinting
## auto: Use FreeType's autohinter
## native: Use the hinting information in the
## font file, if available, and if your
## FreeType library supports it
## either: Use the native hinting information,
## or the autohinter if none is available.
## For backward compatibility, this value may also be
## True == 'auto' or False == 'none'.
#text.hinting_factor : 8  ## Specifies the amount of softness for hinting in the
## horizontal direction. A value of 1 will hint to full
## pixels. A value of 2 will hint to half pixels etc.
#text.antialiased : True  ## If True (default), the text will be antialiased.
## This only affects the Agg backend.

## The following settings allow you to select the fonts in math mode.
## They map from a TeX font name to a fontconfig font pattern.
## These settings are only used if \textsf{mathtext.fontset} is 'custom'.
## Note that this "custom" mode is unsupported and may go away in the
## future.
#mathtext.cal : cursive
#mathtext.rm : sans
#mathtext.tt : monospace
#mathtext.it : sans:italic
#mathtext.bf : sans:bold
#mathtext.sf : sans
#mathtext.fontset : dejavusans  ## Should be 'dejavusans' (default),
                     ## 'dejavuserif', 'cm' (Computer Modern), 'stix',
                     ## 'stixsans' or 'custom'
#mathtext.fallback_to_cm : True  ## When True, use symbols from the Computer Modern
                               ## fonts when a symbol can not be found in one of
                               ## the custom math fonts.
#mathtext.default : it   ## The default font to use for math.
                     ## Can be any of the \LaTeX\ font names, including
                     ## the special name "regular" for the same font
                     ## used in regular text.

### AXES
## default face and edge color, default tick sizes,
## default fontsizes for ticklabels, and so on. See

## http://matplotlib.org/api/axes_api.html#module-matplotlib.axes

#axes.facecolor : white ## axes background color
#axes.edgecolor : black ## axes edge color
#axes.linewidth : 0.8 ## edge linewidth
#axes.grid : False ## display grid or not
#axes.grid.axis : both ## which axis the grid should apply to
#axes.grid.which : major ## gridlines at major, minor or both ticks
#axes.titlesize : large ## fontsize of the axes title
#axes.titleweight : normal ## font weight of title
#axes.titlepad : 6.0 ## pad between axes and title in points
#axes.labelsize : medium ## fontsize of the x any y labels
#axes.labelpad : 4.0 ## space between label and axis
#axes.labelweight : normal ## weight of the x and y labels
#axes.labelcolor : black
#axes.axisbelow : line ## draw axis gridlines and ticks below
## patches (True); above patches but below
## lines ('line'); or above all (False)
#axes.formatter.limits : -7, 7 ## use scientific notation if log10
## of the axis range is smaller than the
## first or larger than the second
#axes.formatter.use_locale : False ## When True, format tick labels
## according to the user's locale.
## For example, use ',' as a decimal
## separator in the fr_FR locale.
#axes.formatter.use_mathtext : False ## When True, use mathtext for scientific
## notation.
#axes.formatter.min_exponent : 0 ## minimum exponent to format in scientific notation
#axes.formatter.useoffset : True ## If True, the tick label formatter
## will default to labeling ticks relative
## to an offset when the data range is
## small compared to the minimum absolute
## value of the data.
#axes.formatter.offset_threshold : 4 ## When useoffset is True, the offset
## will be used when it can remove
## at least this number of significant
## digits from tick labels.
#axes.spines.left : True ## display axis spines
#axes.spines.bottom : True
#axes.spines.top : True
#axes.spines.right : True
#axes.unicode_minus : True ## use unicode for the minus symbol
## rather than hyphen. See
## http://en.wikipedia.org/wiki/Plus_and_minus_signs

## Character_codes
#axes.prop_cycle : cycler('color', ['1f77b4', 'ff7f0e', '2ca02c', 'd62728', '9467bd',
## '8c564b', 'e377c2', '7f7f7f', 'bcbd22', '17becf'])
## color cycle for plot lines as list of string
## colorspecs: single letter, long name, or web-style hex
## Note the use of string escapes here ('1f77b4'
## ', instead of 1f77b4)
## as opposed to the rest of this file.
#axes.autolimit_mode : data ## How to scale axes limits to the data.
## Use "data" to use data limits, plus some margin
## Use "round_number" move to the nearest "round" number
#axes.xmargin : .05 ## x margin. See "axes.Axes.margins"
#axes.ymargin : .05 ## y margin See "axes.Axes.margins"
#polaraxes.grid : True ## display grid on polar axes
#axes3d.grid : True ## display grid on 3d axes

#### DATES
## These control the default format strings used in AutoDateFormatter.
## Any valid format datetime format string can be used (see the python
## `datetime` for details). For example using '%%z' will use the locale date
## representation
## '%%X' will use the locale time representation and '%%c' will use the full locale
datetime
## representation.
## These values map to the scales:
## {'year': 365, 'month': 30, 'day': 1, 'hour': 1/24, 'minute': 1 / (24 * 60)}
#date.autoformatter.year : %Y
#date.autoformatter.month : %Y-%m
#date.autoformatter.day : %Y-%m-%d
#date.autoformatter.hour : %m-%d %H
#date.autoformatter.minute : %d %H:%M
#date.autoformatter.second : %H:%M:%S
#date.autoformatter.microsecond : %M:%S.%f

#### TICKS
## see http://matplotlib.org/api/axis_api.html#matplotlib.axis.Tick
#tick.top : False ## draw ticks on the top side
#tick.bottom : True ## draw ticks on the bottom side
#tick.labeltop : False ## draw label on the top
#tick.labelbottom : True ## draw label on the bottom
#tick.major.size : 3.5 ## major tick size in points
#tick.minor.size : 2 ## minor tick size in points
#tick.major.width : 0.8 ## major tick width in points
#tick.minor.width : 0.6 ## minor tick width in points
#tick.major.pad : 3.5 ## distance to major tick label in points
#tick.minor.pad : 3.4 ## distance to the minor tick label in points
#tick.color : black ## color of the tick labels
#tick.labelsize : medium ## fontsize of the tick labels
#tick.direction : out ## direction: in, out, or inout
#tick.minor.visible : False ## visibility of minor ticks on x-axis
#tick.major.top : True ## draw x axis top major ticks
#tick.major.bottom : True ## draw x axis bottom major ticks
#tick.minor.top : True ## draw x axis top minor ticks
#tick.minor.bottom : True ## draw x axis bottom minor ticks
#tick.alignment : center ## alignment of xticks

#ytick.left : True ## draw ticks on the left side
#ytick.right : False ## draw ticks on the right side
#ytick.labelleft : True ## draw tick labels on the left side

(continues on next page)
#ytick.labelright  : False ## draw tick labels on the right side
#ytick.major.size : 3.5 ## major tick size in points
#ytick.minor.size : 2  ## minor tick size in points
#ytick.major.width : 0.8 ## major tick width in points
#ytick.minor.width : 0.6 ## minor tick width in points
#ytick.major.pad : 3.5 ## distance to major tick label in points
#ytick.minor.pad : 3.4 ## distance to the minor tick label in points
#ytick.color : black ## color of the tick labels
#ytick.labelsizer : medium ## fontsize of the tick labels
#ytick.direction : out  ## direction: in, out, or inout
#ytick.minor.visible : False ## visibility of minor ticks on y-axis
#ytick.major.left : True  ## draw y axis left major ticks
#ytick.major.right : True  ## draw y axis right major ticks
#ytick.minor.left : True  ## draw y axis left minor ticks
#ytick.minor.right : True  ## draw y axis right minor ticks
#ytick.alignment : center baseline ## alignment of yticks

#### GRIDS
#grid.color : b0b0b0 ## grid color
#grid.linestyle : -  ## solid
#grid.linewidth : 0.8 ## in points
#grid.alpha : 1.0 ## transparency, between 0.0 and 1.0

#### Legend
#legend.loc : best  
#legend.frameon : True ## if True, draw the legend on a background patch
#legend.framealpha : 0.8 ## legend patch transparency
#legend.facecolor : inherit ## inherit from axes.facecolor; or color spec
#legend.edgecolor : 0.8 ## background patch boundary color
#legend.fancybox : True ## if True, use a rounded box for the
## legend background, else a rectangle
#legend.shadow : False ## if True, give background a shadow effect
#legend.numpoints : 1 ## the number of marker points in the legend line
#legend.scatterpoints : 1 ## number of scatter points
#legend.markerscale : 1.0 ## the relative size of legend markers vs. original
#legend.fontsize : medium
#legend.title_fontsize : None ## None sets to the same as the default axes.
## Dimensions as fraction of fontsize:
#legend.borderpad : 0.4 ## border whitespace
#legend.labelspacing : 0.5 ## the vertical space between the legend entries
#legend.handlelength : 2.0 ## the length of the legend lines
#legend.handleheight : 0.7 ## the height of the legend handle
#legend.handlesep : 0.8 ## the space between the legend line and legend text
#legend.borderpad : 0.5 ## the border between the axes and legend edge
#legend.columnspacing : 2.0 ## column separation

#### FIGURE
## See http://matplotlib.org/api/figure_api.html#matplotlib.figure.Figure
#figure.titlesize : large ## size of the figure title (Figure.suptitle())
#figure.titleweight : normal ## weight of the figure title
#figure.figsize : 6.4, 4.8 ## figure size in inches
#figure.dpi : 100 ## figure dots per inch
```
#figure.facecolor : white  ## figure facecolor
#figure.edgecolor : white  ## figure edgecolor
#figure.frameon : True    ## enable figure frame
#figure.max_open_warning : 20  ## The maximum number of figures to open through
                                ## the pyplot interface before emitting a warning.
                                ## If less than one this feature is disabled.

## The figure subplot parameters. All dimensions are a fraction of the
#figure.subplot.left : 0.125 ## the left side of the subplots of the figure
#figure.subplot.right : 0.9  ## the right side of the subplots of the figure
#figure.subplot.bottom : 0.11 ## the bottom of the subplots of the figure
#figure.subplot.top : 0.88  ## the top of the subplots of the figure
#figure.subplot.wspace : 0.2 ## the amount of width reserved for space between
                              ## subplots,
#figure.subplot.hspace : 0.2 ## the amount of height reserved for space between
                              ## subplots,

## Figure layout
#figure.autolayout : False  ## When True, automatically adjust subplot
                            ## parameters to make the plot fit the figure
                            ## using 'tight_layout'
#figure.constrained_layout.use: False ## When True, automatically make plot
                                     ## elements fit on the figure. (Not compatible
                                     ## with 'autolayout', above).
#figure.constrained_layout.h_pad : 0.04167 ## Padding around axes objects. Float
#figure.constrained_layout.w_pad : 0.04167 ## inches. Default is 3./72. inches (3 pts)
#figure.constrained_layout.hspace : 0.02 ## Space between subplot groups. Float
#figure.constrained_layout.wspace : 0.02 ## a fraction of the subplot widths being
                               ## separated.

### IMAGES
#image.aspect : equal        ## equal | auto | a number
#image.interpolation : nearest  ## see help(imshow) for options
#image.cmap : viridis        ## A colormap name, gray etc...
#image.lut : 256             ## the size of the colormap lookup table
#image.origin : upper        ## lower | upper
#image.resample : True       ## When True, all the images on a set of axes are
                                ## combined into a single composite image before
                                ## saving a figure as a vector graphics file,
                                ## such as a PDF.

### CONTOUR PLOTS
#contour.negative_linestyle : dashed  ## string or on-off ink sequence
#contour.corner_mask : True     ## True | False | legacy

### ERRORBAR PLOTS
#errorbar.capsize : 0         ## length of end cap on error bars in pixels
```
### HISTOGRAM PLOTS

```
#hist.bins : 10  # The default number of histogram bins.
## If Numpy 1.11 or later is
## installed, may also be `auto`
```

### SCATTER PLOTS

```
#scatter.marker : o  # The default marker type for scatter plots.
#scatter.edgecolors : face  # The default edgecolors for scatter plots.
```

### Agg rendering

```
### Warning: experimental, 2008/10/10
#agg.path.chunksize : 0  # 0 to disable; values in the range
## 10000 to 100000 can improve speed slightly
## and prevent an Agg rendering failure
## when plotting very large data sets,
## especially if they are very gappy.
## It may cause minor artifacts, though.
## A value of 20000 is probably a good
## starting point.
```

### PATHS

```
#path.simplify : True  # When True, simplify paths by removing "invisible"
## points to reduce file size and increase rendering
## speed
#path.simplify_threshold : 0.111111111111  # The threshold of similarity below which
## vertices will be removed in the
## simplification process
#path.snap : True  # When True, rectilinear axis-aligned paths will be snapped to
## the nearest pixel when certain criteria are met. When False,
## paths will never be snapped.
#path.sketch : None  # May be none, or a 3-tuple of the form (scale, length,
## randomness).
## *scale* is the amplitude of the wiggle
## perpendicular to the line (in pixels). *length* in
## pixels). *randomness* is the factor by which
## the length is randomly scaled.
#path.effects : []  #
```

### SAVING FIGURES

```
## the default savefig params can be different from the display params
## e.g., you may want a higher resolution, or to make the figure
## background white
#savefig.dpi : figure  # figure dots per inch or 'figure'
#savefig.facecolor : white  # figure facecolor when saving
#savefig.edgecolor : white  # figure edgcolor when saving
#savefig.format : png  # png, ps, pdf, svg
#savefig.bbox : standard  # 'tight' or 'standard'.
## 'tight' is incompatible with pipe-based animation
## backends but will workd with temporary file based
## ffmpeg:
## e.g. setting animation.writer to ffmpeg will not work,
## use ffmpeg_file instead
```

(continues on next page)
#savefig.pad_inches : 0.1
## Padding to be used when bbox is set to 'tight'
#savefig.jpeg_quality: 95
## when a jpeg is saved, the default quality parameter.
#savefig.directory : ~
## default directory in savefig dialog box,
## leave empty to always use current working directory
#savefig.transparent : False
## setting that controls whether figures are saved with a
## transparent background by default
#savefig.orientation : portrait
## Orientation of saved figure

### tk backend params
#tk.window_focus : False
## Maintain shell focus for TkAgg

### ps backend params
#ps.papersize : letter
## auto, letter, legal, ledger, A0-A10, B0-B10
#ps.useafm : False
## use of afm fonts, results in small files
#ps.usedistiller : False
## Experimental: may produce smaller files.
## xpdf intended for production of publication,
## but requires ghostscript, xpdf and ps2eps
#ps.distiller.res : 6000
## dpi
#ps.fonttype : 3
## Output Type 3 (Type3) or Type 42 (TrueType)

### pdf backend params
#pdf.compression : 6
## integer from 0 to 9
## 0 disables compression (good for debugging)
#pdf.fonttype : 3
## Output Type 3 (Type3) or Type 42 (TrueType)
#pdf.use14corefonts : False
#pdf.inheritcolor : False

### svg backend params
#svg.image_inline : True
## write raster image data directly into the svg file
#svg.fonttype : path
## How to handle SVG fonts:
## none: Assume fonts are installed on the machine where the SVG will be viewed.
## path: Embed characters as paths -- supported by most SVG renderers
#svg.hashsalt : None
## if not None, use this string as hash salt
## instead of uuid4

### pgf parameter
#pgf.rcfonts : True
#pgf.preamble : ## see text.latex.preamble for documentation
#pgf.texsystem : xelatex

### docstring params
##docstring.hardcopy = False
## set this when you want to generate hardcopy docstring

## Event keys to interact with figures/plots via keyboard.
## Customize these settings according to your needs.
## Leave the field(s) empty if you don't need a key-map. (i.e., fullscreen : '')
#keymap.fullscreen : f, ctrl+f
## toggling
#keymap.home : h, r, home
## home or reset mnemonic
#keymap.back : left, c, backspace, MouseButton.BACK
## forward / backward keys
#keymap.forward : right, v, MouseButton.FORWARD
## for quick navigation
#keymap.pan : p
## pan mnemonic

(continues on next page)
### ANIMATION settings

- **animation.html**: `none` — How to display the animation as HTML in the IPython notebook. 'html5' uses HTML5 video tag; 'jshtml' creates a Javascript animation.
- **animation.writer**: `ffmpeg` — MovieWriter 'backend' to use.
- **animation.codec**: `h264` — Codec to use for writing movie.
- **animation.bitrate**: `-1` — Controls size/quality tradeoff for movie. `-1` implies let utility auto-determine.
- **animation.frame_format**: `png` — Controls frame format used by temp files.
- **animation.html_args**: — Additional arguments to pass to html writer.
- **animation_ffmpeg_path**: `ffmpeg` — Path to ffmpeg binary. Without full path SPATH is searched.
- **animation_ffmpeg_args**: — Additional arguments to pass to ffmpeg.
- **animation_avconv_path**: `avconv` — Path to avconv binary. Without full path SPATH is searched.
- **animation_avconv_args**: — Additional arguments to pass to avconv.
- **animation_convert_path**: `convert` — Path to ImageMagick's convert binary. On Windows use the full path since convert is also the name of a system tool.
- **animation_convert_args**: — Additional arguments to pass to convert.
- **animation.embed_limit**: `20.0` — Limit, in MB, of size of base64 encoded animation in HTML (i.e. IPython notebook).

---

### 2.2 Intermediate

These tutorials cover some of the more complicated classes and functions in Matplotlib. They can be useful for particular custom and complex visualizations.

**Note:** Click [here](#) to download the full example code

#### 2.2.1 Artist tutorial

Using Artist objects to render on the canvas.

There are three layers to the matplotlib API.
• the `matplotlib.backend_bases.FigureCanvas` is the area onto which the figure is drawn
• the `matplotlib.backend_bases.Renderer` is the object which knows how to draw on the FigureCanvas
• and the `matplotlib.artist.Artist` is the object that knows how to use a renderer to paint onto the canvas.

The `FigureCanvas` and `Renderer` handle all the details of talking to user interface toolkits like `wxPython` or drawing languages like PostScript®, and the `Artist` handles all the high level constructs like representing and laying out the figure, text, and lines. The typical user will spend 95% of their time working with the `Artist`

There are two types of `Artists`: primitives and containers. The primitives represent the standard graphical objects we want to paint onto our canvas: `Line2D`, `Rectangle`, `Text`, `AxesImage`, etc., and the containers are places to put them (`Axes`, `Axes` and `Figure`). The standard use is to create a `Figure` instance, use the `Figure` to create one or more `Axes` or `Subplot` instances, and use the `Axes` or `Subplot` instance helper methods to create the primitives. In the example below, we create a `Figure` instance using `matplotlib.pyplot.figure()`, which is a convenience method for instantiating `Figure` instances and connecting them with your user interface or drawing toolkit `FigureCanvas`. As we will discuss below, this is not necessary – you can work directly with PostScript, PDF `Gtk+`, or `wxPython` `FigureCanvas` instances, instantiate your `Figures` directly and connect them yourselves – but since we are focusing here on the `Artist` API we’ll let `pyplot` handle some of those details for us:

```python
import matplotlib.pyplot as plt
fig = plt.figure()
ax = fig.add_subplot(2, 1, 1) # two rows, one column, first plot
```

The `Axes` is probably the most important class in the `matplotlib` API, and the one you will be working with most of the time. This is because the `Axes` is the plotting area into which most of the objects go, and the `Axes` has many special helper methods (`plot()`, `text()`, `hist()`, `imshow()`), to create the most common graphics primitives (`Line2D`, `Text`, `Rectangle`, `Image`, respectively). These helper methods will take your data (e.g., `numpy` arrays and strings) and create primitive `Artist` instances as needed (e.g., `Line2D`), add them to the relevant containers, and draw them when requested. Most of you are probably familiar with the `Subplot`, which is just a special case of an `Axes` that lives on a regular rows by columns grid of `Subplot` instances. If you want to create an `Axes` at an arbitrary location, simply use the `add_axes()` method which takes a list of `[left, bottom, width, height]` values in 0-1 relative figure coordinates:

```python
fig2 = plt.figure()
ax2 = fig2.add_axes([0.15, 0.1, 0.7, 0.3])
```

Continuing with our example:

```python
import numpy as np
t = np.arange(0.0, 1.0, 0.01)
s = np.sin(2*np.pi*t)
line, = ax.plot(t, s, color='blue', lw=2)
```

In this example, `ax` is the `Axes` instance created by the `fig.add_subplot` call above (remember `Subplot` is just a subclass of `Axes`) and when you call `ax.plot`, it creates a `Line2D` instance and adds it to the `Axes` `lines` list. In the interactive `ipython` session below, you can see that the `Axes` `lines` list is length one and contains the same line that was returned by the `line, = ax.plot...` call:
In [101]: ax.lines[0]
Out[101]: <matplotlib.lines.Line2D instance at 0x19a95710>

In [102]: line
Out[102]: <matplotlib.lines.Line2D instance at 0x19a95710>

If you make subsequent calls to `ax.plot` (and the hold state is “on” which is the default) then additional lines will be added to the list. You can remove lines later simply by calling the list methods; either of these will work:

```python
del ax.lines[0]
ax.lines.remove(line)  # one or the other, not both!
```

The Axes also has helper methods to configure and decorate the x-axis and y-axis tick, tick labels and axis labels:

```python
xtext = ax.set_xlabel('my xdata')  # returns a Text instance
ytext = ax.set_ylabel('my ydata')
```

When you call `ax.set_xlabel`, it passes the information on the `Text` instance of the `XAxis`. Each Axes instance contains an `XAxis` and a `YAxis` instance, which handle the layout and drawing of the ticks, tick labels and axis labels.

Try creating the figure below.

```python
import numpy as np
import matplotlib.pyplot as plt

fig = plt.figure()
fig.subplots_adjust(top=0.8)
ax1 = fig.add_subplot(211)
ax1.set_ylabel('volts')
ax1.set_title('a sine wave')

t = np.arange(0.0, 1.0, 0.01)
s = np.sin(2*np.pi*t)
line, = ax1.plot(t, s, color='blue', lw=2)

# Fixing random state for reproducibility
np.random.seed(19680801)

ax2 = fig.add_axes([0.15, 0.1, 0.7, 0.3])
n, bins, patches = ax2.hist(np.random.randn(1000), 50, facecolor='yellow', edgecolor='yellow')
ax2.set_xlabel('time (s)')

plt.show()
```
Customizing your objects

Every element in the figure is represented by a matplotlib Artist, and each has an extensive list of properties to configure its appearance. The figure itself contains a Rectangle exactly the size of the figure, which you can use to set the background color and transparency of the figures. Likewise, each Axes bounding box (the standard white box with black edges in the typical matplotlib plot, has a Rectangle instance that determines the color, transparency, and other properties of the Axes. These instances are stored as member variables Figure.patch and Axes.patch ("Patch" is a name inherited from MATLAB, and is a 2D "patch" of color on the figure, e.g., rectangles, circles and polygons). Every matplotlib Artist has the following properties
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alpha</td>
<td>The transparency - a scalar from 0-1</td>
</tr>
<tr>
<td>animated</td>
<td>A boolean that is used to facilitate animated drawing</td>
</tr>
<tr>
<td>axes</td>
<td>The axes that the Artist lives in, possibly None</td>
</tr>
<tr>
<td>clip_box</td>
<td>The bounding box that clips the Artist</td>
</tr>
<tr>
<td>clip_on</td>
<td>Whether clipping is enabled</td>
</tr>
<tr>
<td>clip_path</td>
<td>The path the artist is clipped to</td>
</tr>
<tr>
<td>contains</td>
<td>A picking function to test whether the artist contains the pick point</td>
</tr>
<tr>
<td>figure</td>
<td>The figure instance the artist lives in, possibly None</td>
</tr>
<tr>
<td>label</td>
<td>A text label (e.g., for auto-labeling)</td>
</tr>
<tr>
<td>picker</td>
<td>A python object that controls object picking</td>
</tr>
<tr>
<td>transform</td>
<td>The transformation</td>
</tr>
<tr>
<td>visible</td>
<td>A boolean whether the artist should be drawn</td>
</tr>
<tr>
<td>zorder</td>
<td>A number which determines the drawing order</td>
</tr>
<tr>
<td>rasterized</td>
<td>Boolean; Turns vectors into raster graphics (for compression &amp; eps transparency)</td>
</tr>
</tbody>
</table>

Each of the properties is accessed with an old-fashioned setter or getter (yes we know this irritates Pythonistas and we plan to support direct access via properties or traits but it hasn’t been done yet). For example, to multiply the current alpha by a half:

```python
a = o.get_alpha()
o.set_alpha(0.5*a)
```

If you want to set a number of properties at once, you can also use the `set` method with keyword arguments. For example:

```python
o.set(alpha=0.5, zorder=2)
```

If you are working interactively at the python shell, a handy way to inspect the `Artist` properties is to use the `matplotlib.artist.getp()` function (simply `getp()` in pyplot), which lists the properties and their values. This works for classes derived from `Artist` as well, e.g., `Figure` and `Rectangle`. Here are the `Figure` rectangle properties mentioned above:

```
In [149]: matplotlib.artist.getp(fig.patch)
    alpha = 1.0
    animated = False
    antialiased or aa = True
    axes = None
    clip_box = None
    clip_on = False
    clip_path = None
    contains = None
    edgecolor or ec = w
    facecolor or fc = 0.75
    figure = Figure(8.125x6.125)
    fill = 1
    hatch = None
    height = 1
    label =
    linewidth or lw = 1.0
```

(continues on next page)
picker = None
transform = <Affine object at 0x134cca84>
verts = ((0, 0), (0, 1), (1, 1), (1, 0))
visible = True
width = 1
window_extent = <Bbox object at 0x134acbcc>
x = 0
y = 0
zorder = 1

The docstrings for all of the classes also contain the Artist properties, so you can consult the interactive “help” or the matplotlib.artist for a listing of properties for a given object.

Object containers

Now that we know how to inspect and set the properties of a given object we want to configure, we need to know how to get at that object. As mentioned in the introduction, there are two kinds of objects: primitives and containers. The primitives are usually the things you want to configure (the font of a Text instance, the width of a Line2D) although the containers also have some properties as well – for example the Axes Artist is a container that contains many of the primitives in your plot, but it also has properties like the xscale to control whether the xaxis is ‘linear’ or ‘log’. In this section we’ll review where the various container objects store the Artists that you want to get at.

Figure container

The top level container Artist is the matplotlib.figure.Figure, and it contains everything in the figure. The background of the figure is a Rectangle which is stored in Figure.patch. As you add subplots (add_subplot()) and axes (add_axes()) to the figure these will be appended to the Figure.axes. These are also returned by the methods that create them:

```python
In [156]: fig = plt.figure()
In [157]: ax1 = fig.add_subplot(211)
In [158]: ax2 = fig.add_axes([0.1, 0.1, 0.7, 0.3])
In [159]: ax1
Out[159]: <matplotlib.axes.Subplot instance at 0xd54b26c>
In [160]: print(fig.axes)
[<matplotlib.axes.Subplot instance at 0xd54b26c>, <matplotlib.axes.Axes instance at 0xd3f0b2c>]
```

Because the figure maintains the concept of the "current axes" (see Figure.gca and Figure.sca) to support the pylab/pyplot state machine, you should not insert or remove axes directly from the axes list, but rather use the add_subplot() and add_axes() methods to insert, and the delaxes() method to delete. You are free however, to iterate over the list of axes or index into it to get access to Axes instances you want to customize. Here is an example which turns all the axes grids on:
The figure also has its own text, lines, patches and images, which you can use to add primitives directly. The default coordinate system for the `Figure` will simply be in pixels (which is not usually what you want) but you can control this by setting the transform property of the `Artist` you are adding to the figure.

More useful is “figure coordinates” where (0, 0) is the bottom-left of the figure and (1, 1) is the top-right of the figure which you can obtain by setting the `Artist` transform to `fig.transFigure`:

```python
import matplotlib.pyplot as plt

fig = plt.figure()

l1 = plt.Line2D([0, 1], [0, 1], transform=fig.transFigure, figure=fig)
l2 = plt.Line2D([0, 1], [1, 0], transform=fig.transFigure, figure=fig)
fig.lines.extend([l1, l2])

plt.show()
```

Here is a summary of the Artists the figure contains
### Axes container

The `matplotlib.axes.Axes` is the center of the matplotlib universe – it contains the vast majority of all the Artists used in a figure with many helper methods to create and add these Artists to itself, as well as helper methods to access and customize the Artists it contains. Like the `Figure`, it contains a `Patch` patch which is a `Rectangle` for Cartesian coordinates and a `Circle` for polar coordinates; this patch determines the shape, background and border of the plotting region:

```python
ax = fig.add_subplot(111)
rect = ax.patch  # a Rectangle instance
rect.set_facecolor('green')
```

When you call a plotting method, e.g., the canonical `plot()` and pass in arrays or lists of values, the method will create a `matplotlib.lines.Line2D()` instance, update the line with all the Line2D properties passed as keyword arguments, add the line to the `Axes.lines` container, and returns it to you:

```python
In [213]: x, y = np.random.rand(2, 100)
In [214]: line, = ax.plot(x, y, '-', color='blue', linewidth=2)
```

`plot` returns a list of lines because you can pass in multiple x, y pairs to plot, and we are unpacking the first element of the length one list into the line variable. The line has been added to the `Axes.lines` list:

```python
In [229]: print(ax.lines)
[[<matplotlib.lines.Line2D instance at 0xd378b0c>]]
```

Similarly, methods that create patches, like `bar()` creates a list of rectangles, will add the patches to the `Axes.patches` list:

```python
In [233]: n, bins, rectangles = ax.hist(np.random.randn(1000), 50, facecolor='yellow')
In [234]: rectangles
Out[234]: <a list of 50 Patch objects>
In [235]: print(len(ax.patches))
```

You should not add objects directly to the `Axes.lines` or `Axes.patches` lists unless you know exactly what you are doing, because the `Axes` needs to do a few things when it creates and adds an object. It sets the figure and axes property of the Artist, as well as the default `Axes` transformation (unless a transformation is set). It also inspects the data contained in the

<table>
<thead>
<tr>
<th>Figure attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>axes</td>
<td>A list of Axes instances (includes Subplot)</td>
</tr>
<tr>
<td>patch</td>
<td>The Rectangle background</td>
</tr>
<tr>
<td>images</td>
<td>A list of FigureImage patches - useful for raw pixel display</td>
</tr>
<tr>
<td>legends</td>
<td>A list of Figure Legend instances (different from Axes.legends)</td>
</tr>
<tr>
<td>lines</td>
<td>A list of Figure Line2D instances (rarely used, see Axes.lines)</td>
</tr>
<tr>
<td>patches</td>
<td>A list of Figure patches (rarely used, see Axes.patches)</td>
</tr>
<tr>
<td>texts</td>
<td>A list Figure Text instances</td>
</tr>
</tbody>
</table>
Artist to update the data structures controlling auto-scaling, so that the view limits can be adjusted to contain the plotted data. You can, nonetheless, create objects yourself and add them directly to the Axes using helper methods like `add_line()` and `add_patch()`. Here is an annotated interactive session illustrating what is going on:

```python
In [262]: fig, ax = plt.subplots()

# create a rectangle instance
In [263]: rect = matplotlib.patches.Rectangle((1,1), width=5, height=12)

# by default the axes instance is None
In [264]: print(rect.get_axes())
None

# and the transformation instance is set to the "identity transform"
In [265]: print(rect.get_transform())
<Affine object at 0x13695544>

# now we add the Rectangle to the Axes
In [266]: ax.add_patch(rect)

# and notice that the ax.add_patch method has set the axes
# instance
In [267]: print(rect.get_axes())
Axes(0.125,0.1;0.775x0.8)

# and the transformation has been set too
In [268]: print(rect.get_transform())
<Affine object at 0x15009ca4>

# the default axes transformation is ax.transData
In [269]: print(ax.transData)
<Affine object at 0x15009ca4>

# notice that the xlims of the Axes have not been changed
In [270]: print(ax.get_xlim())
(0.0, 1.0)

# but the data limits have been updated to encompass the rectangle
In [271]: print(ax.dataLim.bounds)
(1.0, 1.0, 5.0, 12.0)

# we can manually invoke the auto-scaling machinery
In [272]: ax.autoscale_view()

# and now the xlim are updated to encompass the rectangle
In [273]: print(ax.get_xlim())
(1.0, 6.0)

# we have to manually force a figure draw
In [274]: ax.figure.canvas.draw()
```

There are many, many Axes helper methods for creating primitive Artists and adding them to their respective containers. The table below summarizes a small sampling of them, the kinds
of Artist they create, and where they store them

<table>
<thead>
<tr>
<th>Helper method</th>
<th>Artist</th>
<th>Container</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

In addition to all of these Artists, the Axes contains two important Artist containers: the XAxis and YAxis, which handle the drawing of the ticks and labels. These are stored as instance variables xaxis and yaxis. The XAxis and YAxis containers will be detailed below, but note that the Axes contains many helper methods which forward calls on to the Axis instances so you often do not need to work with them directly unless you want to. For example, you can set the font color of the XAxis ticklabels using the Axes helper method:

```python
for label in ax.get_xticklabels():
    label.set_color('orange')
```

Below is a summary of the Artists that the Axes contains

<table>
<thead>
<tr>

</tbody>
</table>

Axis containers

The matplotlib.axis.Axis instances handle the drawing of the tick lines, the grid lines, the tick labels and the axis label. You can configure the left and right ticks separately for the y-axis, and the upper and lower ticks separately for the x-axis. The Axis also stores the data and view intervals used in auto-scaling, panning and zooming, as well as the Locator and Formatter instances which control where the ticks are placed and how they are represented as strings.

Each Axis object contains a label attribute (this is what pyplot modifies in calls to xlabel() and ylabel()) as well as a list of major and minor ticks. The ticks are XTick and YTick instances, which contain the actual line and text primitives that render the ticks and ticklabels. Because the ticks are dynamically created as needed (e.g., when panning and zooming), you should access the lists of major and minor ticks through their accessor methods get_major_ticks()
and `get_minor_ticks()`. Although the ticks contain all the primitives and will be covered below, `Axis` instances have accessor methods that return the tick lines, tick labels, tick locations etc.:

```python
fig, ax = plt.subplots()
axis = ax.xaxis
axis.get_ticklocs()
```

```
axis.get_ticklabels()
```

**note there are twice as many ticklines as labels because by** default there are tick lines at the top and bottom but only tick labels below the xaxis; this can be customized

```python
axis.get_ticklines()
```

by default you get the major ticks back

```python
axis.get_ticklines()
```

but you can also ask for the minor ticks

```python
axis.get_ticklines(minor=True)
```

```
# Here is a summary of some of the useful accessor methods of the ``Axis``
# (these have corresponding setters where useful, such as
```

(continues on next page)
# set_major_formatter)
#
# ====================== =========================================================
# Accessor method Description
# ====================== =========================================================
# get_scale The scale of the axis, e.g., 'log' or 'linear'
# get_view_interval The interval instance of the axis view limits
# get_data_interval The interval instance of the axis data limits
# get_gridlines A list of grid lines for the Axis
# get_label The axis label - a Text instance
# get_ticklabels A list of Text instances - keyword minor=True/False
# get_ticklines A list of Line2D instances - keyword minor=True/False
# get_ticklocs A list of Tick locations - keyword minor=True/False
# get_major_locator The matplotlib.ticker.Locator instance for major ticks
# get_major_formatter The matplotlib.ticker.Formatter instance for major ticks
# get_minor_locator The matplotlib.ticker.Locator instance for minor ticks
# get_minor_formatter The matplotlib.ticker.Formatter instance for minor ticks
# get_major_ticks A list of Tick instances for major ticks
# get_minor_ticks A list of Tick instances for minor ticks
# grid Turn the grid on or off for the major or minor ticks
# ====================== =========================================================
#
# Here is an example, not recommended for its beauty, which customizes
# the axes and tick properties

# plt.figure creates a matplotlib.figure.Figure instance
fig = plt.figure()
rect = fig.patch  # a rectangle instance
rect.set_facecolor('lightgoldenrodyellow')

ax1 = fig.add_axes([0.1, 0.3, 0.4, 0.4])
rect = ax1.patch
rect.set_facecolor('lightslategray')

for label in ax1.xaxis.get_ticklabels():
    # label is a Text instance
    label.set_color('red')
    label.set_rotation(45)
    label.set_fontsize(16)

for line in ax1.yaxis.get_ticklines():
    # line is a Line2D instance
    line.set_color('green')
    line.set_markersize(25)
    line.set_markeredgewidth(3)

plt.show()
Tick containers

The `matplotlib.axis.Tick` is the final container object in our descent from the `Figure` to the `Axes` to the `Axis` to the `Tick`. The `Tick` contains the tick and grid line instances, as well as the label instances for the upper and lower ticks. Each of these is accessible directly as an attribute of the `Tick`.

<table>
<thead>
<tr>
<th>Tick attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tick1line</td>
<td>Line2D instance</td>
</tr>
<tr>
<td>tick2line</td>
<td>Line2D instance</td>
</tr>
<tr>
<td>gridline</td>
<td>Line2D instance</td>
</tr>
<tr>
<td>label1</td>
<td>Text instance</td>
</tr>
<tr>
<td>label2</td>
<td>Text instance</td>
</tr>
</tbody>
</table>

Here is an example which sets the formatter for the right side ticks with dollar signs and colors them green on the right side of the yaxis:

```python
import matplotlib.ticker as ticker

# Fixing random state for reproducibility
np.random.seed(19680801)
```
fig, ax = plt.subplots()
ax.plot(100*np.random.rand(20))

formatter = ticker.FormatStrFormatter('$$%.2f$$')
ax.yaxis.set_major_formatter(formatter)

for tick in ax.yaxis.get_major_ticks():
    tick.label1.set_visible(False)
    tick.label2.set_visible(True)
    tick.label2.set_color('green')

plt.show()
This legend guide is an extension of the documentation available at `legend()` - please ensure you are familiar with contents of that documentation before proceeding with this guide.

This guide makes use of some common terms, which are documented here for clarity:

**legend entry** A legend is made up of one or more legend entries. An entry is made up of exactly one key and one label.

**legend key** The colored/patterned marker to the left of each legend label.

**legend label** The text which describes the handle represented by the key.

**legend handle** The original object which is used to generate an appropriate entry in the legend.

### Controlling the legend entries

Calling `legend()` with no arguments automatically fetches the legend handles and their associated labels. This functionality is equivalent to:

```python
handles, labels = ax.get_legend_handles_labels()
ax.legend(handles, labels)
```

The `get_legend_handles_labels()` function returns a list of handles/artists which exist on the Axes which can be used to generate entries for the resulting legend - it is worth noting however that not all artists can be added to a legend, at which point a "proxy" will have to be created (see Creating artists specifically for adding to the legend (aka. Proxy artists) for further details).

For full control of what is being added to the legend, it is common to pass the appropriate handles directly to `legend()`:

```python
line_up, = plt.plot([1,2,3], label='Line 2')
line_down, = plt.plot([3,2,1], label='Line 1')
plt.legend(handles=[line_up, line_down])
```

In some cases, it is not possible to set the label of the handle, so it is possible to pass through the list of labels to `legend()`:

```python
line_up, = plt.plot([1,2,3], label='Line 2')
line_down, = plt.plot([3,2,1], label='Line 1')
plt.legend([line_up, line_down], ['Line Up', 'Line Down'])
```

### Creating artists specifically for adding to the legend (aka. Proxy artists)

Not all handles can be turned into legend entries automatically, so it is often necessary to create an artist which *can*. Legend handles don’t have to exists on the Figure or Axes in order to be used.

Suppose we wanted to create a legend which has an entry for some data which is represented by a red color:

```python
import matplotlib.patches as mpatches
import matplotlib.pyplot as plt
```

(continues on next page)
red_patch = mpatches.Patch(color='red', label='The red data')
plt.legend(handles=[red_patch])
plt.show()

There are many supported legend handles, instead of creating a patch of color we could have created a line with a marker:

```
import matplotlib.lines as mlines

blue_line = mlines.Line2D([], [], color='blue', marker='*',
                           markersize=15, label='Blue stars')
plt.legend(handles=[blue_line])
plt.show()
```
Legend location

The location of the legend can be specified by the keyword argument `loc`. Please see the documentation at `legend()` for more details.

The `bbox_to_anchor` keyword gives a great degree of control for manual legend placement. For example, if you want your axes legend located at the figure's top right-hand corner instead of the axes' corner, simply specify the corner's location, and the coordinate system of that location:

```python
plt.legend(bbox_to_anchor=(1, 1),
           bbox_transform=plt.gcf().transFigure)
```

More examples of custom legend placement:

```python
plt.subplot(211)
plt.plot([1, 2, 3], label="test1")
plt.plot([3, 2, 1], label="test2")

# Place a legend above this subplot, expanding itself to
# fully use the given bounding box.
plt.legend(bbox_to_anchor=(0., 1.02, 1., .102), loc='lower left',
           ncol=2, mode="expand", borderaxespad=0.)
```

(continues on next page)
Multiple legends on the same Axes

Sometimes it is more clear to split legend entries across multiple legends. Whilst the instinctive approach to doing this might be to call the `legend()` function multiple times, you will find that only one legend ever exists on the Axes. This has been done so that it is possible to call `legend()` repeatedly to update the legend to the latest handles on the Axes, so to persist old legend instances, we must add them manually to the Axes:

```python
plt.subplot(223)
plt.plot([1, 2, 3], label="test1")
plt.plot([3, 2, 1], label="test2")
# Place a legend to the right of this smaller subplot.
plt.legend(bbox_to_anchor=(1.05, 1), loc='upper left', borderaxespad=0.)
plt.show()
```

```python
line1, = plt.plot([1, 2, 3], label="Line 1", linestyle='--')
line2, = plt.plot([3, 2, 1], label="Line 2", linewidth=4)
# Create a legend for the first line.
```

(continues on next page)
first_legend = plt.legend(handles=[line1], loc='upper right')

# Add the legend manually to the current Axes.
ax = plt.gca().add_artist(first_legend)

# Create another legend for the second line.
plt.legend(handles=[line2], loc='lower right')
plt.show()

Legend Handlers

In order to create legend entries, handles are given as an argument to an appropriate
HandlerBase subclass. The choice of handler subclass is determined by the following rules:

1. Update get_legend_handler_map() with the value in the handler_map keyword.
2. Check if the handle is in the newly created handler_map.
3. Check if the type of handle is in the newly created handler_map.
4. Check if any of the types in the handle’s mro is in the newly created handler_map.

For completeness, this logic is mostly implemented in get_legend_handler().
All of this flexibility means that we have the necessary hooks to implement custom handlers for our own type of legend key.

The simplest example of using custom handlers is to instantiate one of the existing `HandlerBase` subclasses. For the sake of simplicity, let’s choose `matplotlib.legend_handler.HandlerLine2D` which accepts a `numpoints` argument (note `numpoints` is a keyword on the `legend()` function for convenience). We can then pass the mapping of instance to Handler as a keyword to `legend`.

```python
from matplotlib.legend_handler import HandlerLine2D

line1, = plt.plot([3, 2, 1], marker='o', label='Line 1')
line2, = plt.plot([1, 2, 3], marker='o', label='Line 2')

plt.legend(handler_map={line1: HandlerLine2D(numpoints=4)})
```

As you can see, “Line 1” now has 4 marker points, where “Line 2” has 2 (the default). Try the above code, only change the map’s key from `line1` to `type(line1)`. Notice how now both `Line2D` instances get 4 markers.

Along with handlers for complex plot types such as errorbars, stem plots and histograms, the default handler_map has a special tuple handler (`HandlerTuple`) which simply plots the handles on top of one another for each item in the given tuple. The following example demonstrates combining two legend keys on top of one another:

```python
from numpy.random import randn
```

(continues on next page)
```
z = randn(10)
red_dot, = plt.plot(z, "ro", markersize=15)
    # Put a white cross over some of the data.
white_cross, = plt.plot(z[5:], "w+", markeredgewidth=3, markersize=15)
plt.legend([red_dot, (red_dot, white_cross)], ["Attr A", "Attr A+B"])
```

The `HandlerTuple` class can also be used to assign several legend keys to the same entry:
```
from matplotlib.legend_handler import HandlerLine2D, HandlerTuple
p1, = plt.plot([1, 2.5, 3], 'r-d')
p2, = plt.plot([3, 2, 1], 'k-o')
l = plt.legend([(p1, p2)], ['Two keys'], numpoints=1,
               handler_map={tuple: HandlerTuple(ndivide=None))}
```
Implementing a custom legend handler

A custom handler can be implemented to turn any handle into a legend key (handles don’t necessarily need to be matplotlib artists). The handler must implement a “legend_artist” method which returns a single artist for the legend to use. Signature details about the "legend_artist" are documented at `legend_artist()`.

```python
import matplotlib.patches as mpatches

class AnyObject(object):
    pass

class AnyObjectHandler(object):
    def legend_artist(self, legend, orig_handle, fontsize, handlebox):
        x0, y0 = handlebox.xdescent, handlebox.ydescent
        width, height = handlebox.width, handlebox.height
        patch = mpatches.Rectangle([x0, y0], width, height, facecolor='red',
                                   edgecolor='black', hatch='xx', lw=3,
                                   transform=handlebox.get_transform())
        handlebox.add_artist(patch)
```

(continues on next page)
plt.legend([AnyObject()], ['My first handler'],
            handler_map={AnyObject: AnyObjectHandler()})

Alternatively, had we wanted to globally accept AnyObject instances without needing to manually set the handler_map keyword all the time, we could have registered the new handler with:

```python
from matplotlib.legend import Legend
Legend.update_default_handler_map({AnyObject: AnyObjectHandler()})
```

Whilst the power here is clear, remember that there are already many handlers implemented and what you want to achieve may already be easily possible with existing classes. For example, to produce elliptical legend keys, rather than rectangular ones:

```python
from matplotlib.legend_handler import HandlerPatch

class HandlerEllipse(HandlerPatch):
    def create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans):
        # (continues on next page)
```
center = 0.5 * width - 0.5 * xdescent, 0.5 * height - 0.5 * ydescent
p = mpatches.Ellipse(xy=center, width=width + xdescent,
                      height=height + ydescent)
            self.update_prop(p, orig_handle, legend)
p.set_transform(trans)
            return [p]

c = mpatches.Circle((0.5, 0.5), 0.25, facecolor="green",
                      edgecolor="red", linewidth=3)
plt.gca().add_patch(c)

plt.legend([c], ["An ellipse, not a rectangle"],
            handler_map={mpatches.Circle: HandlerEllipse()})

### 2.2.3 Styling with cycler

Demo of custom property-cycle settings to control colors and other style properties for multi-line plots.

**Note:** More complete documentation of the `cycler` API can be found [here](https://matplotlib.org/stable/api/cycler_api.html).

This example demonstrates two different APIs:

1. Setting the default rc parameter specifying the property cycle. This affects all subsequent axes (but not axes already created).
2. Setting the property cycle for a single pair of axes.

```python
from cycler import cycler
import numpy as np
import matplotlib.pyplot as plt

# First we'll generate some sample data, in this case, four offset sine curves.
x = np.linspace(0, 2 * np.pi, 50)
offsets = np.linspace(0, 2 * np.pi, 4, endpoint=False)
yy = np.transpose([np.sin(x + phi) for phi in offsets])

Now yy has shape

```python
print(yy.shape)
```

Out:

```
(50, 4)
```

So `yy[:, i]` will give you the `i`-th offset sine curve. Let’s set the default prop_cycle using `matplotlib.pyplot.rc()`. We’ll combine a color cycler and a linestyle cycler by adding (+) two `cycler`’s together. See the bottom of this tutorial for more information about combining different cyclers.

```python
default_cycler = (cycler(color=['r', 'g', 'b', 'y']) +
cycler(linestyle=['-', '--', ':', '-.']))

plt.rc('lines', linewidth=4)
plt.rc('axes', prop_cycle=default_cycler)
```

Now we’ll generate a figure with two axes, one on top of the other. On the first axis, we’ll plot with the default cycler. On the second axis, we’ll set the prop_cycler using `matplotlib.axes.Axes.set_prop_cycle()` which will only set the prop_cycle for this `matplotlib.axes.Axes` instance. We’ll use a second `cycler` that combines a color cycler and a linewidth cycler.

```python
custom_cycler = (cycler(color=['c', 'm', 'y', 'k']) +
cycler(lw=[1, 2, 3, 4]))

fig, (ax0, ax1) = plt.subplots(nrows=2)
ax0.plot(yy)
ax0.set_title('Set default color cycle to rgby')
```
ax1.set_prop_cycle(custom_cycler)
ax1.plot(yy)
ax1.set_title('Set axes color cycle to cmyk')

# Add a bit more space between the two plots.
fig.subplots_adjust(hspace=0.3)
plt.show()

Setting prop_cycler in the matplotlibrc file or style files

Remember, if you want to set a custom prop_cycler in your .matplotlibrc file or a style file (style.mplstyle), you can set the axes.prop_cycle property:

```python
axes.prop_cycle : cycler(color='bgrcmyk')
```

Cycling through multiple properties

You can add cyclers:
from cycler import cycler
cc = (cycler(color=list('rgb')) +
      cycler(linestyle=['-', '--', '-.']))
for d in cc:
    print(d)

Results in:

{'color': 'r', 'linestyle': '-'}
{'color': 'g', 'linestyle': '--'}
{'color': 'b', 'linestyle': '-.'}

You can multiply cyclers:

from cycler import cycler
cc = (cycler(color=list('rgb')) *
      cycler(linestyle=['-', '--', '-.']))
for d in cc:
    print(d)

Results in:

{'color': 'r', 'linestyle': '-'}
{'color': 'r', 'linestyle': '--'}
{'color': 'r', 'linestyle': '-.'}
{'color': 'g', 'linestyle': '-'}
{'color': 'g', 'linestyle': '--'}
{'color': 'g', 'linestyle': '-.'}
{'color': 'b', 'linestyle': '-'}
{'color': 'b', 'linestyle': '--'}
{'color': 'b', 'linestyle': '-.'}

Note: Click here to download the full example code

2.2.4 Customizing Figure Layouts Using GridSpec and Other Functions

How to create grid-shaped combinations of axes.

subplots() Perhaps the primary function used to create figures and axes. It’s also similar to matplotlib.pyplot.subplot(), but creates and places all axes on the figure at once. See also matplotlib.Figure.subplots.

GridSpec Specifies the geometry of the grid that a subplot will be placed. The number of rows and number of columns of the grid need to be set. Optionally, the subplot layout parameters (e.g., left, right, etc.) can be tuned.

SubplotSpec Specifies the location of the subplot in the given GridSpec.

subplot2grid() A helper function that is similar to subplot(), but uses 0-based indexing and let subplot to occupy multiple cells. This function is not covered in this tutorial.
Basic Quickstart Guide

These first two examples show how to create a basic 2-by-2 grid using both `subplots()` and `gridspec`.

Using `subplots()` is quite simple. It returns a `Figure` instance and an array of `Axes` objects.

```python
fig1, f1_axes = plt.subplots(ncols=2, nrows=2, constrained_layout=True)
```

For a simple use case such as this, `gridspec` is perhaps overly verbose. You have to create the figure and `GridSpec` instance separately, then pass elements of gridspec instance to the `add_subplot()` method to create the axes objects. The elements of the gridspec are accessed in generally the same manner as numpy arrays.

```python
fig2 = plt.figure(constrained_layout=True)
spec2 = gridspec.GridSpec(ncols=2, nrows=2, figure=fig2)
f2_ax1 = fig2.add_subplot(spec2[0, 0])
f2_ax2 = fig2.add_subplot(spec2[0, 1])
```

(continues on next page)
The power of gridspec comes in being able to create subplots that span rows and columns. Note the Numpy slice syntax for selecting the part of the gridspec each subplot will occupy.

Note that we have also used the convenience method Figure.add_gridspec instead of gridspec. GridSpec, potentially saving the user an import, and keeping the namespace cleaner.

```python
fig3 = plt.figure(constrained_layout=True)
gs = fig3.add_gridspec(3, 3)
f3_ax1 = fig3.add_subplot(gs[0, :])
f3_ax1.set_title('gs[0, :]')
f3_ax2 = fig3.add_subplot(gs[1, :-1])
f3_ax2.set_title('gs[1, :-1]')
f3_ax3 = fig3.add_subplot(gs[1:, -1])
f3_ax3.set_title('gs[1:, -1]')
f3_ax4 = fig3.add_subplot(gs[-1, 0])
f3_ax4.set_title('gs[-1, 0]')
f3_ax5 = fig3.add_subplot(gs[-1, -2])
f3_ax5.set_title('gs[-1, -2]')
```
gridspec is also indispensable for creating subplots of different widths via a couple of methods. The method shown here is similar to the one above and initializes a uniform grid specification, and then uses numpy indexing and slices to allocate multiple “cells” for a given subplot.

```
fig4 = plt.figure(constrained_layout=True)
spec4 = fig4.add_gridspec(ncols=2, nrows=2)
anno_opts = dict(xy=(0.5, 0.5), xycoords='axes fraction',
                 va='center', ha='center')

f4_ax1 = fig4.add_subplot(spec4[0, 0])
f4_ax1.annotate('GridSpec[0, 0]', **anno_opts)
fig4.add_subplot(spec4[0, 1]).annotate('GridSpec[0, 1:]', **anno_opts)
fig4.add_subplot(spec4[1, 0]).annotate('GridSpec[1:, 0]', **anno_opts)
fig4.add_subplot(spec4[1, 1]).annotate('GridSpec[1:, 1]', **anno_opts)
```
Another option is to use the `width_ratios` and `height_ratios` parameters. These keyword arguments are lists of numbers. Note that absolute values are meaningless, only their relative ratios matter. That means that `width_ratios=[2, 4, 8]` is equivalent to `width_ratios=[1, 2, 4]` within equally wide figures. For the sake of demonstration, we'll blindly create the axes within *for* loops since we won't need them later.

```python
fig5 = plt.figure(constrained_layout=True)
widths = [2, 3, 1.5]
heights = [1, 3, 2]
spec5 = fig5.add_gridspec(ncols=3, nrows=3, width_ratios=widths,
                           height_ratios=heights)
for row in range(3):
    for col in range(3):
        ax = fig5.add_subplot(spec5[row, col])
        label = 'Width: {}
Height: {}'.format(widths[col], heights[row])
        ax.annotate(label, (0.1, 0.5), xycoords='axes fraction', va='center')
```

2.2. Intermediate
Learning to use `width_ratios` and `height_ratios` is particularly useful since the top-level function `subplots()` accepts them within the `gridspec_kw` parameter. For that matter, any parameter accepted by `GridSpec` can be passed to `subplots()` via the `gridspec_kw` parameter. This example recreates the previous figure without directly using a gridspec instance.

```python
gs_kw = dict(width_ratios=widths, height_ratios=heights)
fig6, f6_axes = plt.subplots(ncols=3, nrows=3, constrained_layout=True,
                           gridspec_kw=gs_kw)
for r, row in enumerate(f6_axes):
    for c, ax in enumerate(row):
        label = ('Width: {}
        Height: {}').format(widths[c], heights[r])
        ax.annotate(label, (0.1, 0.5), xycoords='axes fraction', va='center')
```

The `subplots` and `gridspec` methods can be combined since it is sometimes more convenient to make most of the subplots using `subplots` and then remove some and combine them. Here we create a layout with the bottom two axes in the last column combined.

```python
fig7, f7_axs = plt.subplots(ncols=3, nrows=3)
gs = f7_axs[1, 2].get_gridspec()
# remove the underlying axes
for ax in f7_axs[1:, -1]:
    ax.remove()
axbig = fig7.add_subplot(gs[1:, -1])
axbig.annotate('Big Axes
nGridSpec[1:, -1]', (0.1, 0.5),
                 xycoords='axes fraction', va='center')
fig7.tight_layout()
```
Fine Adjustments to a Gridspec Layout

When a GridSpec is explicitly used, you can adjust the layout parameters of subplots that are created from the GridSpec. Note this option is not compatible with constrained_layout or Figure.tight_layout which both adjust subplot sizes to fill the figure.

```python
fig8 = plt.figure(constrained_layout=False)
gs1 = fig8.add_gridspec(nrows=3, ncols=3, left=0.05, right=0.48, wspace=0.05)
f8_ax1 = fig8.add_subplot(gs1[:-1, :])
f8_ax2 = fig8.add_subplot(gs1[-1, :-1])
f8_ax3 = fig8.add_subplot(gs1[-1, -1])
```
This is similar to `subplots_adjust()`, but it only affects the subplots that are created from the given GridSpec.

For example, compare the left and right sides of this figure:

```python
fig9 = plt.figure(constrained_layout=False)
gs1 = fig9.add_gridspec(nrows=3, ncols=3, left=0.05, right=0.48, wspace=0.05)
f9_ax1 = fig9.add_subplot(gs1[:-1, :])
f9_ax2 = fig9.add_subplot(gs1[-1, :-1])
f9_ax3 = fig9.add_subplot(gs1[-1, -1])

gs2 = fig9.add_gridspec(nrows=3, ncols=3, left=0.55, right=0.98, hspace=0.05)
f9_ax4 = fig9.add_subplot(gs2[:, :-1])
f9_ax5 = fig9.add_subplot(gs2[:1, -1])
f9_ax6 = fig9.add_subplot(gs2[1:, -1])
```
GridSpec using SubplotSpec

You can create GridSpec from the SubplotSpec, in which case its layout parameters are set to that of the location of the given SubplotSpec.

Note this is also available from the more verbose `gridspec.GridSpecFromSubplotSpec`.

```python
fig10 = plt.figure(constrained_layout=True)
gs0 = fig10.add_gridspec(1, 2)

gs00 = gs0[0].subgridspec(2, 3)
gs01 = gs0[1].subgridspec(3, 2)

for a in range(2):
    for b in range(3):
        fig10.add_subplot(gs00[a, b])
        fig10.add_subplot(gs01[b, a])
```
A Complex Nested GridSpec using SubplotSpec

Here's a more sophisticated example of nested GridSpec where we put a box around each cell of the outer 4x4 grid, by hiding appropriate spines in each of the inner 3x3 grids.

```python
import numpy as np
from itertools import product

def squiggle_xy(a, b, c, d, i=np.arange(0.0, 2*np.pi, 0.05)):
    return np.sin(i*a)*np.cos(i*b), np.sin(i*c)*np.cos(i*d)

fig11 = plt.figure(figsize=(8, 8), constrained_layout=False)

# gridspec inside gridspec
outer_grid = fig11.add_gridspec(4, 4, wspace=0.0, hspace=0.0)

for i in range(16):
    inner_grid = outer_grid[i].subgridspec(3, 3, wspace=0.0, hspace=0.0)
    a, b = int(i/4)+1, i % 4+1
    for j, (c, d) in enumerate(product(range(1, 4), repeat=2)):
        # (continues on next page)
```
```python
ax = fig11.add_subplot(inner_grid[j])
ax.plot(*squiggle_xy(a, b, c, d))
ax.set_xticks([])
ax.set_yticks([])
fig11.add_subplot(ax)

all_axes = fig11.get_axes()

# show only the outside spines
for ax in all_axes:
    for sp in ax.spines.values():
        sp.set_visible(False)
    if ax.is_first_row():
        ax.spines['top'].set_visible(True)
    if ax.is_last_row():
        ax.spines['bottom'].set_visible(True)
    if ax.is_first_col():
        ax.spines['left'].set_visible(True)
    if ax.is_last_col():
        ax.spines['right'].set_visible(True)

plt.show()
```
References

The usage of the following functions and methods is shown in this example:

```python
matplotlib.pyplot.subplots
matplotlib.figure.Figure.add_gridspec
matplotlib.figure.Figure.add_subplot
matplotlib.gridspec.GridSpec
matplotlib.gridspec.SubplotSpec.subgridspec
matplotlib.gridspec.GridSpecFromSubplotSpec
```
2.2.5 Constrained Layout Guide

How to use constrained-layout to fit plots within your figure cleanly.

`constrained_layout` automatically adjusts subplots and decorations like legends and colorbars so that they fit in the figure window while still preserving, as best they can, the logical layout requested by the user.

`constrained_layout` is similar to `tight_layout`, but uses a constraint solver to determine the size of axes that allows them to fit.

`constrained_layout` needs to be activated before any axes are added to a figure. Two ways of doing so are

- using the respective argument to `subplots()` or `figure()`, e.g.:

  ```python
  plt.subplots(constrained_layout=True)
  ```

- activate it via `rcParams`, like:

  ```python
  plt.rcParams['figure.constrained_layout.use'] = True
  ```

Those are described in detail throughout the following sections.

**Warning:** Currently Constrained Layout is experimental. The behaviour and API are subject to change, or the whole functionality may be removed without a deprecation period. If you require your plots to be absolutely reproducible, get the Axes positions after running Constrained Layout and use `ax.set_position()` in your code with `constrained_layout=False`.

Simple Example

In Matplotlib, the location of axes (including subplots) are specified in normalized figure coordinates. It can happen that your axis labels or titles (or sometimes even ticklabels) go outside the figure area, and are thus clipped.

```python
# sphinx_gallery_thumbnail_number = 18

import matplotlib.pyplot as plt
import matplotlib.colors as mcolors
import matplotlib.gridspec as gridspec
import numpy as np

plt.rcParams['savefig.facecolor'] = "0.8"
plt.rcParams['figure.figsize'] = 4.5, 4.
```

(continues on next page)
def example_plot(ax, fontsize=12, nodec=False):
    ax.plot([1, 2])
    axlocator_params(nbins=3)
    if not nodec:
        ax.set_xlabel('x-label', fontsize=fontsize)
        ax.set_ylabel('y-label', fontsize=fontsize)
        ax.set_title('Title', fontsize=fontsize)
    else:
        ax.set_xticklabels('')
        ax.set_yticklabels('')

fig, ax = plt.subplots(constrained_layout=False)
example_plot(ax, fontsize=24)

To prevent this, the location of axes needs to be adjusted. For subplots, this can be done by adjusting the subplot params (*Move the edge of an axes to make room for tick labels*). However, specifying your figure with the `constrained_layout=True` kwarg will do the adjusting automatically.

fig, ax = plt.subplots(constrained_layout=True)
example_plot(ax, fontsize=24)
When you have multiple subplots, often you see labels of different axes overlapping each other.

```python
fig, axs = plt.subplots(2, 2, constrained_layout=False)
for ax in axs.flat:
    example_plot(ax)
```
Specifying `constrained_layout=True` in the call to `plt.subplots` causes the layout to be properly constrained.

```python
fig, axs = plt.subplots(2, 2, constrained_layout=True)
for ax in axs.flat:
    example_plot(ax)
```
If you create a colorbar with the `colorbar()` command you need to make room for it. `constrained_layout` does this automatically. Note that if you specify `use_gridspec=True` it will be ignored because this option is made for improving the layout via `tight_layout`.

**Note:** For the `pcolorsh` `kwargs (pc_kwargs)` we use a dictionary. Below we will assign one colorbar to a number of axes each containing a `ScalarMappable`; specifying the norm and colormap ensures the colorbar is accurate for all the axes.

```python
arr = np.arange(100).reshape((10, 10))
norm = mcolors.Normalize(vmin=0., vmax=100.)
# see note above: this makes all pcolorsh calls consistent:
pc_kwargs = {'rasterized': True, 'cmap': 'viridis', 'norm': norm}
fig, ax = plt.subplots(figsize=(4, 4), constrained_layout=True)
im = ax.pcolorsh(arr, **pc_kwargs)
fig.colorbar(im, ax=ax, shrink=0.6)
```
If you specify a list of axes (or other iterable container) to the ax argument of `colorbar`, `constrained_layout` will take space from the specified axes.

```python
define code block
```
If you specify a list of axes from inside a grid of axes, the colorbar will steal space appropriately, and leave a gap, but all subplots will still be the same size.

```python
fig, axs = plt.subplots(3, 3, figsize=(4, 4), constrained_layout=True)
for ax in axs.flat:
    im = ax.pcolormesh(arr, **pc_kwargs)
fig.colorbar(im, ax=axs[1:, 1], shrink=0.8)
fig.colorbar(im, ax=axs[:, -1], shrink=0.6)
```
Note that there is a bit of a subtlety when specifying a single axes as the parent. In the following, it might be desirable and expected for the colorbars to line up, but they don’t because the colorbar paired with the bottom axes is tied to the subplotspec of the axes, and hence shrinks when the gridspec-level colorbar is added.

```python
fig, axs = plt.subplots(3, 1, figsize=(4, 4), constrained_layout=True)
for ax in axs[:-1]:
    im = ax.pcolormesh(arr, **pc_kwargs)
fig.colorbar(im, ax=axs[-1], shrink=0.6)
im = axs[-1].pcolormesh(arr, **pc_kwargs)
fig.colorbar(im, ax=axs[-1], shrink=0.6)
```
The API to make a single-axes behave like a list of axes is to specify it as a list (or other iterable container), as below:

```python
fig, axs = plt.subplots(3, 1, figsize=(4, 4), constrained_layout=True)
for ax in axs[:-2]:
    im = ax.pcolormesh(arr, **pc_kwargs)
fig.colorbar(im, ax=axs[:-2], shrink=0.6)
im = axs[2].pcolormesh(arr, **pc_kwargs)
fig.colorbar(im, ax=axs[2], shrink=0.6)
```
Suptitle

constrained_layout can also make room for suptitle.

```python
def draw_plot():
    fig, axs = plt.subplots(2, 2, figsize=(4, 4), constrained_layout=True)
    for ax in axs.flat:
        im = ax.pcolormesh(arr, **pc_kwargs)
    fig.colorbar(im, ax=axs, shrink=0.6)
    fig.suptitle('Big Suptitle')
```

2.2. Intermediate
Legends

Legends can be placed outside of their parent axis. Constrained-layout is designed to handle this for `Axes.legend()`. However, constrained-layout does not handle legends being created via `Figure.legend()` (yet).

```python
fig, ax = plt.subplots(constrained_layout=True)
ax.plot(np.arange(10), label='This is a plot')
ax.legend(loc='center left', bbox_to_anchor=(0.8, 0.5))
```
However, this will steal space from a subplot layout:

```python
def draw_spines(ax, top=False, right=False):
    ax.spines['top'].set_visible(top)
    ax.spines['right'].set_visible(right)
fig, axs = plt.subplots(1, 2, figsize=(4, 2), constrained_layout=True)
axs[0].plot(np.arange(10))
axs[1].plot(np.arange(10), label='This is a plot')
axs[1].legend(loc='center left', bbox_to_anchor=(0.8, 0.5))
```

In order for a legend or other artist to not steal space from the subplot layout, we can `leg.set_in_layout(False)`. Of course this can mean the legend ends up cropped, but can be useful if the plot is subsequently called with `fig.savefig('outname.png', bbox_inches='tight')`. Note, however, that the legend’s `get_in_layout` status will have to be toggled again to make the saved file work, and we must manually trigger a draw if we want `constrained_layout` to adjust the size of the axes before printing.

```python
fig, axs = plt.subplots(1, 2, figsize=(4, 2), constrained_layout=True)
```
axs[0].plot(np.arange(10))
axs[1].plot(np.arange(10), label='This is a plot')
leg = axs[1].legend(loc='center left', bbox_to_anchor=(0.8, 0.5))
leg.set_in_layout(False)
# trigger a draw so that constrained_layout is executed once
# before we turn it off when printing....
fig.canvas.draw()
# we want the legend included in the bbox_inches='tight' calcs.
leg.set_in_layout(True)
# we don't want the layout to change at this point.
fig.set_constrained_layout(False)
fig.savefig('CL01.png', bbox_inches='tight', dpi=100)

The saved file looks like:

A better way to get around this awkwardness is to simply use the legend method provided by
Figure.legend:

fig, axs = plt.subplots(1, 2, figsize=(4, 2), constrained_layout=True)
axs[0].plot(np.arange(10))
lines = axs[1].plot(np.arange(10), label='This is a plot')
labels = [l.get_label() for l in lines]
leg = fig.legend(lines, labels, loc='center left',
                 bbox_to_anchor=(0.8, 0.5), bbox_transform=axs[1].transAxes)
fig.savefig('CL02.png', bbox_inches='tight', dpi=100)
Padding and Spacing

For constrained_layout, we have implemented a padding around the edge of each axes. This padding sets the distance from the edge of the plot, and the minimum distance between adjacent plots. It is specified in inches by the keyword arguments `w_pad` and `h_pad` to the function `set_constrained_layout_pads`:

```python
fig, axs = plt.subplots(2, 2, constrained_layout=True)
for ax in axs.flat:
    example_plot(ax, nodec=True)
    ax.set_xticklabels(''
    ax.set_yticklabels(''
fig.set_constrained_layout_pads(w_pad=4./72., h_pad=4./72.,
    hspace=0., wspace=0.)
```

```python
fig, axs = plt.subplots(2, 2, constrained_layout=True)
for ax in axs.flat:
    example_plot(ax, nodec=True)
    ax.set_xticklabels(''
    ax.set_yticklabels(''
fig.set_constrained_layout_pads(w_pad=2./72., h_pad=2./72.,
    hspace=0., wspace=0.)
```
Spacing between subplots is set by `wspace` and `hspace`. There are specified as a fraction of the size of the subplot group as a whole. If the size of the figure is changed, then these spaces change in proportion. Note in the blow how the space at the edges doesn’t change from the above, but the space between subplots does.
fig, axs = plt.subplots(2, 2, constrained_layout=True)
for ax in axs.flat:
    example_plot(ax, nodec=True)
    ax.set_xticklabels('')
    ax.set_yticklabels('')
fig.set_constrained_layout_pads(w_pad=2./72., h_pad=2./72.,
                                hspace=0.2, wspace=0.2)

Spacing with colorbars

Colorbars will be placed \texttt{wspace} and \texttt{hspace} apart from other subplots. The padding between the colorbar and the axis it is attached to will never be less than \texttt{w_pad} (for a vertical colorbar) or \texttt{h_pad} (for a horizontal colorbar). Note the use of the \texttt{pad} kwarg here in the \texttt{colorbar} call. It defaults to 0.02 of the size of the axis it is attached to.

fig, axs = plt.subplots(2, 2, constrained_layout=True)
for ax in axs.flat:
    pc = ax.pcolormesh(arr, **pc_kwargs)
    fig.colorbar(pc, ax=ax, shrink=0.6, pad=0)
    ax.set_xticklabels('')
    ax.set_yticklabels('')
fig.set_constrained_layout_pads(w_pad=2./72., h_pad=2./72.,
                                hspace=0.2, wspace=0.2)
In the above example, the colorbar will not ever be closer than 2 pts to the plot, but if we want it a bit further away, we can specify its value for `pad` to be non-zero.

```python
fig, axs = plt.subplots(2, 2, constrained_layout=True)
for ax in axs.flat:
    pc = ax.pcolormesh(arr, **pc_kwargs)
    ax.set_xticklabels('')
    ax.set_yticklabels('')
fig.set_constrained_layout_pads(w_pad=2./72., h_pad=2./72.,
                                hspace=0.2, wspace=0.2)
```
There are five rcParams that can be set, either in a script or in the matplotlibrc file. They all have the prefix `figure.constrained_layout`:

- **use**: Whether to use constrained_layout. Default is False
- **w_pad, h_pad**: Padding around axes objects. Float representing inches. Default is 3/.72 inches (3 pts)
- **wspace, hspace**: Space between subplot groups. Float representing a fraction of the subplot widths being separated. Default is 0.02.

```python
plt.rcParams['figure.constrained_layout.use'] = True
fig, axs = plt.subplots(2, 2, figsize=(3, 3))
for ax in axs.flat:
    example_plot(ax)
```
Use with GridSpec

constrained_layout is meant to be used with subplots() or GridSpec() and add_subplot().

Note that in what follows constrained_layout=True

```python
fig = plt.figure()

gs1 = gridspec.GridSpec(2, 1, figure=fig)
ax1 = fig.add_subplot(gs1[0])
ax2 = fig.add_subplot(gs1[1])

example_plot(ax1)
example_plot(ax2)
```
More complicated gridspec layouts are possible. Note here we use the convenience functions `add_gridspec` and `subgridspec`.

```python
fig = plt.figure()

gs0 = fig.add_gridspec(1, 2)

gs1 = gs0[0].subgridspec(2, 1)
ax1 = fig.add_subplot(gs1[0])
ax2 = fig.add_subplot(gs1[1])

example_plot(ax1)
example_plot(ax2)

gs2 = gs0[1].subgridspec(3, 1)

for ss in gs2:
    ax = fig.add_subplot(ss)
    example_plot(ax)
    ax.set_title('"
    ax.set_xlabel('"
    ax.set_xlabel("x-label", fontsize=12)
```
Note that in the above the left and columns don’t have the same vertical extent. If we want the top and bottom of the two grids to line up then they need to be in the same gridspec:

```python
fig = plt.figure()

gs0 = fig.add_gridspec(6, 2)

ax1 = fig.add_subplot(gs0[:3, 0])
ax2 = fig.add_subplot(gs0[3:, 0])

example_plot(ax1)
example_plot(ax2)

ax = fig.add_subplot(gs0[0:2, 1])
example_plot(ax)
ax = fig.add_subplot(gs0[2:4, 1])
example_plot(ax)
ax = fig.add_subplot(gs0[4:, 1])
example_plot(ax)
```
This example uses two gridspecs to have the colorbar only pertain to one set of pcolors. Note how the left column is wider than the two right-hand columns because of this. Of course, if you wanted the subplots to be the same size you only needed one gridspec.

def docomplicated(suptitle=None):
    fig = plt.figure()
    gs0 = fig.add_gridspec(1, 2, figure=fig, width_ratios=[1., 2.])
    gsl = gs0[0].subgridspec(2, 1)
    gsr = gs0[1].subgridspec(2, 2)

    for gs in gsl:
        ax = fig.add_subplot(gs)
        example_plot(ax)
        axs + [ax]
    for gs in gsr:
        ax = fig.add_subplot(gs)
        pcm = ax.pcolormesh(arr, *pc_kwargs)
        ax.set_xlabel('x-label')
        ax.set_ylabel('y-label')
        ax.set_title('title')
        axs += [ax]
    fig.colorbar(pcm, ax=axs)
    if suptitle is not None:
        fig.suptitle(suptitle)

docomplicated()
Manually setting axes positions

There can be good reasons to manually set an axes position. A manual call to `set_position` will set the axes so `constrained_layout` has no effect on it anymore. (Note that `constrained_layout` still leaves the space for the axes that is moved).

```python
fig, axs = plt.subplots(1, 2)
example_plot(axs[0], fontsize=12)
axs[1].set_position([0.2, 0.2, 0.4, 0.4])
```
If you want an inset axes in data-space, you need to manually execute the layout using `fig.execute_constrained_layout()` call. The inset figure will then be properly positioned. However, it will not be properly positioned if the size of the figure is subsequently changed. Similarly, if the figure is printed to another backend, there may be slight changes of location due to small differences in how the backends render fonts.

```python
from matplotlib.transforms import Bbox

fig, axs = plt.subplots(1, 2)
example_plot(axs[0], fontsize=12)
fig.execute_constrained_layout()
# put into data-space:
bb_data_ax2 = Bbox.from_bounds(0.5, 1., 0.2, 0.4)
disp_coords = axs[0].transData.transform(bb_data_ax2)
fig_coords_ax2 = fig.transFigure.inverted().transform(disp_coords)
bb_ax2 = Bbox(fig_coords_ax2)
ax2 = fig.add_axes(bb_ax2)
```
Manually turning off `constrained_layout`

`constrained_layout` usually adjusts the axes positions on each draw of the figure. If you want to get the spacing provided by `constrained_layout` but not have it update, then do the initial draw and then call `fig.set_constrained_layout(False)`. This is potentially useful for animations where the tick labels may change length.

Note that `constrained_layout` is turned off for ZOOM and PAN GUI events for the backends that use the toolbar. This prevents the axes from changing position during zooming and panning.

Limitations

Incompatible functions

`constrained_layout` will not work on subplots created via the `subplot` command. The reason is that each of these commands creates a separate `GridSpec` instance and `constrained_layout` uses (nested) gridspecs to carry out the layout. So the following fails to yield a nice layout:

```python
fig = plt.figure()
ax1 = plt.subplot(221)
ax2 = plt.subplot(223)
ax3 = plt.subplot(122)

eample_plot(ax1)
eample_plot(ax2)
eample_plot(ax3)
```
Of course that layout is possible using a gridspec:

```python
fig = plt.figure()
gs = fig.add_gridspec(2, 2)

ax1 = fig.add_subplot(gs[0, 0])
ax2 = fig.add_subplot(gs[1, 0])
ax3 = fig.add_subplot(gs[:, 1])

example_plot(ax1)
example_plot(ax2)
example_plot(ax3)
```
Similarly, `subplot2grid()` doesn’t work for the same reason: each call creates a different parent gridspec.

```python
fig = plt.figure()
ax1 = plt.subplot2grid((3, 3), (0, 0))
ax2 = plt.subplot2grid((3, 3), (0, 1), colspan=2)
ax3 = plt.subplot2grid((3, 3), (1, 0), colspan=2, rowspan=2)
ax4 = plt.subplot2grid((3, 3), (1, 2), rowspan=2)

element_plot(ax1)
element_plot(ax2)
element_plot(ax3)
element_plot(ax4)
```
The way to make this plot compatible with `constrained_layout` is again to use `gridspec` directly.

```python
fig = plt.figure()
gs = fig.add_gridspec(3, 3)

ax1 = fig.add_subplot(gs[0, 0])
ax2 = fig.add_subplot(gs[0, 1:])
ax3 = fig.add_subplot(gs[1:, 0:2])
ax4 = fig.add_subplot(gs[1:, -1])

element_plot(ax1)
element_plot(ax2)
element_plot(ax3)
element_plot(ax4)
```
Other Caveats

- constrained_layout only considers ticklabels, axis labels, titles, and legends. Thus, other artists may be clipped and also may overlap.

- It assumes that the extra space needed for ticklabels, axis labels, and titles is independent of original location of axes. This is often true, but there are rare cases where it is not.

- There are small differences in how the backends handle rendering fonts, so the results will not be pixel-identical.

Debugging

Constrained-layout can fail in somewhat unexpected ways. Because it uses a constraint solver the solver can find solutions that are mathematically correct, but that aren’t at all what the user wants. The usual failure mode is for all sizes to collapse to their smallest allowable value. If this happens, it is for one of two reasons:

1. There was not enough room for the elements you were requesting to draw.

2. There is a bug - in which case open an issue at https://github.com/matplotlib/matplotlib/issues.

If there is a bug, please report with a self-contained example that does not require outside data or dependencies (other than numpy).
Notes on the algorithm

The algorithm for the constraint is relatively straightforward, but has some complexity due to the complex ways we can layout a figure.

Figure layout

Figures are laid out in a hierarchy:

1. Figure: `fig = plt.figure()`
   a. Gridspec `gs0 = gridspec.GridSpec(1, 2, figure=fig)`
      i. Subplotspec: `ss = gs[0, 0]`
         1. Axes: `ax0 = fig.add_subplot(ss)`
      ii. Subplotspec: `ss = gs[0, 1]`
         1. Gridspec: `gsR = gridspec.GridSpecFromSubplotSpec(2, 1, ss)`
            • Subplotspec: `ss = gsR[0, 0]`
               - Axes: `axR0 = fig.add_subplot(ss)`
            • Subplotspec: `ss = gsR[1, 0]`
               - Axes: `axR1 = fig.add_subplot(ss)`

Each item has a layoutbox associated with it. The nesting of gridspecs created with `GridSpecFromSubplotSpec` can be arbitrarily deep.

Each Axes has two layoutboxes. The first one, `ax._layoutbox` represents the outside of the Axes and all its decorations (i.e. ticklabels, axis labels, etc.). The second layoutbox corresponds to the Axes’ `ax.position`, which sets where in the figure the spines are placed.

Why so many stacked containers? Ideally, all that would be needed are the Axes layout boxes. For the Gridspec case, a container is needed if the Gridspec is nested via `GridSpecFromSubplotSpec`. At the top level, it is desirable for symmetry, but it also makes room for `suptitle`.

For the Subplotspec/Axes case, Axes often have colorbars or other annotations that need to be packaged inside the Subplotspec, hence the need for the outer layer.

Simple case: one Axes

For a single Axes the layout is straightforward. The Figure and outer Gridspec layoutboxes coincide. The Subplotspec and Axes boxes also coincide because the Axes has no colorbar. Note the difference between the red `pos` box and the green `ax` box is set by the size of the decorations around the Axes.

In the code, this is accomplished by the entries in `do_constrained_layout()` like:

```python
ax._poslayoutbox.edit_left_margin_min(-bbox.x0 + pos.x0 + w_padt)
```
from matplotlib._layoutbox import plot_children

fig, ax = plt.subplots(constrained_layout=True)
extample_plot(ax, fontsize=24)
plot_children(fig, fig._layoutbox, printit=False)

Simple case: two Axes

For this case, the Axes layoutboxes and the Subplotspec boxes still co-incide. However, because the decorations in the right-hand plot are so much smaller than the left-hand, so the right-hand layoutboxes are smaller.

The Subplotspec boxes are laid out in the code in the subroutine arange_subplotspecs(), which simply checks the subplotspecs in the code against one another and stacks them appropriately.

The two pos axes are lined up. Because they have the same minimum row, they are lined up at the top. Because they have the same maximum row they are lined up at the bottom. In the code this is accomplished via the calls to layoutbox.align. If there was more than one row, then the same horizontal alignment would occur between the rows.

The two pos axes are given the same width because the subplotspecs occupy the same number of columns. This is accomplished in the code where dcols0 is compared to dcolsC. If they are equal, then their widths are constrained to be equal.

While it is a bit subtle in this case, note that the division between the Subplotspecs is not centered, but has been moved to the right to make space for the larger labels on the left-hand plot.
Two Axes and colorbar

Adding a colorbar makes it clear why the Subplotspec layoutboxes must be different from the axes layoutboxes. Here we see the left-hand subplotspec has more room to accommodate the colorbar, and that there are two green ax boxes inside the ss box.

Note that the width of the pos boxes is still the same because of the constraint on their widths because their subplotspecs occupy the same number of columns (one in this example).

The colorbar layout logic is contained in `make_axes` which calls `_constrained_layout`, `layoutcolorbarsingle()` for cbars attached to a single axes, and `_constrained_layout`, `layoutcolorbargridspec()` if the colorbar is associated with a gridspec.
Colorbar associated with a Gridspec

This example shows the Subplotspec layoutboxes being made smaller by a colorbar layoutbox. The size of the colorbar layoutbox is set to be shrink smaller than the vertical extent of the pos layoutboxes in the gridspec, and it is made to be centered between those two points.

```python
fig, axs = plt.subplots(2, 2, constrained_layout=True)
for ax in axs.flat:
    im = ax.pcolormesh(arr, **pc_kwargs)
fig.colorbar(im, ax=axs, shrink=0.6)
plot_children(fig, fig._layoutbox, printit=False)
```
Uneven sized Axes

There are two ways to make axes have an uneven size in a Gridspec layout, either by specifying them to cross Gridspecs rows or columns, or by specifying width and height ratios.

The first method is used here. The constraint that makes the heights be correct is in the code where \( \text{drows}_C < \text{drows}_0 \) which in this case would be 1 is less than 2. So we constrain the height of the 1-row Axes to be less than half the height of the 2-row Axes.

**Note:** This algorithm can be wrong if the decorations attached to the smaller axes are very large, so there is an unaccounted-for edge case.

```python
fig = plt.figure(constrained_layout=True)
gs = gridspec.GridSpec(2, 2, figure=fig)
ax = fig.add_subplot(gs[::, 0])
im = ax.pcolormesh(arr, **pc_kwargs)
ax = fig.add_subplot(gs[0, 1])
im = ax.pcolormesh(arr, **pc_kwargs)
ax = fig.add_subplot(gs[1, 1])
im = ax.pcolormesh(arr, **pc_kwargs)
plot_children(fig, fig._layoutbox, printit=False)
```
Height and width ratios are accommodated with the same part of the code with the smaller axes always constrained to be less in size than the larger.

```python
fig = plt.figure(constrained_layout=True)
gs = gridspec.GridSpec(3, 2, figure=fig,
    height_ratios=[1., 0.5, 1.5],
    width_ratios=[1.2, 0.8])
ax = fig.add_subplot(gs[:, :2])
im = ax.pcolormesh(arr, **pc_kwargs)
ax = fig.add_subplot(gs[2, :])
im = ax.pcolormesh(arr, **pc_kwargs)
ax = fig.add_subplot(gs[0, 1])
im = ax.pcolormesh(arr, **pc_kwargs)
ax = fig.add_subplot(gs[1:, :])
im = ax.pcolormesh(arr, **pc_kwargs)
plot_children(fig, fig._layoutbox, printit=False)
```
Empty gridspec slots

The final piece of the code that has not been explained is what happens if there is an empty gridspec opening. In that case a fake invisible axes is added and we proceed as before. The empty gridspec has no decorations, but the axes position in made the same size as the occupied Axes positions.

This is done at the start of `_constrained_layout.do_constrained_layout()` (hassubplotspec).

```python
textwrapfig = plt.figure(constrained_layout=True)
gs = gridspec.GridSpec(1, 3, figure=fig)
ax = fig.add_subplot(gs[0])
im = ax.pcolormesh(arr, **pc_kwargs)
ax = fig.add_subplot(gs[-1])
im = ax.pcolormesh(arr, **pc_kwargs)
plot_children(fig, fig._layoutbox, printit=False)
plt.show()
```
Other notes

The layout is called only once. This is OK if the original layout was pretty close (which it should be in most cases). However, if the layout changes a lot from the default layout then the decorators can change size. In particular the x and ytick labels can change. If this happens, then we should probably call the whole routine twice.

Total running time of the script: 0 minutes 7.359 seconds

2.2.6 Tight Layout guide

How to use tight-layout to fit plots within your figure cleanly.

tight layout automatically adjusts subplot params so that the subplot(s) fits in to the figure area. This is an experimental feature and may not work for some cases. It only checks the extents of ticklabels, axis labels, and titles.

An alternative to tight_layout is constrained_layout.

Simple Example

In matplotlib, the location of axes (including subplots) are specified in normalized figure coordinates. It can happen that your axis labels or titles (or sometimes even ticklabels) go outside
the figure area, and are thus clipped.

```python
# sphinx_gallery_thumbnail_number = 7

import matplotlib.pyplot as plt
import numpy as np

plt.rcParams['savefig.facecolor'] = "0.8"

def example_plot(ax, fontsize=12):
    ax.plot([1, 2])
    ax.locator_params(nbins=3)
    ax.set_xlabel('x-label', fontsize=fontsize)
    ax.set_ylabel('y-label', fontsize=fontsize)
    ax.set_title('Title', fontsize=fontsize)

plt.close('all')
fig, ax = plt.subplots()
example_plot(ax, fontsize=24)
```

To prevent this, the location of axes needs to be adjusted. For subplots, this can be done by adjusting the subplot params (*Move the edge of an axes to make room for tick labels*). Matplotlib v1.1 introduces a new command `tight_layout()` that does this automatically for
Note that `matplotlib.pyplot.tight_layout()` will only adjust the subplot params when it is called. In order to perform this adjustment each time the figure is redrawn, you can call `fig.set_tight_layout(True)`, or, equivalently, set the `figure.autolayout` rcParam to True.

When you have multiple subplots, often you see labels of different axes overlapping each other.

```python
plt.close('all')

fig, ((ax1, ax2), (ax3, ax4)) = plt.subplots(nrows=2, ncols=2)
example_plot(ax1)
example_plot(ax2)
example_plot(ax3)
example_plot(ax4)
```
`tight_layout()` will also adjust spacing between subplots to minimize the overlaps.

```python
fig, ((ax1, ax2), (ax3, ax4)) = plt.subplots(nrows=2, ncols=2)
example_plot(ax1)
example_plot(ax2)
example_plot(ax3)
example_plot(ax4)
plt.tight_layout()
```
`tight_layout()` can take keyword arguments of `pad`, `w_pad` and `h_pad`. These control the extra padding around the figure border and between subplots. The pads are specified in fraction of fontsize.

```python
fig, ((ax1, ax2), (ax3, ax4)) = plt.subplots(nrows=2, ncols=2)
example_plot(ax1)
example_plot(ax2)
example_plot(ax3)
example_plot(ax4)
plt.tight_layout(pad=0.4, w_pad=0.5, h_pad=1.0)
```
tight_layout() will work even if the sizes of subplots are different as far as their grid specification is compatible. In the example below, ax1 and ax2 are subplots of a 2x2 grid, while ax3 is of a 1x2 grid.

```python
plt.close('all')
fig = plt.figure()

ax1 = plt.subplot(221)
ax2 = plt.subplot(223)
ax3 = plt.subplot(122)

example_plot(ax1)
example_plot(ax2)
example_plot(ax3)

plt.tight_layout()
```
It works with subplots created with `subplot2grid()`. In general, subplots created from the gridspec (Customizing Figure Layouts Using GridSpec and Other Functions) will work.

```python
plt.close('all')
fig = plt.figure()

ax1 = plt.subplot2grid((3, 3), (0, 0))
ax2 = plt.subplot2grid((3, 3), (0, 1), colspan=2)
ax3 = plt.subplot2grid((3, 3), (1, 0), colspan=2, rowspan=2)
ax4 = plt.subplot2grid((3, 3), (1, 2), rowspan=2)

example_plot(ax1)
example_plot(ax2)
example_plot(ax3)
example_plot(ax4)

plt.tight_layout()
```
Although not thoroughly tested, it seems to work for subplots with aspect != “auto” (e.g., axes with images).

```python
arr = np.arange(100).reshape((10, 10))
plt.close('all')
fig = plt.figure(figsize=(5, 4))

ax = plt.subplot(111)
im = ax.imshow(arr, interpolation="none")
plt.tight_layout()
```
Caveats

- `tight_layout()` only considers ticklabels, axis labels, and titles. Thus, other artists may be clipped and also may overlap.

- It assumes that the extra space needed for ticklabels, axis labels, and titles is independent of original location of axes. This is often true, but there are rare cases where it is not.

- `pad=0` clips some of the texts by a few pixels. This may be a bug or a limitation of the current algorithm and it is not clear why it happens. Meanwhile, use of pad at least larger than 0.3 is recommended.

Use with GridSpec

GridSpec has its own `tight_layout()` method (the pyplot api `tight_layout()` also works).

```python
import matplotlib.gridspec as gridspec

plt.close('all')
fig = plt.figure()

gs1 = gridspec.GridSpec(2, 1)
ax1 = fig.add_subplot(gs1[0])
ax2 = fig.add_subplot(gs1[1])

eample_plot(ax1)
```

(continues on next page)
You may provide an optional `rect` parameter, which specifies the bounding box that the subplots will be fit inside. The coordinates must be in normalized figure coordinates and the default is (0, 0, 1, 1).

```python
fig = plt.figure()

gs1 = gridspec.GridSpec(2, 1)
ax1 = fig.add_subplot(gs1[0])
ax2 = fig.add_subplot(gs1[1])

example_plot(ax1)
example_plot(ax2)

gs1.tight_layout(fig, rect=[0, 0, 0.5, 1])
```
For example, this can be used for a figure with multiple gridspecs.

```python
fig = plt.figure()

gs1 = gridspec.GridSpec(2, 1)
ax1 = fig.add_subplot(gs1[0])
ax2 = fig.add_subplot(gs1[1])

example_plot(ax1)
example_plot(ax2)

gs1.tight_layout(fig, rect=[0, 0, 0.5, 1])

gs2 = gridspec.GridSpec(3, 1)

for ss in gs2:
    ax = fig.add_subplot(ss)
    example_plot(ax)
    ax.set_title("")
    ax.set_xlabel("x-label", fontsize=12)

ax.set_xlabel("x-label", fontsize=12)

gs2.tight_layout(fig, rect=[0.5, 0, 1, 1], h_pad=0.5)
```

(continues on next page)
# We may try to match the top and bottom of two grids ::

top = min(gs1.top, gs2.top)
bottom = max(gs1.bottom, gs2.bottom)

gs1.update(top=top, bottom=bottom)
gs2.update(top=top, bottom=bottom)
plt.show()

While this should be mostly good enough, adjusting top and bottom may require adjustment of hspace also. To update hspace & vspace, we call `tight_layout()` again with updated rect argument. Note that the rect argument specifies the area including the ticklabels, etc. Thus, we will increase the bottom (which is 0 for the normal case) by the difference between the bottom from above and the bottom of each gridspec. Same thing for the top.

```python
fig = plt.gcf()

gs1 = gridspec.GridSpec(2, 1)
ax1 = fig.add_subplot(gs1[0])
ax2 = fig.add_subplot(gs1[1])

example_plot(ax1)
```
example_plot(ax2)

gs1.tight_layout(fig, rect=[0, 0, 0.5, 1])

gs2 = gridspec.GridSpec(3, 1)

for ss in gs2:
    ax = fig.add_subplot(ss)
    example_plot(ax)
    ax.set_title("")
    ax.set_xlabel("x-label")

    ax.set_xlabel("x-label", fontsize=12)

gs2.tight_layout(fig, rect=[0.5, 0, 1, 1], h_pad=0.5)

top = min(gs1.top, gs2.top)
bottom = max(gs1.bottom, gs2.bottom)

gs1.update(top=top, bottom=bottom)
gs2.update(top=top, bottom=bottom)

top = min(gs1.top, gs2.top)
bottom = max(gs1.bottom, gs2.bottom)

gs1.tight_layout(fig, rect=[None, 0 + (bottom-gs1.bottom), 0.5, 1 - (gs1.top-top)])
gs2.tight_layout(fig, rect=[0.5, 0 + (bottom-gs2.bottom), None, 1 - (gs2.top-top)],
h_pad=0.5)
Legends and Annotations

Pre Matplotlib 2.2, legends and annotations were excluded from the bounding box calculations that decide the layout. Subsequently these artists were added to the calculation, but sometimes it is undesirable to include them. For instance in this case it might be good to have the axes shring a bit to make room for the legend:

```python
fig, ax = plt.subplots(figsize=(4, 3))
lines = ax.plot(range(10), label='A simple plot')
ax.legend(bbox_to_anchor=(0.7, 0.5), loc='center left',)
fig.tight_layout()
plt.show()
```
However, sometimes this is not desired (quite often when using `fig.savefig('outname.png', bbox_inches='tight')`). In order to remove the legend from the bounding box calculation, we simply set its bounding box with `leg.set_in_layout(False)` and the legend will be ignored.

```python
fig, ax = plt.subplots(figsize=(4, 3))
lines = ax.plot(range(10), label='B simple plot')
leg = ax.legend(bbox_to_anchor=(0.7, 0.5), loc='center left',)
leg.set_in_layout(False)
fig.tight_layout()
plt.show()
```

Use with AxesGrid1

While limited, the axes_grid1 toolkit is also supported.
from mpl_toolkits.axes_grid1 import Grid

plt.close('all')
fig = plt.figure()
grid = Grid(fig, rect=111, nrows_ncols=(2, 2),
    axes_pad=0.25, label_mode='L',
)

for ax in grid:
    example_plot(ax)
    ax.title.set_visible(False)

plt.tight_layout()
Another option is to use AxesGrid1 toolkit to explicitly create an axes for colorbar.

```python
from mpl_toolkits.axes_grid1 import make_axes_locatable

plt.close('all')
arr = np.arange(100).reshape((10, 10))
fig = plt.figure(figsize=(4, 4))
im = plt.imshow(arr, interpolation="none")

divider = make_axes_locatable(fig.axes[0])
cax = divider.append_axes("right", "5\%", pad="3\%")
plt.colorbar(im, cax=cax)

plt.tight_layout()
```
Total running time of the script: 0 minutes 1.919 seconds

2.2.7 origin and extent in imshow

`imshow()` allows you to render an image (either a 2D array which will be color-mapped (based on `norm` and `cmap`) or and 3D RGB(A) array which will be used as-is) to a rectangular region in dataspace. The orientation of the image in the final rendering is controlled by the `origin` and `extent` kwargs (and attributes on the resulting `AxesImage` instance) and the data limits of the axes.

The `extent` kwarg controls the bounding box in data coordinates that the image will fill specified as `(left, right, bottom, top)` in data coordinates, the `origin` kwarg controls how the image fills that bounding box, and the orientation in the final rendered image is also affected by the axes limits.

**Hint:** Most of the code below is used for adding labels and informative text to the plots. The described effects of `origin` and `extent` can be seen in the plots without the need to follow all code details.

For a quick understanding, you may want to skip the code details below and directly continue with the discussion of the results.
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.gridspec import GridSpec

                left=left, right=right, bottom=bottom, top=top))

            ax.annotate(text, **text_kargs)
            ax.axis('off')

    return columns

Default extent

First, let’s have a look at the default extent=None

generate_imshow_demo_grid(extents=[None])
Generally, for an array of shape \((M, N)\), the first index runs along the vertical, the second index runs along the horizontal. The pixel centers are at integer positions ranging from 0 to \(N' = N - 1\) horizontally and from 0 to \(M' = M - 1\) vertically. \texttt{origin} determines how the data is filled in the bounding box.

For \texttt{origin='lower'}:
- \([0, 0]\) is at (left, bottom)
- \([M', 0]\) is at (left, top)
- \([0, N']\) is at (right, bottom)
- \([M', N']\) is at (right, top)

\texttt{origin='upper'} reverses the vertical axes direction and filling:
- \([0, 0]\) is at (left, top)
- \([M', 0]\) is at (left, bottom)
- \([0, N']\) is at (right, top)
- \([M', N']\) is at (right, bottom)

In summary, the position of the \([0, 0]\) index as well as the extent are influenced by \texttt{origin}:

<table>
<thead>
<tr>
<th>\texttt{origin}</th>
<th>([0, 0]) position</th>
<th>extent</th>
</tr>
</thead>
<tbody>
<tr>
<td>upper</td>
<td>top left</td>
<td>((-0.5, \text{numcols}-0.5, \text{numrows}-0.5, -0.5))</td>
</tr>
<tr>
<td>lower</td>
<td>bottom left</td>
<td>((-0.5, \text{numcols}-0.5, -0.5, \text{numrows}-0.5))</td>
</tr>
</tbody>
</table>

The default value of \texttt{origin} is set by \texttt{rcParams["image.origin"]} which defaults to 'upper' to match the matrix indexing conventions in math and computer graphics image indexing conventions.

**Explicit extent**

By setting \texttt{extent} we define the coordinates of the image area. The underlying image data is interpolated/resampled to fill that area.

If the axes is set to autoscale, then the view limits of the axes are set to match the \texttt{extent} which ensures that the coordinate set by \texttt{(left, bottom)} is at the bottom left of the axes! However, this may invert the axis so they do not increase in the 'natural' direction.
```python
extents = [(-0.5, 6.5, -0.5, 5.5),
           (-0.5, 6.5, 5.5, -0.5),
           (6.5, -0.5, -0.5, 5.5),
           (6.5, -0.5, 5.5, -0.5)]

columns = generate_imshow_demo_grid(extents)
set_extent_None_text(columns['upper'][1])
set_extent_None_text(columns['lower'][0])
```
Explicit extent and axes limits

If we fix the axes limits by explicitly setting `set_xlim` / `set_ylim`, we force a certain size and orientation of the axes. This can decouple the 'left-right' and 'top-bottom' sense of the image from the orientation on the screen.

In the example below we have chosen the limits slightly larger than the extent (note the white areas within the Axes).

While we keep the extents as in the examples before, the coordinate (0, 0) is now explicitly put at the bottom left and values increase to up and to the right (from the viewer point of view). We can see that:

- The coordinate (left, bottom) anchors the image which then fills the box going towards the (right, top) point in data space.
- The first column is always closest to the 'left'.
- `origin` controls if the first row is closest to 'top' or 'bottom'.
- The image may be inverted along either direction.
- The 'left-right' and 'top-bottom' sense of the image may be uncoupled from the orientation on the screen.

```python
generate_imshow_demo_grid(extents=[None] + extents,
                          xlim=(-2, 8), ylim=(-1, 6))
```
**2.2. Intermediate**

- **extent=**
  - **origin: upper**
    - None
  - **left: -0.5**
    - **right: 6.5**
    - **bottom: -0.5**
    - **top: 5.5**
  - **origin: lower**
    - None
  - **left: -0.5**
    - **right: 6.5**
    - **bottom: 5.5**
    - **top: 0.5**
  - **left: 6.5**
    - **right: -0.5**
    - **bottom: -0.5**
    - **top: 5.5**
2.3 Advanced

These tutorials cover advanced topics for experienced Matplotlib users and developers.

Note: Click here to download the full example code

2.3.1 Path Tutorial

Defining paths in your Matplotlib visualization.

The object underlying all of the matplotlib.patch objects is the Path, which supports the standard set of moveto, lineto, curveto commands to draw simple and compound outlines consisting of line segments and splines. The Path is instantiated with a (N,2) array of (x,y) vertices, and a N-length array of path codes. For example to draw the unit rectangle from (0,0) to (1,1), we could use this code

```python
import matplotlib.pyplot as plt
from matplotlib.path import Path
import matplotlib.patches as patches

verts = [
    (0., 0.), # left, bottom
    (0., 1.), # left, top
    (1., 1.), # right, top
    (1., 0.), # right, bottom
    (0., 0.), # ignored
]

codes = [
    Path.MOVETO,
    Path.LINETO,
    Path.LINETO,
    Path.LINETO,
    Path.LINETO,
    Path.CLOSEPOLY,
]

path = Path(verts, codes)

fig, ax = plt.subplots()
patch = patches.PathPatch(path, facecolor='orange', lw=2)
ax.add_patch(patch)
ax.set_xlim(-2, 2)
ax.set_ylim(-2, 2)
plt.show()
```
The following path codes are recognized

<table>
<thead>
<tr>
<th>Code</th>
<th>Vertices</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STOP</td>
<td>1 (ignored)</td>
<td>A marker for the end of the entire path (currently not required and ignored)</td>
</tr>
<tr>
<td>MOVETO</td>
<td>1</td>
<td>Pick up the pen and move to the given vertex.</td>
</tr>
<tr>
<td>LINETO</td>
<td>1</td>
<td>Draw a line from the current position to the given vertex.</td>
</tr>
<tr>
<td>CURVE3</td>
<td>2 (1 control point, 1 endpoint)</td>
<td>Draw a quadratic Bézier curve from the current position, with the given control point, to the given end point.</td>
</tr>
<tr>
<td>CURVE4</td>
<td>3 (2 control points, 1 endpoint)</td>
<td>Draw a cubic Bezier curve from the current position, with the given control points, to the given end point.</td>
</tr>
<tr>
<td>CLOSEPOLY</td>
<td>(point itself is ignored)</td>
<td>Draw a line segment to the start point of the current polyline.</td>
</tr>
</tbody>
</table>

**Bézier example**

Some of the path components require multiple vertices to specify them: for example CURVE 3 is a Bézier curve with one control point and one end point, and CURVE4 has three vertices for the two control points and the end point. The example below shows a CURVE4 Bézier spline - the Bézier curve will be contained in the convex hull of the start point, the two control points, and the end point.
verts = [
    (0., 0.),  # P0
    (0.2, 1.),  # P1
    (1., 0.8),  # P2
    (0.8, 0.),  # P3
]

codes = [
    Path.MOVETO,
    Path.CURVE4,
    Path.CURVE4,
    Path.CURVE4,
]

path = Path(verts, codes)

fig, ax = plt.subplots()
patch = patches.PathPatch(path, facecolor='none', lw=2)
ax.add_patch(patch)

xs, ys = zip(*verts)
ax.plot(xs, ys, 'x--', lw=2, color='black', ms=10)

ax.text(-0.05, -0.05, 'P0')
ax.text(0.15, 1.05, 'P1')
ax.text(1.05, 0.85, 'P2')
ax.text(0.85, -0.05, 'P3')

ax.set_xlim(-0.1, 1.1)
ax.set_ylim(-0.1, 1.1)
plt.show()
Compound paths

All of the simple patch primitives in matplotlib, Rectangle, Circle, Polygon, etc, are implemented with simple path. Plotting functions like `hist()` and `bar()`, which create a number of primitives, e.g., a bunch of Rectangles, can usually be implemented more efficiently using a compound path. The reason `bar()` creates a list of rectangles and not a compound path is largely historical: the `Path` code is comparatively new and `bar()` predates it. While we could change it now, it would break old code, so here we will cover how to create compound paths, replacing the functionality in `bar`, in case you need to do so in your own code for efficiency reasons, e.g., you are creating an animated bar plot.

We will make the histogram chart by creating a series of rectangles for each histogram bar: the rectangle width is the bin width and the rectangle height is the number of datapoints in that bin. First we’ll create some random normally distributed data and compute the histogram. Because numpy returns the bin edges and not centers, the length of `bins` is 1 greater than the length of `n` in the example below:

```
# histogram our data with numpy
data = np.random.randn(1000)
n, bins = np.histogram(data, 100)
```

We’ll now extract the corners of the rectangles. Each of the `left`, `bottom`, etc, arrays below is `len(n)`, where `n` is the array of counts for each histogram bar:
# get the corners of the rectangles for the histogram
left = np.array(bins[:-1])
right = np.array(bins[1:])
bottom = np.zeros(len(left))
top = bottom + n

nrects = len(left)
nverts = nrects*(1+3+1)
verts = np.zeros((nverts, 2))
codes = np.ones(nverts, int) * path.Path.LINETO
codes[0::5] = path.Path.MOVETO
codes[4::5] = path.Path.CLOSEPOLY
verts[0::5, 0] = left
verts[0::5, 1] = bottom
verts[1::5, 0] = left
verts[1::5, 1] = top
verts[2::5, 0] = right
verts[2::5, 1] = top
verts[3::5, 0] = right
verts[3::5, 1] = bottom

All that remains is to create the path, attach it to a PathPatch, and add it to our axes:

barpath = path.Path(verts, codes)
patch = patches.PathPatch(barpath, facecolor='green',
edgecolor='yellow', alpha=0.5)
ax.add_patch(patch)

import numpy as np
import matplotlib.patches as patches
import matplotlib.path as path

fig, ax = plt.subplots()
# Fixing random state for reproducibility
np.random.seed(19680801)

# histogram our data with numpy
data = np.random.randn(1000)
n, bins = np.histogram(data, 100)

# get the corners of the rectangles for the histogram
left = np.array(bins[:-1])
right = np.array(bins[1:])
bottom = np.zeros(len(left))
top = bottom + n
nrects = len(left)
nverts = nrects*(1+3+1)
verts = np.zeros((nverts, 2))

(continues on next page)
codes = np.ones(nverts, int) * path.Path.LINETO
codes[0:5] = path.Path.MOVE_TO
codes[4:5] = path.Path.CLOSEPOLY
verts[0:5, 0] = left
verts[0:5, 1] = bottom
verts[1:5, 0] = left
verts[1:5, 1] = top
verts[2:5, 0] = right
verts[2:5, 1] = top
verts[3:5, 0] = right
verts[3:5, 1] = bottom

barpath = path.Path(verts, codes)
patch = patches.PathPatch(barpath, facecolor='green',
                           edgecolor='yellow', alpha=0.5)
ax.add_patch(patch)

ax.set_xlim(left[0], right[-1])
ax.set_ylim(bottom.min(), top.max())
plt.show()
2.3.2 Path effects guide

Defining paths that objects follow on a canvas.

Matplotlib’s `patheffects` module provides functionality to apply a multiple draw stage to any Artist which can be rendered via a `Path`.

Artists which can have a path effect applied to them include `Patch`, `Line2D`, `Collection` and even `Text`. Each artist’s path effects can be controlled via the `set_path_effects` method (`set_path_effects`), which takes an iterable of `AbstractPathEffect` instances.

The simplest path effect is the `Normal` effect, which simply draws the artist without any effect:

```python
import matplotlib.pyplot as plt
import matplotlib.patheffects as path_effects

fig = plt.figure(figsize=(5, 1.5))
text = fig.text(0.5, 0.5, 'Hello path effects world!
This is the normal path effect.
Pretty dull, huh?',
               ha='center', va='center', size=20)
text.set_path_effects([path_effects.Normal()])
plt.show()
```

Hello path effects world!
This is the normal path effect.
Pretty dull, huh?

Whilst the plot doesn’t look any different to what you would expect without any path effects, the drawing of the text now been changed to use the path effects framework, opening up the possibilities for more interesting examples.

Adding a shadow

A far more interesting path effect than `Normal` is the drop-shadow, which we can apply to any of our path based artists. The classes `SimplePatchShadow` and `SimpleLineShadow` do precisely this by drawing either a filled patch or a line patch below the original artist:

```python
import matplotlib.patheffects as path_effects

text = plt.text(0.5, 0.5, 'Hello path effects world!',
                path_effects=[path_effects.withSimplePatchShadow()])

plt.plot([0, 3, 2, 5], linewidth=5, color='blue',
         (continues on next page)
Notice the two approaches to setting the path effects in this example. The first uses the `with*` classes to include the desired functionality automatically followed with the "normal" effect, whereas the latter explicitly defines the two path effects to draw.

**Making an artist stand out**

One nice way of making artists visually stand out is to draw an outline in a bold color below the actual artist. The *Stroke* path effect makes this a relatively simple task:

```python
fig = plt.figure(figsize=(7, 1))
text = fig.text(0.5, 0.5, 'This text stands out because of
its black border.', color='white',
ha='center', va='center', size=30)
text.set_path_effects([path_effects.Stroke(linewidth=3, foreground='black'),
                      path_effects.Normal()])
plt.show()
```
It is important to note that this effect only works because we have drawn the text path twice; once with a thick black line, and then once with the original text path on top.

You may have noticed that the keywords to Stroke and SimplePatchShadow and SimpleLineShadow are not the usual Artist keywords (such as facecolor and edgecolor etc.). This is because with these path effects we are operating at lower level of matplotlib. In fact, the keywords which are accepted are those for a matplotlib.backend_bases.GraphicsContextBase instance, which have been designed for making it easy to create new backends - and not for its user interface.

Greater control of the path effect artist

As already mentioned, some of the path effects operate at a lower level than most users will be used to, meaning that setting keywords such as facecolor and edgecolor raise an AttributeError. Luckily there is a generic PathPatchEffect path effect which creates a PathPatch class with the original path. The keywords to this effect are identical to those of PathPatch:

```python
fig = plt.figure(figsize=(8, 1))
t = fig.text(0.02, 0.5, 'Hatch shadow', fontsize=75, weight=1000, va='center')
t.set_path_effects([path_effects.PathPatchEffect(offset=(4, -4), hatch='xxxx', facecolor='gray'),
                   path_effects.PathPatchEffect(edgecolor='white', linewidth=1.1, facecolor='black')])
plt.show()
```

Note: Click here to download the full example code

2.3.3 Transformations Tutorial

Like any graphics packages, Matplotlib is built on top of a transformation framework to easily move between coordinate systems, the userland data coordinate system, the axes coordinate system, the figure coordinate system, and the display coordinate system. In 95% of your plotting, you won’t need to think about this, as it happens under the hood, but as you push the limits of custom figure generation, it helps to have an understanding of these objects so you can reuse the existing transformations Matplotlib makes available to you, or create your own (see matplotlib.transforms). The table below summarizes the some useful coordinate systems, the transformation object you should use to work in that coordinate system, and the description of that system. In the Transformation Object Column, ax is a Axes instance, and fig is a Figure instance.
<table>
<thead>
<tr>
<th>Coordinates</th>
<th>Transformation object</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;data&quot;</td>
<td>ax.transData</td>
<td>The coordinate system for the data, controlled by xlim and ylim.</td>
</tr>
<tr>
<td>&quot;axes&quot;</td>
<td>ax.transAxes</td>
<td>The coordinate system of the Axes; (0, 0) is bottom left of the axes, and (1, 1) is top right of the axes.</td>
</tr>
<tr>
<td>&quot;figure&quot;</td>
<td>fig.transFigure</td>
<td>The coordinate system of the Figure; (0, 0) is bottom left of the figure, and (1, 1) is top right of the figure.</td>
</tr>
<tr>
<td>&quot;figure-inches&quot;</td>
<td>fig.dpi_scale_trans</td>
<td>The coordinate system of the Figure in inches; (0, 0) is bottom left of the figure, and (width, height) is the top right of the figure in inches.</td>
</tr>
<tr>
<td>&quot;display&quot;</td>
<td>None, or IdentityTransform()</td>
<td>The pixel coordinate system of the display window; (0, 0) is bottom left of the window, and (width, height) is top right of the display window in pixels.</td>
</tr>
<tr>
<td>&quot;xaxis&quot;, &quot;yaxis&quot;</td>
<td>ax.get_xaxis_transform(), ax.get_yaxis_transform()</td>
<td>Blended coordinate systems; use data coordinates on one of the axis and axes coordinates on the other.</td>
</tr>
</tbody>
</table>

All of the transformation objects in the table above take inputs in their coordinate system, and transform the input to the display coordinate system. That is why the display coordinate system has None or the Transformation Object column – it already is in display coordinates. The transformations also know how to invert themselves, to go from display back to the native coordinate system. This is particularly useful when processing events from the user interface, which typically occur in display space, and you want to know where the mouse click or keypress occurred in your data coordinate system.

Note that specifying objects in display coordinates will change their location if the dpi of the figure changes. This can cause confusion when printing or changing screen resolution, because the object can change location and size. Therefore it is most common for artists placed in an axes or figure to have their transform set to something other than the IdentityTransform(); the default when an artist is placed on an axes using add_artist is for the transform to be ax.transData.

Data coordinates

Let’s start with the most commonly used coordinate, the data coordinate system. Whenever you add data to the axes, Matplotlib updates the datalimits, most commonly updated with the set_xlim() and set_ylim() methods. For example, in the figure below, the data limits stretch from 0 to 10 on the x-axis, and -1 to 1 on the y-axis.

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.patches as mpatches

x = np.arange(0, 10, 0.005)
y = np.exp(-x/2.) * np.sin(2*np.pi*x)

fig, ax = plt.subplots()
ax.plot(x, y)
ax.set_xlim(0, 10)
ax.set_ylim(-1, 1)
```
You can use the `ax.transData` instance to transform from your data to your display coordinate system, either a single point or a sequence of points as shown below:

```python
In [14]: type(ax.transData)
Out[14]: <class 'matplotlib.transforms.CompositeGenericTransform'>

In [15]: ax.transData.transform((5, 0))
Out[15]: array([335.175, 247.0])

In [16]: ax.transData.transform(((5, 0), (1, 2)))
Out[16]: array([[335.175, 247.0],
              [132.435, 642.2]])
```

You can use the `inverted()` method to create a transform which will take you from display to data coordinates:

```python
In [41]: inv = ax.transData.inverted()

In [42]: type(inv)
```

(continues on next page)
Out[42]: `<class 'matplotlib.transforms.CompositeGenericTransform'>`

In [43]: inv.transform((335.175, 247.))
Out[43]: array([5., 0.])

If you are typing along with this tutorial, the exact values of the display coordinates may differ if you have a different window size or dpi setting. Likewise, in the figure below, the display labeled points are probably not the same as in the ipython session because the documentation figure size defaults are different.

```python
x = np.arange(0, 10, 0.005)
y = np.exp(-x/2.) * np.sin(2*np.pi*x)

fig, ax = plt.subplots()
ax.plot(x, y)
ax.set_xlim(0, 10)
ax.set_ylim(-1, 1)

xdata, ydata = 5, 0
xdisplay, ydisplay = ax.transData.transform_point((xdata, ydata))

bbox = dict(boxstyle="round", fc="0.8")
arrowprops = dict(
    arrowstyle="->",
    connectionstyle="angle,angleA=0,angleB=90,rad=10")

offset = 72
ax.annotate('data = (%.1f, %.1f)' % (xdata, ydata),
            (xdata, ydata), xytext=(-2*offset, offset),
            textcoords='offset points', bbox=bbox, arrowprops=arrowprops)

disp = ax.annotate('display = (%.1f, %.1f)' % (xdisplay, ydisplay),
                   (xdisplay, ydisplay), xytext=(0.5*offset, -offset),
                   xycoords='figure pixels',
                   textcoords='offset points',
                   bbox=bbox, arrowprops=arrowprops)

plt.show()
```
Note: If you run the source code in the example above in a GUI backend, you may also find that the two arrows for the data and display annotations do not point to exactly the same point. This is because the display point was computed before the figure was displayed, and the GUI backend may slightly resize the figure when it is created. The effect is more pronounced if you resize the figure yourself. This is one good reason why you rarely want to work in display space, but you can connect to the 'on_draw' Event to update figure coordinates on figure draws; see Event handling and picking.

When you change the x or y limits of your axes, the data limits are updated so the transformation yields a new display point. Note that when we just change the ylim, only the y-display coordinate is altered, and when we change the xlim too, both are altered. More on this later when we talk about the Bbox.

In [54]: ax.transData.transform((5, 0))
Out[54]: array([ 335.175,  247.  ])

In [55]: ax.set_ylim(-1, 2)
Out[55]: (-1, 2)

In [56]: ax.transData.transform((5, 0))
Out[56]: array([ 338.175,  181.13333333])

(continues on next page)
Axes coordinates

After the data coordinate system, axes is probably the second most useful coordinate system. Here the point (0, 0) is the bottom left of your axes or subplot, (0.5, 0.5) is the center, and (1.0, 1.0) is the top right. You can also refer to points outside the range, so (-0.1, 1.1) is to the left and above your axes. This coordinate system is extremely useful when placing text in your axes, because you often want a text bubble in a fixed, location, e.g., the upper left of the axes pane, and have that location remain fixed when you pan or zoom. Here is a simple example that creates four panels and labels them 'A', 'B', 'C', 'D' as you often see in journals.

```python
fig = plt.figure()
for i, label in enumerate(['A', 'B', 'C', 'D']):
    ax = fig.add_subplot(2, 2, i+1)
    ax.text(0.05, 0.95, label, transform=ax.transAxes,
            fontsize=16, fontweight='bold', va='top')
plt.show()
```
You can also make lines or patches in the axes coordinate system, but this is less useful in my experience than using `ax.transAxes` for placing text. Nonetheless, here is a silly example which plots some random dots in data space, and overlays a semi-transparent `Circle` centered in the middle of the axes with a radius one quarter of the axes – if your axes does not preserve aspect ratio (see `set_aspect()`), this will look like an ellipse. Use the pan/zoom tool to move around, or manually change the data xlim and ylim, and you will see the data move, but the circle will remain fixed because it is not in data coordinates and will always remain at the center of the axes.

```python
fig, ax = plt.subplots()
x, y = 10*np.random.rand(2, 1000)
ax.plot(x, y, 'go', alpha=0.2)  # plot some data in data coordinates

circ = mpatches.Circle((0.5, 0.5), 0.25, transform=ax.transAxes,
                        facecolor='blue', alpha=0.75)
ax.add_patch(circ)
plt.show()
```
Blended transformations

Drawing in blended coordinate spaces which mix axes with data coordinates is extremely useful, for example to create a horizontal span which highlights some region of the y-data but spans across the x-axis regardless of the data limits, pan or zoom level, etc. In fact these blended lines and spans are so useful, we have built in functions to make them easy to plot (see `axhline()`, `axvline()`, `axhspan()`, `axvspan()`) but for didactic purposes we will implement the horizontal span here using a blended transformation. This trick only works for separable transformations, like you see in normal Cartesian coordinate systems, but not on inseparable transformations like the `PolarTransform`.

```python
import matplotlib.transforms as transforms

fig, ax = plt.subplots()
x = np.random.randn(1000)

ax.hist(x, 30)
ax.set_title(r'$\sigma=1 \backslash dots \backslash \sigma=2$', fontsize=16)

# the x coords of this transformation are data, and the
# y coord are axes
trans = transforms.blended_transform_factory(
(continues on next page)
```
ax.transData, ax.transAxes)

# highlight the 1..2 stddev region with a span.
# We want x to be in data coordinates and y to
# span from 0..1 in axes coords
rect = mpatches.Rectangle((1, 0), width=1, height=1,
    transform=trans, color='yellow',
    alpha=0.5)

ax.add_patch(rect)

plt.show()

\[\sigma = 1 \ldots \sigma = 2\]

Note: The blended transformations where x is in data coords and y in axes coordinates is so useful that we have helper methods to return the versions mpl uses internally for drawing ticks, ticklabels, etc. The methods are `matplotlib.axes.Axes.get_xaxis_transform()` and `matplotlib.axes.Axes.get_yaxis_transform()`. So in the example above, the call to `blended_transform_factory()` can be replaced by `get_xaxis_transform`:

```
trans = ax.get_xaxis_transform()
```
Plotting in physical units

Sometimes we want an object to be a certain physical size on the plot. Here we draw the same circle as above, but in physical units. If done interactively, you can see that changing the size of the figure does not change the offset of the circle from the lower-left corner, does not change its size, and the circle remains a circle regardless of the aspect ratio of the axes.

```python
fig, ax = plt.subplots(figsize=(5,4))
x, y = 10*np.random.rand(2,1000)
ax.plot(x, y*10., 'go', alpha=0.2)  # plot some data in data coordinates
# add a circle in fixed-units
circ = mpatches.Circle((2.5, 2), 1.0, transform=fig.dpi_scale_trans,
                        facecolor='blue', alpha=0.75)
ax.add_patch(circ)
plt.show()
```

If we change the figure size, the circle does not change its absolute position and is cropped.

```python
fig, ax = plt.subplots(figsize=(7,2))
x, y = 10*np.random.rand(2,1000)
ax.plot(x, y*10., 'go', alpha=0.2)  # plot some data in data coordinates
# add a circle in fixed-units
circ = mpatches.Circle((2.5, 2), 1.0, transform=fig.dpi_scale_trans,
                        facecolor='blue', alpha=0.75)
ax.add_patch(circ)
plt.show()
```
Another use is putting a patch with a set physical dimension around a data point on the axes. Here we add together two transforms. The first sets the scaling of how large the ellipse should be and the second sets its position. The ellipse is then placed at the origin, and then we use the helper transform `ScaledTranslation` to move it to the right place in the `ax.transData` coordinate system. This helper is instantiated with:

```python
trans = ScaledTranslation(xt, yt, scale_trans)
```

where `xt` and `yt` are the translation offsets, and `scale_trans` is a transformation which scales `xt` and `yt` at transformation time before applying the offsets.

Note the use of the plus operator on the transforms below. This code says: first apply the scale transformation `fig.dpi_scale_trans` to make the ellipse the proper size, but still centered at `(0, 0)`, and then translate the data to `xdata[0]` and `ydata[0]` in data space.

In interactive use, the ellipse stays the same size even if the axes limits are changed via zoom.

```python
fig, ax = plt.subplots()
xdata, ydata = (0.2, 0.7), (0.5, 0.5)
ax.plot(xdata, ydata, "o")
ax.set_xlim((0, 1))

trans = (fig.dpi_scale_trans +
         transforms.ScaledTranslation(xdata[0], ydata[0], ax.transData))

# plot an ellipse around the point that is 150 x 130 points in diameter...
circle = mpatches.Ellipse((0, 0), 150/72, 130/72, angle=40,
                          fill=None, transform=trans)
ax.add_patch(circle)
plt.show()
```
**Note:** The order of transformation matters. Here the ellipse is given the right dimensions in display space first and then moved in data space to the correct spot. If we had done the ScaledTranslation first, then xdata[0] and ydata[0] would first be transformed to display coordinates ([ 358.4 475.2] on a 200-dpi monitor) and then those coordinates would be scaled by fig.dpi_scale_trans pushing the center of the ellipse well off the screen (i.e. [ 71680. 95040.]).

**Using offset transforms to create a shadow effect**

Another use of `ScaledTranslation` is to create a new transformation that is offset from another transformation, e.g., to place one object shifted a bit relative to another object. Typically you want the shift to be in some physical dimension, like points or inches rather than in data coordinates, so that the shift effect is constant at different zoom levels and dpi settings.

One use for an offset is to create a shadow effect, where you draw one object identical to the first just to the right of it, and just below it, adjusting the zorder to make sure the shadow is drawn first and then the object it is shadowing above it.

Here we apply the transforms in the **opposite** order to the use of `ScaledTranslation` above. The plot is first made in data units (ax.transData) and then shifted by dx and dy points using `fig.dpi_scale_trans`. (In typography, a 'point' [https://en.wikipedia.org/wiki/Point_%28typography%29] is 1/72 inches, and by specifying your offsets in points, your figure...
Matplotlib, Release 3.1.1

will look the same regardless of the dpi resolution it is saved in.)

```
fig, ax = plt.subplots()

# make a simple sine wave
x = np.arange(0., 2., 0.01)
y = np.sin(2*np.pi*x)
line, = ax.plot(x, y, lw=3, color='blue')

# shift the object over 2 points, and down 2 points
dx, dy = 2/72., -2/72.
offset = transforms.ScaledTranslation(dx, dy, fig.dpi_scale_trans)
shadow_transform = ax.transData + offset

# now plot the same data with our offset transform;
# use the zorder to make sure we are below the line
ax.plot(x, y, lw=3, color='gray',
        transform=shadow_transform,
        zorder=0.5*line.get_zorder())

ax.set_title('creating a shadow effect with an offset transform')
plt.show()
```

Note:  The dpi and inches offset is a common-enough use case that we have a special helper
function to create it in `matplotlib.transforms.offset_copy()`, which returns a new transform with an added offset. So above we could have done:

```python
shadow_transform = transforms.offset_copy(ax.transData,
                                          fig=fig, dx, dy, units='inches')
```

### The transformation pipeline

The `ax.transData` transform we have been working with in this tutorial is a composite of three different transformations that comprise the transformation pipeline from data -> display coordinates. Michael Droettboom implemented the transformations framework, taking care to provide a clean API that segregated the nonlinear projections and scales that happen in polar and logarithmic plots, from the linear affine transformations that happen when you pan and zoom. There is an efficiency here, because you can pan and zoom in your axes which affects the affine transformation, but you may not need to compute the potentially expensive nonlinear scales or projections on simple navigation events. It is also possible to multiply affine transformation matrices together, and then apply them to coordinates in one step. This is not true of all possible transformations.

Here is how the `ax.transData` instance is defined in the basic separable axis `Axes` class:

```python
self.transData = self.transScale + (self.transLimits + self.transAxes)
```

We’ve been introduced to the `transAxes` instance above in `Axes coordinates`, which maps the (0, 0), (1, 1) corners of the axes or subplot bounding box to display space, so let’s look at these other two pieces.

`self.transLimits` is the transformation that takes you from data to axes coordinates; i.e., it maps your view xlim and ylim to the unit space of the axes (and `transAxes` then takes that unit space to display space). We can see this in action here:

```python
In [80]: ax = subplot(111)
In [81]: ax.set_xlim(0, 10)
Out[81]: (0, 10)
In [82]: ax.set_ylim(-1, 1)
Out[82]: (-1, 1)
In [84]: ax.transLimits.transform((0, -1))
Out[84]: array([ 0., 0.])
In [85]: ax.transLimits.transform((10, -1))
Out[85]: array([ 1., 0.])
In [86]: ax.transLimits.transform((10, 1))
Out[86]: array([ 1., 1.])
In [87]: ax.transLimits.transform((5, 0))
Out[87]: array([ 0.5, 0.5])
```

and we can use this same inverted transformation to go from the unit axes coordinates back to data coordinates.
The final piece is the `self.transScale` attribute, which is responsible for the optional non-
linear scaling of the data, e.g., for logarithmic axes. When an Axes is initially setup, this is
just set to the identity transform, since the basic Matplotlib axes has linear scale, but when
you call a logarithmic scaling function like `semilogx()` or explicitly set the scale to logarithmic
with `set_yscale()`, then the `ax.transScale` attribute is set to handle the nonlinear projection.
The scales transforms are properties of the respective `xaxis` and `yaxis` `Axis` instances. For
example, when you call `ax.set_xscale('log')`, the `xaxis` updates its scale to a `matplotlib.scale.
LogScale` instance.

For non-separable axes the PolarAxes, there is one more piece to consider, the projection
transformation. The `transData` `matplotlib.projections.polar.PolarAxes` is similar to that for
the typical separable Matplotlib Axes, with one additional piece `transProjection`:

```python
self.transData = self.transScale + self.transProjection + \n    (self.transProjectionAffine + self.transAxes)
```

`transProjection` handles the projection from the space, e.g., latitude and longitude for map
data, or radius and theta for polar data, to a separable Cartesian coordinate system. There
are several projection examples in the `matplotlib.projections` package, and the best way to
learn more is to open the source for those packages and see how to make your own, since
Matplotlib supports extensible axes and projections. Michael Droettboom has provided a nice
tutorial example of creating a Hammer projection axes; see /gallery/misc/custom_projection.

### 2.4 Colors

Matplotlib has support for visualizing information with a wide array of colors and colormaps.
These tutorials cover the basics of how these colormaps look, how you can create your own,
and how you can customize colormaps for your use case.

For even more information see the examples page.

**Note:** Click here to download the full example code

#### 2.4.1 Specifying Colors

Matplotlib recognizes the following formats to specify a color:

- an RGB or RGBA (red, green, blue, alpha) tuple of float values in [0, 1] (e.g., (0.1, 0.2,
  0.5) or (0.1, 0.2, 0.5, 0.3));
- a hex RGB or RGBA string (e.g., '#' or '0f0f0f80'; case-insensitive);
- a string representation of a float value in [0, 1] inclusive for gray level (e.g., '0.5');
- one of {'b', 'g', 'r', 'c', 'm', 'y', 'k', 'w'};
- a X11/CSS4 color name (case-insensitive);
- a name from the xkcd color survey, prefixed with 'xkcd:' (e.g., 'xkcd:sky blue'; case
  insensitive);
• one of the Tableau Colors from the ‘T10’ categorical palette (the default color cycle): 
  'tab:pink', 'tab:gray', 'tab:olive', 'tab:cyan'} (case-insensitive);

• a “CN” color spec, i.e. 'C' followed by a number, which is an index into the default property cycle 
  (matplotlib.rcParams['axes.prop_cycle']); the indexing is intended to occur at rendering time, and defaults to black if the cycle does not include color.

“Red”, “Green”, and “Blue” are the intensities of those colors, the combination of which span the colorspace.

How “Alpha” behaves depends on the zorder of the Artist. Higher zorder Artists are drawn on top of lower Artists, and “Alpha” determines whether the lower artist is covered by the higher. If the old RGB of a pixel is RGBold and the RGB of the pixel of the Artist being added is RGBnew with Alpha alpha, then the RGB of the pixel is updated to: 
  \[ \text{RGB} = \text{RGBold} \times (1 - \text{Alpha}) + \text{RGBnew} \times \text{Alpha} \].

Alpha of 1 means the old color is completely covered by the new Artist, Alpha of 0 means that pixel of the Artist is transparent.

For more information on colors in matplotlib see
• the /gallery/color/color_demo example;
• the matplotlib.colors API;
• the /gallery/color/named_colors example.

“CN” color selection

“CN” colors are converted to RGBA as soon as the artist is created. For example,

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib as mpl

th = np.linspace(0, 2*np.pi, 128)

def demo(sty):
    mpl.style.use(sty)
    fig, ax = plt.subplots(figsize=(3, 3))

    ax.set_title('style: {!r}'.format(sty), color='C0')

    ax.plot(th, np.cos(th), 'C1', label='C1')
    ax.plot(th, np.sin(th), 'C2', label='C2')
    ax.legend()

demo('default')
demo('seaborn')
```
will use the first color for the title and then plot using the second and third colors of each style’s `mpl.rcParams['axes.prop_cycle']`.

**xkcd v X11/CSS4**

The xkcd colors are derived from a user survey conducted by the webcomic xkcd. Details of the survey are available on the xkcd blog.

Out of 148 colors in the CSS color list, there are 95 name collisions between the X11/CSS4 names and the xkcd names, all but 3 of which have different hex values. For example, 'blue' maps to '#0000FF' whereas 'xkcd:blue' maps to '#0343DF'. Due to these name collisions all of the xkcd colors have 'xkcd:' prefixed. As noted in the blog post, while it might be interesting to re-define the X11/CSS4 names based on such a survey, we do not do so unilaterally.

The name collisions are shown in the table below; the color names where the hex values agree are shown in bold.
import matplotlib._color_data as mcd
import matplotlib.patches as mpatch

overlap = {name for name in mcd.CSS4_COLORS
           if "xkcd:" + name in mcd.XKCD_COLORS}

fig = plt.figure(figsize=[4.8, 16])
ax = fig.add_axes([0, 0, 1, 1])

for j, n in enumerate(sorted(overlap, reverse=True)):
    weight = None
    cn = mcd.CSS4_COLORS[n]
    xkcd = mcd.XKCD_COLORS["xkcd:" + n].upper()
    if cn == xkcd:
        weight = 'bold'

    r1 = mpatch.Rectangle((0, j), 1, 1, color=cn)
    r2 = mpatch.Rectangle((1, j), 1, 1, color=xkcd)
    txt = ax.text(2, j+.5, ' ' + n, va='center', fontsize=10,
                  weight=weight)
    ax.add_patch(r1)
    ax.add_patch(r2)
    ax.axhline(j, color='k')

ax.text(.5, j + 1.5, 'X11', ha='center', va='center')
ax.text(1.5, j + 1.5, 'xkcd', ha='center', va='center')
ax.set_xlim(0, 3)
ax.set_ylim(0, j + 2)
ax.axis('off')

2.4.2 Customized Colorbars Tutorial

This tutorial shows how to build colorbars without an attached plot.

Customized Colorbars

ColorbarBase puts a colorbar in a specified axes, and can make a colorbar for a given colormap; it does not need a mappable object like an image. In this tutorial we will explore what can be done with standalone colorbar.

Basic continuous colorbar

Set the colormap and norm to correspond to the data for which the colorbar will be used. Then create the colorbar by calling ColorbarBase and specify axis, colormap, norm and orientation as parameters. Here we create a basic continuous colorbar with ticks and labels. For more information see the colorbar API.

```python
import matplotlib.pyplot as plt
import matplotlib as mpl

fig, ax = plt.subplots(figsize=(6, 1))
fig.subplots_adjust(bottom=0.5)

cmap = mpl.cm.cool
norm = mpl.colors.Normalize(vmin=5, vmax=10)

cb1 = mpl.colorbar.ColorbarBase(ax, cmap=cmap,
                                norm=norm,
                                orientation='horizontal')

cb1.set_label('Some Units')
fig.show()
```

Discrete intervals colorbar

The second example illustrates the use of ListedColormap which generates a colormap from a set of listed colors, colors.BoundaryNorm() which generates a colormap index based on discrete intervals and extended ends to show the "over" and "under" value colors. Over and under
are used to display data outside of the normalized [0,1] range. Here we pass colors as gray shades as a string encoding a float in the 0-1 range.

If a `ListedColormap` is used, the length of the bounds array must be one greater than the length of the color list. The bounds must be monotonically increasing.

This time we pass some more arguments in addition to previous arguments to `ColorbarBase`. For the out-of-range values to display on the colorbar, we have to use the `extend` keyword argument. To use `extend`, you must specify two extra boundaries. Finally spacing argument ensures that intervals are shown on colorbar proportionally.

```python
fig, ax = plt.subplots(figsize=(6, 1))
fig.subplots_adjust(bottom=0.5)

cmap = mpl.colors.ListedColormap(['red', 'green', 'blue', 'cyan'])
cmap.set_over('0.25')
cmap.set_under('0.75')

bounds = [1, 2, 4, 7, 8]
norm = mpl.colors.BoundaryNorm(bounds, cmap.N)
cb2 = mpl.colorbar.ColorbarBase(ax, cmap=cmap,
    norm=norm,
    boundaries=[0] + bounds + [13],
    extend='both',
    ticks=bounds,
    spacing='proportional',
    orientation='horizontal')

cb2.set_label('Discrete intervals, some other units')
fig.show()
```

**Colorbar with custom extension lengths**

Here we illustrate the use of custom length colorbar extensions, used on a colorbar with discrete intervals. To make the length of each extension the same as the length of the interior colors, use `extendfrac='auto'`.

```python
fig, ax = plt.subplots(figsize=(6, 1))
fig.subplots_adjust(bottom=0.5)

cmap = mpl.colors.ListedColormap(['royalblue', 'cyan',
                                   'yellow', 'orange'])
cmap.set_over('red')
cmap.set_under('blue')

bounds = [-1.0, -0.5, 0.0, 0.5, 1.0]
norm = mpl.colors.BoundaryNorm(bounds, cmap.N)
```

(continues on next page)
2.4.3 Creating Colormaps in Matplotlib

Matplotlib has a number of built-in colormaps accessible via `matplotlib.cm.get_cmap`. There are also external libraries like `palettable` that have many extra colormaps.

However, we often want to create or manipulate colormaps in Matplotlib. This can be done using the class `ListedColormap` and a Nx4 numpy array of values between 0 and 1 to represent the RGBA values of the colormap. There is also a `LinearSegmentedColormap` class that allows colormaps to be specified with a few anchor points defining segments, and linearly interpolating between the anchor points.

### Getting colormaps and accessing their values

First, getting a named colormap, most of which are listed in *Choosing Colormaps in Matplotlib* requires the use of `matplotlib.cm.get_cmap`, which returns a `matplotlib.colors.ListedColormap` object. The second argument gives the size of the list of colors used to define the colormap, and below we use a modest value of 12 so there are not a lot of values to look at.

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib import cm
from matplotlib.colors import ListedColormap, LinearSegmentedColormap

viridis = cm.get_cmap('viridis', 12)
print(viridis)
```

Out:

```
<matplotlib.colors.ListedColormap object at 0x7f7cb99ced30>
```
The object `viridis` is a callable, that when passed a float between 0 and 1 returns an RGBA value from the colormap:

```
print(viridis(0.56))
```

Out:

```
(0.119512, 0.607464, 0.540218, 1.0)
```

The list of colors that comprise the colormap can be directly accessed using the `colors` property, or it can be accessed indirectly by calling `viridis` with an array of values matching the length of the colormap. Note that the returned list is in the form of an RGBA Nx4 array, where N is the length of the colormap.

```
print('viridis.colors', viridis.colors)
print('viridis(range(12))', viridis(range(12)))
print('viridis(np.linspace(0, 1, 12))', viridis(np.linspace(0, 1, 12)))
```

Out:

```
viridis.colors [[0.267004 0.004874 0.329415 1. ]
    [0.283072 0.130895 0.449241 1. ]

    [0.119512 0.607464 0.540218 1. ]
    [0.166383 0.690856 0.496502 1. ]
    [0.319809 0.770914 0.411152 1. ]
    [0.525776 0.833491 0.288127 1. ]
    [0.762373 0.876424 0.137064 1. ]
    [0.993248 0.906157 0.143936 1. ]]

viridis(np.linspace(0, 1, 12)) [[0.267004 0.004874 0.329415 1. ]
    [0.283072 0.130895 0.449241 1. ]
    [0.262138 0.242286 0.520837 1. ]
    [0.220057 0.343307 0.549413 1. ]
    [0.177423 0.437527 0.557565 1. ]
    [0.143343 0.522773 0.556295 1. ]
    [0.119512 0.607464 0.540218 1. ]
    [0.166383 0.690856 0.496502 1. ]
    [0.319809 0.770914 0.411152 1. ]
    [0.525776 0.833491 0.288127 1. ]
    [0.762373 0.876424 0.137064 1. ]
    [0.993248 0.906157 0.143936 1. ]]

(continues on next page)
The colormap is a lookup table, so “oversampling” the colormap returns nearest-neighbor interpolation (note the repeated colors in the list below)

```python
print('viridis(np.linspace(0, 1, 15))', viridis(np.linspace(0, 1, 15)))
```

Out:

```
viridis(np.linspace(0, 1, 15)) [[0.267004 0.004874 0.329415 1. ]
[0.267004 0.004874 0.329415 1. ]
[0.262138 0.242286 0.520837 1. ]
[0.220057 0.343307 0.557565 1. ]
[0.143343 0.522773 0.556295 1. ]
[0.116833 0.607464 0.540218 1. ]
[0.116833 0.607464 0.540218 1. ]
[0.166383 0.690856 0.496502 1. ]
[0.319809 0.770914 0.411152 1. ]
[0.525776 0.833491 0.288127 1. ]
[0.762373 0.876424 0.137064 1. ]
[0.993248 0.906157 0.143936 1. ]
[0.993248 0.906157 0.143936 1. ]
```

Creating listed colormaps

This is essential the inverse operation of the above where we supply a Nx4 numpy array with all values between 0 and 1, to `ListedColormap` to make a new colormap. This means that any numpy operations that we can do on a Nx4 array make carpentry of new colormaps from existing colormaps quite straight forward.

Suppose we want to make the first 25 entries of a 256-length “viridis” colormap pink for some reason:

```python
viridis = cm.get_cmap('viridis', 256)
newcolors = viridis(np.linspace(0, 1, 256))
pink = np.array([248/256, 24/256, 148/256, 1])
newcolors[:,:25,:25] = pink
newcmp = ListedColormap(newcolors)
```

```python
def plot_examples(cms):
    
    helper function to plot two colormaps

    np.random.seed(19680801)
data = np.random.randn(30, 30)

    fig, axs = plt.subplots(1, 2, figsize=(6, 3), constrained_layout=True)
```
for [ax, cmap] in zip(axs, cms):
    psm = ax.pcolormesh(data, cmap=cmap, rasterized=True, vmin=-4, vmax=4)
    fig.colorbar(psm, ax=ax)
plt.show()

plot_examples([viridis, newcmp])

We can easily reduce the dynamic range of a colormap; here we choose the middle 0.5 of the colormap. However, we need to interpolate from a larger colormap, otherwise the new colormap will have repeated values.

viridisBig = cm.get_cmap('viridis', 512)
newcmp = ListedColormap(viridisBig(np.linspace(0.25, 0.75, 256)))
plot_examples([viridis, newcmp])

and we can easily concatenate two colormaps:
Of course we need not start from a named colormap, we just need to create the Nx4 array to pass to `ListedColormap`. Here we create a brown colormap that goes to white....

```python
N = 256
vals = np.ones((N, 4))
vals[:, 0] = np.linspace(90/256, 1, N)
vals[:, 1] = np.linspace(39/256, 1, N)
vals[:, 2] = np.linspace(41/256, 1, N)
newcmp = ListedColormap(vals)
plot_examples([viridis, newcmp])
```
Creating linear segmented colormaps

`LinearSegmentedColormap` class specifies colormaps using anchor points between which RGB(A) values are interpolated.

The format to specify these colormaps allows discontinuities at the anchor points. Each anchor point is specified as a row in a matrix of the form `[x[i] yleft[i] yright[i]]`, where `x[i]` is the anchor, and `yleft[i]` and `yright[i]` are the values of the color on either side of the anchor point.

If there are no discontinuities, then `yleft[i]=yright[i]`:

```python
cdict = {
    'red': [[0.0, 0.0, 0.0],
             [0.5, 1.0, 1.0],
             [1.0, 1.0, 1.0]],
    'green': [[0.0, 0.0, 0.0],
               [0.25, 0.0, 0.0],
               [0.75, 1.0, 1.0],
               [1.0, 1.0, 1.0]],
    'blue': [[0.0, 0.0, 0.0],
              [0.5, 0.0, 0.0],
              [1.0, 1.0, 1.0]]}

def plot_linearmap(cdict):
    newcmp = LinearSegmentedColormap('testCmap', segmentdata=cdict, N=256)
    rgba = newcmp(np.linspace(0, 1, 256))
    fig, ax = plt.subplots(figsize=(4, 3), constrained_layout=True)
    col = ['r', 'g', 'b']
    for xx in [0.25, 0.5, 0.75]:
        ax.axvline(xx, color='0.7', linestyle='--')
    for i in range(3):
        ax.plot(np.arange(256)/256, rgba[:, i], color=col[i])
    ax.set_xlabel('index')
```

(continues on next page)
In order to make a discontinuity at an anchor point, the third column is different than the second. The matrix for each of "red", "green", "blue", and optionally "alpha" is set up as:

```
cdict['red'] = [...]  
  [x[i]   yleft[i]  yright[i]],  
  [x[i+1] yleft[i+1] yright[i+1]],  
  [...]  
```

and for values passed to the colormap between x[i] and x[i+1], the interpolation is between yright[i] and yleft[i+1].

In the example below there is a discontinuity in red at 0.5. The interpolation between 0 and 0.5 goes from 0.3 to 1, and between 0.5 and 1 it goes from 0.9 to 1. Note that red[0, 1], and red[2, 2] are both superfluous to the interpolation because red[0, 1] is the value to the left of 0, and red[2, 2] is the value to the right of 1.0.

```
cdict['red'] = [[0.0, 0.0, 0.3],  
                [0.5, 1.0, 0.9],  
                [1.0, 1.0, 1.0]]  
plot_linearmap(cdict)  
```
References

The use of the following functions, methods, classes and modules is shown in this example:

```python
import matplotlib
matplotlib.axes.Axes.pcolormesh
matplotlib.figure.Figure.colorbar
matplotlib.colors
matplotlib.colors.LinearSegmentedColormap
matplotlib.colors.ListedColormap
matplotlib.cm
matplotlib.cm.get_cmap
```

**Note:** Click [here](#) to download the full example code

### 2.4.4 Colormap Normalization

Objects that use colormaps by default linearly map the colors in the colormap from data values $v_{min}$ to $v_{max}$. For example:

```python
pcm = ax.pcolormesh(x, y, Z, vmin=-1., vmax=1., cmap='RdBu_r')
```

will map the data in $Z$ linearly from -1 to +1, so $Z=0$ will give a color at the center of the colormap $RdBu_r$ (white in this case).

Matplotlib does this mapping in two steps, with a normalization from [0,1] occurring first, and then mapping onto the indices in the colormap. Normalizations are classes defined in the `matplotlib.colors()` module. The default, linear normalization is `matplotlib.colors.Normalize()`.
Artists that map data to color pass the arguments $v_{min}$ and $v_{max}$ to construct a `matplotlib.colors.Normalize()` instance, then call it:

```python
In [1]: import matplotlib as mpl
In [2]: norm = mpl.colors.Normalize(vmin=-1., vmax=1.)
In [3]: norm(0.)
Out[3]: 0.5
```

However, there are sometimes cases where it is useful to map data to colormaps in a non-linear fashion.

**Logarithmic**

One of the most common transformations is to plot data by taking its logarithm (to the base-10). This transformation is useful to display changes across disparate scales. Using `colors.LogNorm()` normalizes the data via $\log_{10}$. In the example below, there are two bumps, one much smaller than the other. Using `colors.LogNorm()`, the shape and location of each bump can clearly be seen:

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.colors as colors
import matplotlib.cbook as cbook

N = 100
X, Y = np.mgrid[-3:3:complex(0, N), -2:2:complex(0, N)]

# A low hump with a spike coming out of the top right. Needs to have
# z/colour axis on a log scale so we see both hump and spike. linear
# scale only shows the spike.
Z1 = np.exp(-(X)**2 - (Y)**2)
Z2 = np.exp(-(X * 10)**2 - (Y * 10)**2)
Z = Z1 + 50 * Z2

fig, ax = plt.subplots(2, 1)

pcm = ax[0].pcolor(X, Y, Z,
                   norm=colors.LogNorm(vmin=Z.min(), vmax=Z.max()),
                   cmap='PuBu_r')
fig.colorbar(pcm, ax=ax[0], extend='max')

pcm = ax[1].pcolor(X, Y, Z, cmap='PuBu_r')
fig.colorbar(pcm, ax=ax[1], extend='max')
plt.show()
```
Symmetric logarithmic

Similarly, it sometimes happens that there is data that is positive and negative, but we would
still like a logarithmic scaling applied to both. In this case, the negative numbers are also
scaled logarithmically, and mapped to smaller numbers; e.g., if vmin=-vmax, then they the
negative numbers are mapped from 0 to 0.5 and the positive from 0.5 to 1.

Since the logarithm of values close to zero tends toward infinity, a small range around zero
needs to be mapped linearly. The parameter linthresh allows the user to specify the size of
this range (-linthresh, linthresh). The size of this range in the colormap is set by linscale.
When linscale == 1.0 (the default), the space used for the positive and negative halves of the
linear range will be equal to one decade in the logarithmic range.

```python
N = 100
X, Y = np.mgrid[-3:3:complex(0, N), -2:2:complex(0, N)]
Z1 = np.exp(-X**2 - Y**2)
Z2 = np.exp(-(X - 1)**2 - (Y - 1)**2)
Z = (Z1 - Z2) * 2

fig, ax = plt.subplots(2, 1)

pcm = ax[0].pcolormesh(X, Y, Z,
    norm=colors.SymLogNorm(linthresh=0.03, linscale=0.03),
)
vmin=-1.0, vmax=1.0),

    cmap='RdBu_r')
fig.colorbar(pcm, ax=ax[0], extend='both')

pcm = ax[1].pcolormesh(X, Y, Z, cmap='RdBu_r', vmin=-np.max(Z))
fig.colorbar(pcm, ax=ax[1], extend='both')
plt.show()

Power-law

Sometimes it is useful to remap the colors onto a power-law relationship (i.e. \( y = x^\gamma \), where \( \gamma \) is the power). For this we use the colors.PowerNorm(). It takes as an argument \( \gamma \). (\( \gamma = 1.0 \) will just yield the default linear normalization):

**Note:** There should probably be a good reason for plotting the data using this type of transformation. Technical viewers are used to linear and logarithmic axes and data transformations. Power laws are less common, and viewers should explicitly be made aware that they have been used.
```python
N = 100
X, Y = np.mgrid[0:3:complex(0, N), 0:2:complex(0, N)]
Z1 = (1 + np.sin(Y * 10.)) * X**2.

fig, ax = plt.subplots(2, 1)
pcm = ax[0].pcolormesh(X, Y, Z1, norm=colors.PowerNorm(gamma=0.5),
                       cmap='PuBu_g')
fig.colorbar(pcm, ax=ax[0], extend='max')

pcm = ax[1].pcolormesh(X, Y, Z1, cmap='PuBu_g')
fig.colorbar(pcm, ax=ax[1], extend='max')
plt.show()
```

**Discrete bounds**

Another normalization that comes with Matplotlib is `colors.BoundaryNorm()`. In addition to `vmin` and `vmax`, this takes as arguments boundaries between which data is to be mapped. The colors are then linearly distributed between these “bounds”. For instance:

```
In [4]: import matplotlib.colors as colors
```
Note unlike the other norms, this norm returns values from 0 to $ncolors$-1.

In [5]: bounds = np.array([-0.25, -0.125, 0, 0.5, 1])

In [6]: norm = colors.BoundaryNorm(boundaries=bounds, ncolors=4)

In [7]: print(norm([-0.2, -0.15, -0.02, 0.3, 0.8, 0.99]))
[0 0 1 2 3 3]

2.4. Colors

The `BoundaryNorm` class provides a way to define a custom colormap by specifying a set of boundaries.

```python
import matplotlib.pyplot as plt
import numpy as np
from matplotlib import colors

N = 100
X, Y = np.mgrid[-3:3:complex(0, N), -2:2:complex(0, N)]
Z1 = np.exp(-X**2 - Y**2)
Z2 = np.exp(-(X - 1)**2 - (Y - 1)**2)
Z = (Z1 - Z2) * 2

fig, ax = plt.subplots(3, 1, figsize=(8, 8))
ax = ax.flatten()
# even bounds gives a contour-like effect
bounds = np.linspace(-1, 1, 10)
norm = colors.BoundaryNorm(boundaries=bounds, ncolors=256)
pcm = ax[0].pcolormesh(X, Y, Z,
                        norm=norm,
                        cmap='RdBu_r')
fig.colorbar(pcm, ax=ax[0], extend='both', orientation='vertical')

# uneven bounds changes the colormapping:
bounds = np.array([-0.25, -0.125, 0, 0.5, 1])
norm = colors.BoundaryNorm(boundaries=bounds, ncolors=256)
pcm = ax[1].pcolormesh(X, Y, Z, norm=norm, cmap='RdBu_r')
fig.colorbar(pcm, ax=ax[1], extend='both', orientation='vertical')

pcm = ax[2].pcolormesh(X, Y, Z, cmap='RdBu_r', vmin=-np.max(Z))
fig.colorbar(pcm, ax=ax[2], extend='both', orientation='vertical')
plt.show()
DivergingNorm: Different mapping on either side of a center

Sometimes we want to have a different colormap on either side of a conceptual center point, and we want those two colormaps to have different linear scales. An example is a topographic map where the land and ocean have a center at zero, but land typically has a greater elevation range than the water has depth range, and they are often represented by a different colormap.

```python
filename = cbook.get_sample_data('topobathy.npz', asfileobj=False)
with np.load(filename) as dem:
    topo = dem['topo']
    longitude = dem['longitude']
    latitude = dem['latitude']
```

(continues on next page)
fig, ax = plt.subplots()
# make a colormap that has land and ocean clearly delineated and of the
# same length (256 + 256)
colors_undersea = plt.cm.terrain(np.linspace(0, 0.17, 256))
colors_land = plt.cm.terrain(np.linspace(0.25, 1, 256))
all_colors = np.vstack((colors_undersea, colors_land))
terrain_map = colors.LinearSegmentedColormap.from_list('terrain_map',
    all_colors)

# make the norm: Note the center is offset so that the land has more
# dynamic range:
divnorm = colors.DivergingNorm(vmin=-500., vcenter=0, vmax=4000)

pcm = ax.pcolormesh(longitude, latitude, topo, rasterized=True, norm=divnorm,
     cmap=terrain_map,)
# Simple geographic plot, set aspect ratio because distance between lines of
# longitude depends on latitude.
ax.set_aspect(1 / np.cos(np.deg2rad(49)))
fig.colorbar(pcm, shrink=0.6)
plt.show()
Custom normalization: Manually implement two linear ranges

The `DivergingNorm` described above makes a useful example for defining your own norm.

```python
class MidpointNormalize(colors.Normalize):
    def __init__(self, vmin=None, vmax=None, vcenter=None, clip=False):
        self.vcenter = vcenter
        colors.Normalize.__init__(self, vmin, vmax, clip)

    def __call__(self, value, clip=None):
        # I'm ignoring masked values and all kinds of edge cases to make a
        # simple example...
        x, y = [self.vmin, self.vcenter, self.vmax], [0, 0.5, 1]
        return np.ma.masked_array(np.interp(value, x, y))
```

```python
fig, ax = plt.subplots()
midnorm = MidpointNormalize(vmin=-500., vcenter=0, vmax=4000)
pcm = ax.pcolormesh(longitude, latitude, topo, rasterized=True, norm=midnorm, cmap=terrain_map)
ax.set_aspect(1 / np.cos(np.deg2rad(49)));
fig.colorbar(pcm, shrink=0.6, extend='both')
plt.show()
```
2.4.5 Choosing Colormaps in Matplotlib

Matplotlib has a number of built-in colormaps accessible via `matplotlib.cm.get_cmap`. There are also external libraries like [?] and [?] that have many extra colormaps. Here we briefly discuss how to choose between the many options. For help on creating your own colormaps, see *Creating Colormaps in Matplotlib*.

Overview

The idea behind choosing a good colormap is to find a good representation in 3D colorspace for your data set. The best colormap for any given data set depends on many things including:

- Whether representing form or metric data ([?])
- Your knowledge of the data set (e.g., is there a critical value from which the other values deviate?)
- If there is an intuitive color scheme for the parameter you are plotting
- If there is a standard in the field the audience may be expecting

For many applications, a perceptually uniform colormap is the best choice — one in which equal steps in data are perceived as equal steps in the color space. Researchers have found that the human brain perceives changes in the lightness parameter as changes in the data much better than, for example, changes in hue. Therefore, colormaps which have monotonically increasing lightness through the colormap will be better interpreted by the viewer. A wonderful example of perceptually uniform colormaps is [?].

Color can be represented in 3D space in various ways. One way to represent color is using CIELAB. In CIELAB, color space is represented by lightness, \( L^* \); red-green, \( a^* \); and yellow-blue, \( b^* \). The lightness parameter \( L^* \) can then be used to learn more about how the matplotlib colormaps will be perceived by viewers.

An excellent starting resource for learning about human perception of colormaps is from [?].

Classes of colormaps

Colormaps are often split into several categories based on their function (see, e.g., [?]):

1. Sequential: change in lightness and often saturation of color incrementally, often using a single hue; should be used for representing information that has ordering.
2. Diverging: change in lightness and possibly saturation of two different colors that meet in the middle at an unsaturated color; should be used when the information being plotted has a critical middle value, such as topography or when the data deviates around zero.
3. Cyclic: change in lightness of two different colors that meet in the middle and beginning/end at an unsaturated color; should be used for values that wrap around at the endpoints, such as phase angle, wind direction, or time of day.
4. Qualitative: often are miscellaneous colors; should be used to represent information which does not have ordering or relationships.

```python
# sphinx_gallery_thumbnail_number = 2
import numpy as np
import matplotlib as mpl
import matplotlib.pyplot as plt
from matplotlib import cm
from colorspacious import cspace_converter
from collections import OrderedDict

cmaps = OrderedDict()

Sequential

For the Sequential plots, the lightness value increases monotonically through the colormaps. This is good. Some of the \(L^*\) values in the colormaps span from 0 to 100 (binary and the other grayscale), and others start around \(L^* = 20\). Those that have a smaller range of \(L^*\) will accordingly have a smaller perceptual range. Note also that the \(L^*\) function varies amongst the colormaps: some are approximately linear in \(L^*\) and others are more curved.

```python
cmaps['Perceptually Uniform Sequential'] = ['viridis', 'plasma', 'inferno', 'magma', 'cividis']
cmaps['Sequential'] = ['Greys', 'Purples', 'Blues', 'Greens', 'Oranges', 'Reds', 'YlOrBr', 'YlOrRd', 'OrRd', 'PuRd', 'RdPu', 'BuPu', 'GnBu', 'PuBu', 'YlGnBu', 'PuBuGn', 'BuGn', 'YlGn']
```

Sequential2

Many of the \(L^*\) values from the Sequential2 plots are monotonically increasing, but some (autumn, cool, spring, and winter) plateau or even go both up and down in \(L^*\) space. Others (afmhot, copper, gist_heat, and hot) have kinks in the \(L^*\) functions. Data that is being represented in a region of the colormap that is at a plateau or kink will lead to a perception of banding of the data in those values in the colormap (see [?] for an excellent example of this).

```python
cmaps['Sequential (2)'] = ['binary', 'gist_yarg', 'gist_gray', 'gray', 'bone', 'pink', 'spring', 'summer', 'autumn', 'winter', 'cool', 'Wistia', 'hot', 'afmhot', 'gist_heat', 'copper']
```

Diverging

For the Diverging maps, we want to have monotonically increasing \(L^*\) values up to a maximum, which should be close to \(L^* = 100\), followed by monotonically decreasing \(L^*\) values. We are looking for approximately equal minimum \(L^*\) values at opposite ends of the colormap. By these measures, BrBG and RdBu are good options. coolwarm is a good option, but it doesn’t span a wide range of \(L^*\) values (see grayscale section below).
For Cyclic maps, we want to start and end on the same color, and meet a symmetric center point in the middle. $L^*$ should change monotonically from start to middle, and inversely from middle to end. It should be symmetric on the increasing and decreasing side, and only differ in hue. At the ends and middle, $L^*$ will reverse direction, which should be smoothed in $L^*$ space to reduce artifacts. See [?] for more information on the design of cyclic maps.

The often-used HSV colormap is included in this set of colormaps, although it is not symmetric to a center point. Additionally, the $L^*$ values vary widely throughout the colormap, making it a poor choice for representing data for viewers to see perceptually. See an extension on this idea at [?].

For Cyclic maps, we want to start and end on the same color, and meet a symmetric center point in the middle. $L^*$ should change monotonically from start to middle, and inversely from middle to end. It should be symmetric on the increasing and decreasing side, and only differ in hue. At the ends and middle, $L^*$ will reverse direction, which should be smoothed in $L^*$ space to reduce artifacts. See [?] for more information on the design of cyclic maps.

The often-used HSV colormap is included in this set of colormaps, although it is not symmetric to a center point. Additionally, the $L^*$ values vary widely throughout the colormap, making it a poor choice for representing data for viewers to see perceptually. See an extension on this idea at [?].

Qualitative colormaps are not aimed at being perceptual maps, but looking at the lightness parameter can verify that for us. The $L^*$ values move all over the place throughout the colormap, and are clearly not monotonically increasing. These would not be good options for use as perceptual colormaps.

The often-used jet colormap is included in this set of colormaps. We can see that the $L^*$ values vary widely throughout the colormap, making it a poor choice for representing data for viewers to see perceptually. See an extension on this idea at [?].

Some of the miscellaneous colormaps have particular uses for which they have been created. For example, gist earth, ocean, and terrain all seem to be created for plotting topography (green/brown) and water depths (blue) together. We would expect to see a divergence in these colormaps, then, but multiple kinks may not be ideal, such as in gist_earth and terrain. CMRmap was created to convert well to grayscale, though it does appear to have some small kinks in $L^*$. cubehelix was created to vary smoothly in both lightness and hue, but appears to have a small hump in the green hue area.

The often-used jet colormap is included in this set of colormaps. We can see that the $L^*$ values vary widely throughout the colormap, making it a poor choice for representing data for viewers to see perceptually. See an extension on this idea at [?].
First, we’ll show the range of each colormap. Note that some seem to change more “quickly” than others.

```python
nrows = max(len(cmap_list) for cmap_category, cmap_list in cmaps.items())
gradient = np.linspace(0, 1, 256)
gradient = np.vstack((gradient, gradient))

def plot_color_gradients(cmap_category, cmap_list, nrows):
    fig, axes = plt.subplots(nrows=nrows)
    fig.subplots_adjust(top=0.95, bottom=0.01, left=0.2, right=0.99)
    axes[0].set_title(cmap_category + ' colormaps', fontsize=14)

    for ax, name in zip(axes, cmap_list):
        ax.imshow(gradient, aspect='auto', cmap=plt.get_cmap(name))
        pos = list(ax.get_position().bounds)
        x_text = pos[0] - 0.01
        fig.text(x_text, y_text, name, va='center', ha='right', fontsize=10)

    # Turn off *all* ticks & spines, not just the ones with colormaps.
    for ax in axes:
        ax.set_axis_off()

for cmap_category, cmap_list in cmaps.items():
    plot_color_gradients(cmap_category, cmap_list, nrows)

plt.show()

Diverging colormaps

Cyclic colormaps
It is important to pay attention to conversion to grayscale for color plots, since they may be printed on black and white printers. If not carefully considered, your readers may end up with indecipherable plots because the grayscale changes unpredictably through the colormap.

Conversion to grayscale is done in many different ways [?]. Some of the better ones use a linear combination of the rgb values of a pixel, but weighted according to how we perceive color intensity. A nonlinear method of conversion to grayscale is to use the $L^*$ values of the pixels. In general, similar principles apply for this question as they do for presenting one’s information perceptually; that is, if a colormap is chosen that is monotonically increasing in
values, it will print in a reasonable manner to grayscale.

With this in mind, we see that the Sequential colormaps have reasonable representations in grayscale. Some of the Sequential2 colormaps have decent enough grayscale representations, though some (autumn, spring, summer, winter) have very little grayscale change. If a colormap like this was used in a plot and then the plot was printed to grayscale, a lot of the information may map to the same gray values. The Diverging colormaps mostly vary from darker gray on the outer edges to white in the middle. Some (PuOr and seismic) have noticeably darker gray on one side than the other and therefore are not very symmetric. coolwarm has little range of gray scale and would print to a more uniform plot, losing a lot of detail. Note that overlaid, labeled contours could help differentiate between one side of the colormap vs. the other since color cannot be used once a plot is printed to grayscale. Many of the Qualitative and Miscellaneous colormaps, such as Accent, hsv, and jet, change from darker to lighter and back to darker gray throughout the colormap. This would make it impossible for a viewer to interpret the information in a plot once it is printed in grayscale.

```
mpl.rcParams.update({'font.size': 14})

# Indices to step through colormap.
x = np.linspace(0.0, 1.0, 100)
gradient = np.linspace(0, 1, 256)
gradient = np.vstack((gradient, gradient))

def plot_color_gradients(cmap_category, cmap_list):
    fig, axes = plt.subplots(nrows=len(cmap_list), ncols=2)
    fig.subplots_adjust(top=0.95, bottom=0.01, left=0.2, right=0.99, wspace=0.05)
    fig.suptitle(cmap_category + ' colormaps', fontsize=14, y=1.0, x=0.6)
    for ax, name in zip(axes, cmap_list):
        # Get RGB values for colormap.
        rgb = cm.get_cmap(plt.get_cmap(name))(x)[np.newaxis, :, :]
        # Get colormap in CAM02-UCS colorspace. We want the lightness.
        lab = cspace_converter("sRGB1", "CAM02-UCS")(rgb)
        L = lab[0, :, 0]
        L = np.float32(np.vstack((L, L, L)))
        ax[0].imshow(gradient, aspect='auto', cmap=plt.get_cmap(name))
        ax[1].imshow(L, aspect='auto', cmap='binary_r', vmin=0., vmax=100.)
        pos = list(ax[0].get_position().bounds)
        x_text = pos[0] - 0.01
        fig.text(x_text, y_text, name, va='center', ha='right', fontsize=10)

    # Turn off *all* ticks & spines, not just the ones with colormaps.

There is a lot of information available about color blindness (e.g., [?]). Additionally, there are tools available to convert images to how they look for different types of color vision deficiencies.

The most common form of color vision deficiency involves differentiating between red and green. Thus, avoiding colormaps with both red and green will avoid many problems in general.

2.5 Text

matplotlib has extensive text support, including support for mathematical expressions, truetype support for raster and vector outputs, newline separated text with arbitrary rotations, and unicode support. These tutorials cover the basics of working with text in Matplotlib.
2.5.1 Text in Matplotlib Plots

Introduction to plotting and working with text in Matplotlib.

Matplotlib has extensive text support, including support for mathematical expressions, true-type support for raster and vector outputs, newline separated text with arbitrary rotations, and unicode support.

Because it embeds fonts directly in output documents, e.g., for postscript or PDF, what you see on the screen is what you get in the hardcopy. FreeType support produces very nice, anti-aliased fonts, that look good even at small raster sizes. Matplotlib includes its own matplotlib.font_manager (thanks to Paul Barrett), which implements a cross platform, W3C compliant font finding algorithm.

The user has a great deal of control over text properties (font size, font weight, text location and color, etc.) with sensible defaults set in the rc file. And significantly, for those interested in mathematical or scientific figures, Matplotlib implements a large number of TeX math symbols and commands, supporting mathematical expressions anywhere in your figure.

Basic text commands

The following commands are used to create text in the pyplot interface and the object-oriented API:

<table>
<thead>

</tbody>
</table>

All of these functions create and return a Text instance, which can be configured with a variety of font and other properties. The example below shows all of these commands in action, and more detail is provided in the sections that follow.

```python
import matplotlib
import matplotlib.pyplot as plt

fig = plt.figure()
fig.suptitle('bold figure suptitle', fontsize=14, fontweight='bold')

ax = fig.add_subplot(111)
fig.subplots_adjust(top=0.85)
ax.set_title('axes title')
```

(continues on next page)
ax.set_xlabel('xlabel')
ax.set_ylabel('ylabel')

ax.text(3, 8, 'boxed italics text in data coords', style='italic',
        bbox={'facecolor': 'red', 'alpha': 0.5, 'pad': 10})

ax.text(2, 6, r'an equation: $E=mc^2$', fontsize=15)

ax.text(3, 2, 'unicode: Institut für Festkörperphysik')

ax.text(0.95, 0.01, 'colored text in axes coords',
        verticalalignment='bottom', horizontalalignment='right',
        transform=ax.transAxes,
        color='green', fontsize=15)

ax.plot([2], [1], 'o')
ax.annotate('annotate', xy=(2, 1), xytext=(3, 4),
            arrowprops=dict(facecolor='black', shrink=0.05))

ax.axis([0, 10, 0, 10])

plt.show()
Labels for x- and y-axis

Specifying the labels for the x- and y-axis is straightforward, via the `set_xlabel` and `set_ylabel` methods.

```python
import matplotlib.pyplot as plt
import numpy as np

x1 = np.linspace(0.0, 5.0, 100)
y1 = np.cos(2 * np.pi * x1) * np.exp(-x1)

fig, ax = plt.subplots(figsize=(5, 3))
fig.subplots_adjust(bottom=0.15, left=0.2)
ax.plot(x1, y1)
ax.set_xlabel('time [s]')
ax.set_ylabel('Damped oscillation [V]')
plt.show()
```
The x- and y-labels are automatically placed so that they clear the x- and y-ticklabels. Compare
the plot below with that above, and note the y-label is to the left of the one above.

```python
fig, ax = plt.subplots(figsize=(5, 3))
fig.subplots_adjust(bottom=0.15, left=0.2)
ax.plot(x1, y1 * 10000)
ax.set_xlabel('time [s]')
ax.set_ylabel('Damped oscillation [V]')
plt.show()
```

If you want to move the labels, you can specify the `labelpad` keyword argument, where the
value is points (1/72", the same unit used to specify fontsizes).

```python
fig, ax = plt.subplots(figsize=(5, 3))
fig.subplots_adjust(bottom=0.15, left=0.2)
```
Or, the labels accept all the `Text` keyword arguments, including `position`, via which we can manually specify the label positions. Here we put the xlabel to the far left of the axis. Note, that the y-coordinate of this position has no effect - to adjust the y-position we need to use the `labelpad` kwarg.

```python
fig, ax = plt.subplots(figsize=(5, 3))
fig.subplots_adjust(bottom=0.15, left=0.2)
ax.plot(x1, y1)
ax.set_xlabel('time [s]', position=(0., 1e6), horizontalalignment='left')
ax.set_ylabel('Damped oscillation [V]
')
plt.show()
```
All the labelling in this tutorial can be changed by manipulating the `matplotlib.font_manager.FontProperties` method, or by named kwargs to `set_xlabel`.

```python
from matplotlib.font_manager import FontProperties

font = FontProperties()
font.set_family('serif')
font.set_name('Times New Roman')
font.set_style('italic')

fig, ax = plt.subplots(figsize=(5, 3))
fig.subplots_adjust(bottom=0.15, left=0.2)
ax.plot(x1, y1)
ax.set_xlabel('time [s]', fontsize='large', fontweight='bold')
ax.set_ylabel('Damped oscillation [V]', fontproperties=font)

plt.show()
```
Finally, we can use native TeX rendering in all text objects and have multiple lines:

```python
fig, ax = plt.subplots(figsize=(5, 3))
fig.subplots_adjust(bottom=0.2, left=0.2)
ax.plot(x1, np.cumsum(y1**2))
ax.set_xlabel('time [s] 
This was a long experiment')
ax.set_ylabel(r'$\int Y^2 \, dt \ [V^2 \, s]$')
plt.show()
```

Titles

Subplot titles are set in much the same way as labels, but there is the `loc` keyword arguments that can change the position and justification from the default value of `loc=center`. 
fig, axs = plt.subplots(3, 1, figsize=(5, 6), tight_layout=True)
locs = ['center', 'left', 'right']
for ax, loc in zip(axs, locs):
    ax.plot(x1, y1)
    ax.set_title('Title with loc at ' + loc, loc=loc)
plt.show()

Vertical spacing for titles is controlled via `rcParams["axes.titlepad"]`, which defaults to 5 points. Setting to a different value moves the title.

fig, ax = plt.subplots(figsize=(5, 3))
fig.subplots_adjust(top=0.8)
ax.plot(x1, y1)
ax.set_title('Vertically offset title', pad=30)
plt.show()
Placing ticks and ticklabels is a very tricky aspect of making a figure. Matplotlib does the best it can automatically, but it also offers a very flexible framework for determining the choices for tick locations, and how they are labelled.

**Terminology**

*Axes* have an *matplotlib.axis* object for the *ax.xaxis* and *ax.yaxis* that contain the information about how the labels in the axis are laid out.

The axis API is explained in detail in the documentation to *axis*.

An Axis object has major and minor ticks. The Axis has a *matplotlib.xaxis.set_major_locator* and *matplotlib.xaxis.set_minor_locator* methods that use the data being plotted to determine the location of major and minor ticks. There are also *matplotlib.xaxis.set_major_formatter* and *matplotlib.xaxis.set_minor_formatters* methods that format the tick labels.

**Simple ticks**

It often is convenient to simply define the tick values, and sometimes the tick labels, overriding the default locators and formatters. This is discouraged because it breaks interactive navigation of the plot. It also can reset the axis limits: note that the second plot has the ticks we asked for, including ones that are well outside the automatic view limits.

```python
fig, axs = plt.subplots(2, 1, figsize=(5, 3), tight_layout=True)
axs[0].plot(x1, y1)
axs[1].plot(x1, y1)
axs[1].xaxis.set_ticks(np.arange(0., 8.1, 2.))
plt.show()
```
We can of course fix this after the fact, but it does highlight a weakness of hard-coding the ticks. This example also changes the format of the ticks:

```python
fig, axs = plt.subplots(2, 1, figsize=(5, 3), tight_layout=True)
axs[0].plot(x1, y1)
axs[1].plot(x1, y1)
ticks = np.arange(0., 8.1, 2.)
# list comprehension to get all tick labels...
tickla = ['%1.2f' % tick for tick in ticks]
axs[1].xaxis.set_ticks(ticks)
axs[1].xaxis.set_ticklabels(tickla)
axs[1].set_xlim(axs[0].get_xlim())
plt.show()
```
Tick Locators and Formatters

Instead of making a list of all the ticklabels, we could have used a `matplotlib.ticker.FormatStrFormatter` and passed it to the `ax.xaxis`.

```python
def example_locator():
    fig, axs = plt.subplots(2, 1, figsize=(5, 3), tight_layout=True)
    axs[0].plot(x1, y1)
    axs[1].plot(x1, y1)
    ticks = np.arange(0., 8.1, 2.)
    formatter = matplotlib.ticker.FormatStrFormatter('{x:1.1f}')
    axs[1].xaxis.set_major_formatter(formatter)
    axs[1].set_xlim(axs[0].get_xlim())
    plt.show()
```

And of course we could have used a non-default locator to set the tick locations. Note we still pass in the tick values, but the x-limit fix used above is not needed.

```python
def example_locator():
    fig, axs = plt.subplots(2, 1, figsize=(5, 3), tight_layout=True)
    axs[0].plot(x1, y1)
    axs[1].plot(x1, y1)
    formatter = matplotlib.ticker.FormatStrFormatter('%1.1f')
    locator = matplotlib.ticker.FixedLocator(ticks)
    axs[1].xaxis.set_major_locator(locator)
    axs[1].xaxis.set_major_formatter(formatter)
    plt.show()
```
The default formatter is the \texttt{matplotlib.ticker.MaxNLocator} called as \texttt{ticker.MaxNLocator(self, nbins=\textquotesingle auto\textquotesingle, steps=[1, 2, 2.5, 5, 10])} The \textit{steps} keyword contains a list of multiples that can be used for tick values. i.e. in this case, 2, 4, 6 would be acceptable ticks, as would 20, 40, 60 or 0.2, 0.4, 0.6. However, 3, 6, 9 would not be acceptable because 3 doesn’t appear in the list of steps.

\texttt{nbins=\textquotesingle auto\textquotesingle} uses an algorithm to determine how many ticks will be acceptable based on how long the axis is. The fontsize of the ticklabel is taken into account, but the length of the tick string is not (because its not yet known.) In the bottom row, the ticklabels are quite large, so we set \texttt{nbins=4} to make the labels fit in the right-hand plot.

```python
fig, axs = plt.subplots(2, 2, figsize=(8, 5), tight_layout=True)
for n, ax in enumerate(axs.flat):
    ax.plot(x1*10., y1)

formatter = matplotlib.ticker.FormatStrFormatter('\%1.1f')
locator = matplotlib.ticker.MaxNLocator(nbins='auto', steps=[1, 4, 10])
axs[0, 1].xaxis.set_major_locator(locator)
axs[0, 1].xaxis.set_major_formatter(formatter)

formatter = matplotlib.ticker.FormatStrFormatter('\%1.5f')
locator = matplotlib.ticker.AutoLocator()
axs[1, 0].xaxis.set_major_formatter(formatter)
axs[1, 0].xaxis.set_major_locator(locator)

formatter = matplotlib.ticker.FormatStrFormatter('\%1.5f')
locator = matplotlib.ticker.MaxNLocator(nbins=4)
axs[1, 1].xaxis.set_major_formatter(formatter)
axs[1, 1].xaxis.set_major_locator(locator)

plt.show()
```
Finally, we can specify functions for the formatter using `matplotlib.ticker.FuncFormatter`.

```python
def formatoddticks(x, pos):
    '''Format odd tick positions'''
    if x % 2:
        return '%1.2f' % x
    else:
        return ''

fig, ax = plt.subplots(figsize=(5, 3), tight_layout=True)
ax.plot(x1, y1)
formatter = matplotlib.ticker.FuncFormatter(formatoddticks)
locator = matplotlib.ticker.MaxNLocator(nbins=6)
ax.xaxis.set_major_formatter(formatter)
ax.xaxis.set_major_locator(locator)
plt.show()
```
Matplotlib can accept `datetime.datetime` and `numpy.datetime64` objects as plotting arguments. Dates and times require special formatting, which can often benefit from manual intervention. In order to help, dates have special Locators and Formatters, defined in the `matplotlib.dates` module.

A simple example is as follows. Note how we have to rotate the tick labels so that they don't over-run each other.

```python
import datetime

fig, ax = plt.subplots(figsize=(5, 3), tight_layout=True)
base = datetime.datetime(2017, 1, 1, 0, 0, 1)
time = [base + datetime.timedelta(days=x) for x in range(len(y1))]

ax.plot(time, y1)
ax.tick_params(axis='x', rotation=70)
plt.show()
```
We can pass a format to `matplotlib.dates DateFormatter`. Also note that the 29th and the next month are very close together. We can fix this by using the `dates.DayLocator` class, which allows us to specify a list of days of the month to use. Similar formatters are listed in the `matplotlib.dates` module.

```python
import matplotlib.dates as mdates

locator = mdates.DayLocator(bymonthday=[1, 15])
formatter = mdates.DateFormatter('%b %d')

fig, ax = plt.subplots(figsize=(5, 3), tight_layout=True)
ax.xaxis.set_major_locator(locator)
ax.xaxis.set_major_formatter(formatter)
ax.plot(time, y1)
ax.tick_params(axis='x', rotation=70)
plt.show()
```
2.5.2 Text properties and layout

Controlling properties of text and its layout with Matplotlib.

The matplotlib.text.Text instances have a variety of properties which can be configured via keyword arguments to the text commands (e.g., title(), xlabel() and text()).

<table>
<thead>
<tr>
<th>Property</th>
<th>Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>alpha</td>
<td>float</td>
</tr>
<tr>

</tr>
<tr>
<td>y</td>
<td>float</td>
</tr>
<tr>
<td>zorder</td>
<td>any number</td>
</tr>
</tbody>
</table>

You can lay out text with the alignment arguments horizontalalignment, verticalalignment, and multialignment. horizontalalignment controls whether the x positional argument for the text indicates the left, center or right side of the text bounding box. verticalalignment controls
whether the y positional argument for the text indicates the bottom, center or top side of the text bounding box. multialignment, for newline separated strings only, controls whether the different lines are left, center or right justified. Here is an example which uses the text() command to show the various alignment possibilities. The use of transform=ax.transAxes throughout the code indicates that the coordinates are given relative to the axes bounding box, with 0,0 being the lower left of the axes and 1,1 the upper right.

```python
import matplotlib.pyplot as plt
import matplotlib.patches as patches

# build a rectangle in axes coords
left, width = .25, .5
bottom, height = .25, .5
right = left + width
top = bottom + height

fig = plt.figure()
ax = fig.add_axes([0, 0, 1, 1])

# axes coordinates are 0,0 is bottom left and 1,1 is upper right
p = patches.Rectangle(
    (left, bottom), width, height,
    fill=False, transform=ax.transAxes, clip_on=False
)

ax.add_patch(p)

ax.text(left, bottom, 'left top',
    horizontalalignment='left',
    verticalalignment='top',
    transform=ax.transAxes)

ax.text(left, bottom, 'left bottom',
    horizontalalignment='left',
    verticalalignment='bottom',
    transform=ax.transAxes)

ax.text(right, top, 'right bottom',
    horizontalalignment='right',
    verticalalignment='bottom',
    transform=ax.transAxes)

ax.text(right, top, 'right top',
    horizontalalignment='right',
    verticalalignment='top',
    transform=ax.transAxes)

ax.text(right, bottom, 'center top',
    horizontalalignment='center',
    verticalalignment='top',
    transform=ax.transAxes)

ax.text(left, 0.5*(bottom+top), 'right center',

(continues on next page)
horizontalalignment='right',
verticalalignment='center',
rotation='vertical',
transform=ax.transAxes)

ax.text(left, 0.5*(bottom+top), 'left center',
horizontalalignment='left',
verticalalignment='center',
rotation='vertical',
transform=ax.transAxes)

ax.text(0.5*(left+right), 0.5*(bottom+top), 'middle',
horizontalalignment='center',
verticalalignment='center',
fontsize=20, color='red',
transform=ax.transAxes)

ax.text(right, 0.5*(bottom+top), 'centered',
horizontalalignment='center',
verticalalignment='center',
rotation='vertical',
transform=ax.transAxes)

ax.text(left, top, 'rotated
with newlines',
horizontalalignment='center',
verticalalignment='center',
rotation=45,
transform=ax.transAxes)

ax.set_axis_off()
plt.show()
### 2.5.3 Default Font

The base default font is controlled by a set of rcParams. To set the font for mathematical expressions, use the rcParams beginning with `mathtext` (see `mathtext`).

<table>
<thead>
<tr>
<th>rcParam</th>
<th>usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>'font.family'</td>
<td>List of either names of font or {'cursive', 'fantasy', 'monospace', 'sans', 'sans serif', 'sans-serif', 'serif'}.</td>
</tr>
<tr>
<td>'font.style'</td>
<td>The default style, ex 'normal', 'italic'.</td>
</tr>
<tr>
<td>'font.variant'</td>
<td>Default variant, ex 'normal', 'small-caps' (untested)</td>
</tr>
<tr>
<td>'font.stretch'</td>
<td>Default stretch, ex 'normal', 'condensed' (incomplete)</td>
</tr>
<tr>
<td>'font.weight'</td>
<td>Default weight. Either string or integer</td>
</tr>
<tr>
<td>'font.size'</td>
<td>Default font size in points. Relative font sizes ('large', 'x-small') are computed against this size.</td>
</tr>
</tbody>
</table>

The mapping between the family aliases (\{'cursive', 'fantasy', 'monospace', 'sans', 'sans serif', 'sans-serif', 'serif'\}) and actual font names is controlled by the following rc-Params:
family alias | rcParam with mappings
--- | ---
'serif' | 'font.serif'
'monospace' | 'font.monospace'
'fantasy' | 'font.fantasy'
'cursive' | 'font.cursive'
{'sans', 'sans serif', 'sans-serif'} | 'font.sans-serif'

which are lists of font names.

Text with non-latin glyphs

As of v2.0 the default font contains glyphs for many western alphabets, but still does not cover all of the glyphs that may be required by mpl users. For example, DejaVu has no coverage of Chinese, Korean, or Japanese.

To set the default font to be one that supports the code points you need, prepend the font name to 'font.family' or the desired alias lists

```
matplotlib.rcParams['font.sans-serif'] = ['Source Han Sans TW', 'sans-serif']
```

or set it in your .matplotlibrc file:

```
font.sans-serif: Source Han Sans TW, Arial, sans-serif
```

To control the font used on per-artist basis use the 'name', 'fontname' or 'fontproperties' kwargs documented above.

On linux, fc-list can be a useful tool to discover the font name; for example

```
$ fc-list :lang=zh family
Noto to Sans Mono CJK TC,Noto Sans Mono CJK TC Bold
Noto Sans CJK TC,Noto Sans CJK TC Medium
Noto Sans CJK TC,Noto Sans CJK TC DemiLight
Noto Sans CJK TC,Noto Sans CJK TC Black
Noto Sans Mono CJK TC,Noto Sans Mono CJK TC Regular
Noto Sans CJK SC,Noto Sans CJK SC Light
```

lists all of the fonts that support Chinese.

**Note:** Click here to download the full example code

### 2.5.4 Annotations

Annotating text with Matplotlib.
2.5.5 Basic annotation

The uses of the basic `text()` will place text at an arbitrary position on the Axes. A common use case of text is to annotate some feature of the plot, and the `annotate()` method provides helper functionality to make annotations easy. In an annotation, there are two points to consider: the location being annotated represented by the argument `xy` and the location of the text `xytext`. Both of these arguments are `(x, y)` tuples.

![Annotation Basic](image)

**Fig. 23: Annotation Basic**

In this example, both the `xy` (arrow tip) and `xytext` locations (text location) are in data coordinates. There are a variety of other coordinate systems one can choose – you can specify the coordinate system of `xy` and `xytext` with one of the following strings for `xycoords` and `textcoords` (default is ‘data’).
<table>
<thead>
<tr>
<th>argument</th>
<th>coordinate system</th>
</tr>
</thead>
<tbody>
<tr>
<td>'figure points'</td>
<td>points from the lower left corner of the figure</td>
</tr>
<tr>
<td>'figure pixels'</td>
<td>pixels from the lower left corner of the figure</td>
</tr>
<tr>
<td>'figure fraction'</td>
<td>0,0 is lower left of figure and 1,1 is upper right</td>
</tr>
<tr>
<td>'axes points'</td>
<td>points from lower left corner of axes</td>
</tr>
<tr>
<td>'axes pixels'</td>
<td>pixels from lower left corner of axes</td>
</tr>
<tr>
<td>'axes fraction'</td>
<td>0,0 is lower left of axes and 1,1 is upper right</td>
</tr>
<tr>
<td>'data'</td>
<td>use the axes data coordinate system</td>
</tr>
</tbody>
</table>

For example to place the text coordinates in fractional axes coordinates, one could do:

```python
tax.annotate('local max', xy=(3, 1), xycoords='data',
            xytext=(0.8, 0.95), textcoords='axes fraction',
            arrowprops=dict(facecolor='black', shrink=0.05),
            horizontalalignment='right', verticalalignment='top',
            )
```

For physical coordinate systems (points or pixels) the origin is the bottom-left of the figure or axes.

Optionally, you can enable drawing of an arrow from the text to the annotated point by giving a dictionary of arrow properties in the optional keyword argument `arrowprops`:

<table>
<thead>
<tr>
<th>arrowprops key</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>the width of the arrow in points</td>
</tr>
<tr>
<td>frac</td>
<td>the fraction of the arrow length occupied by the head</td>
</tr>
<tr>
<td>headwidth</td>
<td>the width of the base of the arrow head in points</td>
</tr>
<tr>
<td>shrink</td>
<td>move the tip and base some percent away from the annotated point and text</td>
</tr>
<tr>
<td>**kwargs</td>
<td>any key for <code>matplotlib.patches.Polygon</code>, e.g., facecolor</td>
</tr>
</tbody>
</table>

In the example below, the `xy` point is in native coordinates (`xycoords` defaults to 'data'). For a polar axes, this is in (theta, radius) space. The text in this example is placed in the fractional figure coordinate system. `matplotlib.text.Text` keyword args like `horizontalalignment`, `verticalalignment` and `fontsize` are passed from `annotate` to the `Text` instance.

For more on all the wild and wonderful things you can do with annotations, including fancy arrows, see `Advanced Annotation` and `/gallery/text_labels_and_annotations/annotation_demo`. Do not proceed unless you have already read `Basic annotation`, `text()` and `annotate()`!

### 2.5.6 Advanced Annotation

#### Annotating with Text with Box

Let’s start with a simple example.

The `text()` function in the pyplot module (or text method of the Axes class) takes `bbox` keyword argument, and when given, a box around the text is drawn.
Fig. 24: Annotation Polar

Fig. 25: Annotate Text Arrow
bbox_props = dict(boxstyle="rarrow,pad=0.3", fc="cyan", ec="b", lw=2)
t = ax.text(0, 0, "Direction", ha="center", va="center", rotation=45,
           size=15,
           bbox=bbox_props)

The patch object associated with the text can be accessed by:

bb = t.get_bbox_patch()

The return value is an instance of FancyBboxPatch and the patch properties like facecolor, edgewidth, etc. can be accessed and modified as usual. To change the shape of the box, use the set_boxstyle method.

bb.set_boxstyle("rarrow", pad=0.6)

The arguments are the name of the box style with its attributes as keyword arguments. Currently, following box styles are implemented.

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circle</td>
<td>circle</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>DArrow</td>
<td>darrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>LArrow</td>
<td>larrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>RArrow</td>
<td>rarrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>Round</td>
<td>round</td>
<td>pad=0.3,rounding_size=None</td>
</tr>
<tr>
<td>Round4</td>
<td>round4</td>
<td>pad=0.3,rounding_size=None</td>
</tr>
<tr>
<td>Roundtooth</td>
<td>roundtooth</td>
<td>pad=0.3,tooth_size=None</td>
</tr>
<tr>
<td>Sawtooth</td>
<td>sawtooth</td>
<td>pad=0.3,tooth_size=None</td>
</tr>
<tr>
<td>Square</td>
<td>square</td>
<td>pad=0.3</td>
</tr>
</tbody>
</table>

Note that the attribute arguments can be specified within the style name with separating comma (this form can be used as "boxstyle" value of bbox argument when initializing the text instance)

bb.set_boxstyle("rarrow,pad=0.6")

**Annotating with Arrow**

The annotate() function in the pyplot module (or annotate method of the Axes class) is used to draw an arrow connecting two points on the plot.

```python
ax.annotate("Annotation",
            xy=(x1, y1), xycoords='data',
            xytext=(x2, y2), textcoords='offset points',
            )
```

This annotates a point at xy in the given coordinate (xycoords) with the text at xytext given in textcoords. Often, the annotated point is specified in the data coordinate and the annotating text in offset points. See annotate() for available coordinate systems.

An arrow connecting two points (xy & xytext) can be optionally drawn by specifying the arrowprops argument. To draw only an arrow, use empty string as the first argument.
The arrow drawing takes a few steps.

1. A connecting path between two points are created. This is controlled by `connectionstyle` key value.

2. If patch object is given (`patchA & patchB`), the path is clipped to avoid the patch.

3. The path is further shrunk by given amount of pixels (`shrinkA & shrinkB`)

4. The path is transmuted to arrow patch, which is controlled by the `arrowstyle` key value.
Fig. 28: Annotate Explain

The creation of the connecting path between two points is controlled by `connectionstyle` key and the following styles are available.

<table>
<thead>
<tr>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>angle</td>
<td>angleA=90,angleB=0,rad=0.0</td>
</tr>
<tr>
<td>angle3</td>
<td>angleA=90,angleB=0</td>
</tr>
<tr>
<td>arc</td>
<td>angleA=0,angleB=0,armA=None,armB=None,rad=0.0</td>
</tr>
<tr>
<td>arc3</td>
<td>rad=0.0</td>
</tr>
<tr>
<td>bar</td>
<td>armA=0.0,armB=0.0,fraction=0.3,angle=None</td>
</tr>
</tbody>
</table>

Note that "3" in `angle3` and `arc3` is meant to indicate that the resulting path is a quadratic spline segment (three control points). As will be discussed below, some arrow style options can only be used when the connecting path is a quadratic spline.

The behavior of each connection style is (limitedly) demonstrated in the example below. (Warning: The behavior of the `bar` style is currently not well defined, it may be changed in the future).

Fig. 29: Connectionstyle Demo

The connecting path (after clipping and shrinking) is then mutated to an arrow patch, accord-
ing to the given arrowstyle.

<table>
<thead>
<tr>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>None</td>
</tr>
<tr>
<td>-&gt;</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>-&gt;</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>-</td>
<td>widthB=1.0, lengthB=0.2, angleB=None</td>
</tr>
<tr>
<td></td>
<td>-</td>
</tr>
<tr>
<td>-</td>
<td>&gt;</td>
</tr>
<tr>
<td>&lt;-&gt;</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>&lt;=</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>&lt;-</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>&lt;-</td>
<td>&gt;</td>
</tr>
<tr>
<td>fancy</td>
<td>head_length=0.4, head_width=0.4, tail_width=0.4</td>
</tr>
<tr>
<td>simple</td>
<td>head_length=0.5, head_width=0.5, tail_width=0.2</td>
</tr>
<tr>
<td>wedge</td>
<td>tail_width=0.3, shrink_factor=0.5</td>
</tr>
</tbody>
</table>

Fig. 30: Fancyarrow Demo

Some arrowstyles only work with connection styles that generate a quadratic-spline segment. They are fancy, simple, and wedge. For these arrow styles, you must use the "angle3" or "arc3" connection style.

If the annotation string is given, the patchA is set to the bbox patch of the text by default.

As in the text command, a box around the text can be drawn using the bbox argument.
By default, the starting point is set to the center of the text extent. This can be adjusted with `relpos` key value. The values are normalized to the extent of the text. For example, (0,0) means lower-left corner and (1,1) means top-right.

---

**Placing Artist at the anchored location of the Axes**

There are classes of artists that can be placed at an anchored location in the Axes. A common example is the legend. This type of artist can be created by using the OffsetBox class. A few predefined classes are available in `mpl_toolkits.axes_grid1.anchored_artists` others in `matplotlib.offsetbox`.

```python
from matplotlib.offsetbox import AnchoredText
at = AnchoredText("Figure 1a",
    prop=dict(size=15), frameon=True,
    loc='upper left',
)
at.patch.set_boxstyle("round,pad=0.,rounding_size=0.2")
ax.add_artist(at)
```

The `loc` keyword has same meaning as in the legend command.

A simple application is when the size of the artist (or collection of artists) is known in pixel size during the time of creation. For example, if you want to draw a circle with fixed size of 20 pixel x 20 pixel (radius = 10 pixel), you can utilize `AnchoredDrawingArea`. The instance is created with a size of the drawing area (in pixels), and arbitrary artists can added to the drawing area. Note that the extents of the artists that are added to the drawing area are not related to the placement of the drawing area itself. Only the initial size matters.
from mpl_toolkits.axes_grid1.anchored_artists import AnchoredDrawingArea

ada = AnchoredDrawingArea(20, 20, 0, 0,
                           loc='upper right', pad=0., frameon=False)
p1 = Circle((10, 10), 10)
ada.drawing_area.add_artist(p1)
p2 = Circle((30, 10), 5, fc="r")
ada.drawing_area.add_artist(p2)

The artists that are added to the drawing area should not have a transform set (it will be overridden) and the dimensions of those artists are interpreted as a pixel coordinate, i.e., the radius of the circles in above example are 10 pixels and 5 pixels, respectively.

The ellipse in the above example will have width and height corresponding to 0.1 and 0.4 in data coordinates and will be automatically scaled when the view limits of the axes change.

Sometimes, you want your artists to scale with the data coordinate (or coordinates other than canvas pixels). You can use AnchoredAuxTransformBox class. This is similar to AnchoredDrawingArea except that the extent of the artist is determined during the drawing time respecting the specified transform.

box = AnchoredAuxTransformBox(ax.transData, loc='upper left')
el = Ellipse((0,0), width=0.1, height=0.4, angle=30)  # in data coordinates!
box.drawing_area.add_artist(el)

The ellipse in the above example will have width and height corresponding to 0.1 and 0.4 in data coordinates and will be automatically scaled when the view limits of the axes change.

As in the legend, the bbox_to_anchor argument can be set. Using the HPacker and VPacker, you can have an arrangement(?) of artist as in the legend (as a matter of fact, this is how the legend is created).
Note that unlike the legend, the `bbox_transform` is set to `IdentityTransform` by default.

**Using Complex Coordinates with Annotations**

The Annotation in matplotlib supports several types of coordinates as described in *Basic annotation*. For an advanced user who wants more control, it supports a few other options.

1. *`Transform` instance*. For example,

```python
ax.annotate("Test", xy=(0.5, 0.5), xycoords=ax.transAxes)
```

is identical to

```python
ax.annotate("Test", xy=(0.5, 0.5), xycoords="axes fraction")
```

With this, you can annotate a point in other axes.

```python
ax1, ax2 = subplot(121), subplot(122)
ax2.annotate("Test", xy=(0.5, 0.5), xycoords=ax1.transData,
               xytext=(0.5, 0.5), textcoords=ax2.transData,
               arrowprops=dict(arrowstyle="->"))
```

2. *`Artist` instance*. The xy value (or xytext) is interpreted as a fractional coordinate of the bbox (return value of `get_window_extent`) of the artist.

```python
an1 = ax.annotate("Test 1", xy=(0.5, 0.5), xycoords="data",
                  va="center", ha="center",
                  bbox=dict(boxstyle="round", fc="w"))
an2 = ax.annotate("Test 2", xy=(1, 0.5), xycoords=an1,
                  # (1,0.5) of the an1's bbox
```

(continues on next page)
Matplotlib, Release 3.1.1

(continued from previous page)

```python
xytext=(30,0), textcoords="offset points",
va="center", ha="left",
bbox=dict(boxstyle="round", fc="w"),
arrowprops=dict(arrowstyle="-">")
```

Fig. 38: Annotation with Simple Coordinates

Note that it is your responsibility that the extent of the coordinate artist (an1 in above example) is determined before an2 gets drawn. In most cases, it means that an2 needs to be drawn later than an1.

3. A callable object that returns an instance of either BboxBase or Transform. If a transform is returned, it is the same as 1 and if a bbox is returned, it is the same as 2. The callable object should take a single argument of the renderer instance. For example, the following two commands give identical results

```python
an2 = ax.annotate("Test 2", xy=(1, 0.5), xycoords=an1,
                     xytext=(30,0), textcoords="offset points")
an2 = ax.annotate("Test 2", xy=(1, 0.5), xycoords=an1.get_window_extent,
                     xytext=(30,0), textcoords="offset points")
```

4. A tuple of two coordinate specifications. The first item is for the x-coordinate and the second is for the y-coordinate. For example,

```python
annotate("Test", xy=(0.5, 1), xycoords="data", "axes fraction")
```

0.5 is in data coordinates, and 1 is in normalized axes coordinates. You may use an artist or transform as with a tuple. For example,

![Fig. 39: Annotation with Simple Coordinates 2](image)

5. Sometimes, you want your annotation with some "offset points", not from the annotated point but from some other point. OffsetFrom is a helper class for such cases.

You may take a look at this example /gallery/text_labels_and_annotations/annotation_demo.
Using ConnectionPatch

The ConnectionPatch is like an annotation without text. While the annotate function is recommended in most situations, the ConnectionPatch is useful when you want to connect points in different axes.

```python
from matplotlib.patches import ConnectionPatch
xy = (0.2, 0.2)
con = ConnectionPatch(xyA=xy, xyB=xy, coordsA="data", coordsB="data",
                     axesA=ax1, axesB=ax2)
an2.add_artist(con)
```

The above code connects point xy in the data coordinates of ax1 to point xy in the data coordinates of ax2. Here is a simple example.

While the ConnectionPatch instance can be added to any axes, you may want to add it to the axes that is latest in drawing order to prevent overlap by other axes.

Advanced Topics

Zoom effect between Axes

`mpl_toolkits.axes_grid1.inset_locator` defines some patch classes useful for interconnecting two axes. Understanding the code requires some knowledge of how mpl’s transform works. But, utilizing it will be straightforward.

Define Custom BoxStyle

You can use a custom box style. The value for the boxstyle can be a callable object in the following forms.
def __call__(self, x0, y0, width, height, mutation_size,
             aspect_ratio=1.):
    ": type: Base Path

    Given the location and size of the box, return the path of
    the box around it.

    *x0*, *y0*, *width*, *height* : location and size of the box
    *mutation_size* : a reference scale for the mutation.
    *aspect_ratio* : aspect-ratio for the mutation.

    return path

Here is a complete example.

However, it is recommended that you derive from the matplotlib.patches.BoxStyle._Base as demonstrated below.

Similarly, you can define a custom ConnectionStyle and a custom ArrowStyle. See the source code of lib/matplotlib/patches.py and check how each style class is defined.

**Note:** Click here to download the full example code
2.5.7 Writing mathematical expressions

An introduction to writing mathematical expressions in Matplotlib.

You can use a subset TeX markup in any matplotlib text string by placing it inside a pair of dollar signs ($).

Note that you do not need to have TeX installed, since Matplotlib ships its own TeX expression parser, layout engine, and fonts. The layout engine is a fairly direct adaptation of the layout algorithms in Donald Knuth’s TeX, so the quality is quite good (matplotlib also provides a `usetex` option for those who do want to call out to TeX to generate their text (see Text rendering With LaTeX).

Any text element can use math text. You should use raw strings (precede the quotes with an 'r'), and surround the math text with dollar signs ($), as in TeX. Regular text and mathtext can be interleaved within the same string. Mathtext can use DejaVu Sans (default), DejaVu Serif, the Computer Modern fonts (from (La)TeX), STIX fonts (with are designed to blend well with Times), or a Unicode font that you provide. The mathtext font can be selected with the customization variable `mathtext.fontset` (see Customizing Matplotlib with style sheets and rcParams).

Here is a simple example:

```python
# plain text
plt.title('alpha > beta')
```

produces “alpha > beta”.

Whereas this:

```python
# math text
plt.title(r'$\alpha > \beta$')
```

produces “$\alpha > \beta$”.

**Note:** Mathtext should be placed between a pair of dollar signs ($). To make it easy to display monetary values, e.g., "$100.00", if a single dollar sign is present in the entire string, it will be displayed verbatim as a dollar sign. This is a small change from regular TeX, where the dollar sign in non-math text would have to be escaped ("\$`).

**Note:** While the syntax inside the pair of dollar signs ($) aims to be TeX-like, the text outside does not. In particular, characters such as:
have special meaning outside of math mode in TeX. Therefore, these characters will behave
differently depending on the rcParam text.usetex flag. See the usetex tutorial for more infor-
mation.

Subscripts and superscripts

To make subscripts and superscripts, use the \_ and ^ symbols:

\[ \alpha_i > \beta_i \]

Some symbols automatically put their sub/superscripts under and over the operator. For
example, to write the sum of \( x_i \) from 0 to \( \infty \), you could do:

\[ \sum_{i=0}^{\infty} x_i \]

Fractions, binomials, and stacked numbers

Fractions, binomials, and stacked numbers can be created with the \frac{}, \binom{}{} and
\genfrac{}{}{}{}{} commands, respectively:

\[ \frac{3}{4} \binom{3}{4} \genfrac{}{}{}{}{}{0}{3}{4} \]

produces

\[ \frac{3}{4} \binom{3}{4} \genfrac{}{}{}{}{}{0}{3}{4} \]

Fractions can be arbitrarily nested:

\[ \frac{5 - \frac{1}{x}}{4} \]

produces

\[ \frac{5 - \frac{1}{x}}{4} \]

Note that special care needs to be taken to place parentheses and brackets around fractions.
Doing things the obvious way produces brackets that are too small:

\[ (5 - \frac{1}{x}) \]

The solution is to precede the bracket with \left and \right to inform the parser that those
brackets encompass the entire object.
Radicals

Radicals can be produced with the \( \sqrt{} \) command. For example:

\[
\sqrt{2}
\]

Any base can (optionally) be provided inside square brackets. Note that the base must be a simple expression, and can not contain layout commands such as fractions or sub/superscripts:

\[
\sqrt{x}
\]

Fonts

The default font is italics for mathematical symbols.

**Note:** This default can be changed using the `mathtext.default` rcParam. This is useful, for example, to use the same font as regular non-math text for math text, by setting it to `regular`.

To change fonts, e.g., to write “sin” in a Roman font, enclose the text in a font command:

\[
s(t) = A \sin(2\omega t)
\]

More conveniently, many commonly used function names that are typeset in a Roman font have shortcuts. So the expression above could be written as follows:

\[
s(t) = A \sin(2\omega t)
\]

Here “s” and “t” are variable in italics font (default), “sin” is in Roman font, and the amplitude “A” is in calligraphy font. Note in the example above the calligraphy A is squished into the sin. You can use a spacing command to add a little whitespace between them:

\[
s(t) = A \sin(2\omega t)
\]

The choices available with all fonts are:
<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>\mathrm{Roman}</td>
<td>Roman</td>
</tr>
<tr>
<td>\mathit{Italic}</td>
<td>Italic</td>
</tr>
<tr>
<td>\mathtt{Typewriter}</td>
<td>Typewriter</td>
</tr>
<tr>
<td>\mathcal{CALLIGRAPHY}</td>
<td>CALLIGRAPHY</td>
</tr>
</tbody>
</table>

When using the STIX fonts, you also have the choice of:

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>\mathbb{blackboard}</td>
<td>⨟⅁ℸ⋊⅁∖</td>
</tr>
<tr>
<td>\mathrm{\mathbb{blackboard}}</td>
<td>⨟⅁ℸ⋊⅁∖</td>
</tr>
<tr>
<td>\mathfrak{Fraktur}</td>
<td>Fraktur</td>
</tr>
<tr>
<td>\mathsf{sansserif}</td>
<td>sansserif</td>
</tr>
<tr>
<td>\mathrm{\mathsf{sansserif}}</td>
<td>sansserif</td>
</tr>
</tbody>
</table>

There are also three global “font sets” to choose from, which are selected using the `mathtext.fontset` parameter in `matplotlibrc`.

**cm**: Computer Modern (TeX)

\[ \mathcal{R} \prod_{i=\alpha_i+1}^{\infty} a_i \sin(2\pi f x_i) \]

**stix**: STIX (designed to blend well with Times)

\[ \mathcal{R} \prod_{i=\alpha_i+1}^{\infty} a_i \sin(2\pi f x_i) \]

**stixsans**: STIX sans-serif

\[ \mathcal{R} \prod_{i=\alpha_i+1}^{\infty} a_i \sin(2\pi f x_i) \]

Additionally, you can use `\mathdefault{...}` or its alias `\mathregular{...}` to use the font used for regular text outside of mathtext. There are a number of limitations to this approach, most notably that far fewer symbols will be available, but it can be useful to make math expressions blend well with other text in the plot.

**Custom fonts**

mathtext also provides a way to use custom fonts for math. This method is fairly tricky to use, and should be considered an experimental feature for patient users only. By setting the `rcParam mathtext.fontset` to `custom`, you can then set the following parameters, which control which font file to use for a particular set of math characters.
Each parameter should be set to a fontconfig font descriptor (as defined in the yet-to-be-written font chapter).

The fonts used should have a Unicode mapping in order to find any non-Latin characters, such as Greek. If you want to use a math symbol that is not contained in your custom fonts, you can set the rcParam `mathtext.fallback_to_cm` to `True` which will cause the mathtext system to use characters from the default Computer Modern fonts whenever a particular character cannot be found in the custom font.

Note that the math glyphs specified in Unicode have evolved over time, and many fonts may not have glyphs in the correct place for mathtext.

### Accents

An accent command may precede any symbol to add an accent above it. There are long and short forms for some of them.

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\acute a</code> or <code>'a</code></td>
<td>ˆa</td>
</tr>
<tr>
<td><code>\bar a</code></td>
<td>˘a</td>
</tr>
<tr>
<td><code>\breve a</code></td>
<td>˘a</td>
</tr>
<tr>
<td><code>\ddot a</code> or <code>''a</code></td>
<td>¨a</td>
</tr>
<tr>
<td><code>\dot a</code> or <code>.a</code></td>
<td>˙a</td>
</tr>
<tr>
<td><code>\grave a</code> or <code>&quot;a</code></td>
<td><code>́a</code></td>
</tr>
<tr>
<td><code>\hat a</code> or <code>^a</code></td>
<td>ˆa</td>
</tr>
<tr>
<td><code>\tilde a</code> or <code>\~a</code></td>
<td>˜a</td>
</tr>
<tr>
<td><code>\vec a</code></td>
<td>⃗a</td>
</tr>
<tr>
<td><code>\overline{abc}</code></td>
<td>abc</td>
</tr>
</tbody>
</table>

In addition, there are two special accents that automatically adjust to the width of the symbols below:

<table>
<thead>
<tr>
<th>Command</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\widehat{xyz}</code></td>
<td>xyẑ</td>
</tr>
<tr>
<td><code>\widetilde{xyz}</code></td>
<td>xyz̃</td>
</tr>
</tbody>
</table>

Care should be taken when putting accents on lower-case i’s and j’s. Note that in the following `\imath` is used to avoid the extra dot over the i:

```
r"$\hat i \ \ \hat \imath$"
```

\hat i  \hat \imath
Symbols

You can also use a large number of the TeX symbols, as in \infty, \leftarrow, \sum, \int.

Lower-case Greek

<table>
<thead>
<tr>
<th>α \alpha</th>
<th>β \beta</th>
<th>χ \chi</th>
<th>δ \delta</th>
<th>f \digamma</th>
<th>ε \epsilon</th>
</tr>
</thead>
<tbody>
<tr>
<td>η \eta</td>
<td>γ \gamma</td>
<td>ι \iota</td>
<td>κ \kappa</td>
<td>λ \lambda</td>
<td>μ \mu</td>
</tr>
<tr>
<td>ν \nu</td>
<td>ω \omega</td>
<td>φ \phi</td>
<td>π \pi</td>
<td>ψ \psi</td>
<td>ρ \rho</td>
</tr>
<tr>
<td>σ \sigma</td>
<td>τ \tau</td>
<td>θ \theta</td>
<td>υ \upsilon</td>
<td>ε \varepsilon</td>
<td>χ \varkappa</td>
</tr>
<tr>
<td>φ \varphi</td>
<td>ω \varpi</td>
<td>ρ \varrho</td>
<td>ζ \varsigma</td>
<td>Θ \vartheta</td>
<td>ξ \xi</td>
</tr>
</tbody>
</table>

Upper-case Greek

<table>
<thead>
<tr>
<th>Δ \Delta</th>
<th>Γ \Gamma</th>
<th>Λ \Lambda</th>
<th>Ω \Omega</th>
<th>Φ \Phi</th>
<th>Π \Pi</th>
<th>Ψ \Psi</th>

## Arrow symbols

| \Downarrow | \Leftarrow | \Longleftarrow | \Leftarrow | \Leftrightarrow |
| \nLeftarrow | \nRightarrow | \nLeftrightarrow | \nLeftarrow | \nRightarrow |
| \nLongleftarrow | \nLongrightarrow | \nLongmapsto | \nLsh |

### Table 2 – continued from previous page

| \smile | \sqcap | \sqcup | \sqsubset | \sqsubseteq |
| \subseteqq | \subsetneq | \subsetneqq | \succ | \succapprox |
| \succcurlyeq | \succeq | \succnapprox | \succsim | \varpropto |
| \therefore | \top | \triangleright | \trianglerighteq | \uplus |
| \vartriangleleft | \vartrianglequet | \vartriangleright | \vartrianglerighteq | \vartripleright |
| \vdash | \vee | \veebar | \wedge | \wr |
### Miscellaneous symbols

| \$ \$  | Å \AA  | \( \) \Finv | ℓ \Game |
| \[ \] | \P | \Re | \$ \S |
| \angle | \backprime | \bigstar | \blacksquare |
| \blacktriangle | \blacktriangledown | \cdots | \checkmark |
| \circledR | \circledS | \clubsuit | \complement |
| \copyright | \dagger | \diamondsuit | \ell |
| \emptyset | \eth | \exists | \flat |
| \forall | \hbar | \heartsuit | \hslash |
| \I | \imath | \infty | \infty |
| \infty | \jmath | \ldots | \measuredangle |
| \neg | \nexists | \oiiint | \partial |
| \prime | \sharp | \spadesuit | \sphericalangle |
| \ss | \triangledown | \varnothing | \vartriangle |
| \vdots | \wp | \yen |

If a particular symbol does not have a name (as is true of many of the more obscure symbols in the STIX fonts), Unicode characters can also be used:

ur'\$\u23ce$'

#### Example

Here is an example illustrating many of these features in context.

![MathText Example](image)

**Fig. 45: Pyplot Mathtext**

**Note:** Click [here](#) to download the full example code

### 2.5.8 Typesetting With XeLaTeX/LuaLaTeX

How to typeset text with the \texttt{pgf} backend in Matplotlib.
Using the pgf backend, matplotlib can export figures as pgf drawing commands that can be processed with pdflatex, xelatex or lualatex. XeLaTeX and LuaLaTeX have full unicode support and can use any font that is installed in the operating system, making use of advanced typographic features of OpenType, AAT and Graphite. Pgf pictures created by `plt.savefig('figure.pgf')` can be embedded as raw commands in LaTeX documents. Figures can also be directly compiled and saved to PDF with `plt.savefig('figure.pdf')` by either switching to the backend

```python
matplotlib.use('pgf')
```

or registering it for handling pdf output

```python
from matplotlib.backends.backend_pgf import FigureCanvasPgf
matplotlib.backend_bases.register_backend('pdf', FigureCanvasPgf)
```

The second method allows you to keep using regular interactive backends and to save xelatex, lualatex or pdflatex compiled PDF files from the graphical user interface.

Matplotlib’s pgf support requires a recent LaTeX installation that includes the TikZ/PGF packages (such as TeXLive), preferably with XeLaTeX or LuaLaTeX installed. If either pdftocairo or ghostscript is present on your system, figures can optionally be saved to PNG images as well. The executables for all applications must be located on your `PATH`.

Rc parameters that control the behavior of the pgf backend:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgf.preamble</td>
<td>Lines to be included in the LaTeX preamble</td>
</tr>
<tr>
<td>pgf.rcfonts</td>
<td>Setup fonts from rc params using the fontspec package</td>
</tr>
<tr>
<td>pgf.texsystem</td>
<td>Either &quot;xelatex&quot; (default), &quot;lualatex&quot; or &quot;pdflatex&quot;</td>
</tr>
</tbody>
</table>

**Note:** TeX defines a set of special characters, such as:

```latex
#$%&\_{}^\{\}
```

Generally, these characters must be escaped correctly. For convenience, some characters (\_,\^,\%) are automatically escaped outside of math environments.

**Multi-Page PDF Files**

The pgf backend also supports multipage pdf files using PdfPages

```python
from matplotlib.backends.backend_pgf import PdfPages
import matplotlib.pyplot as plt

with PdfPages('multipage.pdf', metadata={'author': 'Me'}) as pdf:
    fig1, ax1 = plt.subplots()
    ax1.plot([1, 5, 3])
    pdf.savefig(fig1)

    fig2, ax2 = plt.subplots()
```

(continues on next page)
Font specification

The fonts used for obtaining the size of text elements or when compiling figures to PDF are usually defined in the matplotlib rc parameters. You can also use the LaTeX default Computer Modern fonts by clearing the lists for `font.serif`, `font.sans-serif` or `font.monospace`. Please note that the glyph coverage of these fonts is very limited. If you want to keep the Computer Modern font face but require extended unicode support, consider installing the Computer Modern Unicode fonts `CMU Serif`, `CMU Sans Serif`, etc.

When saving to `.pgf`, the font configuration matplotlib used for the layout of the figure is included in the header of the text file.

Custom preamble

Full customization is possible by adding your own commands to the preamble. Use the `pgf.preamble` parameter if you want to configure the math fonts, using `unicode-math` for example, or for loading additional packages. Also, if you want to do the font configuration yourself instead of using the fonts specified in the rc parameters, make sure to disable `pgf.rcfonts`.

---

```
import matplotlib.pyplot as plt
plt.rcParams.update({
    "font.family": "serif",
    "font.serif": [],        # use latex default serif font
    "font.sans-serif": ["DejaVu Sans"], # use a specific sans-serif font
})

plt.figure(figsize=(4.5, 2.5))
plt.plot(range(5))
plt.text(0.5, 3., "serif")
plt.text(0.5, 2., "monospace", family="monospace")
plt.text(2.5, 2., "sans-serif", family="sans-serif")
plt.text(2.5, 1., "comic sans", family="Comic Sans MS")
plt.xlabel("µ is not $\mu$")
plt.tight_layout(.5)
```
Choosing the TeX system

The TeX system to be used by matplotlib is chosen by the `pgf.texsystem` parameter. Possible values are 'xelatex' (default), 'lualatex' and 'pdflatex'. Please note that when selecting `pdflatex` the fonts and unicode handling must be configured in the preamble.

```python
import matplotlib.pyplot as plt
plt.rcParams.update({
    "pgf.texsystem": "pdflatex",
    "pgf.preamble": [r"\usepackage[utf8x]{inputenc}",
                     r"\usepackage[T1]{fontenc}",
                     r"\usepackage{cmbright}"],
})
plt.figure(figsize=(4.5, 2.5))
plt.plot(range(5))
plt.text(0.5, 3., "serif", family="serif")
plt.text(0.5, 2., "monospace", family="monospace")
plt.text(2.5, 2., "sans-serif", family="sans-serif")
plt.xlabel(r"µ is not $\mu$")
plt.tight_layout(.5)
```

Troubleshooting

- Please note that the TeX packages found in some Linux distributions and MiKTeX installations are dramatically outdated. Make sure to update your package catalog and upgrade or install a recent TeX distribution.
- On Windows, the `PATH` environment variable may need to be modified to include the directories containing the latex, dvipng and ghostscript executables. See [Environment Variables](https://matplotlib.org/3.1.1/users/settings.html#environment-variables) and [Setting environment variables in windows](https://matplotlib.org/3.1.1/users/settings.html#setting-environment-variables-in-windows) for details.
- A limitation on Windows causes the backend to keep file handles that have been opened by your application open. As a result, it may not be possible to delete the corresponding files until the application closes (see [#1324](https://github.com/matplotlib/matplotlib/issues/1324)).
- Sometimes the font rendering in figures that are saved to png images is very bad. This happens when the pdftocairo tool is not available and ghostscript is used for the pdf to png conversion.

- Make sure what you are trying to do is possible in a LaTeX document, that your LaTeX syntax is valid and that you are using raw strings if necessary to avoid unintended escape sequences.

- The `pgf.preamble` rc setting provides lots of flexibility, and lots of ways to cause problems. When experiencing problems, try to minimalize or disable the custom preamble.

- Configuring an `unicode-math` environment can be a bit tricky. The TeXLive distribution for example provides a set of math fonts which are usually not installed system-wide. XeTeX, unlike LuaLaTeX, cannot find these fonts by their name, which is why you might have to specify `\setmathfont{xits-math.otf}` instead of `\setmathfont{XITS Math}` or alternatively make the fonts available to your OS. See this tex.stackexchange.com question for more details.

- If the font configuration used by matplotlib differs from the font setting in your LaTeX document, the alignment of text elements in imported figures may be off. Check the header of your `.pgf` file if you are unsure about the fonts matplotlib used for the layout. Vector images and hence `.pgf` files can become bloated if there are a lot of objects in the graph. This can be the case for image processing or very big scatter graphs. In an extreme case this can cause TeX to run out of memory: “TeX capacity exceeded, sorry” You can configure latex to increase the amount of memory available to generate the `.pdf` image as discussed on tex.stackexchange.com. Another way would be to “rasterize” parts of the graph causing problems using either the `rasterized=True` keyword, or `.set_rasterized(True)` as per this example.

- If you still need help, please see Getting help

**Note:** Click here to download the full example code

### 2.5.9 Text rendering With LaTeX

Rendering text with LaTeX in Matplotlib.

Matplotlib has the option to use LaTeX to manage all text layout. This option is available with the following backends:

- Agg
- PS
- PDF

The LaTeX option is activated by setting `text.usetex : True` in your rc settings. Text handling with matplotlib’s LaTeX support is slower than matplotlib’s very capable `mathtext`, but is more flexible, since different LaTeX packages (font packages, math packages, etc.) can be used. The results can be striking, especially when you take care to use the same fonts in your figures as in the main document.

Matplotlib’s LaTeX support requires a working LaTeX installation, `dvipng` (which may be included with your LaTeX installation), and Ghostscript (GPL Ghostscript 9.0 or later is required). The executables for these external dependencies must all be located on your `PATH`. 

---

Matplotlib, Release 3.1.1
There are a couple of options to mention, which can be changed using \textit{rc settings}. Here is an example matplotlibrc file:

```
font.family : serif
font.serif : Times, Palatino, New Century Schoolbook, Bookman, Computer Modern
font.sans-serif : Helvetica, Avant Garde, Computer Modern Sans serif
font.cursive : Zapf Chancery
font.monospace : Courier, Computer Modern Typewriter
text.usetex : true
```

The first valid font in each family is the one that will be loaded. If the fonts are not specified, the Computer Modern fonts are used by default. All of the other fonts are Adobe fonts. Times and Palatino each have their own accompanying math fonts, while the other Adobe serif fonts make use of the Computer Modern math fonts. See the \textit{PSNFSS} documentation for more details.

To use LaTeX and select Helvetica as the default font, without editing matplotlibrc use:

```python
from matplotlib import rc
rc('font',**{'family':'sans-serif','sans-serif':['Helvetica']})
## for Palatino and other serif fonts use:
#rc('font',**{'family':'serif','serif':['Palatino']})
rc('text', usetex=True)
```

Here is the standard example, \texttt{tex-demo.py}:

![Graph](image)

\textit{Fig. 46:} TeX Demo

Note that display math mode ($$ e=mc^2 $$) is not supported, but adding the command `\displaystyle`, as in \texttt{tex-demo.py}, will produce the same results.

\textbf{Note: } Certain characters require special escaping in TeX, such as:

```
\# $ % & \_ ^ \{ \} \( \) \[ \]
```

Therefore, these characters will behave differently depending on the rcParam \texttt{text.usetex} flag.
usetex with unicode

It is also possible to use unicode strings with the LaTeX text manager, here is an example taken from tex_demo.py. The axis labels include Unicode text:

![Fig. 47: TeX Unicode Demo](image)

Postscript options

In order to produce encapsulated postscript files that can be embedded in a new LaTeX document, the default behavior of matplotlib is to distill the output, which removes some postscript operators used by LaTeX that are illegal in an eps file. This step produces results which may be unacceptable to some users, because the text is coarsely rasterized and converted to bitmaps, which are not scalable like standard postscript, and the text is not searchable. One workaround is to set `ps.distiller.res` to a higher value (perhaps 6000) in your rc settings, which will produce larger files but may look better and scale reasonably. A better workaround, which requires Poppler or Xpdf, can be activated by changing the `ps.usedistiller` rc setting to `xpdf`. This alternative produces postscript without rasterizing text, so it scales properly, can be edited in Adobe Illustrator, and searched text in pdf documents.

Possible hangups

- On Windows, the `PATH` environment variable may need to be modified to include the directories containing the latex, dvipng and ghostscript executables. See Environment Variables and Setting environment variables in windows for details.
- Using MiKTeX with Computer Modern fonts, if you get odd *Agg and PNG results, go to MiKTeX/Options and update your format files
- On Ubuntu and Gentoo, the base texlive install does not ship with the type1cm package. You may need to install some of the extra packages to get all the goodies that come bundled with other latex distributions.
- Some progress has been made so matplotlib uses the dvi files directly for text layout. This allows latex to be used for text layout with the pdf and svg backends, as well as the *Agg and PS backends. In the future, a latex installation may be the only external dependency.
Troubleshooting

- Try deleting your `.matplotlib/tex.cache` directory. If you don't know where to find `.matplotlib`, see `matplotlib configuration and cache directory locations`.
- Make sure LaTeX, dvipng and ghostscript are each working and on your PATH.
- Make sure what you are trying to do is possible in a LaTeX document, that your LaTeX syntax is valid and that you are using raw strings if necessary to avoid unintended escape sequences.
- Most problems reported on the mailing list have been cleared up by upgrading Ghostscript. If possible, please try upgrading to the latest release before reporting problems to the list.
- The `text.latex.preamble` rc setting is not officially supported. This option provides lots of flexibility, and lots of ways to cause problems. Please disable this option before reporting problems to the mailing list.
- If you still need help, please see `Getting help`

2.6 Toolkits

These tutorials cover toolkits designed to extend the functionality of Matplotlib in order to accomplish specific goals.

Note: Click here to download the full example code

2.6.1 Overview of axes_grid1 toolkit

Controlling the layout of plots with the axes_grid toolkit.

What is axes_grid1 toolkit?

`axes_grid1` is a collection of helper classes to ease displaying (multiple) images with Matplotlib. In Matplotlib, the axes location (and size) is specified in the normalized figure coordinates, which may not be ideal for displaying images that needs to have a given aspect ratio. For example, it helps if you have a colorbar whose height always matches that of the image. `ImageGrid`, `RGB Axes` and `AxesDivider` are helper classes that deals with adjusting the location of (multiple) Axes. They provides a framework to adjust the position of multiple axes at the drawing time. `ParasiteAxes` provides twinx(or twiny)-like features so that you can plot different data (e.g., different y-scale) in a same Axes. `AnchoredArtists` includes custom artists which are placed at some anchored position, like the legend.

axes_grid1
A class that creates a grid of Axes. In matplotlib, the axes location (and size) is specified in the normalized figure coordinates. This may not be ideal for images that need to be displayed with a given aspect ratio. For example, displaying images of a same size with some fixed padding between them cannot be easily done in matplotlib. ImageGrid is used in such case.

- The position of each axes is determined at the drawing time (see AxesDivider), so that the size of the entire grid fits in the given rectangle (like the aspect of axes). Note that in this example, the paddings between axes are fixed even if you changes the figure size.
- axes in the same column has a same axes width (in figure coordinate), and similarly, axes in the same row has a same height. The widths (height) of the axes in the same row (column) are scaled according to their view limits (xlim or ylim).
xaxis are shared among axes in a same column. Similarly, yaxis are shared among axes in a same row. Therefore, changing axis properties (view limits, tick location, etc. either by plot commands or using your mouse in interactive backends) of one axes will affect all other shared axes.

When initialized, ImageGrid creates given number (ngrids or ncols * nrows if ngrids is None) of Axes instances. A sequence-like interface is provided to access the individual Axes instances (e.g., grid[0] is the first Axes in the grid. See below for the order of axes).

ImageGrid takes the following arguments,

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fig</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rect</td>
<td></td>
<td></td>
</tr>
<tr>
<td>nrows ncols</td>
<td>number of rows and cols. e.g., (2,2)</td>
<td></td>
</tr>
<tr>
<td>ngrids</td>
<td>None</td>
<td>number of grids. nrows x ncols if None</td>
</tr>
<tr>
<td>direction</td>
<td>&quot;row&quot;</td>
<td>increasing direction of axes number: [row</td>
</tr>
<tr>
<td>axes_pad</td>
<td>0.02</td>
<td>pad between axes in inches</td>
</tr>
<tr>
<td>add_all</td>
<td>True</td>
<td>Add axes to figures if True</td>
</tr>
<tr>
<td>share_all</td>
<td>False</td>
<td>xaxis &amp; yaxis of all axes are shared if True</td>
</tr>
<tr>
<td>aspect</td>
<td>True</td>
<td>aspect of axes</td>
</tr>
<tr>
<td>label_mode</td>
<td>&quot;L&quot;</td>
<td>location of tick labels that will be displayed. &quot;L&quot; (only the lower left axes), &quot;L&quot; (left most and bottom most axes), or &quot;all&quot;.</td>
</tr>
<tr>
<td>cbar_mode</td>
<td>None</td>
<td>[None</td>
</tr>
<tr>
<td>cbar_location</td>
<td>&quot;right&quot;</td>
<td>[right</td>
</tr>
<tr>
<td>cbar_pad</td>
<td>None</td>
<td>pad between image axes and colorbar axes</td>
</tr>
<tr>
<td>cbar_size</td>
<td>&quot;5%&quot;</td>
<td>size of the colorbar</td>
</tr>
<tr>
<td>axes_class</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

rect specifies the location of the grid. You can either specify coordinates of the rectangle to be used (e.g., (0.1, 0.1, 0.8, 0.8) as in the Axes), or the subplot-like position (e.g., "121").

direction means the increasing direction of the axes number.

aspect By default (False), widths and heights of axes in the grid are scaled independently. If True, they are scaled according to their data limits (similar to aspect parameter in mpl).

share_all if True, xaxis and yaxis of all axes are shared.

direction direction of increasing axes number. For "row",

```
grid[0] grid[1]
```

For "column",

```
grid[0] grid[2]
```

You can also create a colorbar (or colorbars). You can have colorbar for each axes (cbar_mode="each"), or you can have a single colorbar for the grid (cbar_mode="single").
The colorbar can be placed on your right, or top. The axes for each colorbar is stored as a `cbar_axes` attribute.

The examples below show what you can do with ImageGrid.

![Fig. 51: Demo Axes Grid](image)

**AxesDivider Class**

Behind the scene, the ImageGrid class and the RGBAaxes class utilize the AxesDivider class, whose role is to calculate the location of the axes at drawing time. While a more about the AxesDivider is (will be) explained in (yet to be written) AxesDividerGuide, direct use of the AxesDivider class will not be necessary for most users. The axes_divider module provides a helper function `make_axes_locatable`, which can be useful. It takes a existing axes instance and create a divider for it.

```python
ax = subplot(1,1,1)
divider = make_axes_locatable(ax)
```

`make_axes_locatable` returns an instance of the AxesLocator class, derived from the Locator. It provides `append_axes` method that creates a new axes on the given side of ("top", "right", "bottom" and "left") of the original axes.

**colorbar whose height (or width) in sync with the master axes**

![Fig. 52: Simple Colorbar](image)
scatter_hist.py with AxesDivider

The "scatter_hist.py" example in mpl can be rewritten using make_axes_locatable.

```python
axScatter = subplot(111)
axScatter.scatter(x, y)
axScatter.set_aspect(1.)

# create new axes on the right and on the top of the current axes.
divider = make_axes_locatable(axScatter)
axHistx = divider.append_axes("top", size=1.2, pad=0.1, sharex=axScatter)
axHisty = divider.append_axes("right", size=1.2, pad=0.1, sharey=axScatter)

# the scatter plot:
# histograms
bins = np.arange(-lim, lim + binwidth, binwidth)
axHistx.hist(x, bins=bins)
axHisty.hist(y, bins=bins, orientation='horizontal')
```

See the full source code below.

![ScatterHist](image)

**Fig. 53: Scatter Hist**

The scatter_hist using the AxesDivider has some advantage over the original scatter_hist.py in mpl. For example, you can set the aspect ratio of the scatter plot, even with the x-axis or y-axis is shared accordingly.

**ParasiteAxes**

The ParasiteAxes is an axes whose location is identical to its host axes. The location is adjusted in the drawing time, thus it works even if the host change its location (e.g., images).

In most cases, you first create a host axes, which provides a few method that can be used to create parasite axes. They are twinx, twiny (which are similar to twinx and twiny in the matplotlib) and twin. twin takes an arbitrary transformation that maps between the data coordinates of the host axes and the parasite axes. draw method of the parasite axes are
Matplotlib, Release 3.1.1

never called. Instead, host axes collects artists in parasite axes and draw them as if they
belong to the host axes, i.e., artists in parasite axes are merged to those of the host axes and
then drawn according to their zorder. The host and parasite axes modifies some of the axes
behavior. For example, color cycle for plot lines are shared between host and parasites. Also,
the legend command in host, creates a legend that includes lines in the parasite axes. To
create a host axes, you may use **host_subplot** or **host_axes** command.

**Example 1. twinx**

![Parasite Simple](image)

Fig. 54: Parasite Simple

**Example 2. twin**

twin without a transform argument assumes that the parasite axes has the same data trans-
form as the host. This can be useful when you want the top(or right)-axis to have different
tick-locations, tick-labels, or tick-formatter for bottom(or left)-axis.

```python
ax2 = ax.twin()  # now, ax2 is responsible for "top" axis and "right" axis
ax2.set_xticks([0., .5*np.pi, np.pi, 1.5*np.pi, 2*np.pi])
ax2.set_xticklabels(["0", r"\frac{1}{2} \pi",
                        r"\pi", r"\frac{3}{2} \pi",
                        r"2 \pi"])
```

A more sophisticated example using twin. Note that if you change the x-limit in the host axes,
the x-limit of the parasite axes will change accordingly.

**AnchoredArtists**

It’s a collection of artists whose location is anchored to the (axes) bbox, like the legend. It
is derived from **OffsetBox** in mpl, and artist need to be drawn in the canvas coordinate. But,
there is a limited support for an arbitrary transform. For example, the ellipse in the example
below will have width and height in the data coordinate.
Fig. 55: Simple Axisline4

Fig. 56: Parasite Simple2

Fig. 57: Simple Anchored Artists
InsetLocator

`mpl_toolkits.axes_grid1.inset_locator` provides helper classes and functions to place your (inset) axes at the anchored position of the parent axes, similarly to AnchoredArtist.

Using `mpl_toolkits.axes_grid1.inset_locator.inset_axes()`, you can have inset axes whose size is either fixed, or a fixed proportion of the parent axes. For example,

```python
inset_axes = inset_axes(parent_axes,
    width="30\%",  # width = 30\% of parent_bbox
    height=1.,    # height : 1 inch
    loc='lower left')
```

creates an inset axes whose width is 30% of the parent axes and whose height is fixed at 1 inch.

You may create your inset whose size is determined so that the data scale of the inset axes to be that of the parent axes multiplied by some factor. For example,

```python
inset_axes = zoomed_inset_axes(ax,
    0.5,  # zoom = 0.5
    loc='upper right')
```

creates an inset axes whose data scale is half of the parent axes. Here is complete examples.

![Inset Locator Demo](image)

**Fig. 58: Inset Locator Demo**

For example, `zoomed_inset_axes()` can be used when you want the inset represents the zoom-up of the small portion in the parent axes. And `mpl_toolkits/axes_grid1/inset_locator` provides a helper function `mark_inset()` to mark the location of the area represented by the inset axes.

![Inset Locator Demo2](image)

**Fig. 59: Inset Locator Demo2**
**RGB Axes**

RGBAxes is a helper class to conveniently show RGB composite images. Like ImageGrid, the location of axes are adjusted so that the area occupied by them fits in a given rectangle. Also, the xaxis and yaxis of each axes are shared.

```python
from mpl_toolkits.axes_grid1.axes_rgb import RGBAxes

fig = plt.figure()
ax = RGBAxes(fig, [0.1, 0.1, 0.8, 0.8])

r, g, b = get_rgb()  # r,g,b are 2-d images
ax.imshow_rgb(r, g, b,
              origin="lower", interpolation="nearest")
```

![Fig. 60: Simple Rgb](image)

**AxesDivider**

The axes_divider module provides helper classes to adjust the axes positions of a set of images at drawing time.

- `axes_size` provides a class of units that are used to determine the size of each axes. For example, you can specify a fixed size.

- `Divider` is the class that calculates the axes position. It divides the given rectangular area into several areas. The divider is initialized by setting the lists of horizontal and vertical sizes on which the division will be based. Then use `new_locator()`, which returns a callable object that can be used to set the `axes_locator` of the axes.

First, initialize the divider by specifying its grids, i.e., horizontal and vertical.

```python
rect = [0.2, 0.2, 0.6, 0.6]
horiz=[h0, h1, h2, h3]
vert=[v0, v1, v2]
divider = Divider(fig, rect, horiz, vert)
```
where, rect is a bounds of the box that will be divided and h0..h3, v0..v2 need to be an instance of classes in the axes_size. They have get_size method that returns a tuple of two floats. The first float is the relative size, and the second float is the absolute size. Consider a following grid.

<table>
<thead>
<tr>
<th>v0</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>v1</td>
<td></td>
</tr>
<tr>
<td>h0</td>
<td>h1</td>
</tr>
</tbody>
</table>

- v0 => 0, 2
- v1 => 2, 0
- v2 => 3, 0

The height of the bottom row is always 2 (axes divider internally assumes that the unit is inches). The first and the second rows have a height ratio of 2:3. For example, if the total height of the grid is 6, then the first and second row will each occupy 2/(2+3) and 3/(2+3) of (6-1) inches. The widths of the horizontal columns will be similarly determined. When the aspect ratio is set, the total height (or width) will be adjusted accordingly.

The mpl_toolkits.axes_grid1.axes_size contains several classes that can be used to set the horizontal and vertical configurations. For example, for vertical configuration one could use:

```python
from mpl_toolkits.axes_grid1.axes_size import Fixed, Scaled
vert = [Fixed(2), Scaled(2), Scaled(3)]
```

After you set up the divider object, then you create a locator instance that will be given to the axes object.:

```python
locator = divider.new_locator(nx=0, ny=1)
ax.set_axes_locator(locator)
```

The return value of the new locator method is an instance of the AxesLocator class. It is a callable object that returns the location and size of the cell at the first column and the second row. You may create a locator that spans over multiple cells.:

```python
locator = divider.new_locator(nx=0, nx=2, ny=1)
```

The above locator, when called, will return the position and size of the cells spanning the first and second column and the first row. In this example, it will return [0:2, 1].

See the example,

You can adjust the size of each axes according to its x or y data limits (AxesX and AxesY).

**Note:** Click [here](#) to download the full example code

### 2.6.2 Overview of axisartist toolkit

The axisartist toolkit tutorial.
Fig. 61: Simple Axes Divider 2

Fig. 62: Simple Axes Divider 3
Warning: *axisartist* uses a custom Axes class (derived from the mpl’s original Axes class). As a side effect, some commands (mostly tick-related) do not work.

The *axisartist* contains a custom Axes class that is meant to support curvilinear grids (e.g., the world coordinate system in astronomy). Unlike mpl’s original Axes class which uses Axes.xaxis and Axes.yaxis to draw ticks, ticklines, etc., *axisartist* uses a special artist (*AxisArtist*) that can handle ticks, ticklines, etc. for curved coordinate systems.

![Demo Floating Axis](image)

**Fig. 63: Demo Floating Axis**

Since it uses special artists, some Matplotlib commands that work on Axes.xaxis and Axes.yaxis may not work.

**axisartist**

The *axisartist* module provides a custom (and very experimental) Axes class, where each axis (left, right, top, and bottom) have a separate associated artist which is responsible for drawing the axis-line, ticks, ticklabels, and labels. You can also create your own axis, which can pass through a fixed position in the axes coordinate, or a fixed position in the data coordinate (i.e., the axis floats around when viewlimit changes).

The axes class, by default, has its xaxis and yaxis invisible, and has 4 additional artists which are responsible for drawing the 4 axis spines in “left”, “right”, “bottom”, and “top”. They are accessed as ax.axis[“left”], ax.axis[“right”], and so on, i.e., ax.axis is a dictionary that contains artists (note that ax.axis is still a callable method and it behaves as an original Axes.axis method in Matplotlib).

To create an axes,

```python
import mpl_toolkits.axisartist as AA
fig = plt.figure()
ax = AA.Axes(fig, [0.1, 0.1, 0.8, 0.8])
fig.add_axes(ax)
```

or to create a subplot
ax = AA.Subplot(fig, 111)
fig.add_subplot(ax)

For example, you can hide the right and top spines using:

```python
ax.axis["right"].set_visible(False)
ax.axis["top"].set_visible(False)
```

![Image 1]

Fig. 64: Simple Axisline3

It is also possible to add a horizontal axis. For example, you may have an horizontal axis at y=0 (in data coordinate).

```python
ax.axis["y=0"] = ax.new_floating_axis(nth_coord=0, value=0)
```

![Image 2]

Fig. 65: Simple Axisartist1

Or a fixed axis with some offset

```python
# make new (right-side) yaxis, but with some offset
ax.axis["right2"] = ax.new_fixed_axis(loc="right",
                                      offset=(20, 0))
```

axisartist with ParasiteAxes

Most commands in the axes_grid1 toolkit can take an axes_class keyword argument, and the commands create an axes of the given class. For example, to create a host subplot with
Here is an example that uses ParasiteAxes.

Fig. 66: Demo Parasite Axes2

**Curvilinear Grid**

The motivation behind the AxisArtist module is to support a curvilinear grid and ticks.

Fig. 67: Demo Curvilinear Grid

**Floating Axes**

AxisArtist also supports a Floating Axes whose outer axes are defined as floating axis.
The `axisartist` namespace includes a derived Axes implementation. The biggest difference is that the artists responsible to draw axis line, ticks, ticklabel and axis labels are separated out from the mpl’s Axis class, which are much more than artists in the original mpl. This change was strongly motivated to support curvilinear grid. Here are a few things that `mpl_toolkits.axisartist.Axes` is different from original Axes from mpl.

- Axis elements (axis line(spine), ticks, ticklabel and axis labels) are drawn by a AxisArtist instance. Unlike Axis, left, right, top and bottom axis are drawn by separate artists. And each of them may have different tick location and different tick labels.

- gridlines are drawn by a Gridlines instance. The change was motivated that in curvilinear coordinate, a gridline may not cross axis-lines (i.e., no associated ticks). In the original Axes class, gridlines are tied to ticks.

- ticklines can be rotated if necessary (i.e, along the gridlines)

In summary, all these changes was to support

- a curvilinear grid.
- a floating axis

![Fig. 68: Demo Floating Axes](image)

![Fig. 69: Demo Floating Axis](image)
mpl_toolkits.axisartist.Axes class defines a axis attribute, which is a dictionary of AxisArtist instances. By default, the dictionary has 4 AxisArtist instances, responsible for drawing of left, right, bottom and top axis.

xaxis and yaxis attributes are still available, however they are set to not visible. As separate artists are used for rendering axis, some axis-related method in mpl may have no effect. In addition to AxisArtist instances, the mpl_toolkits.axisartist.Axes will have gridlines attribute (Gridlines), which obviously draws grid lines.

In both AxisArtist and Gridlines, the calculation of tick and grid location is delegated to an instance of GridHelper class. mpl_toolkits.axisartist.Axes class uses GridHelperRectlinear as a grid helper. The GridHelperRectlinear class is a wrapper around the xaxis and yaxis of mpl’s original Axes, and it was meant to work as the way how mpl’s original axes works. For example, tick location changes using set_ticks method and etc. should work as expected. But change in artist properties (e.g., color) will not work in general, although some effort has been made so that some often-change attributes (color, etc.) are respected.

**AxisArtist**

AxisArtist can be considered as a container artist with following attributes which will draw ticks, labels, etc.

- line
- major_ticks, major_ticklabels
- minor_ticks, minor_ticklabels
- offsetText
- label

**line**

Derived from Line2d class. Responsible for drawing a spinal(?) line.

**major_ticks, minor_ticks**

Derived from Line2d class. Note that ticks are markers.

**major_ticklabels, minor_ticklabels**

Derived from Text. Note that it is not a list of Text artist, but a single artist (similar to a collection).

**axislabel**

Derived from Text.
**Default AxisArtists**

By default, following for axis artists are defined.:

```python
ax.axis['left'], ax.axis['bottom'], ax.axis['right'], ax.axis['top']
```

The ticklabels and axislabel of the top and the right axis are set to not visible.

For example, if you want to change the color attributes of major_ticklabels of the bottom x-axis

```python
ax.axis['bottom'].major_ticklabels.set_color("b")
```

Similarly, to make ticklabels invisible

```python
ax.axis['bottom'].major_ticklabels.set_visible(False)
```

AxisArtist provides a helper method to control the visibility of ticks, ticklabels, and label. To make ticklabel invisible,

```python
ax.axis['bottom'].toggle(ticklabels=False)
```

To make all of ticks, ticklabels, and (axis) label invisible

```python
ax.axis['bottom'].toggle(all=False)
```

To turn all off but ticks on

```python
ax.axis['bottom'].toggle(all=False, ticks=True)
```

To turn all on but (axis) label off

```python
ax.axis['bottom'].toggle(all=True, label=False)
```

ax.axis’s `__getitem__` method can take multiple axis names. For example, to turn ticklabels of “top” and “right” axis on,

```python
ax.axis['top','right'].toggle(ticklabels=True)
```

Note that `ax.axis['top','right']` returns a simple proxy object that translate above code to something like below.

```python
for n in ['top','right']:
    ax.axis[n].toggle(ticklabels=True)
```

So, any return values in the for loop are ignored. And you should not use it anything more than a simple method.

Like the list indexing “:” means all items, i.e.,

```python
ax.axis[:].major_ticks.set_color("r")
```

changes tick color in all axis.

**HowTo**

1. Changing tick locations and label.
Same as the original mpl's axes:

```python
ax.set_xticks([1, 2, 3])
```

2. Changing axis properties like color, etc.

Change the properties of appropriate artists. For example, to change the color of the ticklabels:

```python
ax.axis['left'].major_ticklabels.set_color('r')
```

3. To change the attributes of multiple axis:

```python
ax.axis['left', 'bottom'].major_ticklabels.set_color('r')
```

or to change the attributes of all axis:

```python
ax.axis[:].major_ticklabels.set_color('r')
```

4. To change the tick size (length), you need to use `axis.major_ticks.set_ticksize` method. To change the direction of the ticks (ticks are in opposite direction of ticklabels by default), use `axis.major_ticks.set_tick_out` method.

To change the pad between ticks and ticklabels, use `axis.major_ticklabels.set_pad` method.

To change the pad between ticklabels and axis label, `axis.label.set_pad` method.

**Rotation and Alignment of TickLabels**

This is also quite different from the original mpl and can be confusing. When you want to rotate the ticklabels, first consider using “set_axis_direction” method.

```python
ax1.axis['left'].major_ticklabels.set_axis_direction('top')
ax1.axis['right'].label.set_axis_direction('left')
```

![Fig. 70: Simple Axis Direction01](image)

The parameter for `set_axis_direction` is one of ["left", "right", "bottom", "top"].

You must understand some underlying concept of directions.

1. There is a reference direction which is defined as the direction of the axis line with increasing coordinate. For example, the reference direction of the left x-axis is from bottom to top.

   The direction, text angle, and alignments of the ticks, ticklabels and axis-label is determined with respect to the reference direction
2. *ticklabel_direction* is either the right-hand side (+) of the reference direction or the left-hand side (-).

3. same for the *label_direction*

4. ticks are by default drawn toward the opposite direction of the ticklabels.

5. text rotation of ticklabels and label is determined in reference to the *ticklabel_direction* or *label_direction*, respectively. The rotation of ticklabels and label is anchored.

On the other hand, there is a concept of “axis_direction”. This is a default setting of above properties for each, “bottom”, “left”, “top”, and “right” axis.

<table>
<thead>
<tr>
<th>?</th>
<th>?</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>axislabel</td>
<td>direction</td>
<td>'+'</td>
<td>'−'</td>
<td>'+'</td>
<td>'−'</td>
</tr>
<tr>
<td>axislabel</td>
<td>rotation</td>
<td>180</td>
<td>0</td>
<td>0</td>
<td>180</td>
</tr>
<tr>
<td>axislabel</td>
<td>va</td>
<td>center</td>
<td>top</td>
<td>center</td>
<td>bottom</td>
</tr>
<tr>
<td>axislabel</td>
<td>ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
<tr>
<td>ticklabel</td>
<td>direction</td>
<td>'+'</td>
<td>'−'</td>
<td>'+'</td>
<td>'−'</td>
</tr>
<tr>
<td>ticklabels</td>
<td>rotation</td>
<td>90</td>
<td>0</td>
<td>-90</td>
<td>180</td>
</tr>
<tr>
<td>ticklabel</td>

<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
<tr>
<td>ticklabel</td>
<td>va</td>
<td>center</td>
<td>baseline</td>
<td>center</td>
<td>baseline</td>
</tr>
</tbody>
</table>
And, 'set_axis_direction("top")' means to adjust the text rotation etc, for settings suitable for "top" axis. The concept of axis direction can be more clear with curved axis.

The axis_direction can be adjusted in the AxisArtist level, or in the level of its child artists, i.e., ticks, ticklabels, and axis-label.

ax1.axis["left"].set_axis_direction("top")

changes axis_direction of all the associated artist with the "left" axis, while

ax1.axis["left"].major_ticklabels.set_axis_direction("top")

changes the axis direction of only the major_ticklabels. Note that set_axis_direction in the AxisArtist level changes the ticklabel direction and label_direction, while changing the axis_direction of ticks, ticklabels, and axis-label does not affect them.

If you want to make ticks outward and ticklabels inside the axes, use invert_ticklabel_direction method.

ax.axis[:].invert_ticklabel_direction()

A related method is "set_tick_out". It makes ticks outward (as a matter of fact, it makes ticks toward the opposite direction of the default direction).

ax.axis[:].major_ticks.set_tick_out(True)

So, in summary,

• AxisArtist’s methods
- set_axis_direction: “left”, “right”, “bottom”, or “top”
- set_ticklabel_direction: “+” or “-”
- set_axislabel_direction: “+” or “-”
- invert_ticklabel_direction

• Ticks’ methods (major_ticks and minor_ticks)
  - set_tick_out: True or False
  - set_ticksize: size in points

• TickLabels’ methods (major_ticklabels and minor_ticklabels)
  - set_axis_direction: “left”, “right”, “bottom”, or “top”
  - set_rotation: angle with respect to the reference direction
  - set_ha and set_va: see below

• AxisLabels’ methods (label)
  - set_axis_direction: “left”, “right”, “bottom”, or “top”
  - set_rotation: angle with respect to the reference direction
  - set_ha and set_va

Adjusting ticklabels alignment

Alignment of TickLabels are treated specially. See below

Adjusting pad

To change the pad between ticks and ticklabels

```python
ax.axis["left"].major_ticklabels.set_pad(10)
```

Or ticklabels and axis-label

```python
ax.axis["left"].label.set_pad(10)
```
Fig. 77: Demo Ticklabel Alignment

Fig. 78: Simple Axis Pad
GridHelper

To actually define a curvilinear coordinate, you have to use your own grid helper. A generalised version of grid helper class is supplied and this class should suffice in most of cases. A user may provide two functions which defines a transformation (and its inverse pair) from the curved coordinate to (rectilinear) image coordinate. Note that while ticks and grids are drawn for curved coordinate, the data transform of the axes itself (ax.transData) is still rectilinear (image) coordinate.

```python
from mpl_toolkits.axisartist.grid_helper_curvelinear \
    import GridHelperCurveLinear
from mpl_toolkits.axisartist import Subplot

# from curved coordinate to rectlinear coordinate.
def tr(x, y):
    x, y = np.asarray(x), np.asarray(y)
    return x, y-x

# from rectlinear coordinate to curved coordinate.
def inv_tr(x, y):
    x, y = np.asarray(x), np.asarray(y)
    return x, y+x

grid_helper = GridHelperCurveLinear((tr, inv_tr))
ax1 = Subplot(fig, 1, 1, 1, grid_helper=grid_helper)
fig.add_subplot(ax1)
```

You may use matplotlib’s Transform instance instead (but a inverse transformation must be defined). Often, coordinate range in a curved coordinate system may have a limited range, or may have cycles. In those cases, a more customized version of grid helper is required.

```python
import mpl_toolkits.axisartist.angle_helper as angle_helper

# PolarAxes.PolarTransform takes radian. However, we want our coordinate
# system in degree
tr = Affine2D().scale(np.pi/180., 1.) + PolarAxes.PolarTransform()

# extreme finder : find a range of coordinate.
# 20, 20 : number of sampling points along x, y direction
# The first coordinate (longitude, but theta in polar)
# has a cycle of 360 degree.
# The second coordinate (latitude, but radius in polar) has a minimum of 0
extreme_finder = angle_helper.ExtremeFinderCycle(20, 20,
    lon_cycle = 360,
    lat_cycle = None,
    lon_minmax = None,
    lat_minmax = (0, np.inf),
    )

# Find a grid values appropriate for the coordinate (degree,
# minute, second). The argument is a approximate number of grids.
```

(continues on next page)
grid_locator1 = angle_helper.LocatorDMS(12)

# And also uses an appropriate formatter. Note that, the
# acceptable Locator and Formatter class is a bit different than
# that of mpl's, and you cannot directly use mpl's Locator and
# Formatter here (but may be possible in the future).
tick_formatter1 = angle_helper.FormatterDMS()

grid_helper = GridHelperCurveLinear(tr,
    extreme_finder=extreme_finder,
    grid_locator1=grid_locator1,
    tick_formatter1=tick_formatter1
)

Again, the transData of the axes is still a rectilinear coordinate (image coordinate). You may
manually do conversion between two coordinates, or you may use Parasite Axes for conve-
nience.:

ax1 = SubplotHost(fig, 1, 2, 2, grid_helper=grid_helper)

# A parasite axes with given transform
ax2 = ParasiteAxesAuxTrans(ax1, tr, "equal")
# note that ax2.transData == tr + ax1.transData
# Anything you draw in ax2 will match the ticks and grids of ax1.
ax1.parasites.append(ax2)

Fig. 79: Demo Curvelinear Grid

**FloatingAxis**

A floating axis is an axis one of whose data coordinate is fixed, i.e, its location is not fixed in
Axes coordinate but changes as axes data limits changes. A floating axis can be created using
new_floating_axis method. However, it is your responsibility that the resulting AxisArtist
is properly added to the axes. A recommended way is to add it as an item of Axes's axis
attribute.
# floating axis whose first (index starts from 0) coordinate
# (theta) is fixed at 60

ax1.axis["lat"] = axis = ax1.new_floating_axis(0, 60)
axis.label.set_text(r"$\theta = 60^\circ$")
axis.label.set_visible(True)

See the first example of this page.

Current Limitations and TODO's

The code need more refinement. Here is a incomplete list of issues and TODO’s

• No easy way to support a user customized tick location (for curvilinear grid). A new Locator class needs to be created.
• FloatingAxis may have coordinate limits, e.g., a floating axis of x = 0, but y only spans from 0 to 1.
• The location of axislabel of FloatingAxis needs to be optionally given as a coordinate value. ex, a floating axis of x=0 with label at y=1

Note: Click here to download the full example code

2.6.3 The mplot3d Toolkit

Generating 3D plots using the mplot3d toolkit.

Contents

• The mplot3d Toolkit
  - Getting started
    * Line plots
    * Scatter plots
    * Wireframe plots
    * Surface plots
    * Tri-Surface plots
    * Contour plots
    * Filled contour plots
    * Polygon plots
    * Bar plots
    * Quiver
    * 2D plots in 3D
Getting started

An Axes3D object is created just like any other axes using the projection=’3d’ keyword. Create a new matplotlib.figure.Figure and add a new axes to it of type Axes3D:

```python
import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d import Axes3D
fig = plt.figure()
ax = fig.add_subplot(111, projection='3d')
```

New in version 1.0.0: This approach is the preferred method of creating a 3D axes.

**Note:** Prior to version 1.0.0, the method of creating a 3D axes was different. For those using older versions of matplotlib, change `ax = fig.add_subplot(111, projection='3d')` to `ax = Axes3D(fig)`.

See the mplot3d FAQ for more information about the mplot3d toolkit.

Line plots

Axes3D.plot(self, xs, ys, *args, zdir=’z’, **kwargs)
Plot 2D or 3D data.

**Parameters**

- **xs** [1D array-like] x coordinates of vertices.
- **ys** [1D array-like] y coordinates of vertices.
- **zs** [scalar or 1D array-like] z coordinates of vertices; either one for all points or one for each point.
- **zdir** [{‘x’, ‘y’, ‘z’}] When plotting 2D data, the direction to use as z (‘x’, ‘y’ or ‘z’); defaults to ‘z’.

**kwargs** Other arguments are forwarded to matplotlib.axes.Axes.plot.

Scatter plots

Axes3D.scatter(self, xs, ys, zs=0, zdir=’z’, s=20, c=None, depthshade=True, *args, **kwargs)
Create a scatter plot.

**Parameters**

- **xs, ys** [array-like] The data positions.
- **zs** [float or array-like, optional, default: 0] The z-positions. Either an array of the same length as xs and ys or a single value to place all points in the same plane.
**zdir** [{‘x’, ‘y’, ‘z’, ‘-x’, ‘-y’, ‘-z’}, optional, default: ‘z’] The axis direction for the zs. This is useful when plotting 2D data on a 3D Axes. The data must be passed as *xs, ys*. Setting *zdir* to ‘y’ then plots the data to the x-z-plane. See also /gallery/mplot3d/2dcollections3d.

**s** [scalar or array-like, optional, default: 20] The marker size in points**2**. Either an array of the same length as *xs* and *ys* or a single value to make all markers the same size.

**c** [color, sequence, or sequence of color, optional] The marker color. Possible values:
- A single color format string.
- A sequence of color specifications of length *n*.
- A sequence of *n* numbers to be mapped to colors using *cmap* and *norm*.
- A 2-D array in which the rows are RGB or RGBA.

For more details see the *c* argument of *scatter*.

**depthshade** [bool, optional, default: True] Whether to shade the scatter markers to give the appearance of depth.

***kwargs** All other arguments are passed on to *scatter*.

**Returns**

**paths** [*PathCollection*]

**Wireframe plots**

`Axes3D.plot_wireframe(self, X, Y, Z, *args, **kwargs)`

Plot a 3D wireframe.

**Note:** The *rcount* and *ccount* kwargs, which both default to 50, determine the maximum number of samples used in each direction. If the input data is larger, it will be
Parameters

- **X, Y, Z** [2d arrays] Data values.
- **rcount, ccount** [int] Maximum number of samples used in each direction. If the input data is larger, it will be downsampling (by slicing) to these numbers of points. Setting a count to zero causes the data to be not sampled in the corresponding direction, producing a 3D line plot rather than a wireframe plot. Defaults to 50.
  
  New in version 2.0.

- **rstride, cstride** [int] Downsampling stride in each direction. These arguments are mutually exclusive with `rcount` and `ccount`. If only one of `rstride` or `cstride` is set, the other defaults to 1. Setting a stride to zero causes the data to be not sampled in the corresponding direction, producing a 3D line plot rather than a wireframe plot.

  'classic' mode uses a default of `rstride = cstride = 1` instead of the new default of `rcount = ccount = 50`.

- **kwargs** Other arguments are forwarded to `Line3DCollection`.

Surface plots

Axes3D.plot_surface(self, X, Y, Z, *args, norm=None, vmin=None, vmax=None, lightsource=None, **kwargs)

Create a surface plot.

By default it will be colored in shades of a solid color, but it also supports color mapping by supplying the `cmap` argument.

**Note:** The `rcount` and `ccount` kwargs, which both default to 50, determine the maximum number of samples used in each direction. If the input data is larger, it will be
downsampled (by slicing) to these numbers of points.

**Parameters**

- **X, Y, Z** [2d arrays] Data values.
- **rcount, ccount** [int] Maximum number of samples used in each direction. If the input data is larger, it will be downsampled (by slicing) to these numbers of points. Defaults to 50.
  
  New in version 2.0.
- **rstride, cstride** [int] Downsampling stride in each direction. These arguments are mutually exclusive with **rcount** and **ccount**. If only one of **rstride** or **cstride** is set, the other defaults to 10.
  
  ‘classic’ mode uses a default of **rstride = cstride = 10** instead of the new default of **rcount = ccount = 50**.
- **color** [color-like] Color of the surface patches.
- **cmap** [Colormap] Colormap of the surface patches.
- **facecolors** [array-like of colors.] Colors of each individual patch.
- **norm** [Normalize] Normalization for the colormap.
- **vmin, vmax** [float] Bounds for the normalization.
- **shade** [bool] Whether to shade the facecolors. Defaults to True. Shading is always disabled when **cmap** is specified.
- **lightsource** [LightSource] The lightsource to use when **shade** is True.
- ****kwargs** Other arguments are forwarded to Poly3DCollection.
**Tri-Surface plots**

```
Axes3D.plot_trisurf(self, *args, color=None, norm=None, vmin=None, vmax=None, lightsource=None, **kwargs)
```

Plot a triangulated surface.

The (optional) triangulation can be specified in one of two ways; either:

```
plot_trisurf(triangulation, ...)
```

where triangulation is a `Triangulation` object, or:

```
plot_trisurf(X, Y, ...)  
plot_trisurf(X, Y, triangles, ...) 
plot_trisurf(X, Y, triangles=triangles, ...) 
```

in which case a Triangulation object will be created. See `Triangulation` for an explanation of these possibilities.

The remaining arguments are:

```
plot_trisurf(..., Z)
```

where Z is the array of values to contour, one per point in the triangulation.

**Parameters**

- `X, Y, Z` [array-like] Data values as 1D arrays.
- `color` Color of the surface patches.
- `cmap` A colormap for the surface patches.
- `norm` [Normalize] An instance of Normalize to map values to colors.
- `vmin, vmax` [scalar, optional, default: None] Minimum and maximum value to map.
shade [bool] Whether to shade the facecolors. Defaults to True. Shading is always disabled when cmap is specified.

lightsource [LightSource] The lightsource to use when shade is True.

**kwargs All other arguments are passed on to Poly3DCollection

Examples

New in version 1.2.0: This plotting function was added for the v1.2.0 release.

Contour plots

`Axes3D.contour(self, X, Y, Z, *args, extend3d=False, stride=5, zdir='z', offset=None, **kwargs)`

Create a 3D contour plot.

Parameters

- X, Y, Z [array-likes] Input data.
- extend3d [bool] Whether to extend contour in 3D; defaults to False.
- stride [int] Step size for extending contour.
- zdir [{‘x’, ‘y’, ‘z’}] The direction to use; defaults to ‘z’.
Fig. 84: Trisurf3d
offset [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to zdir

*args, **kwargs Other arguments are forwarded to matplotlib.axes.Axes.contour.

Returns

matplotlib.contour.QuadContourSet

Filled contour plots

Axes3D.contourf(self, X, Y, Z, *args, zdir='z', offset=None, **kwargs)
Create a 3D filled contour plot.

Parameters

X, Y, Z [array-likes] Input data.

zdir [{‘x’, ‘y’, ‘z’}] The direction to use; defaults to ‘z’.

offset [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to zdir

*args, **kwargs Other arguments are forwarded to matplotlib.axes.Axes.contourf.

Returns

matplotlib.contour.QuadContourSet

Notes

New in version 1.1.0: The zdir and offset parameters.
New in version 1.1.0: The feature demoed in the second contourf3d example was enabled as a result of a bugfix for version 1.1.0.
Fig. 86: Contourf3d
Contourf3d 2

Polygon plots

Axes3D.add_collection3d(self, col, zs=0, zdir='z')
Add a 3D collection object to the plot.

2D collection types are converted to a 3D version by modifying the object and adding z coordinate information.

**Supported are:**

- PolyCollection
- LineCollection
- PatchCollection

Fig. 87: Polys3d
Bar plots

Axes3D.bar(self, left, height, zs=0, zdir='z', *args, **kwargs)
Add 2D bar(s).

Parameters

left [1D array-like] The x coordinates of the left sides of the bars.
height [1D array-like] The height of the bars.
zs [scalar or 1D array-like] Z coordinate of bars; if a single value is specified, it will be used for all bars.
zdir [{‘x’, ‘y’, ‘z’}] When plotting 2D data, the direction to use as z (‘x’, ‘y’ or ‘z’); defaults to ‘z’.
**kwargs Other arguments are forwarded to matplotlib.axes.Axes.bar.

Returns

mpl_toolkits.mplot3d.art3d.Patch3DCollection

Fig. 88: Bars3d

Quiver

Axes3D.quiver(X, Y, Z, U, V, W, length=1, arrow_length_ratio=.3, pivot='tail', normalize=False, **kwargs)
Plot a 3D field of arrows.

The arguments could be array-like or scalars, so long as they they can be broadcast together. The arguments can also be masked arrays. If an element in any of argument is masked, then that corresponding quiver element will not be plotted.

Parameters

X, Y, Z [array-like] The x, y and z coordinates of the arrow locations (default is tail of arrow; see pivot kwarg)
U, V, W [array-like] The x, y and z components of the arrow vectors
**length** [float] The length of each quiver, default to 1.0, the unit is the same with the axes

**arrow_length_ratio** [float] The ratio of the arrow head with respect to the quiver, default to 0.3

**pivot** [{'tail', 'middle', 'tip'}] The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name pivot. Default is ‘tail’

**normalize** [bool] When True, all of the arrows will be the same length. This defaults to False, where the arrows will be different lengths depending on the values of u,v,w.

**kwargs** Any additional keyword arguments are delegated to `LineCollection`

```
Fig. 89: Quiver3d
```

2D plots in 3D

```
Fig. 90: 2dcollections3d
```
Text

```
Axes3D.text(self, x, y, z, s, zdir=None, **kwargs)
```

Add text to the plot. `kwargs` will be passed on to `Axes.text`, except for the `zdir` keyword, which sets the direction to be used as the z direction.

![2D Text](image)

**Fig. 91: Text3d**

Subplotting

Having multiple 3D plots in a single figure is the same as it is for 2D plots. Also, you can have both 2D and 3D plots in the same figure.

New in version 1.0.0: Subplotting 3D plots was added in v1.0.0. Earlier version can not do this.

![Subplot3d](image)

**Fig. 92: Subplot3d**

*Mixed Subplots*
3.1 Interactive navigation

All figure windows come with a navigation toolbar, which can be used to navigate through the data set. Here is a description of each of the buttons at the bottom of the toolbar.

The Home, Forward and Back buttons These are akin to a web browser’s home, forward and back controls. Forward and Back are used to navigate back and forth between previously defined views. They have no meaning unless you have already navigated somewhere else using the pan and zoom buttons. This is analogous to trying to click Back on your web browser before visiting a new page or Forward before you have gone back to a page – nothing happens. Home always takes you to the first, default view of your data. Again, all of these buttons should feel very familiar to any user of a web browser.
The Pan/Zoom button This button has two modes: pan and zoom. Click the toolbar button to activate panning and zooming, then put your mouse somewhere over an axes. Press the left mouse button and hold it to pan the figure, dragging it to a new position. When you release it, the data under the point where you pressed will be moved to the point where you released. If you press 'x' or 'y' while panning the motion will be constrained to the x or y axis, respectively. Press the right mouse button to zoom, dragging it to a new position. The x axis will be zoomed in proportionately to the rightward movement and zoomed out proportionately to the leftward movement. The same is true for the y axis and up/down motions. The point under your mouse when you begin the zoom remains stationary, allowing you to zoom in or out around that point as much as you wish. You can use the modifier keys 'x', 'y' or 'CONTROL' to constrain the zoom to the x axis, the y axis, or aspect ratio preserve, respectively.

With polar plots, the pan and zoom functionality behaves differently. The radius axis labels can be dragged using the left mouse button. The radius scale can be zoomed in and out using the right mouse button.

The Zoom-to-rectangle button Click this toolbar button to activate this mode. Put your mouse somewhere over an axes and press a mouse button. Define a rectangular region by dragging the mouse while holding the button to a new location. When using the left mouse button, the axes view limits will be zoomed to the defined region. When using the right mouse button, the axes view limits will be zoomed out, placing the original axes in the defined region.

The Subplot-configuration button Use this tool to configure the appearance of the subplot: you can stretch or compress the left, right, top, or bottom side of the subplot, or the space between the rows or space between the columns.

The Save button Click this button to launch a file save dialog. You can save files with the
following extensions: png, ps, eps, svg and pdf.

3.1.1 Navigation Keyboard Shortcuts

The following table holds all the default keys, which can be overwritten by use of your matplotlibrc (#keymap.*).

<table>
<thead>
<tr>
<th>Command</th>
<th>Keyboard Shortcut(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Home/Reset</td>
<td>h or r or home</td>
</tr>
<tr>
<td>Back</td>
<td>c or left arrow or backspace</td>
</tr>
<tr>
<td>Forward</td>
<td>v or right arrow</td>
</tr>
<tr>
<td>Pan/Zoom</td>
<td>p</td>

<td>Toggle x axis scale (log/linear)</td>
<td>L or k when mouse is over an axes</td>
</tr>
<tr>
<td>Toggle y axis scale (log/linear)</td>
<td>I when mouse is over an axes</td>
</tr>
</tbody>
</table>

If you are using matplotlib.pyplot the toolbar will be created automatically for every figure. If you are writing your own user interface code, you can add the toolbar as a widget. The exact syntax depends on your UI, but we have examples for every supported UI in the matplotlib/examples/user_interfaces directory. Here is some example code for GTK+ 3:

```python
import gi
gi.require_version('Gtk', '3.0')
from gi.repository import Gtk

from matplotlib.figure import Figure
from matplotlib.backends.backend_gtk3agg import FigureCanvas
from matplotlib.backends.backend_gtk3 import (NavigationToolbar2GTK3 as NavigationToolbar)

win = Gtk.Window()
win.connect("destroy", lambda x: Gtk.main_quit())
win.set_default_size(400,300)
win.set_title("Embedding in GTK")

vbox = Gtk.VBox()
win.add(vbox)

fig = Figure(figsize=(5,4), dpi=100)
ax = fig.add_subplot(111)
ax.plot([1,2,3])
```

(continues on next page)
3.2 Using matplotlib in a python shell

**Warning:** This page is significantly out of date

By default, matplotlib defers drawing until the end of the script because drawing can be an expensive operation, and you may not want to update the plot every time a single property is changed, only once after all the properties have changed.

But when working from the python shell, you usually do want to update the plot with every command, e.g., after changing the xlabel(), or the marker style of a line. While this is simple in concept, in practice it can be tricky, because matplotlib is a graphical user interface application under the hood, and there are some tricks to make the applications work right in a python shell.

3.2.1 IPython to the rescue

**Note:** The mode described here still exists for historical reasons, but it is highly advised not to use. It pollutes namespaces with functions that will shadow python built-in and can lead to hard to track bugs. To get IPython integration without imports the use of the `%matplotlib` magic is preferred. See [ipython documentation](#).

Fortunately, ipython, an enhanced interactive python shell, has figured out all of these tricks, and is matplotlib aware, so when you start ipython in the *pylab* mode.

```python
johnh@flag:~> ipython
Python 2.4.5 (#4, Apr 12 2008, 09:09:16)
IPython 0.9.0 -- An enhanced Interactive Python.

In [1]: %pylab
Welcome to pylab, a matplotlib-based Python environment.
For more information, type 'help(pylab)'.

In [2]: x = randn(10000)

In [3]: hist(x, 100)
```
it sets everything up for you so interactive plotting works as you would expect it to. Call
figure() and a figure window pops up, call plot() and your data appears in the figure window.

Note in the example above that we did not import any matplotlib names because in pylab
mode, ipython will import them automatically. ipython also turns on interactive mode for you,
which causes every pyplot command to trigger a figure update, and also provides a matplotlib
aware run command to run matplotlib scripts efficiently. ipython will turn off interactive mode
during a run command, and then restore the interactive state at the end of the run so you can
continue tweaking the figure manually.

There has been a lot of recent work to embed ipython, with pylab support, into various GUI
applications, so check on the ipython mailing list for the latest status.

### 3.2.2 Other python interpreters

If you can’t use ipython, and still want to use matplotlib/pylab from an interactive python
shell, e.g., the plain-ole standard python interactive interpreter, you are going to need to
understand what a matplotlib backend is *What is a backend?*.

With the TkAgg backend, which uses the Tkinter user interface toolkit, you can use matplotlib
from an arbitrary non-gui python shell. Just set your backend : TkAgg and interactive : True
in your matplotlibrc file (see *Customizing Matplotlib with style sheets and rcParams*) and fire
up python. Then:

```python
>>> from pylab import *
>>> plot([1,2,3])
>>> xlabel('hi mom')
```

should work out of the box. This is also likely to work with recent versions of the qt4agg and
gtk3agg backends, and with the macosx backend on the Macintosh. Note, in batch mode,
i.e. when making figures from scripts, interactive mode can be slow since it redraws the
figure with each command. So you may want to think carefully before making this the default
behavior via the matplotlibrc file instead of using the functions listed in the next section.

Gui shells are at best problematic, because they have to run a mainloop, but interactive plot-
ting also involves a mainloop. Ipython has sorted all this out for the primary matplotlib back-
ends. There may be other shells and IDEs that also work with matplotlib in interactive mode,
but one obvious candidate does not: the python IDLE IDE is a Tkinter gui app that does not
support pylab interactive mode, regardless of backend.

### 3.2.3 Controlling interactive updating

The interactive property of the pyplot interface controls whether a figure canvas is drawn on
every pyplot command. If interactive is False, then the figure state is updated on every plot
command, but will only be drawn on explicit calls to draw(). When interactive is True, then
every pyplot command triggers a draw.

The pyplot interface provides 4 commands that are useful for interactive control.

- isinteractive() returns the interactive setting True|False
- ion() turns interactive mode on
- ioff() turns interactive mode off
- draw() forces a figure redraw
When working with a big figure in which drawing is expensive, you may want to turn matplotlib's interactive setting off temporarily to avoid the performance hit:

```python
# create big-expensive-figure
ioff()  # turn updates off
title('now how much would you pay?')
draw()  # force a draw
savefig('alldone', dpi=300)
close()
ion()   # turn updating back on
plot(rand(20), mfc='g', mec='r', ms=40, mew=4, ls='--', lw=3)
```

### 3.3 Event handling and picking

Matplotlib works with a number of user interface toolkits (wxpython, tkinter, qt4, gtk, and macosx) and in order to support features like interactive panning and zooming of figures, it is helpful to the developers to have an API for interacting with the figure via key presses and mouse movements that is “GUI neutral” so we don’t have to repeat a lot of code across the different user interfaces. Although the event handling API is GUI neutral, it is based on the GTK model, which was the first user interface matplotlib supported. The events that are triggered are also a bit richer vis-a-vis matplotlib than standard GUI events, including information like which `matplotlib.axes.Axes` the event occurred in. The events also understand the matplotlib coordinate system, and report event locations in both pixel and data coordinates.

#### 3.3.1 Event connections

To receive events, you need to write a callback function and then connect your function to the event manager, which is part of the `FigureCanvasBase`. Here is a simple example that prints the location of the mouse click and which button was pressed:

```python
fig, ax = plt.subplots()
ax.plot(np.random.rand(10))

def onclick(event):
    print('%s click: button=%d, x=%d, y=%d, xdata=%f, ydata=%f' %
          ('double' if event.dblclick else 'single', event.button,
           event.x, event.y, event.xdata, event.ydata))

cid = fig.canvas.mpl_connect('button_press_event', onclick)
```

The `FigureCanvas` method `mpl_connect()` returns a connection id which is simply an integer. When you want to disconnect the callback, just call:

```python
fig.canvas.mpl_disconnect(cid)
```

**Note:** The canvas retains only weak references to instance methods used as callbacks. Therefore, you need to retain a reference to instances owning such methods. Otherwise the instance will be garbage-collected and the callback will vanish.
This does not affect free functions used as callbacks.

Here are the events that you can connect to, the class instances that are sent back to you when the event occurs, and the event descriptions:

<table>
<thead>
<tr>
<th>Event name</th>
<th>Class and description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'button_press_event'</td>
<td>MouseEvent - mouse button is pressed</td>
</tr>
<tr>
<td>'button_release_event'</td>
<td>MouseEvent - mouse button is released</td>
</tr>
<tr>
<td>'draw_event'</td>
<td>DrawEvent - canvas draw (but before screen update)</td>
</tr>
<tr>
<td>'key_press_event'</td>
<td>KeyEvent - key is pressed</td>
</tr>
<tr>
<td>'key_release_event'</td>
<td>KeyEvent - key is released</td>
</tr>
<tr>
<td>'motion_notify_event'</td>
<td>MouseEvent - mouse motion</td>
</tr>
<tr>
<td>'pick_event'</td>
<td>PickEvent - an object in the canvas is selected</td>
</tr>
<tr>
<td>'resize_event'</td>
<td>ResizeEvent - figure canvas is resized</td>
</tr>
<tr>
<td>'scroll_event'</td>
<td>MouseEvent - mouse scroll wheel is rolled</td>
</tr>
<tr>
<td>'figure_enter_event'</td>
<td>LocationEvent - mouse enters a new figure</td>
</tr>
<tr>
<td>'figure_leave_event'</td>
<td>LocationEvent - mouse leaves a figure</td>
</tr>
<tr>
<td>'axes_enter_event'</td>
<td>LocationEvent - mouse enters a new axes</td>
</tr>
<tr>
<td>'axes_leave_event'</td>
<td>LocationEvent - mouse leaves an axes</td>
</tr>
</tbody>
</table>

### 3.3.2 Event attributes

All matplotlib events inherit from the base class `matplotlib.backend_bases.Event`, which store the attributes:

- **name** the event name
- **canvas** the FigureCanvas instance generating the event
- **guiEvent** the GUI event that triggered the matplotlib event

The most common events that are the bread and butter of event handling are key press/release events and mouse press/release and movement events. The `KeyEvent` and `MouseEvent` classes that handle these events are both derived from the `LocationEvent`, which has the following attributes:

- x x position - pixels from left of canvas
- y y position - pixels from bottom of canvas
- inaxes the Axes instance if mouse is over axes
- xdata x coord of mouse in data coords
- ydata y coord of mouse in data coords

Let’s look a simple example of a canvas, where a simple line segment is created every time a mouse is pressed:

```python
from matplotlib import pyplot as plt

class LineBuilder:
    def __init__(self, line):
        self.line = line
        self.xs = list(line.get_xdata())
        self.ys = list(line.get_ydata())
```

(continues on next page)
The `MouseEvent` that we just used is a `LocationEvent`, so we have access to the data and pixel coordinates in `event.x` and `event.xdata`. In addition to the `LocationEvent` attributes, it has:

- **button** button pressed None, 1, 2, 3, ‘up’, ‘down’ (up and down are used for scroll events)
- **key** the key pressed: None, any character, ‘shift’, ‘win’, or ‘control’

### Draggable rectangle exercise

Write draggable rectangle class that is initialized with a `Rectangle` instance but will move its x,y location when dragged. Hint: you will need to store the original xy location of the rectangle which is stored as `rect.xy` and connect to the press, motion and release mouse events. When the mouse is pressed, check to see if the click occurs over your rectangle (see `matplotlib.patches.Rectangle.contains()`) and if it does, store the rectangle xy and the location of the mouse click in data coords. In the motion event callback, compute the deltax and deltay of the mouse movement, and add those deltas to the origin of the rectangle you stored. The redraw the figure. On the button release event, just reset all the button press data you stored as None.

Here is the solution:

```python
import numpy as np
import matplotlib.pyplot as plt

class DraggableRectangle:
    def __init__(self, rect):
        self.rect = rect
        self.press = None

    def connect(self):
        'connect to all the events we need'
        self.cidpress = self.rect.figure.canvas.mpl_connect('button_press_event', self.on_press)
        self.cidrelease = self.rect.figure.canvas.mpl_connect('button_release_event', self.on_release)
        self.id = self.rect.figure.canvas.mpl_connect('motion_notify_event', self.on_motion)

    def on_press(self, event):
        if event.inaxes != self.line.axes:
            return
        self.press = True
        self.xs.append(event.xdata)
        self.ys.append(event.ydata)
        self.line.set_data(self.xs, self.ys)
        self.line.figure.canvas.draw()

    def on_release(self, event):
        self.press = None

    def on_motion(self, event):
        if self.press:
            deltax = abs(event.xdata - self.xs[-1])
            deltay = abs(event.ydata - self.ys[-1])
            self.xs[-1] += deltax
            self.ys[-1] += deltay
            self.line.set_data(self.xs, self.ys)
            self.line.figure.canvas.draw()

fig = plt.figure()
ax = fig.add_subplot(111)
ax.set_title('click to build line segments')
line, = ax.plot([0], [0])  # empty line
linebuilder = LineBuilder(line)
plt.show()
```

---

(continued on previous page)
self.cidrelease = self.rect.figure.canvas.mpl_connect(
    'button_release_event', self.on_release)
self.cidmotion = self.rect.figure.canvas.mpl_connect(
    'motion_notify_event', self.on_motion)

def on_press(self, event):
    'on button press we will see if the mouse is over us and store some data'
    if event.inaxes != self.rect.axes: return
    contains, attrd = self.rect.contains(event)
    if not contains: return
    print('event contains', self.rect.xy)
    x0, y0 = self.rect.xy
    self.press = x0, y0, event.xdata, event.ydata

def on_motion(self, event):
    'on motion we will move the rect if the mouse is over us'
    if self.press is None: return
    if event.inaxes != self.rect.axes: return
    x0, y0, xpress, ypress = self.press
    dx = event.xdata - xpress
    dy = event.ydata - ypress
    #print('x0=%f, xpress=%f, event.xdata=%f, dx=%f, x0+dx=%f' %
    #    (x0, xpress, event.xdata, dx, x0+dx))
    self.rect.set_x(x0+dx)
    self.rect.set_y(y0+dy)

    self.rect.figure.canvas.draw()

def on_release(self, event):
    'on release we reset the press data'
    self.press = None
    self.rect.figure.canvas.draw()

def disconnect(self):
    'disconnect all the stored connection ids'
    self.rect.figure.canvas.mpl_disconnect(self.cidpress)
    self.rect.figure.canvas.mpl_disconnect(self.cidrelease)
    self.rect.figure.canvas.mpl_disconnect(self.cidmotion)

fig = plt.figure()
ax = fig.add_subplot(111)
rects = ax.bar(range(10), 20*np.random.rand(10))
drs = []
for rect in rects:
    dr = DraggableRectangle(rect)
    dr.connect()
    drs.append(dr)

plt.show()

Extra credit: use the animation blit techniques discussed in the animations recipe to make
the animated drawing faster and smoother.

Extra credit solution:

```python
# draggable rectangle with the animation blit techniques; see
# http://www.scipy.org/Cookbook/Matplotlib/Animations
import numpy as np
import matplotlib.pyplot as plt

class DraggableRectangle:
    lock = None  # only one can be animated at a time

    def __init__(self, rect):
        self.rect = rect
        self.press = None
        self.background = None

    def connect(self):
        'connect to all the events we need'
        self.cidpress = self.rect.figure.canvas.mpl_connect('button_press_event', self.on_press)
        self.cidrelease = self.rect.figure.canvas.mpl_connect('button_release_event', self.on_release)
        self.cidmotion = self.rect.figure.canvas.mpl_connect('motion_notify_event', self.on_motion)

    def on_press(self, event):
        'on button press we will see if the mouse is over us and store some data'
        if event.inaxes != self.rect.axes: return
        if DraggableRectangle.lock is not None: return
        contains, attrd = self.rect.contains(event)
        if not contains: return
        print('event contains', self.rect.xy)
        x0, y0 = self.rect.xy
        self.press = x0, y0, event.xdata, event.ydata
        DraggableRectangle.lock = self

    def on_release(self, event):
        'on button release we will remove the x,y data'
        if DraggableRectangle.lock is None: return
        DraggableRectangle.lock = None
        self.press = None

    def on_motion(self, event):
        'on motion we will move the rect if the mouse is over us'
        if DraggableRectangle.lock is not self: return
        if event.inaxes != self.rect.axes: return
        x0, y0 = self.rect.xy
        x1, y1 = event.xdata, event.ydata
        self.rect.set_x0(x0 + x1 - x0)
        self.rect.set_y0(y0 + y1 - y0)

    def background_reset(self):
        self.background = self.rect.figure.canvas.copy_from_bbox(self.rect.axes.bbox)

    def background_redraw(self):
        self.background = self.rect.figure.canvas.copy_from_bbox(self.rect.axes.bbox)

def animate(fig, ax, line, x, y):
    while True:
        ax.set_xdata(x)
        ax.set_ydata(y)
        fig.canvas.draw_idle()
```

(continues on next page)
x0, y0, xpress, ypress = self.press
dx = event.xdata - xpress
dy = event.ydata - ypress
self.rect.set_x(x0+dx)
self.rect.set_y(y0+dy)

canvas = self.rect.figure.canvas
axes = self.rect.axes
# restore the background region
canvas.restore_region(self.background)

# redraw just the current rectangle
axes.draw_artist(self.rect)

# blit just the redrawn area
canvas.blit(axes.bbox)

def on_release(self, event):
    # on release we reset the press data
    if DraggableRectangle.lock is not self:
        return

    self.press = None
    DraggableRectangle.lock = None

    # turn off the rect animation property and reset the background
    self.rect.set_animated(False)
    self.background = None

    # redraw the full figure
    self.rect.figure.canvas.draw()

def disconnect(self):
    # disconnect all the stored connection ids
    self.rect.figure.canvas.mpl_disconnect(self.cidpress)
    self.rect.figure.canvas.mpl_disconnect(self.cidrelease)
    self.rect.figure.canvas.mpl_disconnect(self.cidmotion)

fig = plt.figure()
ax = fig.add_subplot(111)
rects = ax.bar(range(10), 20*np.random.rand(10))
drs = []
for rect in rects:
    dr = DraggableRectangle(rect)
    dr.connect()
    drs.append(dr)

plt.show()
3.3.3 Mouse enter and leave

If you want to be notified when the mouse enters or leaves a figure or axes, you can connect to the figure/axes enter/leave events. Here is a simple example that changes the colors of the axes and figure background that the mouse is over:

```python
""
Illustrate the figure and axes enter and leave events by changing the
frame colors on enter and leave
""
import matplotlib.pyplot as plt
def enter_axes(event):
    print('enter_axes', event.inaxes)
    event.inaxes.patch.set_facecolor('yellow')
    event.canvas.draw()
def leave_axes(event):
    print('leave_axes', event.inaxes)
    event.inaxes.patch.set_facecolor('white')
    event.canvas.draw()
def enter_figure(event):
    print('enter_figure', event.canvas.figure)
    event.canvas.figure.patch.set_facecolor('red')
    event.canvas.draw()
def leave_figure(event):
    print('leave_figure', event.canvas.figure)
    event.canvas.figure.patch.set_facecolor('grey')
    event.canvas.draw()
fig1 = plt.figure()
fig1.suptitle('mouse hover over figure or axes to trigger events')
ax1 = fig1.add_subplot(211)
ax2 = fig1.add_subplot(212)
fig1.canvas.mpl_connect('figure_enter_event', enter_figure)
fig1.canvas.mpl_connect('figure_leave_event', leave_figure)
fig1.canvas.mpl_connect('axes_enter_event', enter_axes)
fig1.canvas.mpl_connect('axes_leave_event', leave_axes)
fig2 = plt.figure()
fig2.suptitle('mouse hover over figure or axes to trigger events')
ax1 = fig2.add_subplot(211)
ax2 = fig2.add_subplot(212)
fig2.canvas.mpl_connect('figure_enter_event', enter_figure)
fig2.canvas.mpl_connect('figure_leave_event', leave_figure)
fig2.canvas.mpl_connect('axes_enter_event', enter_axes)
fig2.canvas.mpl_connect('axes_leave_event', leave_axes)
plt.show()
```
3.3.4 Object picking

You can enable picking by setting the `picker` property of an `Artist` (e.g., a matplotlib `Line2D`, `Text`, `Patch`, `Polygon`, `AxesImage`, etc...)

There are a variety of meanings of the `picker` property:

- `None`: picking is disabled for this artist (default)
- `boolean`: if True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist
- `float`: if picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if its data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
- `function`: if picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event. The signature is `hit, props = picker(artist, mouseevent)` to determine the hit test. If the mouse event is over the artist, return `hit=True` and props is a dictionary of properties you want added to the `PickEvent` attributes.

After you have enabled an artist for picking by setting the `picker` property, you need to connect to the figure canvas pick_event to get pick callbacks on mouse press events. e.g.:

```python
def pick_handler(event):
    mouseevent = event.mouseevent
    artist = event.artist
    # now do something with this...
```

The `PickEvent` which is passed to your callback is always fired with two attributes:

- `mouseevent` the mouse event that generate the pick event. The mouse event in turn has attributes like `x` and `y` (the coords in display space, e.g., pixels from left, bottom) and `xdata`, `ydata` (the coords in data space). Additionally, you can get information about which buttons were pressed, which keys were pressed, which `Axes` the mouse is over, etc. See `matplotlib.backend_bases.MouseEvent` for details.

- `artist` the `Artist` that generated the pick event.

Additionally, certain artists like `Line2D` and `PatchCollection` may attach additional meta data like the indices into the data that meet the picker criteria (e.g., all the points in the line that are within the specified epsilon tolerance)

**Simple picking example**

In the example below, we set the line picker property to a scalar, so it represents a tolerance in points (72 points per inch). The onpick callback function will be called when the pick event it within the tolerance distance from the line, and has the indices of the data vertices that are within the pick distance tolerance. Our onpick callback function simply prints the data that are under the pick location. Different matplotlib Artists can attach different data to the PickEvent. For example, `Line2D` attaches the `ind` property, which are the indices into the line data under the pick point. See `pick()` for details on the `PickEvent` properties of the line. Here is the code:
import numpy as np
import matplotlib.pyplot as plt

fig = plt.figure()
ax = fig.add_subplot(111)
ax.set_title('click on points')

line, = ax.plot(np.random.rand(100), 'o', picker=5)  # 5 points tolerance

def onpick(event):
    thisline = event.artist
    xdata = thisline.get_xdata()
    ydata = thisline.get_ydata()
    ind = event.ind
    points = tuple(zip(xdata[ind], ydata[ind]))
    print('onpick points:', points)

fig.canvas.mpl_connect('pick_event', onpick)

plt.show()
if event.artist!=line: return True

N = len(event.ind)
if not N: return True

figi = plt.figure()
for subplotnum, dataind in enumerate(event.ind):
    ax = figi.add_subplot(N,1,subplotnum+1)
    ax.plot(X[dataind])
    ax.text(0.05, 0.9, 'mu=\%1.3f
    sigma=\%1.3f\%(xs[dataind], ys[dataind]),
    transform=ax.transAxes, va='top')
    ax.set_ylim(-0.5, 1.5)
figi.show()
return True

fig.canvas.mpl_connect('pick_event', onpick)

plt.show()
4.1 What’s new in Matplotlib 3.1

For a list of all of the issues and pull requests since the last revision, see the GitHub Stats.

Table of Contents

- Whats New
  - What’s new in Matplotlib 3.1
    * New Features
      - ConciseDateFormatter
      - Secondary x/y Axis support
      - FuncScale for arbitrary axes scales
      - Legend for scatter
      - Matplotlib no longer requires framework app build on MacOSX backend
    * Figure, FigureCanvas, and Backends
      - Figure.frameon is now a direct proxy for the Figure patch visibility state
      - pil_kwargs argument added to savefig
      - Add inaxes method to FigureCanvasBase
      - cairo backend defaults to pycairo instead of cairocffi
    * Axes and Artists
      - axes_grid1 and axisartist Axes no longer draw spines twice
      - Return type of ArtistInspector.get_aliases changed
      - ConnectionPatch accepts arbitrary transforms
      - mplot3d Line3D now allows {set,get}_data_3d
      - Axes3D.voxels now shades the resulting voxels
    * Axis and Ticks
      - Added Axis.get_inverted and Axis.set_inverted
      - Adjust default minor tick spacing
- EngFormatter now accepts `usetex`, `useMathText` as keyword only arguments

* Animation and Interactivity
  - Support for forward/backward mouse buttons
  - progress_callback argument to `save()`
  - Add `cache_frame_data` keyword-only argument into `animation.FuncAnimation`
  - Endless Looping GIFs with PillowWriter
  - Adjusted `matplotlib.widgets.Slider` to have vertical orientation
  - Improved formatting of image values under cursor when a colorbar is present
  - `MouseEvent` button attribute is now an `IntEnum`

* Configuration, Install, and Development
  - The `MATPLOTLIBRC` environment variable can now point to any “file” path
  - Allow LaTeX code `pgf.preamble` and `text.latex.preamble` in `MATPLOTLIBRC` file
  - New logging API

### 4.1.1 New Features

**ConciseDateFormatter**

The automatic date formatter used by default can be quite verbose. A new formatter can be accessed that tries to make the tick labels appropriately concise.

**Secondary x/y Axis support**

A new method provides the ability to add a second axis to an existing axes via `Axes.secondary_xaxis` and `Axes.secondary_yaxis`. See `/gallery/subplots_axes_and_figures/secondary_axis` for examples.

**FuncScale for arbitrary axes scales**

A new `FuncScale` class was added (and `FuncTransform`) to allow the user to have arbitrary scale transformations without having to write a new subclass of `ScaleBase`. This can be accessed by:

```python
ax.set_yscale('function', functions=(forward, inverse))
```

where `forward` and `inverse` are callables that return the scale transform and its inverse. See the last example in `/gallery/scales/scales`.
4.1. What’s new in Matplotlib 3.1
Legend for scatter

A new method for creating legends for scatter plots has been introduced. Previously, in order to obtain a legend for a `scatter()` plot, one could either plot several scatters, each with an individual label, or create proxy artists to show in the legend manually. Now, `PathCollection` provides a method `legend_elements()` to obtain the handles and labels for a scatter plot in an automated way. This makes creating a legend for a scatter plot as easy as

![Legend for scatter plot](image)

An example can be found in `automatedlegendcreation`.

**Matplotlib no longer requires framework app build on MacOSX backend**

Previous versions of matplotlib required a Framework build of python to work. The app type was updated to no longer require this, so the MacOSX backend should work with non-framework python.

This also adds support for the MacOSX backend for PyPy3.

### 4.1.2 Figure, FigureCanvas, and Backends

`Figure.frameon` is now a direct proxy for the `Figure` patch visibility state

Accessing `Figure.frameon` (including via `get_frameon` and `set_frameon` now directly forwards to the visibility of the underlying Rectangle artist (`Figure.patch.get_frameon`, `Figure.patch`).
set_frameon).

**pil_kwargs argument added to savefig**

Matplotlib uses Pillow to handle saving to the JPEG and TIFF formats. The `savefig()` function gained a `pil_kwargs` keyword argument, which can be used to forward arguments to Pillow's `pillow.Image.save()`.

The `pil_kwargs` argument can also be used when saving to PNG. In that case, Matplotlib also uses Pillow's `pillow.Image.save()` instead of going through its own builtin PNG support.

**Add inaxes method to FigureCanvasBase**

The `FigureCanvasBase` class has now an `inaxes` method to check whether a point is in an axes and returns the topmost axes, else None.

**cairo backend defaults to pycairo instead of cairocffi**

This leads to faster import/runtime performance in some cases. The backend will fall back to cairocffi in case pycairo isn’t available.

### 4.1.3 Axes and Artists

**axes_grid1 and axisartist Axes no longer draw spines twice**

Previously, spines of `axes_grid1` and `axisartist` Axes would be drawn twice, leading to a "bold" appearance. This is no longer the case.

**Return type of ArtistInspector.get_aliases changed**

`ArtistInspector.get_aliases` previously returned the set of aliases as `{fullname: {alias1: None, alias2: None, ...}}`. The dict-to-None mapping was used to simulate a set in earlier versions of Python. It has now been replaced by a set, i.e. `{fullname: {alias1, alias2, ...}}`. This value is also stored in `ArtistInspector.aliasd`, which has likewise changed.

**ConnectionPatch accepts arbitrary transforms**

Alternatively to strings like "data" or "axes fraction" `ConnectionPatch` now accepts any `Transform` as input for the `coordsA` and `coordsB` argument. This allows to draw lines between points defined in different user defined coordinate systems. Also see the Connect Simple01 example.

**mplot3d Line3D now allows {set, get}_data_3d**

Lines created with the 3d projection in mplot3d can now access the data using `get_data_3d()` which returns a tuple of array_likes containing the (x, y, z) data. The equivalent `set_data_3d` can be used to modify the data of an existing Line3D.
Axes3D.voxels now shades the resulting voxels

The voxels() method now takes a shade parameter that defaults to True. This shades faces based on their orientation, behaving just like the matching parameters to trisurf() and bar3d(). The plot below shows how this affects the output.

4.1.4 Axis and Ticks

Added Axis.get_inverted and Axis.set_inverted

The Axis.get_inverted and Axis.set_inverted methods query and set whether the axis uses "inverted" orientation (i.e. increasing to the left for the x-axis and to the bottom for the y-axis).

They perform tasks similar to Axes.xaxis_inverted, Axes.yaxis_inverted, Axes.invert_xaxis, and Axes.invert_yaxis, with the specific difference that Axes..set_inverted makes it easier to set the invertedness of an axis regardless of whether it had previously been inverted before.

Adjust default minor tick spacing

Default minor tick spacing was changed from 0.625 to 0.5 for major ticks spaced 2.5 units apart.

EngFormatter now acceptsusetex, useMathText as keyword only arguments

A public API has been added to EngFormatter to control how the numbers in the ticklabels will be rendered. By default, useMathText evaluates to rcParams["axes.formatter.use_mathtext"] andusetex evaluates to rcParams["text.usetex"].
If either is `True` then the numbers will be encapsulated by $\pm$ signs. When using TeX this implies that the numbers will be shown in TeX’s math font. When using mathtext, the $\pm$ signs around numbers will ensure unicode rendering (as implied by mathtext). This will make sure that the minus signs in the ticks are rendered as the unicode=minus (U+2212) when using mathtext (without relying on the `fix_minus` method).

### 4.1.5 Animation and Interactivity

**Support for forward/backward mouse buttons**

Figure managers now support a `button_press` event for mouse buttons, similar to the `key_press` events. This allows binding actions to mouse buttons (see `MouseButton`). The first application of this mechanism is support of forward/backward mouse buttons in figures created with the Qt5 backend.

**`progress_callback` argument to `save()`**

The method `Animation.save` gained an optional `progress_callback` argument to notify the saving progress.

**Add `cache_frame_data` keyword-only argument into `animation.FuncAnimation`**

`matplotlib.animation.FuncAnimation` has been caching frame data by default; however, this caching is not ideal in certain cases e.g. When `FuncAnimation` needs to be only drawn (not saved) interactively and memory required by frame data is quite large. By adding `cache_frame_data` keyword-only argument, users can now disable this caching; thereby, this new argument provides a fix for issue #8528.

**Endless Looping GIFs with PillowWriter**

We acknowledge that most people want to watch a gif more than once. Saving an animation as a gif with PillowWriter now produces an endless looping gif.

**Adjusted `matplotlib.widgets.Slider` to have vertical orientation**

The `matplotlib.widgets.Slider` widget now takes an optional argument `orientation` which indicates the direction ('horizontal' or 'vertical') that the slider should take.

**Improved formatting of image values under cursor when a colorbar is present**

When a colorbar is present, its formatter is now used to format the image values under the mouse cursor in the status bar. For example, for an image displaying the values 10,000 and 10,001, the statusbar will now (using default settings) display the values as 10000 and 10001), whereas both values were previously displayed as 1e+04.
MouseEvent button attribute is now an IntEnum

The button attribute of `MouseEvent` instances can take the values None, 1 (left button), 2 (middle button), 3 (right button), “up” (scroll), and “down” (scroll). For better legibility, the 1, 2, and 3 values are now represented using the `IntEnum` class `matplotlib.backend_bases.MouseButton`, with the values `MouseButton.LEFT (== 1)`, `MouseButton.MIDDLE (== 2)`, and `MouseButton.RIGHT (== 3)`.

4.1.6 Configuration, Install, and Development

The `MATPLOTLIBRC` environment variable can now point to any "file" path

This includes device files; in particular, on Unix systems, one can set `MATPLOTLIBRC` to `/dev/null` to ignore the user’s matplotlibrc file and fall back to Matplotlib’s defaults.

As a reminder, if `MATPLOTLIBRC` points to a directory, Matplotlib will try to load the matplotlibrc file from `$MATPLOTLIBRC/matplotlibrc`.

Allow LaTeX code `pgf.preamble` and `text.latex.preamble` in `MATPLOTLIBRC` file

Previously, the rc file keys `rcParams["pgf.preamble"]` and `rcParams["text.latex.preamble"]` were parsed using commas as separators. This would break valid LaTeX code, such as:

```
\usepackage[protrusion=true, expansion=false]{microtype}
```

The parsing has been modified to pass the complete line to the LaTeX system, keeping all commas. Passing a list of strings from within a Python script still works as it used to.

New logging API

`matplotlib.set_loglevel`/`pyplot.set_loglevel` can be called to display more (or less) detailed logging output.
Note: The following introductory text was written in 2008 by John D. Hunter (1968-2012), the original author of Matplotlib.

Matplotlib is a library for making 2D plots of arrays in Python. Although it has its origins in emulating the MATLAB graphics commands, it is independent of MATLAB, and can be used in a Pythonic, object oriented way. Although Matplotlib is written primarily in pure Python, it makes heavy use of NumPy and other extension code to provide good performance even for large arrays.

Matplotlib is designed with the philosophy that you should be able to create simple plots with just a few commands, or just one! If you want to see a histogram of your data, you shouldn’t need to instantiate objects, call methods, set properties, and so on; it should just work.

For years, I used to use MATLAB exclusively for data analysis and visualization. MATLAB excels at making nice looking plots easy. When I began working with EEG data, I found that I needed to write applications to interact with my data, and developed an EEG analysis application in MATLAB. As the application grew in complexity, interacting with databases, http servers, manipulating complex data structures, I began to strain against the limitations of MATLAB as a programming language, and decided to start over in Python. Python more than makes up for all of MATLAB’s deficiencies as a programming language, but I was having difficulty finding a 2D plotting package (for 3D VTK more than exceeds all of my needs).

When I went searching for a Python plotting package, I had several requirements:

- Plots should look great - publication quality. One important requirement for me is that the text looks good (antialiased, etc.)
- Postscript output for inclusion with TeX documents
- Embeddable in a graphical user interface for application development
- Code should be easy enough that I can understand it and extend it
- Making plots should be easy

Finding no package that suited me just right, I did what any self-respecting Python programmer would do: rolled up my sleeves and dived in. Not having any real experience with computer graphics, I decided to emulate MATLAB’s plotting capabilities because that is something MATLAB does very well. This had the added advantage that many people have a lot of MATLAB experience, and thus they can quickly get up to steam plotting in python. From a developer’s perspective, having a fixed user interface (the pylab interface) has been very useful, because the guts of the code base can be redesigned without affecting user code.
The Matplotlib code is conceptually divided into three parts: the *pylab interface* is the set of functions provided by `matplotlib.pylab` which allow the user to create plots with code quite similar to MATLAB figure generating code (*Pyplot tutorial*). The *Matplotlib frontend* or *Matplotlib API* is the set of classes that do the heavy lifting, creating and managing figures, text, lines, plots and so on (*Artist tutorial*). This is an abstract interface that knows nothing about output. The *backends* are device-dependent drawing devices, aka renderers, that transform the frontend representation to hardcopy or a display device (*What is a backend?*). Example backends: PS creates PostScript® hardcopy, SVG creates Scalable Vector Graphics hardcopy, Agg creates PNG output using the high quality Anti-Grain Geometry library that ships with Matplotlib, GTK embeds Matplotlib in a Gtk+ application, GTKAgg uses the Anti-Grain renderer to create a figure and embed it in a Gtk+ application, and so on for PDF, WxWidgets, Tkinter, etc.

Matplotlib is used by many people in many different contexts. Some people want to automatically generate PostScript files to send to a printer or publishers. Others deploy Matplotlib on a web application server to generate PNG output for inclusion in dynamically-generated web pages. Some use Matplotlib interactively from the Python shell in Tkinter on Windows. My primary use is to embed Matplotlib in a Gtk+ EEG application that runs on Windows, Linux and Macintosh OS X.

• PR #14243: Update docstring of makeMappingArray
• PR #14238: Backport PR #14164 on branch v3.1.x (Fix regexp for dvipng version detection)
• PR #14149: Avoid using axis([xlo, xhi, ylo, yhi]) in examples.
• PR #14164: Fix regexp for dvipng version detection
• PR #13739: Fix pressing tab breaks keymap in CanvasTk

Issues (30):
• #14620: Plotting on a log/logit scale overwrites axis inverting
• #14615: Inverting an axis using its limits does not work for log scale
• #14577: Calling invert_yaxis() on a 3D plot has either no effect or removes ticks
• #14602: NavigationToolbar2Tk save_figure function bug
• #1219: Show fails on figures created with the object-oriented system
• #10167: Segmentation fault with tricontour
• #13723: RuntimeError when saving PDFs via parallel processes (not threads!)
• #14315: Improvement: Better error message if kiwisolver fails to import
• #14356: matplotlib.units.ConversionError on scatter of dates with a NaN in the first position
• #14467: Docs for plt.ginput() have the wrong default value for show_clicks keyword argument.
• #14225: Matplotlib crashes on windows while maximizing plot window when using Multicursor
• #14458: DOC: small inconsistency in errobar docstring
• #14372: Document that view_init() arguments should be in degrees
• #12201: issues clearing rubberband on nbagg at non-default browser zoom
• #13576: pcolorfast misbehaves when changing axis limits
• #14303: Unable to import matplotlib on Windows 10 v1903
• #14283: RendererSVG CSS ‘white-space’ property conflicts with default HTML CSS
• #14293: imshow() producing “inverted” colors since 3.0.3
• #14322: Cannot import matplotlib with Python 3.7.x on Win10Pro
• #14137: Qt5 test auto-skip is not working correctly
• #14301: scatter() fails on nan-containing input when providing edgecolor
• #14318: Don’t try to set missing history buttons.
• #14265: symlog looses some points since 3.1.0 (example given)
• #14274: BUG: plotting with Numpy array subclasses is slow with Matplotlib 3.1.0 (regression)
• #14263: import pyplot issue -
• #14227: Update "working with Mpl on OSX" docs
• #13448: boxplot doesn’t normalize properties before applying them
• #14226: Modify matplotlib TextBox value without triggering callback
• #14232: LinearSegmentedColormap with N=1 gives confusing error message
• #10365: Scatter plot with non-sequence `c` color should give a better Error message.

6.1 Previous GitHub Stats

6.1.1 GitHub Stats for Matplotlib 3.0.2

GitHub stats for 2018/09/18 - 2018/11/09 (tag: v3.0.0)
These lists are automatically generated, and may be incomplete or contain duplicates.
We closed 170 issues and merged 224 pull requests.
The following 49 authors contributed 460 commits.
• Abhinuv Nitin Pitele
• Alon Hershenhorn
• Andras Deak
• Ankur Dedania
• Antony Lee
• Anubhav Shrimal
• Ayappan P
• azure-pipelines[bot]
• Ben Root
• Colin
• Colin Carroll
• Daniele Nicolodi
• David Haberthür
• David Stansby
• Dmitry Mottl
• Elan Ernest
• Elliott Sales de Andrade
• Eric Wieser
• esvhd
• Galen Lynch
GitHub issues and pull requests:

Pull Requests (224):

- **PR #12785**: Use level kwargs in irregular contour example
- **PR #12767**: Make colorbars constructible with dataless ScalarMappables.
- **PR #12775**: Add note to errorbar function about sign of errors
- **PR #12776**: Fix typo in example (on-borad -> on-board).
- **PR #12771**: Do not rely on external stack frame to exist
• PR #12526: Rename jquery files
• PR #12552: Update docs for writing image comparison tests.
• PR #12746: Use skipif, not xfail, for uncomparable image formats.
• PR #12747: Prefer log.warning("%s", ...) to log.warning("%s" % ...).
• PR #11753: FIX: Apply aspect before drawing starts
• PR #12749: Move toolmanager warning from logging to warning.
• PR #12708: Run flake8 in a separate travis environment
• PR #12737: Improve docstring of Arc
• PR #12598: Support Cn colors with n>=10.
• PR #12670: FIX: add setter for hold to un-break basemap
• PR #12693: Workaround Text3D breaking tight_layout()
• PR #12727: Reorder API docs: separate file per module
• PR #12738: Add unobtrusive deprecation note to the first line of the docstring.
• PR #12740: DOC: constrained layout guide (fix: Spacing with colorbars)
• PR #11663: Refactor color parsing of Axes.scatter
• PR #12736: Move deprecation note to end of docstring
• PR #12704: Rename tkinter import from Tk to tk.
• PR #12730: MNT: merge ignore lines in .flake8
• PR #12707: Fix tk error when closing first pyplot figure
• PR #12715: Cleanup dviread.
• PR #12717: Delete some if __name__ == "__main__" clauses.
• PR #12726: Fix test_non_gui_warning for Azure (and mplcairo).
• PR #12720: Improve docs on Axes scales
• PR #12537: Improve error message on failing test_pyplot_up_to_date
• PR #12721: Make get_scale_docs() internal
• PR #12617: Set up CI with Azure Pipelines
• PR #12673: Fix for _axes.scatter() array index out of bound error
• PR #12676: Doc: document textpath module
• PR #12705: Improve docs on Axes limits and direction
• PR #12706: Extend sphinx Makefile to cleanup completely
• PR #12481: Warn if plot_surface Z values contain NaN
• PR #12709: Correctly remove nans when drawing paths with pycairo.
• PR #12685: Make ticks in demo_axes_rgb.py visible
• PR #12691: DOC: Link to “How to make a PR” tutorials as badge and in contributing
• PR #12684: Change ipython block to code-block
• PR #11974: Make code match comment in sankey.

6.1. Previous GitHub Stats
• PR #12440: Make arguments to @deprecated/warn_deprecated keyword-only.
• PR #12683: TST: mark test_constrainedlayout.py::test_colorbar_location as flaky
• PR #12686: Remove deprecation warnings in tests
• PR #12470: Update AutoDateFormatter with locator
• PR #12656: FIX: fix error in colorbar.get_ticks not having valid data
• PR #12586: Improve linestyles example
• PR #12006: Added stacklevel=2 to all warnings.warn calls (issue 10643)
• PR #12651: FIX: ignore non-finite bbox
• PR #12653: Don’t warn when accessing deprecated properties from the class.
• PR #12608: ENH: allow matplotlib.use after getbackend
• PR #12658: Do not warn-deprecated when iterating over rcParams
• PR #12635: FIX: allow non bbox_extra_artists calls
• PR #12659: Add note that developer discussions are private
• PR #12543: Make rcsetup.py flak8 compliant
• PR #12642: Don’t silence TypeErrors in fmt_{x,y}data.
• PR #11667: DOC: update doc requirement
• PR #12442: Deprecate passing drawstyle with linestyle as single string.
• PR #12625: Shorten some docstrings.
• PR #12627: Be a bit more stringent on invalid inputs.
• PR #12561: Properly css-style exceptions in the documentation
• PR #12629: Fix issue with PyPy on macOS
• PR #12615: Fix travis OSX build
• PR #12600: Minor style fixes.
• PR #12607: STY: fix whitespace and escaping
• PR #12603: FIX: don’t import macosx to check if eventloop running
• PR #12599: Fix formatting of docstring
• PR #12569: Don’t confuse uintptr_t and Py_ssize_t.
• PR #12572: Fix singleton hist labels
• PR #12581: Fix hist() error message
• PR #12570: Fix mathtext tutorial for build with Sphinx 1.8.
• PR #12487: Update docs/tests for the deprecation of aname and label1On/label2On/etc.
• PR #12521: Improve docstring of draw_idle()
• PR #12573: BUG: mplot3d: Don’t crash if azim or elev are non-integral
• PR #12574: Remove some unused imports
• PR #12568: Add note regarding builds of old Matplotlibs.
• PR #12555: Clarify horizontalalignment and verticalalignment in suptitle
• PR #12547: Disable sticky edge accumulation if no autoscaling.
• PR #12546: Avoid quadratic behavior when accumulating stickies.
• PR #12159: FIX: colorbar re-check norm before draw for autolables
• PR #12501: Rectified plot error
• PR #11789: endless looping GIFs with PillowWriter
• PR #12525: Fix some flake8 issues
• PR #12431: FIX: allow single-string color for scatter
• PR #12216: Doc: Fix search for sphinx >= 1.8
• PR #12461: FIX: make add_lines work with new colorbar
• PR #12241: FIX: make unused spines invisible
• PR #12516: Don’t handle impossible values for align in hist()
• PR #12504: DOC: clarify min supported version wording
• PR #12507: FIX: make minor ticks formatted with science formatter as well
• PR #12500: Adjust the widths of the messages during the build.
• PR #12492: Simplify radar_chart example.
• PR #12478: MAINT: numpy deprecates asscalar in 1.16
• PR #12363: FIX: errors in get_position changes
• PR #12495: Fix duplicate condition in pathpatch3d example
• PR #11984: Strip out pkg-config machinery for agg and libqhull.
• PR #12463: Document Artist.cursor_data() parameter
• PR #12489: Fix typo in documentation of ylim
• PR #12482: Test slider orientation
• PR #12317: Always install mpl_toolkits.
• PR #12246: Be less tolerant of broken installs.
• PR #12477: Use N{MICRO SIGN} instead of N{GREEK SMALL LETTER MU} in Eng-Formatter.
• PR #12483: Kill FontManager.update_fonts.
• PR #12448: Don’t error if some font directories are not readable.
• PR #12474: Throw ValueError when irregularly gridded data is passed to streamplot.
• PR #12469: Clarify documentation of offsetbox.AnchoredText’s prop kw argument
• PR #12468: Fix set_ylim unit handling
• PR #12466: np.fromstring -> np.frombuffer.
• PR #12369: Improved exception handling on animation failure
• PR #12460: Deprecate RendererBase.strip_math.
• PR #12457: Fix tutorial typos.
• PR #12453: Rollback erroneous commit to whats_new.rst from #10746
• PR #12452: Minor updates to the FAQ.
• PR #10746: Adjusted matplotlib.widgets.Slider to have optional vertical orientatation
• PR #12441: Get rid of a signed-compare warning.
• PR #12430: Deprecate Axes3D.plot_surface(shade=None)
• PR #12435: Fix numpydoc parameter formatting
• PR #12434: Clarify documentation for textprops keyword parameter of TextArea
• PR #12427: Document Artist.get_cursor_data
• PR #12277: FIX: datetime64 now recognized if in a list
• PR #10322: Use np.hypot whereever possible.
• PR #12423: Minor simplifications to backend_svg.
• PR #12293: Make pyplot more tolerant wrt. 3rd-party subclasses.
• PR #12360: Replace axes_grid by axes_grid1 in test
• PR #10356: fix detecting which artist(s) the mouse is over
• PR #12416: Move font cache rebuild out of exception handler
• PR #11891: Group some print()s in backend_ps.
• PR #12165: Remove deprecated mlab code
• PR #12394: DOC: fix CL tutorial to give same output from saved file and example
• PR #12387: Update HTML animation as slider is dragged
• PR #12408: Don’t crash on invalid registry font entries on Windows.
• PR #10088: Deprecate Tick.{gridOn,tick1On,label1On,...} in favor of set_visible.
• PR #12149: Mathtext tutorial fixes
• PR #12393: Deprecate to-days converters in matplotlib dates
• PR #12257: Document standard backends in matplotlib.use()
• PR #12383: Revert change of parameter name in annotate()
• PR #12385: CI: Added Appveyor Python 3.7 build
• PR #12247: Machinery for deprecating properties.
• PR #12371: Move check for ImageMagick Windows path to bin_path().
• PR #12384: Cleanup axislines style.
• PR #12353: Doc: clarify default parameters in scatter docs
• PR #12366: TST: Update test images for new Ghostscript.
• PR #11648: FIX: colorbar placement in constrained layout
• PR #12368: Don’t use stdlib private API in animation.py.
• PR #12351: dviread: find_tex_file: Ensure the encoding on windows
• PR #12244: Merge barchart examples.
• PR #12372: Remove two examples.
• PR #12214: Improve docstring of Annotation
• PR #12347: DOC: add_child_axes to axes_api.rst
• PR #12304: TST: Merge Qt tests into one file.
• PR #12321: maint: setupext.py for freetype had a Catch case for missing ft2build.h
• PR #12340: Catch test deprecation warnings for mlab.demean
• PR #12334: Improve selection of inset indicator connectors.
• PR #1216: Fix some warnings from Travis
• PR #12268: FIX: remove unnecessary self in super-calls, fixes #12265
• PR #12212: font_manager: Fixed problems with Path(...).suffix
• PR #12326: fixed minor spelling error in docstring
• PR #12296: Make FooConverter inherit from ConversionInterface in examples
• PR #12322: Fix the docs build.
• PR #12319: Fix Travis 3.6 builds
• PR #12309: Deduplicate implementations of FooNorm.autoscale{,_None}
• PR #12314: Deprecate axis('normal') in favor of axis('auto').
• PR #12313: BUG: Fix typo in view_limits() for MultipleLocator
• PR #12307: Clarify missing-property error message.
• PR #12274: MNT: put back _hold as read-only attribute on AxesBase
• PR #12260: Fix docs: change from issue #12191, remove “if 1:” blocks in examples
• PR #12163: TST: Defer loading Qt framework until test is run.
• PR #12253: Handle utf-8 output by kpathsea on Windows.
• PR #12301: Ghostscript 9.0 requirement revisited
• PR #12294: Fix expand_dims warnings in triinterpolate
• PR #12292: TST: Modify the bar3d test to show three more angles
• PR #12297: Remove some pytest parameterising warnings
• PR #12261: FIX: parasite axis2 demo
• PR #12278: Document inheriting docstrings
• PR #12262: Simplify empty-rasterized pdf test.
• PR #12269: Add some param docs to BlockingInput methods
• PR #12272: Fix constrained to constrained
• PR #12255: Deduplicate inherited docstrings.
• PR #12254: Improve docstrings of Animations
• PR #12258: Fix CSS for module-level data
• PR #12222: Remove extraneous if 1 statements in demo_axisline_style.py
• PR #12137: MAINT: Vectorize bar3d
• PR #12219: Merge OSXInstalledFonts into findSystemFonts.
• PR #12229: Less ACCEPTS, more numpydoc.
• PR #12209: Doc: Sort named colors example by palette
• PR #12237: Use (float, float) as parameter type for 2D positions in docstrings
• PR #12238: Typo in docs
• PR #12236: Make boilerplate-generated pyplot.py flake8 compliant
• PR #12231: CI: Speed up Appveyor repository cloning
• PR #12228: Fix trivial typo in docs.
• PR #12227: Use (float, float) as parameter type for 2D positions
• PR #12199: Allow disabling specific mouse actions in blocking_input
• PR #12213: Change win32InstalledFonts return value
• PR #12207: FIX: don’t check for interactive framework if none required
• PR #11688: Don’t draw axis (spines, ticks, labels) twice when using parasite axes.
• PR #12210: Axes.tick_params() argument checking
• PR #12211: Fix typo
• PR #12200: Slightly clarify some invalid shape exceptions for image data.
• PR #12151: Don’t pretend @deprecated applies to classmethods.
• PR #12190: Remove some unused variables and imports
• PR #12186: DOC: fix API note about get_tightbbox
• PR #12203: Document legend’s slowness when “best” location is used
• PR #12192: Exclude examples from lgtm analysis
• PR #12196: Give Carreau the ability to mention the backport bot.
• PR #12187: DOC: Update INSTALL.rst
• PR #12164: Fix Annotation.contains.
• PR #12177: FIX: remove cwd from mac font path search
• PR #12182: Fix Flash of Unstyled Content by removing remaining Flipcause integration
• PR #12184: DOC: update “Previous Whats New“ for 2.2 with reference to cividis paper
• PR #12183: Doc: Don’t use Sphinx 1.8
• PR #12171: Remove internal warning due to zsort deprecation
• PR #12166: Document preference order for backend auto selection
• PR #12154: Avoid triggering deprecation warnings with pytest 3.8.
• PR #12030: Speed up canvas redraw for GTK3Agg backend.
• PR #12157: Properly declare the interactive framework for the qt4foo backends.
• PR #12156: Cleanup the GridSpec demos.
• PR #12144: Add explicit getters and setters for Annotation.anncoords.
• PR #12152: Use _warn_external for deprecations warnings.
• PR #12148: BLD: pragmatic fix for building basic_unit example on py37
• PR #12147: DOC: update the gh_stats code

Issues (170):
• #12699: Annotations get cropped out of figures saved with bbox_inches='tight'
• #9217: Weirdness with inline figure DPI settings in Jupyter Notebook
• #4853: %matplotlib notebook creates much bigger figures than %matplotlib inline
• #12780: Vague/misleading exception message in scatter()
• #10239: Weird interaction with Tkinter
• #10045: subplots_adjust() breaks layout of tick labels
• #12765: Matplotlib draws incorrect color
• #11800: Gridspec tutorial
• #12757: up the figure
• #12724: Importing pyplot steals focus on macOS
• #12669: fixing _hold on cartopy broke basemap
• #12687: Plotting text on 3d axes before tight_layout() breaks tight_layout()
• #12734: Wishlist: functionally linked twin axes
• #12576: RcParams is fundamentally broken
• #12641: _axes.py.scatter() array index out of bound / calling from seaborn
• #12703: Error when closing first of several pyplot figures in TkAgg
• #12728: Deprecation Warnings
• #4124: Provide canonical examples of mpl in web frameworks
• #10574: Default color after setting alptha to Patch in legened
• #12702: couldn’t find or load Qt platform plugin “windows” in "".
• #11139: “make clean” doesn’t remove all the build doc files
• #12701: semilogy with NaN prevents display of Title (cairo backend)
• #12696: Process finished with exit code -1 due to matplotlib configuration
• #12692: matplotlib.plot.show always blocks the execution of python script
• #12433: Travis error is MacOS image tolerance of 0.005 for test_constrained_layout.
  py::test_colorbar_location
• #10017: unicode_literals considered harmful
• #12682: using AxesImage.set_clim() shrinks the colorbar
• #12620: Overlapping 3D objects
• #12680: matplotlib ui in thread still blocked
• #11908: Improve linestyle documentation
• #12650: Deprecation warnings when calling help(matplotlib)
• #10643: Most warnings calls do not set the stacklevel
• #12671: make_axes_locatable breaks with matplotlib 3.0
• #12664: plt.scatter crashes because overwrites the colors to an empty list
• #12188: matplotlib 3 pyplot on MacOS bounces rocket icon in dock
• #12648: Regression when calling annotate with nan values for the position
• #12362: In 3.0.0 backend cannot be set if ‘get_backend()’ is run first
• #12649: Over-verbose deprecation warning about examples.directory
• #12661: In version 3.0.0 make_axes_locatable + colorbar does not produce expected result
• #12634: axes_grid1 axes have no keyword argument ‘bbox_extra_artists’
• #12654: Broken ‘Developer Discussions’ link
• #12657: With v3.0.0 mpl_toolkits.axes_grid1.make_axes_locatable().append_axes breaks in Jupyter
• #12645: Markers are offset when ‘facecolor’ or ‘edgecolor’ are set to ‘none’ when plotting data
• #12644: Memory leak with plt.plot in Jupyter Notebooks?
• #12632: Do we need input hooks macosx?
• #12535: AIX Support - Do not undef _XOPEN_SOURCE
• #12626: AttributeError: module ‘matplotlib’ has no attribute ‘artist’
• #11034: Doc Typo: matplotlib.axes.Axes.get_yticklabels / Axis.get_ticklabels
• #12624: make_axes_locatable : Colorbar in the middle instead of bottom while saving a pdf, png.
• #11094: can not use GUI backends inside django request handlers
• #12613: transiently linked interactivity of unshared pair of axes generated with make_axes_locatable
• #12578: macOS builds are broken
• #12612: gui backends do not work inside of flask request handlers
• #12611: Matplotlib 3.0.0 Likely bug TypeError: stackplot() got multiple values for argument ‘x’
• #12610: matplotlibrc causes import to fail 3.0.0 (didn’t crash 2.y.z series)
• #12601: Can’t import matplotlib
• #12597: Please soon add Chinese language support!! It’s to difficult for new people handle character
• #12590: Matplotlib pypi distribution lacks packages for Python 2.7
• #3869: Numeric labels do not work with plt.hist
• #12580: Incorrect hist error message with bad color size
• #12100: document where to get nightly wheels
• #7205: Converting docstrings to numpydoc
• #12564: Saving plot as PNG file prunes tick labels
• #12161: Problems of using sharex options with lines plots and colormesh with colorbar
• #12256: tight_layout for plot with non-clipped screen-unit items causes issues on zoom
• #12545: Program quit unormally without reporting error
• #12532: Incorrect rendering of math symbols
• #12567: Calling pyplot.show() with TkAgg backend on x86 machine raises OverflowError.
• #12571: cannot install because Fatal Python error: initfsencoding: Unable to get the locale encoding
• #12566: Problem installing Version 1.3.1 -> missing pkg-config freetype and libagg
• #12556: Matplotlib 3.0.0 import hangs in clean environment
• #12197: Weird behaviour of suptitle() when horizontalalignment is not ‘center’
• #12550: colorbar resizes in animation
• #12155: Incorrect placement of Colorbar ticks using LogNorm
• #11787: Looping gifs with PillowWriter
• #12533: Plotting with alpha=0 with rasterized=True causes ValueError on saving to pdf
• #12438: Scatter doesn’t accept a list of strings as color spec.
• #12429: scatter() does not accept gray strings anymore
• #12499: run my code failed after i Import pylab failed, python version is 3.6.6
• #12458: add_lines misses lines for matplotlib.colorbar.ColorbarBase
• #12239: 3d axes are collapsed by tight_layout
• #12414: Function to draw angle between two lines
• #12488: inconsistent colorbar tick labels for LogNorm
• #12515: pyplot.step broken in 3.0.0?
• #12355: Error for bbox_inches=’tight’ in savefig with make_axes_locatable
• #12505: ImageGrid in 3.0
• #12502: How can I put the ticks of logarithmic coordinate in the axes?
• #12496: Matplotlib Can’t Plot a Dataset
• #12486: rotate lable of legend ?
• #12291: Importing pyplot crashes on macOS due to missing fontlist-v300.json and then Permission denied: '/opt/local/share/fonts'
• #12480: “close_event” for nbagg/notebook backend
• #12467: Documentation of AnchoredText’s prop keyword argument is misleading
• #12288: New function signatures in pyplot break Cartopy
• #12445: Error on colorbar

6.1. Previous GitHub Stats
• #8760: Traceback from animation.MovieWriter.saving method is confusing because it provides no useful information
• #9205: after the animation encoder (e.g. ffmpeg) fails, the animation framework itself fails internally in various ways while trying to report the error
• #12357: Unclear error when saving Animation using FFMpeg
• #12454: Formatting numerical legend
• #9636: matplotlib crashes upon window resize
• #11473: Continuous plotting cause memory leak 20-50kb/sec
• #12018: No image pop-up or display for plt.imshow() and plt.show()
• #11583: How to draw parallelepipeded with real size scaling?
• #12446: Polar Contour - float() argument must be a string or a number, not ‘AxesParasiteParasiteAuxTrans’
• #12444: Issues with gridspec/tight_layout in matplotlib version 2.2.3
• #11154: Unexpected behavior for Axes3D.plot_surface(shade=None)
• #12409: Calling savefig() multiple times causes crash of Spyder IDE / IPython Kernel dying.
• #9799: FigureCanvasTkAgg - “buffer is of wrong type” error during blit
• #12439: FileNotFoundError for font_manager
• #12437: matplotlib-mac
• #12121: Documentation of TextArea’s fontprops keyword argument is misleading
• #12279: Axes.format_cursor_data lacks documentation and seems unused
• #12428: Simple plot spacing bug: ylabel gets wrongfully removed from plot
• #11190: Images in the docs are too large.
• #12271: error with errorbar with datetime64
• #12405: plt.stackplot() does not work with 3.0.0
• #12282: Axes.imshow tooltip does not get updated when another call to Axes.imshow is made
• #12420: How to remove Rectangle Selector from figure?
• #12391: Constrained Layout tutorial needs some cleanup....
• #12406: Bug with font finding, and here is my fix as well.
• #9051: ParasiteAxes over plotting
• #12325: Annotation change from “s” to “text” in 3.0- documentation
• #12397: plt.show( ) not working (can’t get figures to display in external window) when using jupyter QTconsole
• #12396: Defining arrowprops in draggable annotation disables the pick_event
• #12389: Setting row edge color of matplotlib table
• #12376: The output figure file is strange: there is a lot of blank area on the output figure.
• #11641: constrained_layout and colorbar for a subset of axes
• #12373: Unexpected outcome with matplotlib.pyplot.pcolor()
• #12370: ImageGrid bug when using inline backend
• #12364: pdf image generated by matplotlib with semi transparent lines missing in Word on Windows.
• #12352: TeX rendering broken on master with windows
• #12354: Too many levels of symbolic links
• #12323: indicate_inset_zoom sometimes draws incorrect connector lines
• #12341: Figures not rendering in docker
• #12335: Matplotlib plt.Rectangle Incoherent Results
• #12265: ParasiteAxesAuxTrans pcolor/pcolormesh and contour/contourf broken
• #12337: AttributeError: module `matplotlib.pyplot` has no attribute `hold`
• #11673: Inconsistent font settings when changing style context
• #11693: The rcParams setting for figure.figsize does not change when run from another notebook
• #11725: New mode between non-interactive and interactive?
• #12134: tight_layout flips images when making plots without displaying them
• #12310: plot fails with datetime64[ns] timezone aware objects (for example datetime64[ns, UTC+00:00] )
• #12191: “if 1:” blocks in examples
• #11288: FR: Figure.subplots add optional SubplotSpec parameter
• #12298: c and cmap for plot
• #12286: Sample code given in Matplotlib’s site does not work.
• #11955: UnicodeDecodeError on importing pyplot in python2
• #12208: parasite axis2 demo now crashes with log x-axis
• #8871: Error when using quantities when plotting errorbars
• #6658: literature reference for ‘viridis’ colormap
• #6789: Tutorial pyplot_scales.py crashes when used with plt.tight_layout()
• #6922: imshow does not immediately update shared axes
• #11879: Unable to change filename when saving from figure window
• #12225: In histogram, bars whose count is larger than 2**31 sometimes become negative
• #1461: DOC: keyword arguments to plt.axes, plt.subplot, and fig.add_subplot
• #12173: Cannot import pyplot
• #12217: Python will suddenly not plot anymore
• #12120: Default legend behavior (loc=‘best’) very slow for large amounts of data.
• #12176: import pyplot on MacOS without font cache will search entire subtree of current dir
Matplotlib, Release 3.1.1

- #12146: fix pdf docs
- #12160: MacOS: Cannot import name ‘format_exc’
- #12169: Cannot install 3.0.0 "python setup.py egg_info" failed (freetype & png)
- #12168: pip install v3.0.0 ‘failed with exit status 1181’
- #12107: warnings re: deprecated pytest API with pytest 3.8
- #12162: https://matplotlib.org/users/beginner.html is outdated
- #12010: Popover over plot is very slow
- #6739: Make matplotlib fail more gracefully in headless environments
- #3679: Runtime detection for default backend
- #11340: matplotlib fails to install from source with intel compiler
- #11838: docs do not build on py3.7 due to small change in python handling of -m
- #12115: Plot in JS Animation has larger margin than “normal” PNG plot

6.1.2 GitHub Stats for Matplotlib 3.1.0

GitHub stats for 2018/09/18 - 2019/05/13 (tag: v3.0.0)
These lists are automatically generated, and may be incomplete or contain duplicates.
We closed 161 issues and merged 918 pull requests. The full list can be seen on GitHub
The following 150 authors contributed 3426 commits.

- Abhinuv Nitin Pitale
- Adam J. Stewart
- Alistair Muldal

6.1. Previous GitHub Stats
GitHub issues and pull requests:

Pull Requests (918):

- **PR #14209**: Backport PR #14197 on branch v3.1.x (Minor cleanup of acorr/xcoor docs)
- **PR #14210**: Make intro tutorial less jargony.
- **PR #14197**: Minor cleanup of acorr/xcoor docs
- **PR #14203**: Backport PR #14202 on branch v3.1.x (Fix docstring of Line2D.set_data.)
- **PR #14202**: Fix docstring of Line2D.set_data.
- **PR #14196**: Backport PR #14188 on branch v3.1.x (Clarify scope of MouseEvent attributes)
- **PR #14188**: Clarify scope of MouseEvent attributes
- **PR #14194**: Backport PR #14167 on branch v3.1.x (Fix backend_pgf header.)
- **PR #14193**: Backport PR #14153 on branch v3.1.x (Update qt_compat.py test for already imported binding.)
• PR #14167: Fix backend_pgf header.
• PR #14153: Update qt_compat.py test for already imported binding.
• PR #14190: Backport PR #14176 on branch v3.1.x (Merge doc/api/api_overview and doc/api/index.)
• PR #14192: Unbreak testsuite for pytest 4.5.
• PR #14189: Backport PR #14186 on branch v3.1.x (Update FancyBboxPatch docs to numpydoc style)
• PR #14176: Merge doc/api/api_overview and doc/api/index.
• PR #14186: Update FancyBboxPatch docs to numpydoc style
• PR #14187: Backport PR #13169 on branch v3.1.x (Add example code for current logo)
• PR #14165: Backport PR #14156 on branch v3.1.x (Fix glyph loading in textpath.)
• PR #14156: Fix glyph loading in textpath.
• PR #14162: Backport PR #14150 on branch v3.1.x (Fix deprecation of withdash for figtext().)
• PR #14150: Fix deprecation of withdash for figtext().
• PR #14136: Backport PR #14109 on branch v3.1.x
• PR #14109: Some simple pyplot doc improvements
• PR #14129: Backport PR #14117 on branch v3.1.x (Simplify ribbon_box example.)
• PR #14128: Backport PR #14057 on branch v3.1.x (Improve Gradient bar example)
• PR #14127: Backport PR #14125 on branch v3.1.x (Remove extra keyword from pytest.skip call.)
• PR #14117: Simplify ribbon_box example.
• PR #14136: Backport PR #14109 on branch v3.1.x
• PR #14109: Some simple pyplot doc improvements
• PR #14129: Backport PR #14117 on branch v3.1.x (Simplify ribbon_box example.)
• PR #14128: Backport PR #14057 on branch v3.1.x (Improve Gradient bar example)
• PR #14127: Backport PR #14125 on branch v3.1.x (Remove extra keyword from pytest.skip call.)
• PR #14117: Simplify ribbon_box example.
• PR #14136: Backport PR #14109 on branch v3.1.x
• PR #14109: Some simple pyplot doc improvements
• PR #14129: Backport PR #14117 on branch v3.1.x (Simplify ribbon_box example.)
• PR #14128: Backport PR #14057 on branch v3.1.x (Improve Gradient bar example)
• PR #14127: Backport PR #14125 on branch v3.1.x (Remove extra keyword from pytest.skip call.)
• PR #14117: Simplify ribbon_box example.
• PR #14093: Backport PR #14052 on branch v3.1.x (Check axes identity in image.contains.)
• PR #14092: Backport PR #14056 on branch v3.1.x (FIX: do not try to manage the visibility of un-drawn ticks)
• PR #14091: Backport PR #14078 on branch v3.1.x (Minor fix in multiple subplots example)
• PR #14079: Consistently use axs.flat instead of axs.flatten()
• PR #14087: Cleanup date example.
• PR #14029: Fix doc building with numpydoc 0.9
• PR #14052: Check axes identity in image.contains.
• PR #14056: FIX: do not try to manage the visibility of un-drawn ticks
• PR #14078: Minor fix in multiple subplots example
• PR #14080: Backport PR #14069 on branch v3.1.x (Don’t try to use the colorbar formatter to format RGBA data.)
• PR #14069: Don’t try to use the colorbar formatter to format RGBA data.
• PR #14074: Backport PR #14019 on branch v3.1.x (Update docstring of locator_params())
• PR #14019: Update docstring of locator_params()
• PR #14066: Backport PR #14053 on branch v3.1.x (Improve fill() example)
• PR #14065: Backport PR #14059 on branch v3.1.x (Improve Scatter hist example)
• PR #14067: Backport PR #14062 on branch v3.1.x (Improve advanced quiver example)
• PR #14062: Improve advanced quiver example
• PR #14053: Improve fill() example
• PR #14059: Improve Scatter hist example
• PR #14064: Backport PR #14043 on branch v3.1.x (Ensure errorbars are always drawn on top of bars in ax.bar)
• PR #14043: Ensure errorbars are always drawn on top of bars in ax.bar
• PR #14061: Backport PR #14051 on branch v3.1.x (Add Yellowbrick to third party packages)
• PR #14051: Add Yellowbrick to third party packages
• PR #14050: Backport PR #14048 on branch v3.1.x (Fix Animation.save)
• PR #14049: Backport PR #14047 on branch v3.1.x (Remove references to "Draws" in matplotlib.patches)
• PR #14048: Fix Animation.save
• PR #14047: Remove references to "Draws" in matplotlib.patches
• PR #14037: Backport PR #14033 on branch v3.1.x (Reword add_subplot docstring.)
• PR #14036: Backport PR #14001 on branch v3.1.x ([BUG] DOC: Remove broken references to vischeck)
• PR #14033: Reword add_subplot docstring.
• PR #14032: Backport PR #14030 on branch v3.1.x (Update colorcet link)
• PR #14030: Update colorcet link
• PR #14027: Backport PR #14026 on branch v3.1.x (Fix bug in plot_directive that caused links to plots in different formats to be missing)
• PR #14026: Fix bug in plot_directive that caused links to plots in different formats to be missing
• PR #14012: Backport PR #14008 on branch v3.1.x (Don’t install tests by default.)
• PR #14017: Backport PR #14015 on branch v3.1.x (Fix docstring of pyplot.clim())
• PR #14015: Fix docstring of pyplot.clim()
• PR #14008: Don’t install tests by default.
• PR #14006: Backport PR #13998 on branch v3.1.x (Fix patch contains logic for patches that don’t have any codes)
• PR #14005: Backport PR #14004 on branch v3.1.x (DOC: pin numpydoc to less than 0.9)
• PR #13998: Fix patch contains logic for patches that don’t have any codes
• PR #13999: Backport PR #13992 on branch v3.1.x (FIX: undeprecate MaxNLocator default_params)
• PR #13997: Backport PR #13995 on branch v3.1.x (DOC: explain zorder for gridlines in grid docstring)
• PR #13992: FIX: undeprecate MaxNLocator default_params
• PR #13995: DOC: explain zorder for gridlines in grid docstring
• PR #13990: Backport PR #13989 on branch v3.1.x (FIX: update not replace hist_kwargs when density is passed)
• PR #13989: FIX: update not replace hist_kwargs when density is passed
• PR #13975: Backport PR #13966 on branch v3.1.x (Fix colorbar setting without artist)
• PR #13976: Backport PR #13973 on branch v3.1.x (BUG: Ensure docstrings are not accessed with -OO)
• PR #13856: Whats new page for 3.1
• PR #13966: Fix colorbar setting without artist
• PR #13973: BUG: Ensure docstrings are not accessed with -OO
• PR #13969: Backport PR #13950 on branch v3.1.x (confidence_ellipse_markup)
• PR #13950: confidence_ellipse_markup
• PR #13965: Backport PR #13962 on branch v3.1.x (Fix typo in code example in docstring.)
• PR #13964: Backport PR #13870 on branch v3.1.x (3.1.0 API changes page)
• PR #13962: Fix typo in code example in docstring.
• PR #13870: 3.1.0 API changes page
• PR #13961: Backport PR #13914 on branch v3.1.x (Improve Rainbow text example)
• PR #13960: Backport PR #13958 on branch v3.1.x (Remove transparent fancy legend example)
• PR #13914: Improve Rainbow text example
• PR #13958: Remove transparent fancy legend example
• PR #13956: Backport PR #13908 on branch v3.1.x (Enh control tick deconflict2)
• PR #13955: Backport PR #13941 on branch v3.1.x (Add project_urls to setup)
• PR #13908: Enh control tick deconflict2
• PR #13954: Backport PR #13949 on branch v3.1.x (DOC: Add documentation to Text.set_fontfamily)
• PR #13941: Add project_urls to setup
• PR #13949: DOC: Add documentation to Text.set_fontfamily
• PR #13951: Backport PR #13939 on branch v3.1.x (Bunch of docstring cleanups.)
• PR #13939: Bunch of docstring cleanups.
• PR #13947: Backport PR #13897 on branch v3.1.x (numpydification.)
• PR #13897: numpydification.
• PR #13946: Backport PR #13924 on branch v3.1.x (Followup to deprecation of usetex parameter in get_text_path.)
• PR #13924: Followup to deprecation of usetex parameter in get_text_path.
• PR #13916: Backport PR #13850 on branch v3.1.x (Cleanup STIX Font Demo)
• PR #13915: Backport PR #13835 on branch v3.1.x (Improve Conenctionstyle Demo)
• PR #13850: Cleanup STIX Font Demo
• PR #13835: Improve Conenctionstyle Demo
• PR #13846: Backport PR #13836 on branch v3.1.x (MNT: account for cpython depreca-
tions)
• PR #13898: Backport PR #13896 on branch v3.1.x (Fix cbook.boxplot_stats docstring)
• PR #13896: Fix cbook.boxplot_stats docstring
• PR #13893: Backport PR #13890 on branch v3.1.x (rst seealso -> numpydoc “See Also”).
• PR #13890: rst seealso -> numpydoc “See Also”.
• PR #13888: Backport PR #13862 on branch v3.1.x (Move 3.x API changes to prev_api_changes)
• PR #13862: Move 3.x API changes to prev_api_changes
• PR #13882: Backport PR #13867 on branch v3.1.x (Rename “docs” to “contents” in navigation bar)
• PR #13867: Rename “docs” to “contents” in navigation bar
• PR #13881: Backport PR #13874 on branch v3.1.x (Remove redundant call to Format-
ter.set_locs() before .format_ticks().)
• PR #13874: Remove redundant call to Formatter.set_locs() before .format_ticks().
• PR #13871: Backport PR #13868 on branch v3.1.x (Correctly handle fallout of defining PY_SSIZE_T_CLEAN on Windows.)
• PR #13869: Backport PR #13861 on branch v3.1.x (Fix remaining links in docs)
• PR #13868: Correctly handle fallout of defining PY_SSIZE_T_CLEAN on Windows.
• PR #13861: Fix remaining links in docs
• PR #13849: Backport PR #13845 on branch v3.1.x (Fix some broken documentation links)
• PR #13845: Fix some broken documentation links
• PR #13836: MNT: account for cpython deprecations
• PR #13841: Backport PR #12928 on branch v3.1.x (textpath encoding)
• PR #13842: Backport PR #13827 on branch v3.1.x (Better MovieWriter init error message)
• PR #13838: Backport PR #13570 on branch v3.1.x (Add new example for plotting a confidence_ellipse)
• PR #13827: Better MovieWriter init error message
• PR #13839: Backport PR #13815 on branch v3.1.x (Numpydocify FontManager.findfont())
• PR #13837: Backport PR #8638 on branch v3.1.x (FIX: if bins input to hist is str, treat like no bins)
• PR #12928: textpath encoding
• PR #13815: Numpydocify FontManager.findfont()
• PR #13570: Add new example for plotting a confidence_ellipse
• PR #8638: FIX: if bins input to hist is str, treat like no bins
• PR #13831: Backport PR #13780 on branch v3.1.x (numpydoc ListedColormap parameters)
• PR #13780: numpydoc ListedColormap parameters
• PR #13830: Backport PR #13829 on branch v3.1.x (numpydoc IndexFormatter)
• PR #13829: numpydoc IndexFormatter
• PR #13828: Backport PR #13821 on branch v3.1.x (Remove mathcircled from mathtext docs following its deprecation.)
• PR #13821: Remove mathcircled from mathtext docs following its deprecation.
• PR #13822: Backport PR #13817 on branch v3.1.x (Remove borders from barcode example)
• PR #13820: Backport PR #13816 on branch v3.1.x (Correct windows env variable format)
• PR #13816: Correct windows env variable format
• PR #13817: Remove borders from barcode example
• PR #13814: Merge pull request #13805 from timhoffm/pin-sphinx-1.x
• PR #13813: Backport PR #13764 on branch v3.1.x (Deprecate mathcircled.)
• PR #13764: Deprecate mathcircled.
• PR #13805: Pin Sphinx to 1.x
• PR #13807: Backport PR #13800 on branch v3.1.x (Doc typos.)
• PR #13800: Doc typos.
• PR #13806: Backport PR #13771 on branch v3.1.x (patches.Arc docstring update #13759)
• PR #13804: Backport PR #13766 on branch v3.1.x (Search for fonts in XDG directory as well.)
• PR #13771: patches.Arc docstring update #13759
• PR #13766: Search for fonts in XDG directory as well.
• PR #13794: Backport PR #13695 on branch v3.1.x (numpydocify transform_angles.)
• PR #13793: Backport PR #13762 on branch v3.1.x (Cleanup marker_reference example.)
• PR #13792: Backport PR #13789 on branch v3.1.x (BUG: Fix function signature mismatch for set_clim)
• PR #13791: Backport PR #13787 on branch v3.1.x (Fix failure to import matplotlib.animation on Windows.)
• PR #13695: numpydocify transform_angles.
• PR #13762: Cleanup marker_reference example.
• PR #13789: BUG: Fix function signature mismatch for set_clim
• PR #13787: Fix failure to import matplotlib.animation on Windows.
• PR #13781: Backport PR #13777 on branch v3.1.x (Use class-based directive for mathmpl sphinxext.)
• PR #13790: Backport PR #13564 on branch v3.1.x (Add an option to log progress while saving animations)
• PR #13564: Add an option to log progress while saving animations
• PR #13777: Use class-based directive for mathmpl sphinxext.
• PR #13765: Backport PR #13761 on branch v3.1.x (Deprecate verbose-related rc-Params.)
• PR #13761: Deprecate verbose-related rcParams.
• PR #13760: Backport PR #13719 on branch v3.1.x (Doc: Update timeline example)
• PR #13704: Backport PR #13021 on branch v3.1.x (Undesirable behaviour of Mixed-ModeRenderer)
• PR #13758: Backport PR #13674 on branch v3.1.x (Preserve whitespace in svg output.)
• PR #13719: Doc: Update timeline example
• PR #13674: Preserve whitespace in svg output.
• PR #13755: Backport PR #13741 on branch v3.1.x (FIX: make title move above ticklabels)
• PR #13754: Backport PR #13712 on branch v3.1.x (Deprecate NavigationToolbar2QT.adj_window (unused and always None).)
• PR #13741: FIX: make title move above ticklabels
• PR #13712: Deprecate NavigationToolbar2QT.adj_window (unused and always None).
• PR #13752: Backport PR #13732 on branch v3.1.x (Fix doc markup.)
• PR #13753: Backport PR #13751 on branch v3.1.x (DOC/FIX: try merging comments)
• PR #13751: DOC/FIX: try merging comments
• PR #13732: Fix doc markup.
• PR #13750: Backport PR #13743 on branch v3.1.x (Fix doc warning)
• PR #13743: Fix doc warning
• PR #13747: Backport PR #13745 on branch v3.1.x (Fix stem(use_line_collection))
• PR #13748: Backport PR #13716 on branch v3.1.x (Kill attributes that are never used/updated.)
• PR #13716: Kill attributes that are never used/updated.
• PR #13745: Fix stem(use_line_collection)
• PR #13710: TST: only test agg_filter extensions with baseline images
• PR #13709: Backport PR #8690 on branch v3.1.x
• PR #13707: Backport PR #12760 on branch v3.1.x (Deduplicate implementation of per-backend Tools.)
• PR #13706: Backport PR #13689 on branch v3.1.x (BUG: fix scaling of quiverkey when quiver scale_units='xy')
• PR #13705: Backport PR #12419 on branch v3.1.x (Add DivergingNorm (again, again, again))
• PR #13703: Backport PR #12170 on branch v3.1.x (Deprecate considering *args, **kwargs in Timer.remove_callback.)
• PR #12760: Deduplicate implementation of per-backend Tools.
• PR #13689: BUG: fix scaling of quiverkey when quiver scale_units='xy'
• PR #12419: Add DivergingNorm (again, again, again)
• PR #8690: Adds support for rgba and rgb images to pcolorfast
• PR #13021: Undesirable behaviour of MixedModeRenderer
• PR #12170: Deprecate considering *args, **kwargs in Timer.remove_callback.
• PR #13700: Backport PR #13588 on branch v3.1.x (FIX: fallback to viewlims if no data)
• PR #13694: Backport PR #13677 on branch v3.1.x (Log all failures to extract font properties.)
• PR #13588: FIX: fallback to viewlims if no data
• PR #13692: Backport PR #13677 on branch v3.0.x (Log all failures to extract font properties.)
• PR #13677: Log all failures to extract font properties.
• PR #13691: Backport PR #13687 on branch v3.1.x (Update stem example)
• PR #13687: Update stem example
• PR #13688: Backport PR #13684 on branch v3.1.x (Use format_data_short to format image cursor data.)
• PR #13684: Use format_data_short to format image cursor data.
- PR #13686: Backport PR #13363 on branch v3.1.x (Inline iter_ticks into _update_ticks, and use that in mplot3d.)
- PR #13363: Inline iter_ticks into _update_ticks, and use that in mplot3d.
- PR #13681: Backport PR #13678 on branch v3.1.x (Fix font deduplication logic in createFontList.)
- PR #13678: Fix font deduplication logic in createFontList.
- PR #13669: Backport PR #13667 on branch v3.1.x (Fix incorrect signature in axis() doc.)
- PR #13667: Fix incorrect signature in axis() doc.
- PR #13664: Backport PR #12637 on branch v3.1.x (Tell IPython the correct GUI event loop to use for all backends.)
- PR #13665: Backport PR #13064 on branch v3.1.x (Don’t explicitly add default include paths to Extensions)
- PR #13064: Don’t explicitly add default include paths to Extensions
- PR #13658: Backport PR #13652 on branch v3.1.x (Fix empty FancyArrow crash)
- PR #13652: Fix empty FancyArrow crash
- PR #13655: Backport PR #11692 on branch v3.1.x (Deprecate frameon kwarg and rcParam to savefig.)
- PR #11692: Deprecate frameon kwarg and rcParam to savefig.
- PR #13614: Fix polar get window extent
- PR #13646: Backport PR #13645 on branch v3.1.x (widgets.py fix examples connect -> mpl_connect)
- PR #13645: widgets.py fix examples connect -> mpl_connect
- PR #13644: Backport PR #13612 on branch v3.1.x (Improve Demo Text Rotation Mode)
- PR #13612: Improve Demo Text Rotation Mode
- PR #13636: Backport PR #13621 on branch v3.1.x (Remove asfileobj=False from a bunch of examples loading sample_data.)
- PR #13635: Backport PR #13632 on branch v3.1.x (Clarify tick collision API change doc.)
- PR #13634: Backport PR #13631 on branch v3.1.x (Swicth deprecation of Tick.label to pending.)
- PR #13621: Remove asfileobj=False from a bunch of examples loading sample_data.
- PR #13632: Clarify tick collision API change doc.
- PR #13631: Swicth deprecation of Tick.label to pending.
- PR #13628: Backport PR #13603 on branch v3.1.x
• PR #13603: FIX: continue to bail tight layout if rect supplied
• PR #13627: Backport PR #13622 on branch v3.1.x (Change title of named colors example)

• PR #13508: Backport PR #13413 on branch v3.1.x (Simplify decade up- and down-rounding, and symmetrize expansion of degenerate log scales.)
• PR #13509: Backport PR #13492 on branch v3.1.x (Doc more release updates)
• PR #13492: Doc more release updates
• PR #13413: Simplify decade up- and down-rounding, and symmetrize expansion of degenerate log scales.
• PR #13507: Backport PR #13488 on branch v3.1.x (Animation: interactive zoom/pan with blitting does not work)
• PR #13488: Animation: interactive zoom/pan with blitting does not work
• PR #13505: Backport PR #13459 on branch v3.1.x (Document histogramming pre-binned data.)
• PR #13503: Backport PR #10776 on branch v3.1.x (fix FancyArrowPatch picker fails depending on arrowstyle)
• PR #13504: Backport PR #13123 on branch v3.1.x (Add shading to Axes3D.voxels, and enable it by default)
• PR #13502: Backport PR #13180 on branch v3.1.x (Various TextPath cleanups.)
• PR #13459: Document histogramming pre-binned data.
• PR #13501: Backport PR #13209 on branch v3.1.x (Deprecate support for (n, 1)-shaped error arrays in errorbar().)
• PR #13500: Backport PR #12763 on branch v3.1.x (Remove deprecated rcParams.)
• PR #13123: Add shading to Axes3D.voxels, and enable it by default
• PR #13499: Backport PR #13303 on branch v3.1.x (Unify checking of executable info.)
• PR #10776: fix FancyArrowPatch picker fails depending on arrowstyle
• PR #13180: Various TextPath cleanups.
• PR #13498: Backport PR #13314 on branch v3.1.x (Move major/minor tick overstrike logic to Axis.)
• PR #13209: Deprecate support for (n, 1)-shaped error arrays in errorbar().
• PR #12763: Remove deprecated rcParams.
• PR #13303: Unify checking of executable info.
• PR #13497: Backport PR #13057 on branch v3.1.x (Simplify callable(self._contains) checks)
• PR #13314: Move major/minor tick overstrike logic to Axis.
• PR #13057: Simplify callable(self._contains) checks
• PR #13496: Backport PR #13465 on branch v3.1.x (FIX: polar set_rlim allow bottom-only call)
• PR #13465: FIX: polar set_rlim allow bottom-only call
• PR #13495: Backport PR #12232 on branch v3.1.x (Add helper function to check that an argument is in a list of strings.)
• PR #12232: Add helper function to check that an argument is in a list of strings.
• PR #11708: Revert “Skip wx interactive tests on OSX.”
• PR #13062: Update FAQ re: batch/webserver use.
• PR #12904: Support forward/backward mouse buttons
• PR #12150: Deprecate stackrel.
• PR #13449: Let boxplot() defer rcParams application to bxp()
• PR #13425: API: un-deprecate keyword only args to set_xlim, set_ylim
• PR #13447: Update axes_grid docs
• PR #13473: Deprecate backend_wx.IDLE_DELAY.
• PR #13476: Add font to pyplot.xkcd()
• PR #13475: Cleanup titles of embedding examples.
• PR #13468: Suppress chaining of cache lookup failure in color conversion.
• PR #13467: Add “c” shorthand for “color” for the Text class.
• PR #13398: FIX: let pandas IndexInt64 work for boxplot
• PR #13375: Improve Axes selection in Qt figure options.
• PR #13421: DOC: update release guide
• PR #13275: Simple logging interface.
• PR #13427: Simplify check for tight-bbox finiteness.
• PR #13444: Allow constructing boxplots over multiple calls.
• PR #13385: Remove/rework uses of np.where where possible.
• PR #13441: Make AFM parser both more compliant and less strict.
• PR #13384: Replace np.compress by boolean indexing.
• PR #13422: Clarify IndexError for out-of-bounds indexing of gridspec.
• PR #13443: Remove some outdated comments from rcsetup.py.
• PR #13357: Inherit some docstrings in backend code.
• PR #12380: Stem speedup2
• PR #13368: FIX: Fix shape of hist output when input is multidimensional empty list
• PR #5590: [mpl_toolkits] Fix picking for things drawn on parasite axes
• PR #13323: Move the call to Formatter.set_locs into Formatter.format_ticks.
• PR #13424: Deprecate Quiver.color in favor of Quiver.get_facecolor().
• PR #13434: More smoketesting of pcolorfast.
• PR #13395: Cleanup demo_curvelinear_grid.
• PR #13411: Deemphasize numeric locations for legend() in docs.
• PR #13419: FIX: secondary_axis resize
• PR #13020: Deprecate proj3d.mod.
• PR #13030: Deprecate internal functions exposed in the public API of mplot3d
• PR #13408: test_figure style fixes.
• PR #11127: Legend for Scatter
• PR #11855: Adding the possible to add full command line in animation
• PR #13409: Add nonsingular to the locator base class, and use it in set_*lim too.
• PR #11859: ENH: add secondary x/y axis
• PR #13235: Vectorize mplot3d.art3d.zalpha.
• PR #10411: New “accepts units” decorator
• PR #13403: FIX: remove idle_event
• PR #13069: 5 minor divisions when major ticks are 2.5 units apart
• PR #13402: Fix empty reshape2d
• PR #11683: Reuse axes_grid1’s AxisDict in axisartist, instead of duplicating it.
• PR #12141: Let digits toggle axes nav only if they correspond to an existing axes.
• PR #9845: Add inaxes method to FigureCanvas to check whether point is in an axes.
• PR #13396: mpl_toolkits style fixes.
• PR #11497: Make CI fail if interactive toolkits can’t be tested
• PR #11595: test doc rendering
• PR #13393: Deprecate Spine.is_frame_like.
• PR #13391: Remove colour specification from some examples
• PR #13386: Replace use of np.<ufunc> by operators (</&/†).
• PR #13389: Inherit more docstrings.
• PR #13387: Fix regression in docstring.dedent_interpd.
• PR #13383: Replace np.take by normal indexing.
• PR #13381: Avoid unneeded copies from flatten().
• PR #13354: Properly deprecate non-1D inputs to pie().
• PR #13379: Remove citation entry from FAQ.
• PR #13380: Minor simplifications to scatter3d.
• PR #13173: Decorator for deleting a parameter with a deprecation period.
• PR #8205: [MRG+1] plot_date() after axhline() doesn’t rescale axes
• PR #11027: Specify custom tick space heuristic in MaxNLocator
• PR #13262: Shorten setupext and remove uninformative build log entries.
• PR #13377: Add private helper to internally suppress deprecations.
• PR #13376: Undeprecate case-insensitive “long” colornames.
• PR #13373: Deprecate axis3d.Axis.get_tick_positions.
• PR #13362: Kill the unused, private _get_pixel_distance_along_axis.
• PR #12772: Improve plot() docstring.
• PR #13359: DOC: change language a bit
• PR #13351: Fix: Log Colorbar minorticks_off reverted if ticks set
• PR #13356: More spelling fixes.
• PR #13125: Simplify and tighten the docstring handling API.
• PR #13346: Simplify parsing of tuple in C extension code.
• PR #13282: MAINT install of pinned vers for travis
• PR #13234: FIX: allow colorbar mappable norm to change and do right thing
• PR #13269: Rework a bit axes addition.
• PR #13330: Add Axis.get_inverted and Axis.set_inverted.
• PR #13117: Cleanup matplotlib.use
• PR #13335: Update and factor out Axis.get_tick_positions.
• PR #13324: Cleanup ScalarFormatter; preparatory to moving it to format_ticks.
• PR #13322: Update Axis docs
• PR #13342: Update some (mostly internal) docstrings in image.py.
• PR #11848: Country specific characters in Windows user folder name when locating .tfm-file
• PR #13309: bezier cleanups.
• PR #13334: Inherit some docstrings.
• PR #13332: Rewrite convert_to_string using std::string
• PR #13336: Update imshow docs.
• PR #13331: Try forcing font cache rebuild in flaky ttc test.
• PR #12105: API: make MaxNLocator trim out-of-view ticks before returning
• PR #13329: Pin flake8<3.7 to mitigate issues with flake8-per-file-ignores
• PR #13319: Deprecate dates.{str,bytes}pdate2num.
• PR #13320: Kill some private, unused functions in dates.py.
• PR #12909: Let Formatters format all ticks at once.
• PR #13313: Better explanation of ticks
• PR #13310: Replace *kw by *args.
• PR #13285: Defer checking of tex install to when it is actually used.
• PR #13128: Parameter-renaming decorator
• PR #13307: Spelling fixes.
• PR #13304: TST: deregister pandas
• PR #13300: Trivial bezier cleanups.
• PR #11664: FIX: clean up unit conversion unpacking of data, particularly for dates and pandas series
• PR #9639: Unify querying of executable versions
• PR #13224: numpydocify (some of) mpl_toolkits.
• PR #13301: Replace np.empty + ndarray.fill by np.full.
• PR #13229: Prevent exception when running animation on Agg backend.
• PR #13263: In imsave()'s Pillow-handled case, don’t create a temporary figure.
• PR #13294: Simplify some calculations in polar.py.
• PR #13295: Kill some commented-out code.
• PR #13298: Add note about thread safety to FAQ.
• PR #13299: Don’t emit a non-GUI warning when building the docs on Linux.
• PR #13297: Minor cleanup to OSX FAQ.
• PR #13283: Fix doc style in add_gridspec()
• PR #13129: ENH: add a user-friendly verbose interface
• PR #13279: Remove a useless catch_warnings() from example.
• PR #13268: Select RadioButtons by closest in position.
• PR #13271: Fix animation speed in double_pendulum example
• PR #13265: Allow turning off minor ticks on Colorbar with LogNorm
• PR #13260: Improve docs for format determination in savefig()/imsave().
• PR #12379: MAINT Use np.full when possible
• PR #12905: Add optional parameter use_default_template to rc_file()
• PR #13218: Fix checking of ‘labels’ argument to Sankey.add.
• PR #13256: DOC: reject MEP25 due to being stalled
• PR #13255: TST pandas support bar
• PR #13251: DEBUG-log font-matching results, and print failing logs on CI.
• PR #12818: Enh arbitrary scale
• PR #13187: FIX: bar mixed units, allow ValueError as well
• PR #13232: Fix incorrect kwarg being passed to TextPath.
• PR #13250: Replace safezip() by more informative error message in errorbar().
• PR #13239: Improve sankey logging.
• PR #13247: Simplify and optimize png writing in backend_pdf.
• PR #12455: Warn when “best” loc of legend is used with lots of data
• PR #13233: Remove warning in image_annotated_heatmap, and numpydocify it.
• PR #13248: Remove an unused local variable in backend_gtk3.
• PR #13249: Deprecate an unused “internal” API.
• PR #13243: Rewrite subplots_demo
• PR #13240: FIX: spelling error of local variable in category
• PR #13026: MNT: add a logging call if a categorical string array is all convertible
• PR #13225: Fix a warning in the doc build.
• PR #13227: Make color lowercase in example to avoid warning.
• PR #13217: numpydocify Sankey.add.
• PR #10209: Various backend cleanups.
• PR #13113: Globally cache single TexManager instances.
• PR #13213: Broadcast ‘orientations’ arg to Sankey.add.
• PR #13219: Fix some backend_bases docstrings.
• PR #13214: Reformat Sankey exceptions.
• PR #13211: Deprecate case-insensitive colors.
• PR #13210: Suppress a warning in the test suite.
• PR #13189: Remove cairo-based backends from backend fallback.
• PR #13207: Allow saving PNGs through Pillow instead of the builtin_png module.
• PR #13124: Simplify parsing of errorbar input.
• PR #13162: DOC: better argcheck bar
• PR #8531: Added compression option to save TIFF images
• PR #13094: Allow passing arguments to PIL.Image.save().
• PR #13202: Avoid private API in some examples.
- PR #13197: Cleanup the text of two mpl_toolkits examples.
- PR #13198: Cleanup SkewT example.
- PR #11914: Remove the system_monitor example.
- PR #13196: Deemphasize comment about extremely old Matplotlib versions in example.
- PR #13190: Show returncode when subprocess test fails
- PR #13163: Add explanatory comment to annotation box example
- PR #13104: Remove some more 1-tuples.
- PR #13105: Make GridSpec.update docstring match behavior.
- PR #13127: Deprecate add_subplot(<no positional args>) silently doing nothing.
- PR #13166: Simplify Text.get_usetex.
- PR #13188: Remove an outdated doc point regarding backend selection.
- PR #13107: Cleanup BboxBase docstrings.
- PR #13108: Capitalize some docstrings.
- PR #13115: Check for sphinx_copybutton when building the docs
- PR #13151: Update RadioButtons docs numpydoc style
- PR #13178: Remove :func: markup from mlab docstrings.
- PR #7461: [WIP] add matrix checking function for quiver input
- PR #13089: Ensure that arguments to quiver() are not matrices.
- PR #13179: Avoid calling a deprecated API in axis_artist.
- PR #13170: Don’t try to find TeX-only fonts when layouting TeX text.
- PR #12957: Search also for user fonts on Windows (#12954)
- PR #12951: Make Text._get_layout simpler to follow.
- PR #11385: Add a get_zaxis method for 3d axes.
- PR #13172: Hyperlink DOIs to preferred resolver
- PR #13171: Document how to make colorbars “without” a ScalarMappable.
- PR #12903: FIX: (broken)bar(h) math before units
- PR #13167: Typos on subplot comments and example
- PR #13005: Improve error messages for unit conversion
- PR #13147: Extend joinstyle example
- PR #13165: Change doc string for Axes.arrow()
- PR #13155: Let ffmpeg report errors.
- PR #13149: Update errorbar limits example
- PR #13074: Move_windowing extension into _tkagg.
- PR #13146: Remove an outdated comment in backend_wx.
- PR #13126: FIX: minor log ticks overwrite
- PR #13148: Update example Step Demo
- PR #13138: API: Use class-based directive in sphinxext
- PR #11894: add cache_frame_data kwarg into FuncAnimation. fixes #8528.
- PR #13136: Small cleanups.
- PR #13140: Remove a "cannot show figure in agg" warning in test suite.
- PR #13134: Simplify color conversion backcompat shim.
- PR #13141: Unpin pytest (pytest-cov’s latest release is compatible with it).
- PR #13133: Simplify the polys3d example.
- PR #12158: MNT: simplify valid tick logic
- PR #9867: Factor out common code between pdf and ps backends.
- PR #10111: Add set_data_3d and get_data_3d to Line3d
- PR #12245: Remove (some) features deprecated in mpl2.2
- PR #13119: Deprecate TextToPath.glyph_to_path.
- PR #13122: Pin pytest<4.1 to unbreak CI tests
- PR #13100: Restore the font cache on Travis.
- PR #12792: BUG: Ensure that distinct polygon collections are shaded identically
- PR #13070: cairo backend: default to pycairo
- PR #13114: BUG: calculate colorbar boundaries correctly from values
- PR #13111: Delete an unused private method.
- PR #10841: ENH: new date formatter
- PR #13093: Remove unused fontconfig conf file.
- PR #13063: Use default colour cycle in more examples
- PR #13103: Remove tight_bbox_test example.
- PR #13097: Replace 1-tuples by scalars where possible.
- PR #13027: Qt5 reset signals after non-interactive plotting
- PR #9787: Support (first font of) TTC files.
- PR #11780: ENH: Allow arbitrary coordinates for ConnectionPatch
- PR #12943: Update the font_table example.
- PR #13091: Improve MouseEvent str().
- PR #13095: Remove a duplicate attribute setting.
- PR #13090: Cleanup unused non-public imports.
- PR #13060: Move doc-requirements from root folder
- PR #13078: Convert streamplot to numpydoc
- PR #13088: Don’t use deprecated np.random.random_integers.
- PR #13073: Drop pytest version check in setupext.py.
- PR #12933: Deprecate backend_pgf.LatexManagerFactory.
- PR #12969: Clarify the implementation of _process_plot_var_args.
• PR #12472: Make FontManager.defaultFont a property, to avoid hardcoding the prefix.
• PR #11806: Allow to not draw the labels on pie chart
• PR #11983: Simplify version checks for freetype and libpng.
• PR #13050: FIX: always eraseRect in Qt widget
• PR #13065: FIX: print out the correct ip address when starting webagg
• PR #13061: Make examples that load msft.csv robust against locale changes.
• PR #13042: cairo: remove the append_path() fast path
• PR #13058: pathlibify/cleanup triage_tests.py.
• PR #12995: Don’t split creation of deprecation message and choice of warning class.
• PR #12998: Init MaxNLocator params only once
• PR #11691: Make Figure.frameon a thin wrapper for the patch visibility.
• PR #11735: Change {FigureCanvasAgg,RendererAgg}.buffer_rgba to return a memoryview.
• PR #12831: Reuse scale from sharing axis when calling cla().
• PR #12962: Deprecate setting the same property under two different aliases.
• PR #12973: Fix item check for pandas Series
• PR #13049: Add boxplot.flierprops.markeredgewidth rcParam
• PR #13048: Fix section names for numpydoc
• PR #10928: Simplify (quite a bit...) _preprocess_data
• PR #13039: Speed up Path.iter_segments()
• PR #12992: Adding rcParams[‘scatter.edgecolors’] defaulting to ‘face’
• PR #13014: Drop pgi support for the GTK3 backend
• PR #12215: Cleanup initialization in text()
• PR #13029: Fix vertical alignment of text
• PR #12968: Simpler and stricter process_plot_format.
• PR #12989: Avoid spamming tests with warnings re: deprecation of pprint_val.
• PR #13032: fix typo in docstring in axis_artist.py
• PR #13025: MNT: add one more alias for tacaswell to mailmap
• PR #13010: Fix a format error in documenting_mpl.rst
• PR #12997: Add sphinx-copybutton to docs
• PR #12422: Scatter color: moving #10809 forward
• PR #12999: Format MaxNLocator with numpydoc
• PR #12991: Canonicalize weights extracted for AFM fonts.
• PR #12955: Cleanup cursor_demo.
• PR #12984: Cleanup GTK examples.
• PR #12986: Minor cleanup to double_pendulum example.
• PR #12959: Update the documentation of Cursor
• PR #12945: Correctly get weight & style hints from certain newer Microsoft fonts
• PR #12976: ENH: replace deprecated numpy header
• PR #12975: Fail-fast when trying to run tests with too-old pytest.
• PR #12970: Minor simplifications.
• PR #12974: Remove some checks for Py<3.6 in the test suite.
• PR #12779: Include scatter plots in Qt figure options editor.
• PR #12459: Improve formatting of imshow() cursor data when a colorbar exists.
• PR #12927: MAINT: Correctly handle empty lists in zip unpacking in mplot3d.art3d
• PR #12919: Suppress deprecation warning when testing drawstyle conflict
• PR #12956: Misc. cleanups.
• PR #12924: Deprecate public use of Formatter.pprint_val.
• PR #12947: Support ~ as nonbreaking space in mathtext.
• PR #12944: Fix the title of testing_api
• PR #12136: MAINT: Unify calculation of normal vectors from polygons
• PR #12880: More table documentation
• PR #12940: Avoid pyplot in showcase examples.
• PR #12935: os.PathLike exists on all supported Pythons now.
• PR #12936: Minor updates following bump to Py3.6+.
• PR #12932: Simplify argument checking in Table.__getitem__.
• PR #12930: Shorten an argument check.
• PR #12538: MNT: drop 3.5 testing for 3.1 branch
• PR #12868: Simplify use of Path._fast_from_codes_and_verts.
• PR #12300: API: Polar: allow flipped y/rlims....
• PR #12861: Don’t use deprecated wx.NewId().
• PR #12908: Allow all valid hist.bins strings to be set in the rcparams
• PR #12902: Kill dead code in textpath.
• PR #12885: Improve margins in formlayout
• PR #12877: fooImage -> foo_image in testing/compare.py
• PR #12845: Deprecate silent dropping of unknown arguments to TextPath().
• PR #12852: Cleanup collections docs.
• PR #12888: Properly enable forward/backward buttons on GTK3
• PR #12865: Avoid 1-tick or 0-tick log-scaled axis.
• PR #12844: Remove unused, private _process_text_args.
• PR #12881: Fix string comparison
• PR #12863: FIX: translate timedeltas in _to_ordinalf
• PR #12640: Introduce MouseButton enum for MouseEvent.
• PR #12897: Reword a bit the contour docs.
• PR #12898: Validate rcParams["image.origin"].
• PR #12882: Write error messages to logger instead of stderr
• PR #12889: Deprecate public access to the vendored formlayout module.
• PR #12891: Add Azure Pipelines build badge
• PR #12883: MAINT Use list comprehension
• PR #12886: Properly enable forward/backward buttons on Qt
• PR #12858: Bump oldest supported numpy to 1.11.
• PR #12786: Fix a typo
• PR #12739: make Axes._parse_scatter_color_args static
• PR #12846: Deprecate Path.has_nonfinite.
• PR #12829: Remove unused variables
• PR #12872: Inline references to RendererPS in backend_ps.
• PR #12800: documenting dtype of hist counts
• PR #12842: Fix message in nbagg connection_info()
• PR #12855: Cleanup axes/_base.py.
• PR #12826: Minor code cleanup
• PR #12866: Simplify stride calculations in loglocator.
• PR #12867: Drop compat code for outdated MSVC.
• PR #12218: Improve table docs
• PR #12847: correctly format ticklabels when EngFormatter is used with usetex = True
• PR #12851: Keep Collections and Patches property aliases in sync.
• PR #12849: Update docstrings in path.py, and small cleanups.
• PR #12805: Don’t insert spurious newlines by joining tex.preamble.
• PR #12827: Remove unused imports
• PR #12560: Add matplotlib.testing to the documentation
• PR #12821: MNT: remove debug from update_title_pos
• PR #12764: Cleanup Renderer/GraphicsContext docs.
• PR #12759: Warn on FreeType missing glyphs.
• PR #12799: Reword some colorbar docs.
• PR #12633: Added support for MacOSX backend for PyPy
• PR #12798: Replace assignments to array.shape by calls to reshape().
• PR #11851: Simpler check for whether a Framework Python build is being used.
• PR #12259: BUG: Fix face orientations of bar3d
• PR #12565: Make FontManager.score_weight less lenient.
- PR #12674: Allow “real” LaTeX code for pgf.preamble in matplotlibrc
- PR #12770: Simplify implementation of FontProperties.copy().
- PR #12753: MNT: remove _hold shims to support basemap + cartopy
- PR #12450: Attach a FigureCanvasBase by default to Figures.
- PR #12643: Allow unit input to FancyArrowPatch
- PR #12767: Make colorbars constructible with dataless ScalarMappables.
- PR #12526: Rename jquery files
- PR #12552: Update docs for writing image comparison tests.
- PR #12746: Use skipif, not xfail, for uncomparable image formats.
- PR #12747: Prefer log.warning("%s", ...) to log.warning("%s" % ...).
- PR #11753: FIX: Apply aspect before drawing starts
- PR #12749: Move toolmanager warning from logging to warning.
- PR #12598: Support Cn colors with n>=10.
- PR #12727: Reorder API docs: separate file per module
- PR #12738: Add unobtrusive deprecation note to the first line of the docstring.
- PR #11663: Refactor color parsing of Axes.scatter
- PR #12736: Move deprecation note to end of docstring
- PR #12704: Rename tkinter import from Tk to tk.
- PR #12715: Cleanup dviread.
- PR #12717: Delete some if __name__ == "__main__" clauses.
- PR #10575: FIX patch.update_from to also copy _original_edge/facecolor
- PR #12537: Improve error message on failing test_pyplot_up_to_date
- PR #12721: Make get_scale_docs() internal
- PR #12706: Extend sphinx Makefile to cleanup completely
- PR #12481: Warn if plot_surface Z values contain NaN
- PR #12685: Make ticks in demo_axes_rgb.py visible
- PR #12523: Run flake8 before pytest on travis
- PR #12691: DOC: Link to “How to make a PR” tutorials as badge and in contributing
- PR #11974: Make code match comment in sankey.
- PR #12440: Make arguments to @deprecated/warn_deprecated keyword-only.
- PR #12470: Update AutoDateFormatter with locator
- PR #12586: Improve linestyles example
- PR #12006: Replace warnings.warn with cbook._warn_external or logging.warning
- PR #12659: Add note that developer discussions are private
- PR #12543: Make rcsetup.py flak8 compliant
- PR #12642: Don’t silence TypeErrors in fmt_(x,y)data.
• PR #12442: Deprecate passing drawstyle with linestyle as single string.
• PR #12625: Shorten some docstrings.
• PR #12627: Be a bit more stringent on invalid inputs.
• PR #12629: Fix issue with PyPy on macOS
• PR #10933: Remove "experimental" fontconfig font_manager backend.
• PR #12600: Minor style fixes.
• PR #12570: Fix mathtext tutorial for build with Sphinx 1.8.
• PR #12487: Update docs/tests for the deprecation of aname and label1On/label2On/etc.
• PR #12521: Improve docstring of draw_idle()
• PR #12574: Remove some unused imports
• PR #12568: Add note regarding builds of old Matplotlibs.
• PR #12547: Disable sticky edge accumulation if no autoscaling.
• PR #12546: Avoid quadratic behavior when accumulating stickies.
• PR #11789: endless looping GIFs with PillowWriter
• PR #12525: Fix some flake8 issues
• PR #12516: Don’t handle impossible values for align in hist()
• PR #12500: Adjust the widths of the messages during the build.
• PR #12492: Simplify radar_chart example.
• PR #11984: Strip out pkg-config machinery for agg and libqhull.
• PR #12463: Document Artist.cursor_data() parameter
• PR #12482: Test slider orientation
• PR #12317: Always install mpl_toolkits.
• PR #12246: Be less tolerant of broken installs.
• PR #12477: Use N{MICRO SIGN} instead of N{GREEK SMALL LETTER MU} in EngFormatter.
• PR #12483: Kill FontManager.update_fonts.
• PR #12474: Throw ValueError when irregularly gridded data is passed to streamplot.
• PR #12466: np.fromstring -> np.frombuffer.
• PR #12369: Improved exception handling on animation failure
• PR #12460: Deprecate RendererBase.strip_math.
• PR #12453: Rollback erroneous commit to whats_new.rst from #10746
• PR #12452: Minor updates to the FAQ.
• PR #10746: Adjusted matplotlib.widgets.Slider to have optional vertical orientatation
• PR #12441: Get rid of a signed-compare warning.
• PR #12430: Deprecate Axes3D.plot_surface(shade=None)
• PR #12435: Fix numpydoc parameter formatting
• PR #12434: Clarify documentation for textprops keyword parameter of TextArea
• PR #12427: Document Artist.get_cursor_data
• PR #10322: Use np.hypot whereever possible.
• PR #10809: Fix for scatter not showing points with valid x/y but invalid color
• PR #12423: Minor simplifications to backend_svg.
• PR #10356: fix detecting which artist(s) the mouse is over
• PR #10268: Dvi caching
• PR #10238: Call kpsewhich with more arguments at one time
• PR #10236: Cache kpsewhich results persistently
• PR #4675: Deprecate color keyword argument in scatter
• PR #5054: Diverging norm
• PR #12416: Move font cache rebuild out of exception handler
• PR #4762: Traitlets
• PR #5414: WIP: New FreeType wrappers
• PR #3875: ENH: passing colors (and other optional keyword arguments) to violinplot()
• PR #1959: PS backend optionally jpeg-compresses the embedded images
• PR #11891: Group some print()s in backend_ps.
• PR #12165: Remove deprecated mlab code
• PR #12387: Update HTML animation as slider is dragged
• PR #12333: ENH: add colorbar method to axes
• PR #10088: Deprecate Tick.{gridOn,tick1On,label1On,...} in favor of set_visible.
• PR #12393: Deprecate to-days converters in matplotlib dates
• PR #11232: FIX: fix figure.set_dpi when pixel ratio not 1
• PR #12247: Machinery for deprecating properties.
• PR #12371: Move check for ImageMagick Windows path to bin_path().
• PR #12384: Cleanup axislines style.
• PR #9565: Stem performance boost
• PR #12368: Don’t use stdlib private API in animation.py.
• PR #12351: dviread: find_tex_file: Ensure the encoding on windows
• PR #12372: Remove two examples.
• PR #12356: Fix stripping of CRLF on Windows.
• PR #12283: FIX: errorbar xywhere should return ndarray
• PR #12304: TST: Merge Qt tests into one file.
• PR #12340: Catch test deprecation warnings for mlab.demean
• PR #12296: Make FooConverter inherit from ConversionInterface in examples
• PR #12309: Deduplicate implementations of FooNorm.autoscale{,_None}
- PR #7716: Add ‘truncate’ and ‘join’ methods to colormaps.
- PR #12314: Deprecate axis(‘normal’) in favor of axis(‘auto’).
- PR #12307: Clarify missing-property error message.
- PR #12260: Fix docs: change from issue #12191, remove “if 1:” blocks in examples
- PR #12253: Handle utf-8 output by kpathsea on Windows.
- PR #12292: Modify the bar3d test to show three more angles
- PR #12284: Don’t try to autoscale if no data present to autoscale to
- PR #12255: Deduplicate inherited docstrings.
- PR #12222: Remove extraneous if 1 statements in demo_axisline_style.py
- PR #12137: MAINT: Vectorize bar3d
- PR #12219: Merge OSXInstalledFonts into findSystemFonts.
- PR #12229: Less ACCEP Ts, more numpydoc.
- PR #11621: TST: make E402 a universal flake8 ignore
- PR #12231: CI: Speed up Appveyor repository cloning
- PR #11661: Update blocking_input.py
- PR #12199: Allow disabling specific mouse actions in blocking_input
- PR #12210: Axes.tick_params() argument checking
- PR #12211: Fix typo
- PR #12200: Slightly clarify some invalid shape exceptions for image data.
- PR #12151: Don’t pretend @deprecated applies to classmethods.
- PR #12190: Remove some unused variables and imports
- PR #12192: Exclude examples from lgtm analysis
- PR #12196: Give Carreau the ability to mention the backport bot.
- PR #12171: Remove internal warning due to zsort deprecation
- PR #12030: Speed up canvas redraw for GTK3Agg backend.
- PR #12156: Cleanup the GridSpec demos.
- PR #12144: Add explicit getters and setters for Annotation.anncoords.
- PR #12152: Use _warn_external for deprecations warnings.
- PR #12147: DOC: update the gh_stats code
- PR #12139: Unbreak build re: mplot3d style.
- PR #11367: Raise TypeError on unsupported kwargs of spy()
- PR #9990: Fix and document lightsource argument in mplot3d
- PR #12124: Correctly infer units from emptyy arrays
- PR #11994: Cleanup unused variables and imports
- PR #12122: MNT: re-add chook import art3d
- PR #12086: FIX: make MaxNLocator only follow visible ticks for order of magnitude

6.1. Previous GitHub Stats
• PR #12032: Remove unused imports
• PR #12093: Correct the removal of -Wstrict-prototypes from compiler flags.
• PR #12069: Style fixes for mplot3d.
• PR #11997: Cleanup some axes_grid1 examples
• PR #12098: Improve layout of HTML animation
• PR #12094: Fine-tune logging notes in contributing.rst.
• PR #12079: Clarifications to `im_show()` doc regarding interpolation='none'.
• PR #12068: More style fixes.
• PR #11499: FIX: layout for mixed descent multiline text objects
• PR #11921: FIX: allow reshape 2-D to return a bare 1-d list
• PR #12070: Avoid some uses of np.isscalar.
• PR #12067: DOC: make Line2D docstring definition easier to find
• PR #12054: More style fixes.
• PR #12066: fix indentation in docstring interpolation for spy.
• PR #11931: Remove separate autosummary_inher template.
• PR #12049: Make Poly3DCollection.set_zsort less lenient.
• PR #12050: Various cleanups.
• PR #12038: Modernize ArtistInspector a bit...
• PR #12033: DOC: formatting fixes to mplot3d
• PR #12051: Is bool
• PR #12045: Fix 999.9... edge case in ticker.EngFormatter for negative numbers
• PR #12044: Update doc on the `progressive` and `optimize` keywords in savefig
• PR #12061: Small refactor/simplification.
• PR #12060: INSTALL.rst fixes
• PR #12055: Fix invalid escape in docstring.
• PR #12026: whitespace(-mostly) style cleanup.
• PR #12043: Deprecate get_py2exe_datafiles.
• PR #12046: Make HTMLWriter constructor a bit more strict.
• PR #12034: Doc markup fixes.
• PR #11972: FIX: close mem leak for repeated draw
• PR #12024: Fix typos
• PR #11996: Minor javascript cleanup
• PR #11989: Remove support for ghostscript 8.60.
• PR #12004: Update acorr and xcorr docs to match numpy docs
• PR #11998: No clf() needed after creating a figure
• PR #12001: Do not use an explicit figum in plt.figure(1, ...) in simple cases
• PR #11999: Do not use an explicit fignum plt.figure(1) in simple cases
• PR #11995: Don’t use bare except statements
• PR #11993: DOC: fixed typos
• PR #11992: Use pytest.warns instead of home-baked warnings capture.
• PR #11975: Derive plt.figlegend.__doc__ from Figure.legend.__doc__.
• PR #11980: Remove __version_numpy__; simplify dependencies check.
• PR #11982: Remove and old keyword documentation.
• PR #11981: Some extra typos
• PR #11979: Fix a couple of typos.
• PR #11959: cbook.iterable -> np.iterable.
• PR #11965: Move the removal of the -Wstrict-prototypes flag to setup.py.
• PR #11958: Remove unused code
• PR #11960: Make jpl units a bit less painful to read.
• PR #11951: Improve Artist docstrings
• PR #11954: No need to define _log twice in matplotlib.dates.
• PR #11948: Minor fixes to docs and gitignore.
• PR #11777: Avoid incorrect warning in savefig
• PR #11942: Deprecate Artist.aname and Axes.aname
• PR #11935: Remove ginput demo example
• PR #11939: Improve alias signatures
• PR #11940: Do not use aliases of properties in internal code
• PR #11941: Fix test_large_subscript_title()
• PR #11938: More docstring cleanup of Line2D.
• PR #11920: Add LGTM.com code quality badge
• PR #11922: Improve docstrings of Line2D
• PR #11924: Minor formatting update on alias docstrings
• PR #11926: Minor fix to ginput_demo.
• PR #11912: BLD: update PR template for flake8
• PR #11909: Simplify linestyle and fillstyle reference docs.
• PR #11502: FIX: move title(s) up if subscripts hang too low.
• PR #11906: fix format of bar_of_pie example
• PR #11741: Factor out common code between Patch.draw and FancyArrowPatch.draw.
• PR #11784: Argument checking for grid()
• PR #11888: Factor out a subprocess log-and-check helper.
• PR #11740: Deprecate support for 3rd-party backends without set_hatch_color.
• PR #11884: Deprecate the tk_window_focus function.
• PR #11689: Don’t cache the renderer on the Axes instance.
• PR #11698: For property, use decorator or lambdas.
• PR #11872: Make all builtin cmaps picklable.
• PR #11870: More style fixes.
• PR #11873: Remove mention of deprecated/removed methods from mlab’s docstring.
• PR #11869: Style fixes.
• PR #11874: Remove some remnants of Py2-handling in test_rcparams.
• PR #11865: example file for making a bar of pie chart
• PR #11868: mathtext.py style fixes.
• PR #11854: Accept anything that’s not a directory for $MATPLOTLIBRC.
• PR #11589: WIP ENH secondary axes:
• PR #8449: Including Additional Metadata using the SVG Backend
• PR #11465: ENH: optimize Collection non-affine transform to call transform once

Issues (161):
• #4001: Qt5 Backend: dblclick is always False on ‘mouse_release_event’
• #14152: qt_compat.py performing wrong test for PyQt5
• #10875: Annotation.contains and FancyArrow.contains return incorrect values
• #458: JPG quality keyword in savefig
• #4354: scatter not showing valid x/y points with invalid color
• #14113: scatter could not raise when colors are provided but position data are empty
• #14003: numpydoc 0.9 breaks doc build
• #14054: ticks sometimes disappear when zooming interactively
• #10189: The data decorator does not integrate well with numpydoc
• #14034: pyplot plot raises ValueError when plotting NaN against datetime dates
• #14039: bar plot yerr lines/caps should respect zorder
• #14042: dynamic_image.py + saving animation broken
• #14013: osx backend not usable with ipython/jupyter from conda?
• #13993: Tests files installed by default?
• #13991: MaxNLocator.default_params deprecation may break Cartopy
• #5045: Axes.grid() not honoring specified “zorder” kwarg
• #4371: LaTeX and PGF preambles do not allow commas
• #13982: hist() no longer respects range=... when density=True
• #13963: Dataless colorbars break when updated
• #10381: Issue when setting scatter color in separate method call
• #13618: Minor ticklabels are missing at positions of major ticks.
• #13880: Adding documentation for Text.fontfamily default, set_fontfamily(None)?
• #13865: Appveyor broken
• #8636: plt.hist chooses improper range when using string-based bin options
• #7300: weird mathtext doc markup
• #8862: Replace mathcircled by textcircled
• #13759: DOC: matplotlib.patches.Arc
• #13785: Imshow gives values out of the extent
• #13786: Cannot import matplotlib.animation
• #13561: Progress of animation.save (for long animations)
• #13735: title doesn’t move for ticklables....
• #12175: Example link near markevery in the "What’s new in 3.0" page is malformed/broken
• #13713: Boxplot xlim not correctly calculated
• #11070: Add a “density” kwarg to hist2d
• #11337: Cannot plot fully masked array against datetimes
• #10165: Adapt stem plot
• #10976: ENH: secondary axis for a x or y scale.
• #10763: Cairo in 2.2.0 not working for new backends
• #9737: setupext should not explicitly add /usr/{,local/}include to the include path
• #11217: Crash on zero-length FancyArrow
• #13623: do not cause warning in seaborn
• #13480: Segfault on help('modules') command when matplotlib is installed
• #13604: legend’s framealpha kwarg does not apply when writing to an eps file
• #12311: ‘off’ vs. False bug
• #10237: Setting an alpha value to a Poly3DCollection
• #11781: fill_between interpolation & nan issue
• #1077: 3d plots with aspect='equal'
• #11761: Still naming inconsistency in API on axes limits
• #11623: Regression: "TypeError: Period(‘2000-12-31’, ’D’) is not a string" when a Series with date index was plotted
• #12655: auto-ticks do not handle values near bounds gracefully
• #13487: labellpad is not the spacing between the axis and the label
• #13540: Docs for matplotlib.pyplot.specgram() reference an unsupported mode setting
• #8997: Proposal: Grid arrangement by number of plots
• #6928: Cannot run setup.py build with numpy master
• #12697: Axes are drawn at wrong positions
• #13478: FuncAnimation: interactive zoom/pan with blitting does not work
• #11575: Setting axis ticks in log scale produces duplicate tick labels.
- #13464: `set_rlim(bottom=...)` no longer works
- #12628: Write canonical example of how to use Matplotlib inside a webserver
- #10022: `boxplot`: positions used to take `Int64Index`
- #11647: Disable buttons in `ginput`
- #12987: issues parsing AFM fonts
- #12667: Colorbar ticks....
- #13137: Travis for Python 3.7 sometimes fails due to missing font
- #7969: Stem is slow and will crash if I try to close the window
- #13002: `Hist` color kwarg broken for multiple empty datasets
- #5581: `[mpl_toolkits]` Things drawn on parasite axes don’t fire pick events
- #13417: Secondary axis doesn’t resize properly
- #8120: Inconsistent `inset_axes` position between `show()`, `savefig(format=’png’)` and `savefig(format=’pdf’)`
- #8947: Different result, slower runtime of heatmap between 2.0.0 and 2.0.1
- #13264: Use of logging in matplotlib
- #11602: animation error
- #12925: Python pandas datetime plot xticks in unexpected location
- #11025: `AxesGrid` ticks missing on x-axis
- #10974: Examples not shown in API docs for many methods.
- #13392: `boxplot` broken for empty inputs
- #12345: Need more tests for units and `errorbar`
- #10361: `FigureCanvas.draw()` with `tight_layout ()` needs to be called twice with Matplotlib 2.1.0
- #11376: Temporary styling ignores color cycle
- #11546: `import time`
- #13286: `AttributeError`: ‘float’ object has no attribute ‘deg2rad’
- #11508: bi-directional perceptually flat colormaps in matplotlib?
- #12918: Mac color shows an icon in the dock when using `matplotlib.pyplot`
- #13339: Log Colorbar minorticks_off reverted if ticks set...
- #13228: MPL 3 + Colorbar + PowerNorm bug
- #13096: `Matplotlib.get_backend()`/`matplotlib.use()` cause `NSException` with Anaconda
- #7712: Number of ticks for dates still gives overlapping labels
- #9978: General poor default formatting of datetimes on plot x-axis
- #13253: `imsave` outputs JPEG with wrong dimension
- #11391: Use data argument for scatter plotting timestamps from pandas
- #13145: widgets.RadioButtons: select by closest in position
- #13267: “double-pendulum” example’s speed not correct / varying
• #13257: Allow turning off minorticks for Colorbar with LogNorm?
• #13237: Sankey basic gallery example is not rendered properly.
• #12836: matplotlib.rc_file resets to default template before updating rcparams
• #13186: ax.bar throws when x axis is pandas datetime
• #5397: Expose compression and filter PNG options through savefig
• #13142: Cannot plot bar graph with dates: “TypeError: ufunc subtract cannot use operands with types dtype('<M8[ns]') and dtype('float64')”
• #8530: Feature request: TIFF LZW compression support in savefig()
• #13139: font family ['serif'] not found. Falling back to DejaVu Sans
• #1558: Graceful handling of a numpy matrix
• #12954: Fonts installed in the user directory are not detected (Windows 1809)
• #3644: Feature Request: manually set colorbar without mappable
• #12862: broken_barh appears not to work with datetime/timedelta objects
• #11290: ax.bar doesn’t work correctly when width is a timedelta64 object
• #13156: DOC: matplotlib.pyplot.arrow
• #12990: Unclear error message for plt.xticks(names)
• #12769: Failing to save an animated graph with matplotlib.animation
• #13112: LogNorm colorbar prints double tick labels after set_ticks()
• #13132: BUG: matplotlib.sphinxext.plot_directive uses old function-based API
• #8528: Funcanimation memory leak?
• #8914: line3D set_data only takes in x and y data
• #8768: One one tick in a log-scale axis
• #13121: Tests fail with pytest 4.1
• #13098: Likely incorrect code(?) in colorbar.py
• #12562: Clean up unused imports
• #12106: plt.plot does not plot anything with named arguments
• #5145: Python [Error 17]No usable Temporary file name found
• #13012: qt5agg image quality changes when window is out of focus
• #13055: 127.0.0.1 hardcoded in webagg backend server
• #12971: Pandas Series not supported as data kwarg
• #13022: boxplot not showing symbols with seaborn style sheet
• #13028: Bad rotation_mode/center_baseline combination even if rotation=0
• #12745: Sphinx copy button for code block
• #12801: scatter() should not drop data points at nonfinite coordinates
• #12358: Dropping support for Py3.5 and numpy 1.10
• #12994: Axes range with set_xticks with categoricals
• #12993: Semantics of set_xticks for categoricals
• #12946: ~ in mathrm leads to Unknown symbol: mathrm
• #10704: Add documentation for set_rlim
• #11202: Using of ax.set_ylim() for polar plot leads to “posx and posy should be finite values” error
• #12859: DeprecationWarning: NewId() is deprecated in wxPython.
• #12817: Multiple places where Type Errors on cbook.warn_deprecated will happen
• #12308: #12253 FIX: Handle utf-8 output by kpathsea on Windows – possibly causing issues
• #12804: Usetex produces preamble with one character per line
• #12808: Issue with minor tick spacing in colorbar with custom Normalize class
• #12138: Faces of Axes3d.bar3d are not oriented correctly
• #12591: Adding FancyArrowPatch with datetime coordinates fails
• #11139: “make clean” doesn’t remove all the build doc files
• #11908: Improve linestyle documentation
• #10643: Most warnings calls do not set the stacklevel
• #12532: Incorrect rendering of math symbols
• #11787: Looping gifs with PillowWriter
• #9205: after the animation encoder (e.g. ffmpeg) fails, the animation framework itself fails internally in various ways while trying to report the error
• #11154: Unexpected behavior for Axes3D.plot_surface(shade=None)
• #12121: Documentation of TextArea’s fontprops keyword argument is misleading
• #12191: “if 1:” blocks in examples
• #12107: warnings re: deprecated pytest API with pytest 3.8
• #12010: Popover over plot is very slow
• #12118: Scatter: empty np.arrays with non-numeric dtypes cause TypeError
• #12072: MaxNLocator changes the scientific notation exponent with different number of tick labels
• #11795: Un-align animations created with to_jshtml()? 
• #10201: Available fonts are ignored by font_manager
• #12065: Keyword interpolation behaving improperly while saving to SVG with savefig()
• #11498: Test layout with big descenders and multiple lines inconsistent.
• #11468: Layout managers have problems with titles containing MathText
• #11899: Histogram of list of datetimes
• #11956: apparent memory leak with live plotting
• #11587: Missing filled contours when using contourf
• #11716: errorbar pickling fails when specifying y error bars
• #11557: Hoping add a drawing function ‘patch’ in matplotlib

Previous Github Stats
7.1 List of changes to Matplotlib prior to 2015

This is a list of the changes made to Matplotlib from 2003 to 2015. For more recent changes, please refer to the what’s new or the API changes.

2015-11-16 Levels passed to contour(f) and tricontour(f) must be in increasing order.

2015-10-21 Added TextBox widget

2015-10-21 Added get_ticks_direction()

2015-02-27 Added the rcParam ‘image.composite_image’ to permit users to decide whether they want the vector graphics backends to combine all images within a set of axes into a single composite image. (If images do not get combined, users can open vector graphics files in Adobe Illustrator or Inkscape and edit each image individually.)

2015-02-19 Rewrite of C++ code that calculates contours to add support for corner masking. This is controlled by the ‘corner_mask’ keyword in plotting commands ‘contour’ and ‘contourf’. - IMT

2015-01-23 Text bounding boxes are now computed with advance width rather than ink area. This may result in slightly different placement of text.

2014-10-27 Allowed selection of the backend using the MPLBACKEND environment variable. Added documentation on backend selection methods.

2014-09-27 Overhauled colors.LightSource. Added LightSource.hillshade to allow the independent generation of illumination maps. Added new types of blending for creating more visually appealing shaded relief plots (e.g. blend_mode="overlay", etc, in addition to the legacy "hsv" mode).

2014-06-10 Added Colorbar.remove()

2014-06-07 Fixed bug so radial plots can be saved as ps in py3k.

2014-06-01 Changed the fmt kwarg of errorbar to support the mpl convention that “none” means “don't draw it”, and to default to the empty string, so that plotting of data points is done with the plot() function defaults. Deprecated use of the None object in place “none”.

2014-05-22 Allow the linscale keyword parameter of symlog scale to be smaller than one.

2014-05-20 Added logic to in FontManager to invalidate font-cache if font-family rcparams have changed.
2014-05-16 Fixed the positioning of multi-line text in the PGF backend.

**2014-05-14 Added Axes.add_image() as the standard way to add AxesImage**
instances to Axes. This improves the consistency with add_artist(), add_collection(),
add_contour(), add_line(), add_patch(), and add_table().

**2014-04-27 Improved input clean up in Axes.{h|v}lines** Coerce input into a 1D
ndarrays (after dealing with units).

2014-04-27 removed un-needed cast to float in stem

**2014-04-23 Updated references to “ipython -pylab”** The preferred method for invoking
pylab is now using the “%pylab” magic. -Chris G.

**2014-04-22 Added (re-)generate a simple automatic legend to “Figure Options”**
dialog of the Qt4Agg backend.

**2014-04-22 Added an example showing the difference between** interpolation = ‘none’
and interpolation = ‘nearest’ in imshow() when saving vector graphics files.

**2014-04-22 Added violin plotting functions.** See Axes.violinplot, Axes.violin,
cbook.violin_stats and mlab.GaussianKDE for details.

**2014-04-10 Fixed the triangular marker rendering error.** The “Up” triangle was
rendered instead of “Right” triangle and vice-versa.

**2014-04-08 Fixed a bug in parasite_axes.py by making a list out** of a generator at line
263.

**2014-04-02 Added clipon=False to patch creation of wedges and shadows in pie.**

**2014-02-25 In backend_qt4agg changed from using update -> repaint under**
windows. See comment in source near self._priv_update for longer explanation.

**2014-03-27 Added tests for pie ccw parameter.** Removed pdf and svg images from
tests for pie linewidth parameter.

**2014-03-24 Changed the behaviour of axes to not ignore leading or trailing** patches
of height 0 (or width 0) while calculating the x and y axis limits. Patches having both
height == 0 and width == 0 are ignored.

**2014-03-24 Added bool kwarg (manage_xticks) to boxplot to enable/disable** the
managemnet of the xlimits and ticks when making a boxplot. Default in True which
maintains current behavior by default.

**2014-03-23 Fixed a bug in projections/polar.py by making sure that the theta** value
being calculated when given the mouse coordinates stays within the range of 0 and 2 *
pi.

**2014-03-22 Added the keyword arguments wedgeprops and textprops to pie.** Users
can control the wedge and text properties of the pie in more detail, if they choose.

**2014-03-17 Bug was fixed in append_axes from the AxesDivider class would not**
append axes in the right location with respect to the reference locator axes

2014-03-13 Add parameter ‘clockwise’ to function pie, True by default.

2014-02-28 Added ‘origin’ kwarg to spy

**2014-02-27 Implemented separate horizontal/vertical axes padding to the**
ImageGrid in the AxesGrid toolkit
2014-02-27 Allow mark every property of matplotlib.lines.Line2D to be an int numpy fancy index, slice object, or float. The float behaviour turns on markers at approximately equal display-coordinate-distances along the line.

2014-02-25 In backend_qt4agg changed from using update -> repaint under windows. See comment in source near self._priv_update for longer explanation.

2014-01-02 triplot now returns the artist it adds and support of line and marker kwargs has been improved. GBY

2013-12-30 Made streamplot grid size consistent for different types of density argument. A 30x30 grid is now used for both density=1 and density=(1, 1).

2013-12-03 Added a pure boxplot-drawing method that allow a more complete customization of boxplots. It takes a list of dicts contains stats. Also created a function (cbook.boxplot_stats) that generates the stats needed.

2013-11-28 Added qhull extension module to perform Delaunay triangulation more robustly than before. It is used by tri.Triangulation (and hence all pyplot.tri* methods) and mlab.griddata. Deprecated matplotlib.delaunay module. - IMT

2013-11-05 Add power-law normalization method. This is useful for, e.g., showing small populations in a "hist2d" histogram.

2013-10-27 Added get_rlabel_position and set_rlabel_position methods to PolarAxes to control angular position of radial tick labels.

2013-10-06 Add stride-based functions to mlab for easy creation of 2D arrays with less memory.

2013-10-06 Improve window and detrend functions in mlab, particular support for 2D arrays.

2013-10-06 Improve performance of all spectrum-related mlab functions and plots.

2013-10-06 Added support for magnitude, phase, and angle spectrums to axes.specgram, and support for magnitude, phase, angle, and complex spectrums to mlab-specgram.

2013-10-06 Added magnitude_spectrum, angle_spectrum, and phase_spectrum plots, as well as magnitude_spectrum, angle_spectrum, phase_spectrum, and complex_spectrum functions to mlab

2013-07-12 Added support for datetime axes to 2d plots. Axis values are passed through Axes.convert_xunits/Axes.convert_yunits before being used by contour/contourf, pcolormesh and pcolor.

2013-07-12 Allowed matplotlib.dates.date2num, matplotlib.dates.num2date, and matplotlib.dates.datestr2num to accept n-d inputs. Also factored in support for n-d arrays to matplotlib.dates.DateConverter and matplotlib.units.Registry.

2013-06-26 Refactored the axes module: the axes module is now a folder, containing the following submodule:

- _subplots.py, containing all the subplots helper methods
- _base.py, containing several private methods and a new _AxesBase class. This _AxesBase class contains all the methods that are not directly linked to plots of the "old" Axes
- _axes.py contains the Axes class. This class now inherits from _AxesBase: it contains all "plotting" methods and labelling methods.
This refactoring should not affect the API. Only private methods are not importable from the axes module anymore.

**2013-05-18 Added support for arbitrary rasterization resolutions to the SVG backend.** Previously the resolution was hard coded to 72 dpi. Now the backend class takes a `image_dpi` argument for its constructor, adjusts the image bounding box accordingly and forwards a magnification factor to the image renderer. The code and results now resemble those of the PDF backend. - MW

**2013-05-08 Changed behavior of `hist` when given `stacked=True` and `normed=True`.** Histograms are now stacked first, then the sum is normalized. Previously, each histogram was normalized, then they were stacked.

2013-04-25 Changed all instances of:
```python
from matplotlib import MatplotlibDeprecationWarning as mplDeprecation to:
from cbook import mplDeprecation
```
and removed the import into the matplotlib namespace in `__init__.py` Thomas Caswell

**2013-04-15 Added `axes.xmargin` and `axes.ymargin` to `rcParams` to set default margins on auto-scaling.** - TAC

2013-04-16 Added patheffect support for Line2D objects. -JJL

**2013-03-31 Added support for arbitrary unstructured user-specified triangulations to `Axes3D.tricontourf`** - Damon McDougall

**2013-03-19 Added support for passing `linestyle` kwarg to `step` so all `plot` kwargs are passed to the underlying `plot` call.** - TAC

**2013-02-25 Added classes `CubicTriInterpolator`, `UniformTriRefiner`, `TriAnalyzer` to `matplotlib.tri` module.** - GBy

**2013-01-23 Add `savefig.directory` to `rcParams` to remember and fill in the last directory saved to for figure save dialogs** - Martin Spacek

**2013-01-13 Add `eventplot` method to `axes` and `pyplot` and `EventCollection` class to `collections`.**

**2013-01-08 Added two extra titles to `axes` which are flush with the left and right edges of the plot respectively.** Andrew Dawson

2013-01-07 Add `framealpha` keyword argument to `legend` - PO

2013-01-16 Till Stensitzki added a baseline feature to `stackplot`

**2012-12-22 Added classes for interpolation within triangular grids (LinearTriInterpolator) and to find the triangles in which points lie (TrapezoidMapTriFinder) to `matplotlib.tri` module.** - IMT

**2012-12-05 Added `MatplotlibDeprecationWarning` class for signaling deprecation.** Matplotlib developers can use this class as follows:
```python
from matplotlib import MatplotlibDeprecationWarning as mplDeprecation
```
In light of the fact that Python builtin `DeprecationWarning` are ignored by default as of Python 2.7, this class was put in to allow for the signaling of deprecation, but via `UserWarning` which are not ignored by default. - PI
2012-11-27 Added the mtext parameter for supplying matplotlib.text.Text instances to RendererBase.draw_text and RendererBase.draw_text. This allows backends to utilize additional text attributes, like the alignment of text elements. - pwuertz

2012-11-26 deprecate matplotlib/mpl.py, which was used only in pylab.py and is now replaced by the more suitable import matplotlib as mpl. - PI

2012-11-25 Make rc_context available via pyplot interface - PI

2012-11-16 plt.set_cmap no longer throws errors if there is not already an active colorable artist, such as an image, and just sets up the colormap to use from that point forward. - PI

2012-11-16 Added the function _get_rgba_face, which is identical to _get_rgb_face except it return a (r,g,b,a) tuble, to line2D. Modified Line2D.draw to use get_rgbga_face to get the markerface color so that any alpha set by markerfacecolor will respected. - Thomas Caswell

2012-11-13 Add a symmetric log normalization class to colors.py. Also added some tests for the normalization class. Till Stensitzki

2012-11-12 Make axes.stem take at least one argument. Uses a default range(n) when the first arg not provided. Damon McDougall

2012-11-09 Make plt.subplot() without arguments act as subplot(111) - PI

2012-11-08 Replaced plt.figure and plt.subplot calls by the newer, more convenient single call to plt.subplots() in the documentation examples - PI

2012-10-05 Add support for saving animations as animated GIFs. - JVDP

2012-08-11 Fix path-closing bug in patches.Polygon, so that regardless of whether the path is the initial one or was subsequently set by set_xy(), get_xy() will return a closed path if and only if get_closed() is True. Thanks to Jacob Vanderplas. - EF

2012-08-05 When a norm is passed to contourf, either or both of the vmin, vmax attributes of that norm are now respected. Formerly they were respected only if both were specified. In addition, vmin and/or vmax can now be passed to contourf directly as kwargs. - EF

2012-07-24 Contourf handles the extend kwarg by mapping the extended ranges outside the normed 0-1 range so that they are handled by colormap colors determined by the set_under and set_over methods. Previously the extended ranges were mapped to 0 or 1 so that the “under” and “over” colormap colors were ignored. This change also increases slightly the color contrast for a given set of contour levels. - EF

2012-06-24 Make use of mathtext in tick labels configurable - DSD

2012-06-05 Images loaded through PIL are now ordered correctly - CG

2012-06-02 Add new Axes method and pyplot function, hist2d. - PO

2012-05-31 Remove support for ‘cairo.<format>’ style of backend specification. Deprecate ‘cairo.format’ and ‘savefig.extension’ rcParams and replace with ‘savefig.format’. - Martin Spacek

2012-05-29 pcolormesh now obeys the passed in “edgecolor” kwarg. To support this, the “shading” argument to pcolormesh now only takes “flat” or “gouraud”. To achieve the old “faceted” behavior, pass “edgecolors='k'” - MGD

2012-05-22 Added radius kwarg to pie charts. - HH
2012-05-22 Collections now have a setting “offset_position” to select whether the offsets are given in “screen” coordinates (default, following the old behavior) or “data” coordinates. This is currently used internally to improve the performance of hexbin. As a result, the “draw_path_collection” backend methods have grown a new argument “offset_position”. - MGD

2012-05-04 Add a new argument to pie charts - startingangle - that allows one to specify the angle offset for the first wedge of the chart. - EP

2012-05-03 symlog scale now obeys the logarithmic base. Previously, it was completely ignored and always treated as base e. - MGD

2012-05-03 Allow linscale/x/y keyword to symlog scale that allows the size of the linear portion relative to the logarithmic portion to be adjusted. - MGD

2012-04-14 Added new plot style: stackplot. This new feature supports stacked area plots. - Damon McDougall

2012-04-06 When path clipping changes a LINETO to a MOVETO, it also changes any CLOSEPOLY command to a LINETO to the initial point. This fixes a problem with pdf and svg where the CLOSEPOLY would then draw a line to the latest MOVETO position instead of the intended initial position. - JKS

2012-03-27 Add support to ImageGrid for placing colorbars only at one edge of each column/row. - RMM

2012-03-07 Refactor movie writing into useful classes that make use of pipes to write image data to ffmpeg or mencoder. Also improve settings for these and the ability to pass custom options. - RMM

2012-02-29 errorevery keyword added to errorbar to enable errorbar subsampling. fixes issue #600.

2012-02-28 Added plot_trisurf to the mplot3d toolkit. This supports plotting three dimensional surfaces on an irregular grid. - Damon McDougall

2012-01-23 The radius labels in polar plots no longer use a fixed padding, but use a different alignment depending on the quadrant they are in. This fixes numerical problems when (rmax - rmin) gets too small. - MGD

2012-01-08 Add axes.streamplot to plot streamlines of a velocity field. Adapted from Tom Flannaghan streamplot implementation. - TSY

2011-12-29 ps and pdf markers are now stroked only if the line width is nonzero for consistency with agg, fixes issue #621. - JKS

2011-12-27 Work around an EINTR bug in some versions of subprocess. - JKS

2011-10-25 added support for operatorname to mathtext, including the ability to insert spaces, such as $operatorname{arg,max}$ - PI

2011-08-18 Change api of Axes.get_tightbbox and add an optional keyword parameter call_axes_locator. - JYL

2011-07-29 A new rcParam “axes.formatter.use_locale” was added, that, when True, will use the current locale to format tick labels. This means that, for example, in the fr_FR locale, ’,’ will be used as a decimal separator. - MGD

2011-07-15 The set of markers available in the plot() and scatter() commands has been unified. In general, this gives more options to both than were previously available, however, there is one backward-incompatible change to the markers in scatter:
“d” used to mean “diamond”, it now means “narrow diamond”. “D” can be used for a “diamond”.

-MGD

2011-07-13 Fix numerical problems in symlog scale, particularly when linthresh <= 1.0. Symlog plots may look different if one was depending on the old broken behavior. - MGD

2011-07-10 Fixed argument handling error in tripcolor/triplot/tricontour, issue #203. - IMT

2011-07-08 Many functions added to mplot3d.axes3d to bring Axes3D objects more feature-parity with regular Axes objects. Significant revisions to the documentation as well. - BVR

2011-07-07 Added compatibility with IPython strategy for picking a version of Qt4 support, and an rcParam for making the choice explicitly: backend.qt4. - EF

2011-07-07 Modified AutoMinorLocator to improve automatic choice of the number of minor intervals per major interval, and to allow one to specify this number via a kwarg. - EF

2011-06-28 3D versions of scatter, plot, plot_wireframe, plot_surface, bar3d, and some other functions now support empty inputs. - BVR

2011-06-22 Add set_theta_offset, set_theta_direction and set_theta_zero_location to polar axes to control the location of 0 and directionality of theta. - MGD

2011-06-22 Add axes.labelweight parameter to set font weight to axis labels - MGD.

2011-06-20 Add pause function to pyplot. - EF

2011-06-16 Added bottom keyword parameter for the stem command. Also, implemented a legend handler for the stem plot. - JJL

2011-06-16 Added legend.frameon rcParams. - Mike Kaufman

2011-05-31 Made backend_qt4 compatible with PySide. - Gerald Storer

2011-04-17 Disable keyboard auto-repeat in qt4 backend by ignoring key events resulting from auto-repeat. This makes constrained zoom/pan work. - EF

2011-04-14 interpolation=“nearest” always interpolate images. A new mode “none” is introduced for no interpolation. - JJL

2011-04-03 Fixed broken pick interface to AsteriskCollection objects used by scatter. - EF

2011-04-01 The plot directive Sphinx extension now supports all of the features in the Numpy fork of that extension. These include doctest formatting, an ‘include-source’ option, and a number of new configuration options. - MGD

2011-03-29 Wrapped ViewVCCachedServer definition in a factory function. This class now inherits from urllib2.HTTPSHandler in order to fetch data from github, but HTTPSHandler is not defined if python was built without SSL support. - DSD

2011-03-10 Update pytz version to 2011c, thanks to Simon Cross. - JKS

2011-03-06 Add standalone tests.py test runner script. - JKS

2011-03-06 Set edgecolor to ‘face’ for scatter asterisk-type symbols; this fixes a bug in which these symbols were not responding to the c kwarg. The symbols have no face area, so only the edgecolor is visible. - EF
2011-02-27 Support libpng version 1.5.x; suggestion by Michael Albert. Changed installation specification to a minimum of libpng version 1.2. - EF

2011-02-20 clabel accepts a callable as an fmt kwarg; modified patch by Daniel Hyams. - EF

2011-02-18 scatter([],[]) is now valid. Also fixed issues with empty collections - BVR

2011-02-07 Quick workaround for dviread bug #3175113 - JKS

2011-02-05 Add cbook memory monitoring for Windows, using tasklist. - EF

2011-02-05 Speed up Normalize and LogNorm by using in-place operations and by using float32 for float32 inputs and for ints of 2 bytes or shorter; based on patch by Christoph Gohlke. - EF

2011-02-04 Changed imshow to use rgba as uint8 from start to finish, instead of going through an intermediate step as double precision; thanks to Christoph Gohlke. - EF

2011-01-13 Added zdir and offset arguments to contourf3d to bring contourf3d in feature parity with contour3d. - BVR

2011-01-04 Tag 1.0.1 for release at r8896

2011-01-03 Added display of ticker offset to 3d plots. - BVR

2011-01-03 Turn off tick labeling on interior subplots for pyplots.subplots when sharex/sharey is True. - JDH

2010-12-29 Implement axes_divider:HBox and VBox. -JJL

2010-11-22 Fixed error with Hammer projection. - BVR

2010-11-12 Fixed the placement and angle of axis labels in 3D plots. - BVR

2010-11-07 New rc parameters examples.download and examples.directory allow bypassing the download mechanism in get_sample_data. - JKS

2010-10-04 Fix JPEG saving bug: only accept the kwargs documented by PIL for JPEG files. - JKS

2010-09-15 Remove unused _wxagg extension and numerix.h. - EF

2010-08-25 Add new framework for doing animations with examples.- RM

2010-08-21 Change Axis.set_view_interval() so that when updating an existing interval, it respects the orientation of that interval, and can enlarge but not reduce the interval. This fixes a bug in which Axis.set_ticks would change the view limits of an inverted axis. Whether set_ticks should be affecting the viewLim at all remains an open question. - EF

2010-08-16 Handle NaN's correctly in path analysis routines. Fixes a bug where the best location for a legend was not calculated correctly when the line contains NaNs. - MGD

2010-08-14 Fix bug in patch alpha handling, and in bar color kwarg - EF

2010-08-12 Removed all traces of numerix module after 17 months of deprecation warnings. - EF
2010-08-05 Added keyword arguments 'thetaunits' and 'runits' for polar plots.
   Fixed PolarAxes so that when it set default Formatters, it marked them as such.
   Fixed semilogx and semilogy to no longer blindly reset the ticker information on the
   non-log axis. Axes.arrow can now accept unitized data. - JRE

2010-08-03 Add support for MPLSETUPCFG variable for custom setup.cfg filename.
   Used by sage buildbot to build an mpl w/ no gui support - JDH

2010-08-01 Create directory specified by MPLCONFIGDIR if it does not exist. - ADS

2010-07-20 Return Qt4’s default cursor when leaving the canvas - DSD

2010-07-06 Tagging for mpl 1.0 at r8502

2010-07-05 Added Ben Root’s patch to put 3D plots in arbitrary axes, allowing you to
   mix 3d and 2d in different axes/subplots or to have multiple 3D plots in one figure. See
   examples/mplot3d/subplot3d_demo.py - JDH

2010-07-05 Preferred kwarg names in set_xlim are now ‘left’ and ‘right’; in set_ylim,
   ‘bottom’ and ‘top’; original kwargs are still accepted without complaint. - EF

2010-07-05 TkAgg and FltkAgg backends are now consistent with other interactive
   backends: when used in scripts from the command line (not from ipython -pylab), show
   blocks, and can be called more than once. - EF

2010-07-02 Modified CXX_WrapPython.h to fix “swab bug” on solaris so mpl can
   compile on Solaris with CXX6 in the trunk. Closes tracker bug 3022815 - JDH

2010-06-30 Added autoscale convenience method and corresponding pyplot function
   for simplified control of autoscaling; and changed axis, set_xlim, and set_ylim so that by
   default, they turn off the autoscaling on the relevant axis or axes. Therefore one can call
   set_xlim before plotting a line, for example, and the limits will be retained. - EF

2010-06-20 Added Axes.tick_params and corresponding pyplot function to control
   tick and tick label appearance after an Axes has been created. - EF

2010-06-09 Allow Axes.grid to control minor gridlines; allow Axes.grid and Axis.grid
   to control major and minor gridlines in the same method call. - EF

2010-06-06 Change the way we do split/dividend adjustments in finance.py to handle
   dividends and fix the zero division bug reported in sf bug 2949906 and 2123566. Note
   that volume is not adjusted because the Yahoo CSV does not distinguish between share
   split and dividend adjustments making it near impossible to get volume adjustment
   right (unless we want to guess based on the size of the adjustment or scrape the html
   tables, which we don’t) - JDH

2010-06-06 Updated dateutil to 1.5 and pytz to 2010h.

2010-06-02 Add error_kw kwarg to Axes.bar(). - EF

2010-06-01 Fix pcolormesh() and QuadMesh to pass on kwargs as appropriate. - RM

2010-05-18 Merge mpl_toolkits.gridspec into the main tree. - JJJL

2010-05-04 Improve backend_qt4 so it displays figures with the correct size - DSD

2010-04-20 Added generic support for connecting to a timer for events. This adds
   TimerBase, TimerGTK, TimerQT, TimerWx, and TimerTk to the backends and a
   new_timer() method to each backend’s canvas to allow ease of creating a new timer. - RM

2010-04-20 Added margins() Axes method and pyplot function. - EF

2010-04-18 update the axes_grid documentation. - JJJL
2010-04-18 Control MaxNLocator parameters after instantiation, and Axes.locator_params method, with corresponding pyplot function. -EF

2010-04-18 Control ScalarFormatter offsets directly and via the Axes.ticklabel_format() method, and add that to pyplot. -EF

2010-04-16 Add a close_event to the backends. -RM

2010-04-06 modify axes_grid examples to use axes_grid1 and axisartist. -JJL

2010-04-06 rebase axes_grid using axes_grid1 and axisartist modules. -JJL

2010-04-06 axes_grid toolkit is splitted into two separate modules, axes_grid1 and axisartist. -JJL

2010-04-05 Speed up import: import pytz only if and when it is needed. It is not needed if the rc timezone is UTC. -EF

2010-04-03 Added color kwarg to Axes.hist(), based on work by Jeff Klukas. -EF

2010-03-24 refactor colorbar code so that no cla() is necessary when mappable is changed. -JJL

2010-03-22 fix incorrect rubber band during the zoom mode when mouse leaves the axes. -JJL

2010-03-21 x/y key during the zoom mode only changes the x/y limits. -JJL

2010-03-20 Added pyplot.sca() function suggested by JJL. -EF

2010-03-20 Added conditional support for new Tooltip API in gtk backend. -EF

2010-03-20 Changed plt.fig_subplot() to plt.subplots() after discussion on list, and changed its API to return axes as a numpy object array (with control of dimensions via squeeze keyword). FP

2010-03-13 Manually brought in commits from branch:

```
---
| r8191 | leejoon | 2010-03-13 17:27:57 -0500 (Sat, 13 Mar 2010) | 1 line |
---
fix the bug that handles for scatter are incorrectly set when dpi!=72. Thanks to Ray Speth for the bug report.
---
```

2010-03-03 Manually brought in commits from branch via diff/patch (svnmerge is broken):

```
---
| r8175 | leejoon | 2010-03-03 10:03:30 -0800 (Wed, 03 Mar 2010) | 1 line |
---
fix arguments of allow_rasterization.draw_wrapper
---
| r8174 | jdh2358 | 2010-03-03 09:15:58 -0800 (Wed, 03 Mar 2010) | 1 line |
---
added support for favicon in docs build
---
| r8173 | jdh2358 | 2010-03-03 08:56:16 -0800 (Wed, 03 Mar 2010) | 1 line |
---
applied Mattias get_bounds patch
---
| r8172 | jdh2358 | 2010-03-03 08:31:42 -0800 (Wed, 03 Mar 2010) | 1 line |
```

(continues on next page)
2010-02-25 add annotation_demo3.py that demonstrates new functionality. -JJK

2010-02-25 refactor Annotation to support arbitrary Transform as xycoords or textcoords. Also, if a tuple of two coordinates is provided, they are interpreted as coordinates for each x and y position. -JJK

2010-02-24 Added pyplot.fig_subplot(), to create a figure and a group of subplots in a single call. This offers an easier pattern than manually making figures and calling add_subplot() multiple times. FP

2010-02-17 Added Gokhan’s and Mattias’ customizable keybindings patch for the toolbar. You can now set the keymap.* properties in the matplotlibrc file. Newbindings were added for toggling log scaling on the x-axis. JDH

2010-02-16 Committed TJ’s filled marker patch for left|right|bottom|top|full filled markers. See examples/pylab_examples/filledmarker_demo.py. JDH

2010-02-11 Added ‘bootstrap’ option to boxplot. This allows bootstrap estimates of median confidence intervals. Based on an initial patch by Paul Hobson. -ADS

2010-02-06 Added setup.cfg “basedirlist” option to override setting in setupext.py “basedir” dictionary; added “gnu0” platform requested by Benjamin Drung. -EF

2010-02-03 Made plot_directive use a custom PlotWarning category, so that warnings can be turned into fatal errors easily if desired. -FP

2010-01-29 Added draggable method to Legend to allow mouse drag placement. Thanks Adam Fraser. JDH

2010-01-25 Fixed a bug reported by Olle Engdegard, when using histograms with stepfilled and log=True - MM

2010-01-16 Upgraded CXX to 6.1.1 - JDH

2009-01-16 Don’t create minor ticks on top of existing major ticks. Patch by Neil Crighton. -ADS

2009-01-16 Ensure three minor ticks always drawn (SF# 2924245). Patch by Neil Crighton. -ADS

2010-01-16 Applied patch by Ian Thomas to fix two contouring problems: now contour handles interior masked regions, and the boundaries of line and filled contours coincide. - EF

2009-01-11 The color of legend patch follows the rc parameters axes.facecolor and axes.edgecolor. -JJK

2009-01-11 adjustable of Axes can be “box-forced” which allow sharing axes. -JJK

2009-01-11 Add add_click and pop_click methods in BlockingContourLabeler. -JJK

2010-01-03 Added rcParams[‘axes.color_cycle’] - EF

2010-01-03 Added Pierre’s qt4 formlayout editor and toolbar button - JDH

2009-12-31 Add support for using math text as marker symbols (Thanks to tcb)
2009-12-31 Commit a workaround for a regression in PyQt4-4.6.0,1 - DSD
2009-12-22 Fix cmap data for gist_earth_r, etc. - JJL

2009-12-20 spines: put spines in data coordinates, add set_bounds() call. - ADS

2009-12-18 Don’t limit notch size in boxplot to q1-q3 range, as this is effectively making the data look better than it is. - ADS

2009-12-18 mlab.prctile handles even-length data, such that the median is the mean of the two middle values. - ADS

2009-12-15 Add raw-image (unsampled) support for the ps backend. - JJL

2009-12-14 Add patch_artist kwarg to boxplot, but keep old default. Convert boxplot_demo2.py to use the new patch_artist. - ADS

2009-12-06 axes_grid: reimplemented AxisArtist with FloatingAxes support. Added new examples. - JJL

2009-12-01 Applied Laurent Dufrechou’s patch to improve blitting with the qt4 backend - DSD

2009-11-13 The pdf backend now allows changing the contents of a pdf file’s information dictionary via PdfPages.infodict. - JKS

2009-11-12 font_manager.py should no longer cause EINTR on Python 2.6 (but will on the 2.5 version of subprocess). Also the fc-list command in that file was fixed so now it should actually find the list of fontconfig fonts. - JKS

2009-11-10 Single images, and all images in renderers with option image_nocomposite (i.e. agg, macosx and the svg backend when rc-Params[‘svg.image_noscale’] is True), are now drawn respecting the zorder relative to other artists. (Note that there may now be inconsistencies across backends when more than one image is drawn at varying zorders, but this change introduces correct behavior for the backends in which it’s easy to do so.)

2009-10-21 Make AutoDateLocatormore configurable by adding options to control the maximum and minimum number of ticks. Also add control of the intervals to be used for ticking. This does not change behavior but opens previously hard-coded behavior to runtime modification’. - RMM

2009-10-19 Add “path_effects” support for Text and Patch. See examples/pylab_examples/patheffect_demo.py - JJL

2009-10-19 Add “use_clabeltext” option to clabel. If True, clabels will be created with ClabelText class, which recalculates rotation angle of the label during the drawing time. - JJL

2009-10-16 Make AutoDateFormatter actually use any specified timezone setting. This was only working correctly when no timezone was specified. - RMM

2009-09-27 Beginnings of a capability to test the pdf backend. - JKS

2009-09-27 Add a savefig.extension rcparam to control the default filename extension used by savefig. - JKS

2009-09-21 Tagged for release 0.99.1

2009-09-20 Fix usetex spacing errors in pdf backend. - JKS
2009-09-20 Add Sphinx extension to highlight IPython console sessions, originally authored (I think) by Michael Droetboom. - FP

2009-09-20 Fix off-by-one error in dviread.Tfm, and additionally protect against exceptions in case a dvi font is missing some metrics. - JKS

2009-09-15 Implement draw_text and draw_tex method of backend base using the textpath module. Implement draw_tex method of the svg backend. - JKL

2009-09-15 Don’t fail on AFM files containing floating-point bounding boxes - JKS

2009-09-13 AxesGrid [add modified version of colorbar. Add colorbar] location howto. - JKL

2009-09-07 AxesGrid [implemented axisline style.] Added a demo examples/axes_grid/demo_axisline_style.py- JKL

2009-09-04 Make the textpath class as a separate moduel (textpath.py). Add support for mathtext and tex.- JKL

2009-09-01 Added support for Gouraud interpolated triangles. pcolormesh now accepts shading='gouraud' as an option. - MGD

2009-08-29 Added matplotlib.testing package, which contains a Nose plugin and a decorator that lets tests be marked as KnownFailures - ADS

2009-08-20 Added scaled dict to AutoDateFormatter for customized scales - JKH

2009-08-15 Pyplot interface: the current image is now tracked at the figure and axes level, addressing tracker item 1656374. - EF

2009-08-15 Docstrings are now manipulated with decorators defined in a new module, docstring.py, thanks to Jason Coombs. - EF

2009-08-14 Add support for image filtering for agg back end. See the example demo_agg_filter.py. - JKL

2009-08-09 AnnotationBbox added. Similar to Annotation, but works with OffsetBox instead of Text. See the example demo_annotation_box.py. - JKL

2009-08-07 BboxImage implemented. Two examples, demo_bboximage.py and demo_ribbon_box.py added. - JKL

2009-08-07 In an effort to simplify the backend API, all clipping rectangles and paths are now passed in using GraphicsContext objects, even on collections and images. Therefore:

```python
draw_path_collection(self, master_transform, cliprect, clippath,
    clippath_trans, paths, all_transforms, offsets, offsetTrans, facecolors,
    edgecolors, linewidths, linestyles, antialiaseds, urls)
```

becomes:

```python
draw_path_collection(self, gc, master_transform, paths, all_transforms,
    offsets, offsetTrans, facecolors, edgecolors, linewidths, linestyles, an-
    tialiaseds, urls)
```

```python
draw_quad_mesh(self, master_transform, cliprect, clippath,
    clippath_trans, meshWidth, meshHeight, coordinates, offsets, offsetTrans,
    facecolors, antialiased, showedges)
```

becomes:

```python
draw_quad_mesh(self, gc, master_transform, meshWidth, meshHeight,
    coordinates, offsets, offsetTrans, facecolors, antialiased, showedges)
```
Matplotlib, Release 3.1.1

draw_image(self, x, y, im, bbox, clippath=None, clippath_trans=None)
becomes:
draw_image(self, gc, x, y, im)

- MGD

2009-08-06 Tagging the 0.99.0 release at svn r7397 - JDH
- fixed an alpha colormapping bug posted on sf 2832575
- fix typo in axes_divider.py. use nanmin, nanmax in angle_helper.py (patch by Christoph Gohlke)
- remove dup gui event in enter/leave events in gtk
- lots of fixes for os x binaries (Thanks Russell Owen)
- attach gtk events to mpl events – fixes sf bug 2816580
- applied sf patch 2815064 (middle button events for wx) and patch 2818092 (resize events for wx)
- fixed boilerplate.py so it doesn’t break the ReST docs.
- removed a couple of cases of mlab.load
- fixed rec2csv win32 file handle bug from sf patch 2831018
- added two examples from Josh Hemann: examples/pylab_examples/barchart_demo2.py and examples/pylab_examples/boxplot_demo2.py
- handled sf bugs 2831556 and 2830525; better bar error messages and backend driver configs
- added miktex win32 patch from sf patch 2820194
- apply sf patches 2830233 and 2823885 for osx setup and 64 bit; thanks Michiel

2009-08-04 Made cbook.get_sample_data make use of the ETag and Last-Modified
headers of mod_dav_svn. - JKS

2009-08-03 Add PathCollection; modify contourf to use complex
paths instead of simple paths with cuts. - EF

2009-08-03 Fixed boilerplate.py so it doesn’t break the ReST docs. - JKS

2009-08-03 pylab no longer provides a load and save function. These are available in
matplotlib.mlab, or you can use numpy.loadtxt and numpy.savetxt for text files, or np.save
and np.load for binary numpy arrays. - JDH

2009-07-31 Added cbook.get_sample_data for urllib enabled fetching and
cacheing of data needed for examples. See examples/misc/sample_data_demo.py - JDH

2009-07-31 Tagging 0.99.0.rc1 at 7314 - MGD

2009-07-30 Add set_cmap and register_cmap, and improve get_cmap, to provide convenient handling of user-generated colormaps. Reorganized _cm and cm modules. - EF

2009-07-28 Quiver speed improved, thanks to tip by Ray Speth. -EF

2009-07-27 Simplify argument handling code for plot method. -EF

2009-07-25 Allow "plot(1, 2, 'r*')" to work. -EF
2009-07-22 Added an ‘interp’ keyword to griddata so the faster linear interpolation method can be chosen. Default is ‘nn’, so default behavior (using natural neighbor method) is unchanged (JSW)

2009-07-22 Improved boilerplate.py so that it generates the correct signatures for pyplot functions. - JKS

2009-07-19 Fixed the docstring of Axes.step to reflect the correct meaning of the kwargs “pre” and “post” - See SF bug https://sourceforge.net/tracker/index.php?func=detail&aid=2823304&group_id=80706&atid=560720 - JDH

2009-07-18 Fix support for hatches without color fills to pdf and svg backends. Add an example of that to hatch_demo.py. - JKS

2009-07-17 Removed fossils from swig version of agg backend. - EF

2009-07-14 initial submission of the annotation guide. - JJJL

2009-07-14 axes_grid [minor improvements in anchored_artists and] inset locator. - JJJL

2009-07-14 Fix a few bugs in ConnectionStyle algorithms. Add ConnectionPatch class. - JJJL

2009-07-11 Added a fillstyle Line2D property for half filled markers - see examples/pylab_examples/fillstyle_demo.py JDH

2009-07-08 Attempt to improve performance of qt4 backend, do not call qApp.processEvents while processing an event. Thanks Ole Streicher for tracking this down - DSD

2009-06-24 Add withheader option to mlab.rec2csv and changed use_mrecords default to False in mlab.csv2rec since this is partially broken - JDH

2009-06-24 backend_agg.draw_marker quantizes the main path (as in the draw_path). - JJJL

2009-06-24 axes_grid: floating axis support added. - JJJL

2009-06-14 Add new command line options to backend_driver.py to support running only some directories of tests - JKS

2009-06-13 partial cleanup of mlab and its importation in pylab - EF

2009-06-13 Introduce a rotation_mode property for the Text artist. See examples/pylab_examples/demo_text_rotation_mode.py - JJJL

2009-06-07 add support for bz2 files per sf support request 2794556 - JDH

2009-06-06 added a properties method to the artist and inspector to return a dict mapping property name -> value; see sf feature request 2792183 - JDH

2009-06-06 added Neil’s auto minor tick patch; sf patch #2789713 - JDH

2009-06-06 do not apply alpha to rgba color conversion if input is already rgba - JDH

2009-06-03 axes_grid [Initial check-in of curvilinear grid support. See] examples/axes_grid/demo_curvilinear_grid.py - JJJL

2009-06-01 Add set_color method to Patch - EF

2009-06-01 Spine is now derived from Patch - ADS

2009-06-01 use cbook.is_string_like() instead of isinstance() for spines - ADS

2009-06-01 cla() support for spines - ADS
2009-06-01 Removed support for gtk < 2.4. - EF

2009-05-29 Improved the animation_blit_qt4 example, which was a mix of the object-oriented and pylab interfaces. It is now strictly object-oriented - DSD

2009-05-28 Fix axes_grid toolkit to work with spine patch by ADS. - JJL

2009-05-28 Applied fbianco’s patch to handle scroll wheel events in the qt4 backend - DSD

2009-05-26 Add support for “axis spines” to have arbitrary location. - ADS

2009-05-20 Add an empty matplotlibrc to the tests/ directory so that running tests will use the default set of rcparams rather than the user’s config. - RMM

2009-05-19 Axis.grid(): allow use of which=’major,minor’ to have grid on major and minor ticks. - ADS

2009-05-18 Make psd(), csd(), and cohere() wrap properly for complex/two-sided versions, like specgram() (SF #2791686) - RMM

2009-05-18 Fix the linespacing bug of multiline text (#1239682). See examples/pylab_examples/multiline.py - JJL

2009-05-18 Add annotation_clip attr. for text.Annotation class. If True, annotation is only drawn when the annotated point is inside the axes area. - JJL

2009-05-17 Fix bug(#2749174) that some properties of minor ticks are not conserved - JJL

2009-05-17 applied Michiel’s sf patch 2790638 to turn off gtk event loop in setupext for pygtk=>=2.15.10 - JDH

2009-05-17 applied Michiel’s sf patch 2792742 to speed up Cairo and macosx collections; speedups can be 20x. Also fixes some bugs in which gc got into inconsistent state

2008-05-17 Release 0.98.5.3 at r7107 from the branch - JDH

2009-05-13 An optional offset and bbox support in restore_bbox. Add animation_blit_gtk2.py - JJL

2009-05-13 psfrag in backend_ps now uses baseline-alignment when preview.sty is used ((default is bottom-alignment). Also, a small api improvement in OffsetBox-JJL

2009-05-13 When the x-coordinate of a line is monotonically increasing, it is now automatically clipped at the stage of generating the transformed path in the draw method; this greatly speeds up zooming and panning when one is looking at a short segment of a long time series, for example. - EF

2009-05-11 aspect=1 in log-log plot gives square decades. - JJL

2009-05-08 clabel takes new kwarg, rightside_up; if False, labels will not be flipped to keep them rightside-up. This allows the use of clabel to make streamfunction arrows, as requested by Evan Mason. - EF

2009-05-07 'labelpad' can now be passed when setting x/y labels. This allows controlling the spacing between the label and its axis. - RMM

2009-05-06 print_ps now uses mixed-mode renderer. Axes.draw rasterize artists whose zorder smaller than rasterization_zorder. - JJL

2009-05-06 Per-artist Rasterization, originally by Eric Bruning. - JJ
2009-05-05 Add an example that shows how to make a plot that updates using data from another process. Thanks to Robert Cimrman - RMM

2009-05-05 Add Axes.get_legend_handles_labels method. - JJL

2009-05-04 Fix bug that Text.Annotation is still drawn while set to not visible. - JJL

2009-05-04 Added TJ’s fill_betweenx patch - JDH

2009-05-02 Added options to plotfile based on question from Joseph Smidt and patch by Matthias Michler. - EF

2009-05-01 Changed add_artist and similar Axes methods to return their argument. - EF

2009-04-30 Incorrect eps bbox for landscape mode fixed - JJL

2009-04-28 Fixed incorrect bbox of eps output when usetex=True. - JJL

2009-04-24 Changed use of os.open* to instead use subprocess.Popen. os.popen* are deprecated in 2.6 and are removed in 3.0. - RMM

2009-04-20 Worked on axes_grid documentation. Added axes_grid.inset_locator. - JJL

2009-04-17 Initial check-in of the axes_grid toolkit. - JJL

2009-04-17 Added a support for bbox_to_anchor in offsetbox.AnchoredOffsetbox. Improved a documentation. - JJL

2009-04-16 Fixed a offsetbox bug that multiline texts are not correctly aligned. - JJL

2009-04-16 Fixed a bug in mixed mode renderer that images produced by an rasterizing backend are placed with incorrect size. - JJL

2009-04-14 Added Jonathan Taylor’s Reinier Heeres’ port of John Porters’ mplot3d to svn trunk. Package in mpl_toolkits.mplot3d and demo is examples/mplot3d/demo.py. Thanks Reiner

2009-04-06 The pdf backend now escapes newlines and linefeeds in strings. Fixes sf bug #2708559; thanks to Tiago Pereira for the report.

2009-04-06 texmanager.make_dvi now raises an error if LaTeX failed to create an output file. Thanks to Joao Luis Silva for reporting this. - JKS

2009-04-05 _png.read_png() reads 12 bit PNGs (patch from Tobias Wood) - ADS

2009-04-04 Allow log axis scale to clip non-positive values to small positive value; this is useful for errorbars. - EF

2009-03-28 Make images handle nan in their array argument. A helper, cbook.safe_masked_invalid() was added. - EF

2009-03-25 Make contour and contourf handle nan in their Z argument. - EF

2009-03-20 Add AuxTransformBox in offsetbox.py to support some transformation. anchored_text.py example is enhanced and renamed (anchored_artists.py). - JJL

2009-03-20 Add "bar" connection style for annotation - JJL

2009-03-17 Fix bugs in edge color handling by contour, found by Jae-Joon Lee. - EF

2009-03-14 Added ‘LightSource’ class to colors module for creating shaded relief maps. shading_example.py added to illustrate usage. - JSW

2009-03-11 Ensure wx version >= 2.8; thanks to Sandro Tosi and Chris Barker. - EF
2009-03-10 Fix join style bug in pdf. - JKS
2009-03-07 Add pyplot access to figure number list - EF
2009-02-28 hashing of FontProperties accounts current rcParams - JJL
2009-02-28 Prevent double-rendering of shared axis in twinx, twiny - EF
2009-02-26 Add optional bbox_to_anchor argument for legend class - JJL
2009-02-26 Support image clipping in pdf backend. - JKS
2009-02-25 Improve tick location subset choice in FixedLocator. - EF

2009-02-24 **Deprecate numerix, and strip out all but the numpy** part of the code. - EF

2009-02-21 **Improve scatter argument handling; add an early error** message, allow inputs to have more than one dimension. - EF

2009-02-16 **Move plot_directive.py to the installed source tree. Add** support for inline code content - MGD

2009-02-16 **Move mathmpl.py to the installed source tree so it is** available to other projects. - MGD

2009-02-14 Added the legend title support - JJL

2009-02-10 **Fixed a bug in backend_pdf so it doesn’t break when the setting**
    pdf.use14corefonts=True is used. Added test case in unit/test_pdf_use14corefonts.py. - NGR

2009-02-08 **Added a new imsave function to image.py and exposed it in** the pyplot interface - GR

2009-02-04 **Some reorgnization of the legend code. anchored_text.py added as an example.** - JJL

2009-02-04 Add extent keyword arg to hexbin - ADS

2009-02-04 Fix bug in mathtext related to dots and ldots - MGD

2009-02-03 Change default joinstyle to round - MGD

2009-02-02 Reduce number of marker XObjects in pdf output - JKS

2009-02-02 Change default resolution on polar plot to 1 - MGD

2009-02-02 **Avoid malloc errors in ttconv for fonts that don’t have** e.g., PostName (a version of Tahoma triggered this) - JKS

2009-01-30 **Remove support for pyExcelerator in exceltools** - use xlwt instead - JDH

2009-01-29 **Document ‘resolution’ kwarg for polar plots. Support it** when using pyplot.polar, not just Figure.add_axes. - MGD

2009-01-29 **Rework the nan-handling/clipping/quantizing/simplification** framework so each is an independent part of a pipeline. Expose the C++-implementation of all of this so it can be used from all Python backends. Add rcParam “path.simplify_threshold” to control the threshold of similarity below which vertices will be removed.

2009-01-26 Improved tight bbox option of the savefig. - JJL

2009-01-26 Make curves and NaNs play nice together - MGD

2009-01-21 **Changed the defaults of acorr and xcorr to use** usevlines=True, maxlags=10 and normed=True since these are the best defaults
2009-01-19 Fix bug in quiver argument handling. - EF
2009-01-19 Fix bug in backend_gtk: don’t delete nonexistent toolbar. - EF

2009-01-16 **Implement bbox_inches option for savefig. If bbox_inches is “tight”, try to determine the tight bounding box.** - JJL

2009-01-16 **Fix bug in is_string_like so it doesn’t raise an unnecessary exception.** - EF

2009-01-16 Fix an infinite recursion in the unit registry when searching for a converter for a sequence of strings. Add a corresponding test. - RM

2009-01-16 **Bugfix of C typedef of MPL_Int64 that was failing on Windows XP 64 bit, as reported by George Goussard on numpy mailing list.** - ADS

2009-01-16 **Implemented helper function LinearSegmentedColormap.from_list to facilitate building simple custom colormaps.** See examples/pylab_examples/custom_cmap_fromlist.py - JDH

2009-01-16 **Applied Michiel’s patch for macosx backend to fix rounding bug. Closed sf bug 2508440** - JSW

2009-01-10 **Applied Michiel’s hatch patch for macosx backend and draw_idle patch for qt. Closes sf patched 2497785 and 2468809.** - JDH

2009-01-10 Fix bug in pan/zoom with log coordinates. - EF

2009-01-06 Fix bug in setting of dashed negative contours. - EF

2009-01-06 Be fault tolerant when len(linestyles)>NLev in contour. - MM

2009-01-06 **Added marginals kwarg to hexbin to plot marginal densities** - JDH

2009-01-06 Change user-visible multipage pdf object to PdfPages to avoid accidents with the file-like PdfFile. - JKS

2009-01-05 Fix a bug in pdf usetex: allow using non-embedded fonts. - JKS

2009-01-05 optional use of preview.sty in usetex mode. - JJL

2009-01-02 Allow multipage pdf files. - JKS

2008-12-31 **Improve pdf usetex by adding support for font effects** (slanting and extending). - JKS

2008-12-29 Fix a bug in pdf usetex support, which occurred if the same Type-1 font was used with different encodings, e.g., with Minion Pro and MnSymbol. - JKS

2008-12-20 fix the dpi-dependent offset of Shadow. - JJL

2008-12-20 fix the hatch bug in the pdf backend. minor update in docs and example - JJL

2008-12-19 Add axes Locator attribute in Axes. Two examples are added.

- JJL

2008-12-19 **Update Axes.legend documentation. /api/api_changes.rst is also updated to describe changes in keyword parameters. Issue a warning if old keyword parameters are used.** - JJL

2008-12-18 add new arrow style, a line + filled triangles. -JJL

2008-12-18 Re-Re-Released 0.98.5.2 from v0_98_5_maint at r6679 Released 0.98.5.2 from v0_98_5_maint at r6667

7.1. List of changes to Matplotlib prior to 2015 457
2008-12-18 Removed configobj, experimental traits and doc/mpl_data link - JDH

2008-12-18 Fix bug where a line with NULL data limits prevents subsequent data limits from calculating correctly - MGD

2008-12-17 Major documentation generator changes - MGD

2008-12-17 Applied macosx backend patch with support for path collections, quadmesh, etc... - JDH

2008-12-17 fix dpi-dependent behavior of text bbox and arrow in annotate - JJL

2008-12-17 Add group id support in artist. Two examples which demonstrate svg filter are added. - JJL

2008-12-16 Another attempt to fix dpi-dependent behavior of Legend. - JJL

2008-12-16 Fixed dpi-dependent behavior of Legend and fancybox in Text.

2008-12-16 Added markevery property to Line2D to support subsampling of markers - JDH

2008-12-15 Removed mpl_data symlink in docs. On platforms that do not support symlinks, these become copies, and the font files are large, so the distro becomes unnecessarily bloated. Keeping the mpl_examples dir because relative links are harder for the plot directive and the *.py files are not so large. - JDH

2008-12-15 Fix $innon-math text with usetex off. Document differences between usetex on/off - MGD

2008-12-15 Fix anti-aliasing when auto-snapping - MGD

2008-12-15 Fix grid lines not moving correctly during pan and zoom - MGD

2008-12-12 Preparations to eliminate maskedarray rcParams key: its use will now generate a warning. Similarly, importing the obsolete numerix.npyma will generate a warning. - EF

2008-12-12 Added support for the numpy.histogram() weights parameter to the axes hist() method. Docs taken from numpy - MM

2008-12-12 Fixed warning in hist() with numpy 1.2 - MM

2008-12-12 Removed external packages: configobj and enthought.traits which are only required by the experimental traited config and are somewhat out of date. If needed, install them independently. see:

http://code.enthought.com/pages/traits.html

and:

http://www.voidspace.org.uk/python/configobj.html

2008-12-12 Added support to assign labels to histograms of multiple data. - MM

2008-12-11 Released 0.98.5 at svn r6573

2008-12-11 Use subprocess.Popen instead of os.popen in dviread (Windows problem reported by Jorgen Stenarson) - JKS

2008-12-10 Added Michael’s font_manager fix and Jae-Joon’s figure/subplot fix. Bumped version number to 0.98.5 - JDH
2008-12-09 Released 0.98.4 at svn r6536
2008-12-08 Added mdehoon’s native macosx backend from sf patch 2179017 - JDH
2008-12-08 **Removed the prints in the set_*style commands. Return the** list of printed strings instead - JDH
2008-12-08 **Some of the changes Michael made to improve the output of** the property tables in the rest docs broke or made difficult to use some of the interactive doc helpers, e.g., setp and getp. Having all the rest markup in the ipython shell also confused the docstrings. I added a new rc param docstring.harcopy, to format the docstrings differently for hardcopy and other use. The ArtistInspector could use a little refactoring now since there is duplication of effort between the rest output and the non-rest output - JDH
2008-12-08 **Updated spectral methods (psd, csd, etc.) to scale one-sided** densities by a factor of 2 and, optionally, scale all densities by the sampling frequency. This gives better MatLab compatibility. -RM
2008-12-08 Fixed alignment of ticks in colorbars. -MGD
2008-12-07 **drop the deprecated “new” keyword of np.histogram() for numpy 1.2 or later.** -JJL
2008-12-06 **Fixed a bug in svg backend that new_figure_manager() ignores keywords arguments such as figsize, etc.** -JJL
2008-12-05 **Fixed a bug that the handlelength of the new legend class set too short when numpoints=1** -JJL
2008-12-04 **Added support for data with units (e.g., dates) to Axes.fill_between.** -RM
2008-12-04 **Added fancybox keyword to legend. Also applied some changes for** better look, including baseline adjustment of the multiline texts so that it is center aligned. -JJL
2008-12-02 **The transmuter classes in the patches.py are reorganized as** subclasses of the Style classes. A few more box and arrow styles are added. -JJL
2008-12-02 **Fixed a bug in the new legend class that didn’t allowed** a tuple of coordinate values as loc. -JJL
2008-12-02 **Improve checks for external dependencies, using subprocess** (instead of deprecated popen*) and distutils (for version checking) - DSD
2008-11-30 **Reimplementation of the legend which supports baseline alignment, multi-column, and expand mode.** - JJL
2008-12-01 **Fixed histogram autoscaling bug when bins or range are given** explicitly (fixes Debian bug 503148) - MM
2008-11-25 **Added rCParam axes.unicode_minus which allows plain hypen** for minus when False - JDH
2008-11-25 **Added scatterpoints support in Legend. patch by Erik Tollerud - JJL**
2008-11-24 Fix crash in log ticking. - MGD
2008-11-20 **Added static helper method BrokenHBarCollection.span_where** and Axes/pyplot method fill_between. See examples/pylab/fill_between.py - JDH

7.1. List of changes to Matplotlib prior to 2015

459
2008-11-12 Add $x_{\text{isdata}}$ and $y_{\text{isdata}}$ attributes to Artist instances, and use them to determine whether either or both coordinates are used when updating dataLim. This is used to fix autoscaling problems that had been triggered by axhline, axhspan, axvline, axvspan.

2008-11-11 Update the $\text{psd()}$, $\text{csd()}$, $\text{cohere()}$, and $\text{specgram()}$ methods of Axes and the $\text{csd()}$, $\text{cohere()}$, and $\text{specgram()}$ functions in mlab to be in sync with the changes to $\text{psd()}$. In fact, under the hood, these all call the same core to do computations. - RM

2008-11-11 Add ‘pad_to’ and ‘sides’ parameters to mlab.psd() to allow controlling of zero padding and returning of negative frequency components, respectively. These are added in a way that does not change the API. - RM

2008-11-10 Fix handling of c kwarg by scatter; generalize is_string_like to accept numpy and numpy.ma string array scalars. - RM and EF

2008-11-09 Fix a possible EINVALTR problem in dviread, which might help when saving pdf files from the qt backend. - JKS

2008-11-05 Fix bug with zoom to rectangle and twin axes - MGD

2008-10-24 Added Jae Joon’s fancy arrow, box and annotation enhancements – see examples/pylab_examples/annotation_demo2.py

2008-10-23 Autoscaling is now supported with shared axes - EF

2008-10-23 Fixed exception in dviread that happened with Minion - JKS

2008-10-21 set_xlim, ylim now return a copy of the viewlim array to avoid modify in-place surprises

2008-10-20 Added image thumbnail generating function matplotlib.image.thumbnail. See examples/misc/image_thumbnail.py - JDH

2008-10-20 Applied scatleg patch based on ideas and work by Erik Tollerud and Jae-Joon Lee. - MM

2008-10-11 Fixed bug in pdf backend: if you pass a file object for output instead of a filename, e.g., in a wep app, we now flush the object at the end. - JKS

2008-10-08 Add path simplification support to paths with gaps. - EF

2008-10-05 Fix problem with AFM files that don’t specify the font’s full name or family name. - JKS

2008-10-04 Added ‘scilimits’ kwarg to Axes.ticklabel_format() method, for easy access to the set_powerlimits method of the major ScalarFormatter. - EF

2008-10-04 Experimental new kwarg borderpad to replace pad in legend, based on suggestion by Jae-Joon Lee. - EF

2008-09-27 Allow spy to ignore zero values in sparse arrays, based on patch by Tony Yu. Also fixed plot to handle empty data arrays, and fixed handling of markers in figlegend. - EF

2008-09-24 Introduce drawstyles for lines. Transparently split linestyles like ‘steps,’ into drawstyle ‘steps’ and linestyle ‘-‘. Legends always use drawstyle ‘default’. - MM

2008-09-18 Fixed quiver and quiverkey bugs (failure to scale properly when resizing) and added additional methods for determining the arrow angles - EF

2008-09-18 Fix polar interpolation to handle negative values of theta - MGD
2008-09-14 **Reorganized cbook and mlab methods related to numerical** calculations that have little to do with the goals of those two modules into a separate module numerical_methods.py Also, added ability to select points and stop point selection with keyboard in ginput and manual contour labeling code. Finally, fixed contour labeling bug. - DMK

2008-09-11 Fix backtick in Postscript output. - MGD

2008-09-10 **Path simplification for vector output backends** Leverage the simplification code exposed through path_to_polygons to simplify certain well-behaved paths in the vector backends (PDF, PS and SVG). “path.simplify” must be set to True in matplotlibrc for this to work. - MGD

2008-09-10 **Add “filled” kwarg to Path.intersects_path and Path.intersects_bbox.** - MGD

2008-09-07 **Changed full arrows slightly to avoid an xpdf rendering problem** reported by Friedrich Hagedorn. - JKS

2008-09-07 **Fix conversion of quadratic to cubic Bezier curves in PDF and PS backends.** Patch by Jae-Joon Lee. - JKS

2008-09-06 Added 5-point star marker to plot command - EF

2008-09-05 Fix hatching in PS backend - MGD

2008-09-03 Fix log with base 2 - MGD

2008-09-01 **Added support for bilinear interpolation in** NonUniformImage; patch by Gregory Lielens. - EF

2008-08-28 **Added support for multiple histograms with data of different length** - MM

2008-08-28 Fix step plots with log scale - MGD

2008-08-28 Fix masked arrays with markers in non-Agg backends - MGD

2008-08-28 Fix clip_on kwarg so it actually works correctly - MGD

2008-08-25 Fix locale problems in SVG backend - MGD

2008-08-22 fix quiver so masked values are not plotted - JSW

2008-08-18 improve interactive pan/zoom in qt4 backend on windows - DSD

2008-08-11 **Fix more bugs in NaN/inf handling. In particular, path simplification** (which does not handle NaNs or infs) will be turned off automatically when infs or NaNs are present. Also masked arrays are now converted to arrays with NaNs for consistent handling of masks and NaNs - MGD and EF

2008-08-03 Released 0.98.3 at svn r5947

2008-08-01 Backported memory leak fixes in _ttconv.cpp - MGD

2008-07-31 Added masked array support to griddata. - JSW

2008-07-26 **Added optional C and reduce_C_function arguments to** axes.hexbin(). This allows hexbin to accumulate the values of C based on the x,y coordinates and display in hexagonal bins. - ADS

2008-07-24 **Deprecated (raise NotImplementedError) all the mlab2 functions from matplotlib.mlab out of concern that some of them were not clean room implementations.** JDH
2008-07-24 Rewrite of a significant portion of the clabel code (class ContourLabeler) to improve inlining. - DMK

2008-07-22 Added Barbs polygon collection (similar to Quiver) for plotting wind barbs. Added corresponding helpers to Axes and pyplot as well. (examples/pylab_examples/barb_demo.py shows it off.) - RMM

2008-07-21 Added scikits.delaunay as matplotlib.delaunay. Added griddata function in matplotlib.mlab, with example (griddata_demo.py) in pylab_examples. griddata function will use mpl_toolkits._natgrid if installed. - JSW

2008-07-21 Re-introduced offset_copy that works in the context of the new transforms. - MGD

2008-07-21 Committed patch by Ryan May to add get_offsets and set_offsets to Collections base class - EF

2008-07-21 Changed the “asarray” strategy in image.py so that colormapping of masked input should work for all image types (thanks Klaus Zimmerman) - EF

2008-07-20 Rewrote cbook.delete_masked_points and corresponding unit test to support rgb color array inputs, datetime inputs, etc. - EF

2008-07-20 Renamed unit/axes_unit.py to cbook_unit.py and modified in accord with Ryan’s move of delete_masked_points from axes to cbook. - EF

2008-07-18 Check for nan and inf in axes.delete_masked_points(). This should help hexbin and scatter deal with nans. - ADS

2008-07-17 Added ability to manually select contour label locations. Also added a waitforbuttonpress function. - DMK

2008-07-17 Fix bug with NaNs at end of path (thanks, Andrew Straw for the report) - MGD

2008-07-16 Improve error handling in texmanager, thanks to Ian Henry for reporting - DSD

2008-07-12 Added support for external backends with the “module://my_backend” syntax - JDH

2008-07-11 Fix memory leak related to shared axes. Grouper should store weak references. - MGD

2008-07-10 Bugfix: crash displaying fontconfig pattern - MGD

2008-07-10 Bugfix: [ 2013963 ] update_datalim_bounds in Axes not works - MGD

2008-07-10 Bugfix: [ 2014183 ] multiple imshow() causes gray edges - MGD

2008-07-09 Fix rectangular axes patch on polar plots bug - MGD

2008-07-09 Improve mathtext radical rendering - MGD

2008-07-08 Improve mathtext superscript placement - MGD

2008-07-07 Fix custom scales in pcolormesh (thanks Matthew Turk) - MGD

2008-07-03 Implemented findobj method for artist and pyplot - see examples/pylab_examples/findobj_demo.py - JDH

2008-06-30 Another attempt to fix TextWithDash - DSD

2008-06-30 Removed Qt4 NavigationToolbar2.destroy - it appears to have been unnecessary and caused a bug reported by P. Raybaut - DSD
2008-06-27 Fixed tick positioning bug - MM

**2008-06-27 Fix dashed text bug where text was at the wrong end of the** dash - MGD

2008-06-26 Fix mathtext bug for expressions like $\text{x_{leftarrow}}$ - MGD

2008-06-26 Fix direction of horizontal/vertical hatches - MGD

**2008-06-25 Figure.figurePatch renamed Figure.patch, Axes.axesPatch renamed Axes.patch, Axes.axesFrame renamed Axes.frame, Axes.get_frame, which returns Axes.patch, is deprecated. Examples and users guide updated** - JDH

2008-06-25 Fix rendering quality of pcolor - MGD

2008-06-24 Released 0.98.2 at svn r5667 - (source only for debian) JDH

2008-06-24 Added “transparent” kwarg to savefig. - MGD

**2008-06-24 Applied Stefan’s patch to draw a single centered marker over a line with numpoints==1** - JDH

2008-06-23 Use splines to render circles in scatter plots - MGD

2008-06-22 Released 0.98.1 at revision 5637

**2008-06-22 Removed axes3d support and replaced it with a NotImplementedException for one release cycle**

2008-06-21 fix marker placement bug in backend_ps - DSD

2008-06-20 [ 1978629 ] scale documentation missing/incorrect for log - MGD

**2008-06-20 Added closed kwarg to PolyCollection. Fixes bug [ 1994535 ] still missing lines on graph with svn (r 5548).** - MGD

2008-06-20 Added set/get_closed method to Polygon; fixes error in hist - MM

**2008-06-19 Use relative font sizes (e.g., ‘medium’ and ‘large’) in rcsetup.py and matplotlibrc.template so that text will be scaled by default when changing rc-Params[‘font.size’].** - EF

2008-06-17 Add a generic PatchCollection class that can contain any kind of patch. - MGD

**2008-06-13 Change pie chart label alignment to avoid having labels overwrite the pie** - MGD

**2008-06-12 Added some helper functions to the mathtext parser to return bitmap arrays or write pngs to make it easier to use mathtext outside the context of an mpl figure. modified the mathpng sphinxext to use the mathtext png save functionality** - see examples/api/mathtext_asarray.py - JDH

**2008-06-11 Use matplotlib.mathtext to render math expressions in online docs** - MGD

**2008-06-11 Move PNG loading/saving to its own extension module, and remove duplicate code in _backend_agg.cpp and _image.cpp that does the same thing** - MGD

**2008-06-11 Numerous mathtext bugfixes, primarily related to dpi-independence** - MGD

7.1. List of changes to Matplotlib prior to 2015 463
2008-06-10 Bar now applies the label only to the first patch only, and sets '_nolegend_' for the other patch labels. This lets autolegend work as expected for hist and bar - see https://sourceforge.net/tracker/index.php?func=detail&aid=1986597&group_id=80706&atid=560720 JDH

2008-06-10 Fix text baseline alignment bug. [1985420] Repair of baseline alignment in Text._get_layout. Thanks Stan West - MGD

2008-06-09 Committed Gregor’s image resample patch to downsampling images with new rcparam image.resample - JDH

2008-06-09 Don’t install Enthought.Traits along with matplotlib. For matplotlib developers convenience, it can still be installed by setting an option in setup.cfg while we figure decide if there is a future for the traited config - DSD

2008-06-09 Added range keyword arg to hist() - MM

2008-06-07 Moved list of backends to rcsetup.py; made use of lower case for backend names consistent; use validate_backend when importing backends subpackage - EF

2008-06-06 hist() revision, applied ideas proposed by Erik Tollerud and Olle Engdegard: make histtype=’step’ unfilled by default and introduce histtype=’stepfilled’; use default color cycle; introduce reverse cumulative histogram; new align keyword - MM

2008-06-06 Fix closed polygon patch and also provide the option to not close the polygon - MGD

2008-06-05 Fix some dpi-changing-related problems with PolyCollection, as called by Axes.scatter() - MGD

2008-06-05 Fix image drawing so there is no extra space to the right or bottom - MGD

2006-06-04 Added a figure title command suptitle as a Figure method and pyplot command - see examples/figure_title.py - JDH

2008-06-02 Added support for log to hist with histtype=’step’ and fixed a bug for log-scale stacked histograms - MM

2008-05-29 Released 0.98.0 at revision 5314

2008-05-29 matplotlib.image.imread now no longer always returns RGBA – if the image is luminance or RGB, it will return a MxN or MxNx3 array if possible. Also uint8 is no longer always forced to float.

2008-05-29 Implement path clipping in PS backend - JDH

2008-05-29 Fixed two bugs in texmanager.py: improved comparison of dvipng versions fixed a bug introduced when get_gray method was added - DSD

2008-05-28 Fix crashing of PDFs in xpdf and ghostscript when two-byte characters are used with Type 3 fonts - MGD

2008-05-28 zero width/height Rectangles no longer influence the autoscaler. Useful for log histograms with empty bins - JDH

2008-05-28 Fix rendering of composite glyphs in Type 3 conversion (particularly as evidenced in the Eunjin.ttf Korean font) Thanks Jae-Joon Lee for finding this!

2008-05-27 Rewrote the cm.ScalarMappable callback infrastructure to use cbook.CallbackRegistry rather than custom callback handling. Any users of add_observer/notify of the cm.ScalarMappable should use the cm.ScalarMappable.callbacksSM CallbackRegistry instead. JDH

2008-05-27 Fix TkAgg build on Ubuntu 8.04 (and hopefully a more general solution for other platforms, too.)

2008-05-24 Added PIL support for loading images to imread (if PIL is available) - JDH

2008-05-23 Provided a function and a method for controlling the plot color cycle. - EF

2008-05-23 Major revision of hist(). Can handle 2D arrays and create stacked histogram plots; keyword ‘width’ deprecated and rwidth (relative width) introduced; align=’edge’ changed to center of bin - MM

2008-05-22 Added support for ReST-based documentation using Sphinx. Documents are located in doc/, and are broken up into a users guide and an API reference. To build, run the make.py files. Sphinx-0.4 is needed to build generate xml, which will be useful for rendering equations with mathml, use sphinx from svn until 0.4 is released - DSD

2008-05-21 Fix segfault in TkAgg backend - MGD

2008-05-21 Fix a “local variable unreferenced” bug in plotfile - MM

2008-05-19 Fix crash when Windows cannot access the registry to determine font path [Bug 1966974, thanks Patrik Simons] - MGD

2008-05-16 removed some unneeded code w/ the python 2.4 requirement. cbook no longer provides compatibility for reversed, enumerate, set or izip. removed lib/subprocess, mpl1, sandbox/units, and the swig code. This stuff should remain on the maintenance branch for archival purposes. JDH

2008-05-16 Reorganized examples dir - JDH

2008-05-16 Added 'elinewidth' keyword arg to errorbar, based on patch by Christopher Brown - MM

2008-05-16 Added ‘cumulative’ keyword arg to hist to plot cumulative histograms. For normed hists, this is normalized to one - MM

2008-05-15 Fix Tk backend segfault on some machines - MGD

2008-05-14 Don’t use stat on Windows (fixes font embedding problem) - MGD

2008-05-09 Fix /singlequote (’) in Postscript backend - MGD

2008-05-08 Fix kerning in SVG when embedding character outlines - MGD

2008-05-07 Switched to future numpy histogram semantic in hist - MM

2008-05-06 Fix strange colors when blitting in QtAgg and Qt4Agg - MGD

2008-05-05 pass notify_axes_change to the figure's add_axobserver in the qt backends, like we do for the other backends. Thanks Glenn Jones for the report - DSD

2008-05-02 Added step histograms, based on patch by Erik Tollerud. - MM
2008-05-02 On PyQt <= 3.14 there is no way to determine the underlying Qt version. [1851364] - MGD

2008-05-02 Don’t call sys.exit() when pyemf is not found [1924199] - MGD

2008-05-02 Update subprocess.c from upstream Python 2.5.2 to get a few memory and reference-counting-related bugfixes. See bug 1949978. - MGD

2008-04-30 Added some record array editing widgets for gtk - see examples/rec_edit*.py - JDH

2008-04-29 Fix bug in mlab.sqrtm - MM

2008-04-28 Fix bug in SVG text with Mozilla-based viewers (the symbol tag is not supported) - MGD

2008-04-27 Applied patch by Michiel de Hoon to add hexbin axes method and pyplot function - EF

2008-04-25 Enforce python >= 2.4; remove subprocess build - EF

2008-04-25 Enforce the numpy requirement at build time - JDH

2008-04-24 Make numpy 1.1 and python 2.3 required when importing matplotlib - EF

2008-04-24 Fix compilation issues on VS2003 (Thanks Martin Spacek for all the help) - MGD

2008-04-24 Fix sub/superscripts when the size of the font has been changed - MGD

2008-04-22 Use “svg.embed_char_paths” consistently everywhere - MGD

2008-04-20 Add support to MaxNLocator for symmetric axis autoscaling. - EF

2008-04-20 Fix double-zoom bug. - MM

2008-04-15 Speed up color mapping. - EF

2008-04-12 Speed up zooming and panning of dense images. - EF

2008-04-11 Fix global font rcParam setting after initialization time. - MGD

2008-04-11 Revert commits 5002 and 5031, which were intended to avoid an unnecessary call to draw(). 5002 broke saving figures before show(). 5031 fixed the problem created in 5002, but broke interactive plotting. Unnecessary call to draw still needs resolution - DSD

2008-04-07 Improve color validation in rc handling, suggested by Lev Givon - EF

2008-04-02 Allow to use both linestyle definition arguments, ‘-‘ and ‘solid’ etc. in plots/collections - MM

2008-03-27 Fix saving to Unicode filenames with Agg backend (other backends appear to already work…) (Thanks, Christopher Barker) - MGD

2008-03-26 Fix SVG backend bug that prevents copying and pasting in Inkscape (thanks Kaushik Ghose) - MGD

2008-03-24 Removed an unnecessary call to draw() in the backend_qt* mouseReleaseEvent. Thanks to Ted Drain - DSD

2008-03-23 Fix a pdf backend bug which sometimes caused the outermost gsave to not be balanced with a grestore. - JKS
2008-03-20 Fixed a minor bug in ContourSet._process_linestyles when
len(linestyles)==Nlev - MM

2008-03-19 Changed ma import statements to "from numpy import ma"; this should
work with past and future versions of numpy, whereas "import numpy.ma as ma" will
work only with numpy >= 1.05, and "import numerix.npyma as ma" is obsolete now that
maskedarray is replacing the earlier implementation, as of numpy 1.05.

2008-03-14 Removed an apparently unnecessary call to FigureCanvasAgg.draw in
backend_qt*agg. Thanks to Ted Drain - DSD

2008-03-10 Workaround a bug in backend_qt4agg’s blitting due to a buffer
width/bbox width mismatch in _backend_agg’s copy_from_bbox - DSD

2008-02-29 Fix class Wx toolbar pan and zoom functions (Thanks Jeff Peery) - MGD

2008-02-16 Added some new rec array functionality to mlab (rec_summarize, rec2txt
and rec_groupby). See examples/rec_groupby_demo.py. Thanks to Tim M for rec2txt.

2008-02-12 Applied Erik Tollerud’s span selector patch - JDH
2008-02-11 Update plotting() doc string to refer to getp/setp. - JKS

2008-02-10 Fixed a problem with square roots in the pdf backend with usetex. - JKS
2008-02-08 Fixed minor __str__ bugs so getp(gca()) works. - JKS

2008-02-05 Added getters for title, xlabel, ylabel, as requested by Brandon Kieht - EF
2008-02-05 Applied Gael’s ginput patch and created examples/ginput_demo.py - JDH

2008-02-03 Expose interpnames, a list of valid interpolation methods, as an AxesIm-
age class attribute. - EF

2008-02-03 Added BoundaryNorm, with examples in colorbar_only.py and im-
age_masked.py - EF

2008-02-03 Force dpi=72 in pdf backend to fix picture size bug. - JKS
2008-02-01 Fix doubly-included font problem in Postscript backend - MGD
2008-02-01 Fix reference leak in ft2font Glyph objects. - MGD
2008-01-31 Don’t use unicode strings with usetex by default - DSD

2008-01-31 Fix text spacing problems in PDF backend with some fonts, such as
STIXGeneral.

2008-01-31 Fix sqrt with radical number (broken by making [ and ] work below) - MG

2008-01-27 Applied Martin Teichmann’s patch to improve the Qt4 backend. Uses
Qt’s built-in toolbars and statusbars. See bug 1828848 - DSD

2008-01-10 Moved toolkits to mpl_toolkits, made mpl_toolkits a namespace package - JSWHIT

2008-01-10 Use setup.cfg to set the default parameters (tkagg, numpy) when building
windows installers - DSD
2008-01-10 Fix bug displaying [ and ] in mathtext - MGD

2008-01-10 Fix bug when displaying a tick value offset with scientific notation.
(Manifests itself as a warning that the times symbol can not be found). - MGD
**2008-01-10** Use setup.cfg to set the default parameters (**tkagg**, numpy) when building windows installers - DSD

2008-01-06 Released 0.91.2 at revision 4802

**2007-12-26** Reduce too-late use of matplotlib.use() to a warning instead of an exception, for backwards compatibility - EF

2007-12-25 Fix bug in errorbar, identified by Noriko Minakawa - EF

**2007-12-25** Changed masked array importing to work with the upcoming numpy 1.05 (now the maskedarray branch) as well as with earlier versions. - EF

**2007-12-16** rec2csv saves doubles without losing precision. Also, it does not close filehandles passed in open. - JDH,ADS

**2007-12-13** Moved rec2gtk to matplotlib.toolkits.gtktools and rec2excel to matplotlib.toolkits.exceltools - JDH

**2007-12-12** Support alpha-blended text in the Agg and Svg backends - MGD

2007-12-10 Fix SVG text rendering bug. - MGD

**2007-12-10** Increase accuracy of circle and ellipse drawing by using an 8-piece bezier approximation, rather than a 4-piece one. Fix PDF, SVG and Cairo backends so they can draw paths (meaning ellipses as well). - MGD

2007-12-07 Issue a warning when drawing an image on a non-linear axis. - MGD

**2007-12-06** let widgets.Cursor initialize to the lower x and y bounds rather than 0,0, which can cause havoc for dates and other transforms - DSD

2007-12-06 updated references to mpl data directories for py2exe - DSD

2007-12-06 fixed a bug in rcsetup, see bug 1845057 - DSD

**2007-12-05** Fix how fonts are cached to avoid loading the same one multiple times. (This was a regression since 0.90 caused by the refactoring of font_manager.py) - MGD

2007-12-05 Support arbitrary rotation of usetex text in Agg backend. - MGD

2007-12-04 Support '|' as a character in mathtext - MGD

2007-11-27 Released 0.91.1 at revision 4517

2007-11-27 Released 0.91.0 at revision 4478

**2007-11-13** All backends now support writing to a file-like object, not just a regular file. savefig() can be passed a file-like object in place of a file path. - MGD

**2007-11-13** Improved the default backend selection at build time: SVG -> Agg -> Tk-Agg -> WXAgg -> GTK -> GTKAgg. The last usable backend in this progression will be chosen in the default config file. If a backend is defined in setup.cfg, that will be the default backend - DSD

**2007-11-13** Improved creation of default config files at build time for traited config package - DSD
2007-11-12 Exposed all the build options in setup.cfg. These options are read into a dict called "options" by setupext.py. Also, added "-mpl" tags to the version strings for packages provided by matplotlib. Versions provided by mpl will be identified and updated on subsequent installs - DSD

2007-11-12 Added support for STIX fonts. A new rcParam, mathtext.fontset, can be used to choose between:

   'cm': The TeX/LaTeX Computer Modern fonts  
   'stix': The STIX fonts (see stixfonts.org)  
   'stixsans': The STIX fonts, using sans-serif glyphs by default  
   'custom': A generic Unicode font, in which case the mathtext font must be specified using mathtext.bf, mathtext.it, mathtext.sf etc.

   Added a new example, stix_fonts_demo.py to show how to access different fonts and unusual symbols.

• MGD

2007-11-12 Options to disable building backend extension modules moved from setup.py to setup.cfg - DSD

2007-11-09 Applied Martin Teichmann's patch 1828813: a QPainter is used in paintEvent, which has to be destroyed using the method end(). If matplotlib raises an exception before the call to end - and it does if you feed it with bad data - this method end() is never called and Qt4 will start spitting error messages

2007-11-09 Moved pyparsing back into matplotlib namespace. Don't use system pyparsing, API is too variable from one release to the next - DSD

2007-11-08 Made pylab use straight numpy instead of oldnumeric by default - EF

2007-11-08 Added additional record array utilities to mlab (rec2excel, rec2gtk, rec_join, rec_append_field, rec_drop_field) - JDH

2007-11-08 Updated pytz to version 2007g - DSD

2007-11-08 Updated pyparsing to version 1.4.8 - DSD

2007-11-08 Moved csv2rec to recutils and added other record array utilities - JDH

2007-11-08 If available, use existing pyparsing installation - DSD

2007-11-07 Removed old enthought.traits from lib/matplotlib, added Gael Varoquaux's enthought.traits-2.6b1, which is stripped of setuptools. The package is installed to site-packages if not already available - DSD

2007-11-05 Added easy access to minor tick properties; slight mod of patch by Pierre G-M - EF

2007-11-02 Committed Phil Thompson's patch 1599876, fixes to Qt4Agg backend and qt4 blitting demo - DSD

2007-11-02 Committed Phil Thompson's patch 1599876, fixes to Qt4Agg backend and qt4 blitting demo - DSD

2007-10-31 Made log color scale easier to use with contourf; automatic level generation now works. - EF

2007-10-29 TRANSFORMS REFACTOING
The primary goal of this refactoring was to make it easier to extend matplotlib to support new kinds of projections. This is primarily an internal improvement, and the possible user-visible changes it allows are yet to come.

The transformation framework was completely rewritten in Python (with Numpy). This will make it easier to add new kinds of transformations without writing C/C++ code.

Transforms are composed into a ‘transform tree’, made of transforms whose value depends on other transforms (their children). When the contents of children change, their parents are automatically updated to reflect those changes. To do this an “invalidation” method is used: when children change, all of their ancestors are marked as “invalid”. When the value of a transform is accessed at a later time, its value is recomputed only if it is invalid, otherwise a cached value may be used. This prevents unnecessary recomputations of transforms, and contributes to better interactive performance.

The framework can be used for both affine and non-affine transformations. However, for speed, we want to use the backend renderers to perform affine transformations whenever possible. Therefore, it is possible to perform just the affine or non-affine part of a transformation on a set of data. The affine is always assumed to occur after the non-affine. For any transform:

\[
\text{full transform} = \text{non-affine} + \text{affine}
\]

Much of the drawing has been refactored in terms of compound paths. Therefore, many methods have been removed from the backend interface and replaced with a handful to draw compound paths. This will make updating the backends easier, since there is less to update. It also should make the backends more consistent in terms of functionality.

User visible changes:

• POLAR PLOTS: Polar plots are now interactively zoomable, and the r-axis labels can be interactively rotated. Straight line segments are now interpolated to follow the curve of the r-axis.

• Non-rectangular clipping works in more backends and with more types of objects.

• Sharing an axis across figures is now done in exactly the same way as sharing an axis between two axes in the same figure:

```python
fig1 = figure()
fig2 = figure()
ax1 = fig1.add_subplot(111)
ax2 = fig2.add_subplot(111, sharex=ax1, sharey=ax1)
```

• Linestyles now include steps-pre, steps-post and steps-mid. The old step still works and is equivalent to step-pre.

• Multiple line styles may be provided to a collection.

See API CHANGES for more low-level information about this refactoring.

2007-10-24 Added ax kwarg to Figure.colorbar and pyplot.colorbar - EF

2007-10-19 Removed a gsave/grestore pair surrounding _draw_ps, which was causing a loss graphics state info (see “EPS output problem - scatter & edgecolors” on mpl-dev, 2007-10-29) - DSD
2007-10-15 Fixed a bug in patches. Ellipse that was broken for aspect='auto'. Scale free ellipses now work properly for equal and auto on Agg and PS, and they fall back on a polygonal approximation for nonlinear transformations until we convince ourselves that the spline approximation holds for nonlinear transformations. Added unit/ellipse_compare.py to compare spline with vertex approx for both aspects. JDH

2007-10-05 remove generator expressions from texmanager and mpltraits. generator expressions are not supported by python-2.3 - DSD

2007-10-01 Made matplotlib.use() raise an exception if called after backends has been imported. - EF

2007-09-30 Modified update* methods of Bbox and Interval so they work with reversed axes. Prior to this, trying to set the ticks on a reversed axis failed with an uninformative error message. - EF

2007-09-30 Applied patches to axes3d to fix index error problem - EF

2007-09-24 Applied Eike Welk’s patch reported on mpl-dev on 2007-09-22 Fixes a bug with multiple plot windows in the qt backend, ported the changes to backend_qt4 as well - DSD

2007-09-21 Changed cbook.reversed to yield the same result as the python reversed builtin - DSD

2007-09-13 Theusetex support in the pdf backend is more usable now, so I am enabling it. - JKS

2007-09-12 Fixed a Axes.bar unit bug - JDH

2007-09-10 Made skiprows=1 the default on csv2rec - JDH

2007-09-08 Eliminated gd and paint backends - EF

2007-09-06 .bmp file format is now longer an alias for .raw

2007-09-07 Added clip path support to pdf backend. - JKS

2007-09-06 Fixed a bug in the embedding of Type 1 fonts in PDF. Now it doesn’t crash Preview.app. - JKS

2007-09-06 Refactored image saving code so that all GUI backends can save most image types. See FILETYPES for a matrix of backends and their supported file types. Backend canvases should no longer write their own print_figure() method – instead they should write a print_xxx method for each filetype they can output and add an entry to their class-scoped filetypes dictionary. - MGD

2007-09-05 Fixed Qt version reporting in setupext.py - DSD

2007-09-04 Embedding Type 1 fonts in PDF, and thus usetex support via dviread, sort of works. To test, enable it by renaming _draw_tex to draw_tex. - JKS

2007-09-03 Added ability of errorbar show limits via caret or arrowhead ends on the bars; patch by Manual Metz. - EF
2007-09-03 Created type1font.py, added features to AFM and FT2Font (see API_CHANGES), started work on embedding Type 1 fonts in pdf files. - JKS

2007-09-02 Continued work on dviread.py. - JKS

2007-08-16 Added a set_extent method to AxesImage, allow data extent to be modified after initial call to imshow - DSD

2007-08-14 Fixed a bug in pyqt4 subplots-adjust. Thanks to Xavier Gnata for the report and suggested fix - DSD

2007-08-13 Use pickle to cache entire fontManager; change to using font_manager module-level function findfont wrapper for the fontManager.findfont method - EF

2007-08-11 Numpification and cleanup of mlab.py and some examples - EF

2007-08-06 Removed mathtext2

2007-07-31 Refactoring of distutils scripts.

- Will not fail on the entire build if an optional Python package (e.g., Tkinter) is installed but its development headers are not (e.g., tk-devel). Instead, it will continue to build all other extensions.

- Provide an overview at the top of the output to display what dependencies and their versions were found, and (by extension) what will be built.

- Use pkg-config, when available, to find freetype2, since this was broken on Mac OS-X when using MacPorts in a non-standard location.

2007-07-30 Reorganized configuration code to work with traited config objects. The new config system is located in the matplotlib.config package, but it is disabled by default. To enable it, set NEWCONFIG=True in matplotlib.__init__.py. The new configuration system will still use the old matplotlibrc files by default. To switch to the experimental, traited configuration, set USE_TRAITED_CONFIG=True in config.__init__.py.

2007-07-29 Changed default pcolor shading to flat; added aliases to make collection kwargs agree with setter names, so updating works; related minor cleanups. Removed quiver_classic, scatter_classic, pcolor_classic. - EF

2007-07-26 Major rewrite of mathtext.py, using the TeX box layout model.

There is one (known) backward incompatible change. The font commands (cal, rm, it, tt) now behave as TeX does: they are in effect until the next font change command or the end of the grouping. Therefore uses of $\text{cal}\{R\}$ should be changed to ${\text{cal R}}$. Alternatively, you may use the new LaTeX-style font commands (mathcal, mathrm, mathit, mathtt) which do affect the following group, e.g., $\text{mathcal}\{R\}$.

Other new features include:

- Math may be interspersed with non-math text. Any text with an even number of $’$s (non-escaped) will be sent to the mathtext parser for layout.

- Sub-superscripts are less likely to accidentally overlap.

- Support for sub-superscripts in either order, e.g., $x^{i_j}$ and $x_j^{i}$ are equivalent.

- Double sub-superscripts (e.g., $x_{i_j}$) are considered ambiguous and raise an exception. Use braces to disambiguate.

- $\text{frac}\{x\} \{y\}$ can be used for displaying fractions.
$\sqrt[3]{x}$ can be used to display the radical symbol with a root number and body.

$\left(\frac{x}{y}\right)$ may be used to create parentheses and other delimiters that automatically resize to the height of their contents.

Spacing around operators etc. is now generally more like TeX.

Added support (and fonts) for boldface (bf) and sans-serif (sf) symbols.

Log-like function name shortcuts are supported. For example, $\sin(x)$ may be used instead of $\{\text{rm sin}\}(x)$.

Limited use of kerning for the easy case (same font)

Behind the scenes, the pyparsing.py module used for doing the math parsing was updated to the latest stable version (1.4.6). A lot of duplicate code was refactored out of the Font classes.

MGD

2007-07-19 completed numpification of most trivial cases - NN

2007-07-19 converted non-numpy relics throughout the code - NN

2007-07-19 replaced the Python code in numerix/ by a minimal wrapper around numpy that explicitly mentions all symbols that need to be addressed for further numpification - NN

2007-07-18 make use\text{tex} respect changes to rcParams. texmanager used to only configure itself when it was created, now it reconfigures when rcParams are changed. Thank you Alexander Schmolck for contributing a patch - DSD

2007-07-17 added validation to setting and changing rcParams - DSD

2007-07-17 bugfix segfault in transforms module. Thanks Ben North for the patch. - ADS

2007-07-16 clean up some code in ticker.ScalarFormatter, use unicode to render multiplication sign in offset ticklabel - DSD

2007-07-16 fixed a formatting bug in ticker.ScalarFormatter's scientific notation (10^0 was being rendered as 10 in some cases) - DSD

2007-07-13 Add \text{MPL}_{\text{isfinite64}}() and \text{MPL}_{\text{isinf64}}() for testing doubles in (the now misnamed) MPL_{\text{isnan}}.h. - ADS

2007-07-13 The matplotlib._isnan module removed (use numpy.isnan) - ADS

2007-07-13 Some minor cleanups in _transforms.cpp - ADS

2007-07-13 Removed the rest of the numerix extension code detritus, numpified axes.py, and cleaned up the imports in axes.py - JDH

2007-07-13 Added legend.loc as configurable option that could in future default to 'best'. - NN

2007-07-12 Bugfixes in mlab.py to coerce inputs into numpy arrays. -ADS

2007-07-11 Added linespacing kwarg to text.Text - EF

2007-07-11 Added code to store font paths in SVG files. - MGD

2007-07-10 Store subset of TTF font as a Type 3 font in PDF files. - MGD

2007-07-09 Store subset of TTF font as a Type 3 font in PS files. - MGD
2007-07-09 Applied Paul’s pick restructure pick and add pickers, sourceforge patch 1749829 - JDH

2007-07-09 Applied Allan’s draw_lines agg optimization. JDH

2007-07-08 Applied Carl Worth’s patch to fix cairo draw_arc - SC

2007-07-07 fixed bug 1712099: xpdf distiller on windows - DSD

2007-06-30 Applied patches to tkagg, gtk, and wx backends to reduce memory leakage. Patches supplied by Mike Droettboom; see tracker numbers 1745400, 1745406, 1745408. Also made unit/memleak_gui.py more flexible with command-line options. - EF

2007-06-30 Split defaultParams into separate file rcdefaults (together with validation code). Some heavy refactoring was necessary to do so, but the overall behavior should be the same as before. - NN

2007-06-27 Added MPLCONFIGDIR for the default location for mpl data and configuration. Useful for some apache installs where HOME is not writable. Tried to clean up the logic in _get_config_dir to support non-writable HOME where are writable HOME/.matplotlib already exists - JDH

2007-06-27 Patch for get_py2exe_datafiles() to work with new directory layout. (Thanks Tocer and also Werner Bruhin.) - ADS

2007-06-27 Added a scroll event to the mpl event handling system and implemented it for backends GTK* - other backend users/developers/maintainers, please add support for your backend. - JDH

2007-06-25 Changed default to clip=False in colors.Normalize; modified ColorbarBase for easier colormap display - EF

2007-06-13 Added maskedarray option to rc, numerix - EF

2007-06-11 Python 2.5 compatibility fix for mlab.py - EF

2007-06-10 In matplotlibrc file, use ‘dashed’ | ‘solid’ instead of a pair of floats for contour.negative_linestyle - EF

2007-06-08 Allow plot and fill fmt string to be any mpl string colorspec - EF

2007-06-08 Added gnuplot file plotfile function to pylab - see examples/plotfile_demo.py - JDH

2007-06-07 Disable build of numarray and Numeric extensions for internal MPL use and the numerix layer. - ADS

2007-06-07 Added csv2rec to matplotlib.mlab to support automatically converting csv files to record arrays using type introspection, and turned on native datetime support using the new units support in matplotlib.dates. See examples/loadrec.py ! JDH

2007-06-07 Simplified internal code of _auto_legend_data - NN

2007-06-04 Added labeldistance arg to Axes.pie to control the raidal distance of the wedge labels - JDH
2007-06-03 Turned mathtext in SVG into single <text> with multiple <tspan>
objects (easier to edit in inkscape). - NN

2007-06-02 Released 0.90.1 at revision 3352
2007-06-02 Display only meaningful labels when calling legend() without args. - NN
2007-06-02 Have errorbar follow the color cycle even if line is not plotted. Suppress plotting of errorbar caps for capsize=0. - NN
2007-06-02 Set markers to same alpha value as line. - NN
2007-06-02 Fix mathtext position in svg backend. - NN
2007-06-01 Deprecate Numeric and numarray for use as numerix. Props to Travis - job well done. - ADS
2007-05-18 Added LaTeX unicode support. Enable with the 'text.latex.unicode' rc-Param. This requires the ucs and inputenc LaTeX packages. - ADS
2007-04-23 Fixed some problems with polar - added general polygon clipping to clip the lines and grids to the polar axes. Added support for set_rmax to easily change the maximum radial grid. Added support for polar legend - JDH
2007-04-16 Added Figure.autofmt_xdate to handle adjusting the bottom and rotating the tick labels for date plots when the ticks often overlap - JDH
2007-04-09 Beginnings ofusetex support for pdf backend. - JKS
2007-04-07 Fixed legend/LineCollection bug. Added label support to collections. - EF
2007-04-06 Removed deprecated support for a float value as a gray-scale; now it must be a string, like '0.5'. Added alpha kwarg to ColorConverter.to_rgba_list. - EF
2007-04-06 Fixed rotation of ellipses in pdf backend (sf bug #1690559) -JKS
2007-04-04 More matshow tweaks; documentation updates; new method set_bounds() for formatters and locators. - EF
2007-04-02 Fixed problem with imshow and matshow of integer arrays; fixed problems with changes to color autoscaling. - EF
2007-04-01 Made image color autoscaling work correctly with a tracking colorbar; norm.autoscale now scales unconditionally, while norm.autoscale_None changes only None-valued vmin, vmax. - EF
2007-03-31 Added a qt-based subplot-adjustment dialog - DSD
2007-03-30 Fixed a bug in backend_qt4, reported on mpl-dev - DSD
2007-03-26 Removed colorbar_classic from figure.py; fixed bug in Figure.clsf() in which _axobservers was not getting cleared. Modernization and cleanups. - EF
2007-03-26 Refactored some of the units support - units now live in the respective x and y Axis instances. See also API_CHANGES for some alterations to the conversion interface. JDH
2007-03-25 Fix masked array handling in quiver.py for numpy. (Numeric and numarray support for masked arrays is broken in other ways when using quiver. I didn't pursue that.) - ADS
2007-03-23 Made font_manager.py close opened files. - JKS
2007-03-22 Made imshow default extent match matshow - EF
2007-03-22 Some more niceties for xcorr - a maxlags option, normed now works for xcorr as well as axorr, usevlines is supported, and a zero correlation hline is added. See examples/xcorr_demo.py. Thanks Sameer for the patch. - JDH

2007-03-21 Axes.vlines and Axes.hlines now create and returns a LineCollection, not a list of lines. This is much faster. The kwarg signature has changed, so consult the docs. Modified Axes.errorbar which uses vlines and hlines. See API_CHANGES; the return signature for these three functions is now different

2007-03-20 Refactored units support and added new examples - JDH

2007-03-19 Added Mike’s units patch - JDH

2007-03-18 Matshow as an Axes method; test version matshow1() in pylab; added ‘integer’ Boolean kwarg to MaxNLocator initializer to force ticks at integer locations. - EF

2007-03-17 Preliminary support for clipping to paths agg - JDH

2007-03-17 Text.set_text() accepts anything convertible with ‘%s’ - EF

2007-03-14 Add masked-array support to hist. - EF

2007-03-03 Change barh to take a kwargs dict and pass it to bar. Fixes sf bug #1669506.

2007-03-02 Add rc parameter pdf.inheritcolor, which disables all color-setting operations in the pdf backend. The idea is that you include the resulting file in another program and set the colors (both stroke and fill color) there, so you can use the same pdf file for e.g., a paper and a presentation and have them in the surrounding color. You will probably not want to draw figure and axis frames in that case, since they would be filled in the same color. - JKS

2007-02-26 Prevent building _wxagg.so with broken Mac OS X wxPython. - ADS

2007-02-23 Require setuptools for Python 2.3 - ADS

2007-02-22 WXAgg accelerator updates - KM WXAgg’s C++ accelerator has been fixed to use the correct wxBitmap constructor.

The backend has been updated to use new wxPython functionality to provide fast blit() animation without the C++ accelerator. This requires wxPython 2.8 or later. Previous versions of wxPython can use the C++ acclerator or the old pure Python routines.

setup.py no longer builds the C++ accelerator when wxPython >= 2.8 is present.

The blit() method is now faster regardless of which agg/wxPython conversion routines are used.

2007-02-21 Applied the PDF backend patch by Nicolas Grilly. This impacts several files and directories in matplotlib:

- Created the directory lib/matplotlib/mpl-data/fonts/pdfcorefonts, holding AFM files for the 14 PDF core fonts. These fonts are embedded in every PDF viewing application.
- setup.py: Added the directory pdfcorefonts to package_data.
- lib/matplotlib/__init__.py: Added the default parameter ‘pdf.use14corefonts’. When True, the PDF backend uses only the 14 PDF core fonts.
- lib/matplotlib/afm.py: Added some keywords found in recent AFM files. Added a little workaround to handle Euro symbol.
• lib/matplotlib/fontmanager.py: Added support for the 14 PDF core fonts. These fonts have a dedicated cache (file pdfcorefont.cache), not the same as for other AFM files (file .afmfont.cache). Also cleaned comments to conform to CODING_GUIDE.

• lib/matplotlib/backends/backend_pdf.py: Added support for 14 PDF core fonts. Fixed some issues with incorrect character widths and encodings (works only for the most common encoding, WinAnsiEncoding, defined by the official PDF Reference). Removed parameter ‘dpi’ because it causes alignment issues.

-JKS (patch by Nicolas Grilly)

2007-02-17 Changed ft2font.get_charmap, and updated all the files where get_charmap is mentioned - ES

2007-02-13 Added barcode demo- JDH

2007-02-13 Added binary colormap to cm - JDH

2007-02-13 Added twiny to pylab - JDH

2007-02-12 Moved data files into lib/matplotlib so that setuptools’ develop mode works. Re-organized the mpl-data layout so that this source structure is maintained in the installation. (i.e., the ‘fonts’ and ‘images’ sub-directories are maintained in site-packages.) Suggest removing site-packages/matplotlib/mpl-data and ~/.matplotlib/ttffont.cache before installing - ADS

2007-02-07 Committed Rob Hetland’s patch for qt4: remove references to text()/latin1(), plus some improvements to the toolbar layout - DSD

2007-02-06 Released 0.90.0 at revision 3003

2007-01-22 Extended the new picker API to text, patches and patch collections. Added support for user customizable pick hit testing and attribute tagging of the PickEvent - Details and examples in examples/pick_event_demo.py - JDH

2007-01-16 Begun work on a new pick API using the mpl event handling framework. Artists will define their own pick method with a configurable epsilon tolerance and return pick attrs. All artists that meet the tolerance threshold will fire a PickEvent with artist dependent attrs; e.g., a Line2D can set the indices attribute that shows the indices into the line that are within epsilon of the pick point. See examples/pick_event_demo.py. The implementation of pick for the remaining Artists remains to be done, but the core infrastructure at the level of event handling is in place with a proof-of-concept implementation for Line2D - JDH

2007-01-16 src/_image.cpp: update to use Py_ssize_t (for 64-bit systems). Use return value of fread() to prevent warning messages - SC.

2007-01-15 src/_image.cpp: combine buffer_argb32() and buffer_rgba32() into a new method color_conv(format) - SC

2007-01-14 backend_cairo.py: update draw_arc() so that examples/arctest.py looks correct - SC

2007-01-12 backend_cairo.py: enable clipping. Update draw_image() so that examples/contour_demo.py looks correct - SC

2007-01-12 backend_cairo.py: fix draw_image() so that examples/image_demo.py now looks correct - SC
2007-01-11 Added Axes.xcorr and Axes.acorr to plot the cross correlation of x vs y or the autocorrelation of x. pylab wrappers also provided. See examples/xcorr_demo.py - JDH

2007-01-10 Added “Subplot.label_outer” method. It will set the visibility of the ticklabels so that yticklabels are only visible in the first column and xticklabels are only visible in the last row - JDH

2007-01-02 Added additional kwarg documentation - JDH

2006-12-28 Improved error message for nonpositive input to log transform; added log kwarg to bar, barh, and hist, and modified bar method to behave sensibly by default when the ordinate has a log scale. (This only works if the log scale is set before or by the call to bar, hence the utility of the log kwarg.) - EF

2006-12-27 backend_cairo.py: update draw_image() and _draw_mathtext() to work with numpy - SC

2006-12-20 Fixed xpdf dependency check, which was failing on windows. Removed ps2eps dependency check. - DSD

2006-12-19 Added Tim Leslie’s spectral patch - JDH

2006-12-17 Added rc param ‘axes.formatter.limits’ to control the default threshold for switching to scientific notation. Added convenience method Axes.ticklabel_format() for turning scientific notation on or off on either or both axes. - EF

2006-12-16 Added ability to turn control scientific notation in ScalarFormatter - EF

2006-12-16 Enhanced boxplot to handle more flexible inputs - EF

2006-12-13 Replaced calls to where() in colors.py with much faster clip() and putmask() calls; removed inappropriate uses of getmaskorNone (which should be needed only very rarely); all in response to profiling by David Cournapeau. Also fixed bugs in my 2-D array support from 12-09. - EF

2006-12-09 Replaced spy and spy2 with the new spy that combines marker and image capabilities - EF

2006-12-09 Added support for plotting 2-D arrays with plot: columns are plotted as in Matlab - EF

2006-12-09 Added linewidth kwarg to bar and barh; fixed arg checking bugs - EF

2006-12-07 Made pcolormesh argument handling match pcolor; fixed kwarg handling problem noted by Pierre GM - EF

2006-12-06 Made pcolor support vector X and/or Y instead of requiring 2-D arrays - EF

2006-12-05 Made the default Artist._transform None (rather than invoking identity_transform for each artist only to have it overridden later). Use artist.get_transform() rather than artist._transform, even in derived classes, so that the default transform will be created lazily as needed - JDH

2006-12-03 Added LogNorm to colors.py as illustrated by examples/pcolor_log.py, based on suggestion by Jim McDonald. Colorbar modified to handle LogNorm. Norms have additional “inverse” method. - EF

2006-12-02 Changed class names in colors.py to match convention: normalize -> Normalize, no_norm -> NoNorm. Old names are still available. Changed __init__.py rc defaults to match those in matplotlibrc - EF
2006-11-22 Fixed bug in set_*lim that I had introduced on 11-15 - EF

**2006-11-22** Added examples/clippedline.py, which shows how to clip line data based on view limits - it also changes the marker style when zoomed in - JDH

2006-11-21 **Some spy bug-fixes and added precision arg per Robert C’s suggestion - JDH**

2006-11-19 **Added semi-automatic docstring generation detailing all the kwargs that functions take using the artist introspection tools; e.g., 'help text now details the scatter kwargs that control the Text properties - JDH**

2006-11-17 **Removed obsolete scatter_classic, leaving a stub to raise NotImplementedError; same for pcolor_classic - EF**

2006-11-15 Removed obsolete pcolor_classic - EF

2006-11-15 **Fixed 1588908 reported by Russel Owen; factored nonsingular method out of ticker.py, put it into transforms.py as a function, and used it in set_xlim and set_ylim. - EF**

2006-11-14 **Applied patch 1591716 by Ulf Larssen to fix a bug in apply_aspect. Modified and applied patch 1594894 by mdehoon to fix bugs and improve formatting in lines.py. Applied patch 1573008 by Greg Willden to make psd etc. plot full frequency range for complex inputs. - EF**

2006-11-14 **Improved the ability of the colorbar to track changes in corresponding image, pcolor, or contourf. - EF**

2006-11-11 **Fixed bug that broke Numeric compatibility; added support for alpha to colorbar. The alpha information is taken from the mappable object, not specified as a kwarg. - EF**

2006-11-05 **Added broken_barh function for makring a sequence of horizontal bars broken by gaps – see examples/broken_barh.py**

2006-11-05 **Removed lineprops and markerprops from the Annotation code and replaced them with an arrow configurable with kwarg arrowprops. See examples/annotation_demo.py - JDH**

2006-11-02 **Fixed a pylab subplot bug that was causing axes to be deleted with hspace or wspace equals zero in subplots_adjust - JDH**

2006-10-26 Released 0.87.7 at revision 2835

2006-10-25 Made “tiny” kwarg in Locator nonsingular much smaller - EF

2006-10-17 **Closed sf bug 1562496 update line props dash/solid/cap/join styles - JDH**

2006-10-17 **Complete overhaul of the annotations API and example code - See matplotlib.text.Annotation and examples/annotation_demo.py JDH**

2006-10-12 Committed Manuel Metz’s StarPolygon code and examples/scatter_star_poly.py - JDH

2006-10-11 commented out all default values in matplotlibrc.template Default values should generally be taken from defaultParam in __init__.py - the file matplotlib should only contain those values that the user wants to explicitly change from the default. (see thread “marker color handling” on matplotlib-devel)
2006-10-10 Changed default comment character for load to ‘#’ - JDH

2006-10-10 deactivated rcfile-configurability of markerfacecolor and markeredgecolor. Both are now hardcoded to the special value ‘auto’ to follow the line color. Configurability at run-time (using function arguments) remains functional. - NN

2006-10-07 introduced dummy argument magnification=1.0 to FigImage.make_image to satisfy unit test figimage_demo.py The argument is not yet handled correctly, which should only show up when using non-standard DPI settings in PS backend, introduced by patch #1562394. - NN

2006-10-06 add backend-agnostic example: simple3d.py - NN

2006-09-29 fix line-breaking for SVG-inline images (purely cosmetic) - NN

2006-09-29 reworked set_linestyle and set_marker markeredgecolor and markerfacecolor now default to a special value “auto” that keeps the color in sync with the line color further, the intelligence of axes.plot is cleaned up, improved and simplified. Complete compatibility cannot be guaranteed, but the new behavior should be much more predictable (see patch #1104615 for details) - NN

2006-09-29 changed implementation of clip-path in SVG to work around a limitation in inkscape - NN

2006-09-29 added two options to matplotlibrc: svg.image_inline svg.image_noscale see patch #1533010 for details - NN

2006-09-29 axes.py: cleaned up kwargs checking - NN

2006-09-29 setup.py: cleaned up setup logic - NN

2006-09-29 setup.py: check for required pygtk versions, fixes bug #1460783 - SC

2006-09-27 Released 0.87.6 at revision 2783

2006-09-24 Added line pointers to the Annotation code, and a pylab interface. See matplotlib.text.Annotation, examples/annotation_demo.py and examples/annotation_demo_pylab.py - JDH

2006-09-18 mathtext2.py: The SVG backend now supports the same things that the AGG backend does. Fixed some bugs with rendering, and out of bounds errors in the AGG backend - ES. Changed the return values of math_parse_s_ft2font_svg to support lines (fractions etc.)

2006-09-17 Added an Annotation class to facilitate annotating objects and an examples file examples/annotation_demo.py. I want to add dash support as in TextWithDash, but haven’t decided yet whether inheriting from TextWithDash is the right base class or if another approach is needed - JDH

2006-09-05 Released 0.87.5 at revision 2761

2006-09-04 Added nxutils for some numeric add-on extension code - specifically a better/more efficient inside polygon tester (see unit/inside_poly_.py) - JDH

2006-09-04 Made bitstream fonts the rc default - JDH

2006-08-31 Fixed alpha-handling bug in ColorConverter, affecting collections in general and contour/contourf in particular. - EF
2006-08-30 ft2font.cpp: Added draw_rect_filled method (now used by mathtext2 to draw the fraction bar) to FT2Font - ES

2006-08-29 setupext.py: wrap calls to tk.getvar() with str(). On some systems, getvar returns a Tcl_Obj instead of a string - DSD

2006-08-28 mathtext2.py: Sub/superscripts can now be complex (i.e. fractions etc.). The demo is also updated - ES

2006-08-28 font_manager.py: Added /usr/local/share/fonts to list of X11 font directories - DSD

2006-08-28 mathtext2.py: Initial support for complex fractions. Also, rendering is now completely separated from parsing. The sub/superscripts now work better. Updated the mathtext2_demo.py - ES

2006-08-27 qt backends: don’t create a QApplication when backend is imported, do it when the FigureCanvasQt is created. Simplifies applications where mpl is embedded in qt. Updated embedding_in_qt* examples - DSD

2006-08-27 mathtext2.py: Now the fonts are searched in the OS font dir and in the mpl-data dir. Also env is not a dict anymore. - ES

2006-08-26 minor changes to __init__.py, mathtext2_demo.py. Added matplotlibrc key "mathtext.mathtext2" (removed the key "mathtext2") - ES

2006-08-21 mathtext2.py: Initial support for fractions Updated the mathtext2_demo.py _mathtext_data.py: removed "’ from the unicode dicts mathtext.py: Minor modification (because of _mathtext_data.py)- ES

2006-08-20 Added mathtext2.py: Replacement for mathtext.py. Supports ^,~, r, m, c, sin, cos etc., unicode, recursive nestings, inline math mode. The only backend currently supported is Agg __init__.py: added new rc params for mathtext2 added mathtext2_demo.py example - ES

2006-08-19 Added embedding_in_qt4.py example - DSD

2006-08-11 Added scale free Ellipse patch for Agg - CM

2006-08-10 Added converters to and from julian dates to matplotlib.dates (num2julian and julian2num) - JDH

2006-08-08 Fixed widget locking so multiple widgets could share the event handling - JDH

2006-08-07 Added scale free Ellipse patch to SVG and PS - CM

2006-08-05 Re-organized imports in numerix for numpy 1.0b2 - TEO

2006-08-04 Added draw_markers to PDF backend. - JKS

2006-08-01 figure.py: savefig() update docstring to add support for ‘format’ argument. backend_cairo.py: print_figure() add support ‘format’ argument. - SC

2006-07-31 Don't let postscript's xpdf distiller compress images - DSD

2006-07-31 Added shallowcopy() methods to all Transformations; removed copy_bbox_transform and copy_bbox_transform_shallow from transforms.py; added offset_copy() function to transforms.py to facilitate positioning artists with offsets. See examples/transoffset.py. - EF

2006-07-31 Don't let postscript's xpdf distiller compress images - DSD

7.1. List of changes to Matplotlib prior to 2015
2006-07-29 Fixed numerix polygon bug reported by Nick Fotopoulos. Added inverse_numerix_xy() transform method. Made autoscale_view() preserve axis direction (e.g., increasing down). - EF

2006-07-28 Added shallow bbox copy routine for transforms – mainly useful for copying transforms to apply offset to. - JDH

2006-07-28 Added resize method to FigureManager class for Qt and Gtk backend - CM

2006-07-28 Added subplots_adjust button to Qt backend - CM

2006-07-26 Use numerix more in collections. Quiver now handles masked arrays. - EF

2006-07-22 Fixed bug #1209354 - DSD

2006-07-22 make scatter() work with the kwarg “color”. Closes bug 1285750 - DSD

2006-07-20 backend_cairo.py: require pycairo 1.2.0. print_figure() update to output SVG using cairo.

2006-07-19 Added blitting for Qt4Agg - CM

2006-07-19 Added lasso widget and example examples/lasso_demo.py - JDH

2006-07-18 Added blitting for QtAgg backend - CM

2006-07-17 Fixed bug #1523585: skip nans in semilog plots - DSD

2006-07-12 Add support to render the scientific notation label over the right-side y-axis - DSD

2006-07-11 Released 0.87.4 at revision 2558

2006-07-07 Fixed a usetex bug with older versions of latex - DSD

2006-07-07 Add compatibility for NumPy 1.0 - TEO

2006-06-29 Added a Qt4Agg backend. Thank you James Amundson - DSD

2006-06-26 Fixed a usetex bug. On windows, usetex will process postscript output in the current directory rather than in a temp directory. This is due to the use of spaces and tildes in windows paths, which cause problems with latex. The subprocess module is no longer used. - DSD

2006-06-22 Various changes to bar(), barh(), and hist(). Added ‘edgecolor’ keyword arg to bar() and barh(). The x and y args in barh() have been renamed to width and bottom respectively, and their order has been swapped to maintain a (position, value) order ala matlab. left, height, width and bottom args can now all be scalars or sequences. barh() now defaults to edge alignment instead of center alignment. Added a keyword arg ‘align’ to bar(), barh() and hist() that controls between edge or center bar alignment. Fixed ignoring the rcParams[‘patch.facecolor’] for bar color in bar() and barh(). Fixed ignoring the rcParams[‘lines.color’] for error bar color in bar() and barh(). Fixed a bug where patches would be cleared when error bars were plotted if rcParams[‘axes.hold’] was False. - MAS

2006-06-22 Added support for numerix 2-D arrays as alternatives to a sequence of (x,y) tuples for specifying paths in collections, quiver, contour, pcolor, transforms. Fixed contour bug involving setting limits for color mapping. Added numpy-style all() to numerix. - EF

2006-06-20 Added custom FigureClass hook to pylab interface - see examples/custom_figure_class.py
2006-06-16 Added colormaps from gist (gist_earth, gist_stern, gist_rainbow, gist_gray, gist_yarg, gist_heat, gist_ncar) - JW

2006-06-16 Added a pointer to parent in figure canvas so you can access the container with fig.canvas.manager. Useful if you want to set the window title, e.g., in gtk fig.canvas.manager.window.set_title, though a GUI neutral method would be preferable - JDH

2006-06-16 Fixed colorbar.py to handle indexed colors (i.e., norm = no_norm()) by centering each colored region on its index. - EF

2006-06-15 Added scalex and scaley to Axes.autoscale_view to support selective autoscaling just the x or y axis, and supported these command in plot so you can say plot(something, scaley=False) and just the x axis will be autoscaled. Modified axvline and axhline to support this, so for example axvline will no longer autoscale the y axis. - JDH

2006-06-13 Fix so numpy updates are backward compatible - TEO

2006-06-12 Updated numerix to handle numpy restructuring of oldnumeric - TEO

2006-06-12 Updated numerix.fft to handle numpy restructuring Added ImportError to numerix.linear_algebra for numpy - TEO

2006-06-11 Added quiverkey command to pylab and Axes, using QuiverKey class in quiver.py. Changed pylab and Axes to use quiver2 if possible, but drop back to the newly-renamed quiver_classic if necessary. Modified examples/quiver2.py to illustrate the new quiver and quiverkey. Changed LineCollection implementation slightly to improve compatibility with PolyCollection. - EF

2006-06-11 Fixed a use_tex bug for windows, running latex on files with spaces in their names or paths was failing - DSD

2006-06-09 Made additions to numerix, changes to quiver to make it work with all numeric flavors. - EF

2006-06-09 Added quiver2 function to pylab and method to axes, with implementation via a Quiver class in quiver.py. quiver2 will replace quiver before the next release; it is placed alongside it initially to facilitate testing and transition. See also examples/quiver2_demo.py. - EF

2006-06-08 Minor bug fix to make ticker.py draw proper minus signs with use_tex - DSD

2006-06-06 Released 0.87.3 at revision 2432

2006-05-30 More partial support for polygons with outline or fill, but not both. Made LineCollection inherit from ScalarMappable. - EF

2006-05-29 Yet another revision of aspect-ratio handling. - EF

2006-05-27 Committed a patch to prevent stroking zero-width lines in the svg backend - DSD

2006-05-24 Fixed colorbar positioning bug identified by Helge Avlesen, and improved the algorithm; added a ‘pad’ kwarg to control the spacing between colorbar and parent axes. - EF

2006-05-23 Changed color handling so that collection initializers can take any mpl color arg or sequence of args; deprecated float as grayscale, replaced by string representation of float. - EF
2006-05-19 Fixed bug: plot failed if all points were masked - EF

2006-05-19 Added custom symbol option to scatter - JDH

**2006-05-18 New example, multi_image.py; colorbar fixed to show** offset text when the ScalarFormatter is used; FixedFormatter augmented to accept and display offset text. - EF

**2006-05-14 New colorbar; old one is renamed to colorbar_classic.** New colorbar code is in colorbar.py, with wrappers in figure.py and pylab.py. Fixed aspect-handling bug reported by Michael Mossey. Made backend_bases.draw_quad_mesh() run.- EF

**2006-05-08 Changed handling of end ranges in contourf: replaced** "clip-ends" kwarg with "extend". See docstring for details. -EF

2006-05-08 Added axisbelow to rc - JDH

2006-05-08 If using PyGTK require version 2.2+ - SC

**2006-04-19 Added compression support to PDF backend, controlled by** new pdf.compression rc setting. - JKS

2006-04-19 Added Jouni’s PDF backend

2006-04-18 Fixed a bug that caused agg to not render long lines

**2006-04-16 Masked array support for pcolormesh; made pcolormesh support the same combinations of X,Y,C dimensions as pcolor does; improved (I hope) description of grid used in pcolor; pcolormesh.** - EF

2006-04-14 Reorganized axes.py - EF

**2006-04-13 Fixed a bug Ryan found usingusetex with sans-serif fonts and exponential tick labels - DSD

2006-04-11 Refactored backend_ps and backend_agg to prevent module-level texmanager imports. Now these imports only occur if text.usetex rc setting is true - DSD

2006-04-10 Committed changes required for building mpl on win32 platforms with visual studio. This allows wxpython blitting for fast animations. - CM

2006-04-10 Fixed an off-by-one bug in Axes.change_geometry.

**2006-04-05 Applied Ken’s wx deprecation warning patch closing sf patch #1465371 - JDH

2006-04-05 Added support for the new API in the postscript backend.** Allows values to be masked using nan’s, and faster file creation - DSD

**2006-04-05 Use python’s subprocess module forusetex calls to external programs.** subprocess catches when they exit abnormally so an error can be raised. - DSD

**2006-04-03 Fixed the bug in which widgets would not respond** to events. This regressed the twinx functionality, so I also updated subplots_adjust to update axes that share an x or y with a subplot instance. - CM

**2006-04-02 Moved PBox class to transforms and deleted pbox.py; made pylab axis command a thin wrapper for Axes.axis; more tweaks to aspect-ratio handling; fixed
Axes.specgram to account for the new imshow default of unit aspect ratio; made contour set the Axes.dataLim. - EF

2006-03-31 Fixed the Qt "Underlying C/C++ object deleted" bug. - JRE

2006-03-31 Applied Vasily Sulatskov’s Qt Navigation Toolbar enhancement. - JRE

2006-03-31 Ported Norbert’s rewriting of Halldor’s stineman_interp algorithm to make it numerix compatible and added code to matplotlib.mlab. See examples/interp_demo.py - JDH

2006-03-30 Fixed a bug in aspect ratio handling; blocked potential crashes when panning with button 3; added axis('image') support. - EF

2006-03-28 More changes to aspect ratio handling; new PBox class in new file pbox.py to facilitate resizing and repositioning axes; made PolarAxes maintain unit aspect ratio. - EF

2006-03-23 Refactored TextWithDash class to inherit from, rather than delegate to, the Text class. Improves object inspection and closes bug # 1357969 - DSD

2006-03-22 Improved aspect ratio handling, including pylab interface. Interactive resizing, pan, zoom of images and plots (including panels with a shared axis) should work. Additions and possible refactoring are still likely. - EF

2006-03-21 Added another colorbrewer colormap (RdYlBu) - JSWHIT

2006-03-21 Fixed tickmarks for logscale plots over very large ranges. Closes bug # 1232920 - DSD

2006-03-21 Added Rob Knight’s arrow code; see examples/arrow_demo.py - JDH

2006-03-20 Added support for masking values with nan’s, using ADS’s isnan module and the new API. Works for *Agg backends - DSD

2006-03-20 Added contour:negative_linestyle rcParam - ADS

2006-03-20 Added _isnan extension module to test for nan with Numeric

• ADS

2006-03-17 Added Paul and Alex’s support for faceting with quadmesh in sf patch 1411223 - JDH

2006-03-17 Added Charle Twardy’s pie patch to support colors=None. Closes sf patch 1387861 - JDH

2006-03-17 Applied sophana’s patch to support overlapping axes with toolbar navigation by toggling activation with the ‘a’ key. Closes sf patch 1432252 - JDH

2006-03-17 Applied Aarre’s linestyle patch for backend EMF; closes sf patch 1449279 - JDH

2006-03-17 Applied Jordan Dawe’s patch to support kwarg properties for grid lines in the grid command. Closes sf patch 1451661 - JDH

2006-03-17 Center postscript output on page when using usetex - DSD

2006-03-17 subprocess module built if Python <2.4 even if subprocess can be imported from an egg - ADS

2006-03-17 Added _subprocess.c from Python upstream and hopefully enabled building (without breaking) on Windows, although not tested. - ADS
2006-03-17 Updated subprocess.py to latest Python upstream and reverted name back to subprocess.py - ADS

2006-03-16 Added John Porter’s 3D handling code

2006-03-16 Released 0.87.2 at revision 2150

2006-03-15 Fixed bug in MaxNLocator revealed by daigos@infinite.it. The main change is that Locator.nonsingular now adjusts vmin and vmax if they are nearly the same, not just if they are equal. A new kwarg, “tiny”, sets the threshold. - EF

2006-03-14 Added import of compatibility library for newer numpy linear_algebra - TEO

2006-03-12 Extended “load” function to support individual columns and moved “load” and “save” into matplotlib.mlab so they can be used outside of pylab – see examples/load_converter.py - JDH

2006-03-12 Added AutoDateFormatter and AutoDateLocator submitted by James Evans. Try the load_converter.py example for a demo. - ADS

2006-03-11 Added subprocess module from python-2.4 - DSD

2006-03-11 Fixed landscape orientation support with theusetex option. The backend_ps print_figure method was getting complicated, I added a _print_figure_tex method to maintain some degree of sanity - DSD

2006-03-11 Added “papertype” savefig kwarg for setting postscript papersizes. papertype and ps.papersize rc setting can also be set to “auto” to autoscale pagesizes - DSD

2006-03-09 Apply P-J’s patch to make pstoeps work on windows patch report #1445612 - DSD

2006-03-09 Make backend rc parameter case-insensitive - DSD

2006-03-07 Fixed bug in backend_ps related to C0-C6 papersizes, which were causing problems with postscript viewers. Supported page sizes include letter, legal, ledger, A0-A10, and B0-B10 - DSD

2006-03-07 Released 0.87.1

2006-03-04 backend_cairo.py: fix get_rgb() bug reported by Keith Briggs. Require pycairo 1.0.2. Support saving png to file-like objects. - SC

2006-03-03 Fixed pcolor handling of vmin, vmax - EF

2006-03-02 Improve page sizing withusetex with the latex geometry package. Closes bug # 1441629 - DSD

2006-03-02 Fixed dpi problem withusetex png output. Accepted a modified version of patch # 1441809 - DSD

2006-03-01 Fixed axis(‘scaled’) to deal with case xmax < xmin - JSWHIT

2006-03-01 Added reversed colormaps (with ‘_r’ appended to name) - JSWHIT

2006-02-27 Improved eps bounding boxes withusetex - DSD

2006-02-27 Test svn commit, again!

2006-02-27 Fixed two dependency checking bugs related tousetex on Windows - DSD
2006-02-27 Made the rc deprecation warnings a little more human readable.
2006-02-26 Update the previous gtk.main_quit() bug fix to use gtk.main_level()
  • SC
2006-02-24 Implemented alpha support in contour and contourf - EF
2006-02-22 Fixed gtk main quit bug when quit was called before mainloop. - JDH
2006-02-22 Small change to colors.py to workaround apparent bug in numpy masked array module - JSWHIT
2006-02-22 Fixed bug in ScalarMappable.to_rgba() reported by Ray Jones, and fixed incorrect fix found by Jeff Whitaker - EF

2006-02-22 Released 0.87
2006-02-21 Fixed portrait/landscape orientation in postscript backend - DSD
2006-02-21 Fix bug introduced in yesterday’s bug fix - SC
2006-02-20 backend_gtk.py FigureCanvasGTK.draw(): fix bug reported by David Tremouilles - SC
2006-02-20 Remove the “pygtk.require(‘2.4’)” error from examples/embedding_in_gtk2.py - SC
2006-02-18 backend_gtk.py FigureCanvasGTK.draw(): simplify to use (rather than duplicate) the expose_event() drawing code - SC
2006-02-12 Added stagger or waterfall plot capability to LineCollection; illustrated in examples/collections.py. - EF
2006-02-11 Massive cleanup of the usetex code in the postscript backend. Possibly fixed the clipping issue users were reporting with older versions of ghostscript - DSD
2006-02-11 Added autolim kwarg to axes.add_collection. Changed collection get_verts() methods accordingly. - EF
2006-02-09 added a temporary rc parameter text.dvipnghack, to allow Mac users to get nice results with the usetex option. - DSD
2006-02-09 Fixed a bug related to setting font sizes with the usetex option. - DSD
2006-02-09 Fixed a bug related to usetex’s latex code. - DSD
2006-02-09 Modified behavior of font.size rc setting. You should define font.size in pts, which will set the “medium” or default fontsize. Special text sizes like axis labels or tick labels can be given relative font sizes like small, large, x-large, etc. and will scale accordingly. - DSD
2006-02-08 Added py2exe specific datapath check again. Also added new py2exe helper function get_py2exe_datafiles for use in py2exe setup.py scripts. - CM
2006-02-02 Added box function to pylab
2006-02-02 Fixed a problem in setupext.py, tk library formatted in unicode caused build problems - DSD
2006-02-01 Dropped TeX engine support in usetex to focus on LaTeX. - DSD

7.1. List of changes to Matplotlib prior to 2015
2006-01-29 **Improved usetex option to respect the serif, sans-serif, monospace, and cursive rc settings. Removed the font.latex.package rc setting, it is no longer required** - DSD

2006-01-29 Fixed tex’s caching to include font.family rc information - DSD

2006-01-29 **Fixed subpixel rendering bug in *Agg that was causing** uneven gridlines - JDH

2006-01-28 **Added fontcmd to backend_ps’s RendererPS.draw_tex, to support other font families in eps output** - DSD

2006-01-28 **Added MaxNLocator to ticker.py, and changed contour.py to use it by default.** - EF

2006-01-28 **Added fontcmd to backend_ps’s RendererPS.draw_tex, to support other font families in eps output** - DSD

2006-01-27 **Buffered reading of matplotlibrc parameters in order to allow ‘verbose’ settings to be processed first (allows verbose.report during rc validation process)** - DSD

2006-01-27 **Removed setuptools support from setup.py and created a separate setupegg.py file to replace it.** - CM

2006-01-26 **Replaced the ugly datapath logic with a cleaner approach from http://wiki.python.org/moin/DistutilsInstallDataScattered. Overrides the install_data command.** - CM

2006-01-24 **Don’t use character typecodes in cntr.c — changed to use defined type-numbers instead.** - TEO

2006-01-24 Fixed some bugs in usetex’s and ps.usedistiller’s dependency

2006-01-24 Added masked array support to scatter - EF

2006-01-24 **Fixed some bugs in usetex’s and ps.usedistiller’s dependency checking** - DSD

2006-01-24 Released 0.86.2

2006-01-20 **Added a converters dict to pylab load to convert selected columns to float** - especially useful for files with date strings, uses a datestr2num converter - JDH

2006-01-20 **Added datestr2num to matplotlib dates to convert a string or sequence of strings to a matplotlib datenum**

2006-01-18 **Added quadrilateral pcolormesh patch 1409190 by Alex Mont and Paul Kienzle** - this is *Agg only for now. See examples/quadmesh_demo.py - JDH

2006-01-18 Added Jouni’s boxplot patch - JDH

2006-01-18 Added comma delimiter for pylab save - JDH

2006-01-12 Added Ryan’s legend patch - JDH

2006-1-12 Fixed numpy / numeric to use .dtype.char to keep in SYNC with numpy SVN

2006-1-11 Released 0.86.1

2006-1-11 Fixed setup.py for win32 build and added rc template to the MANIFEST.in
**2006-1-10** Added xpdf distiller option. matplotlibrc ps.usedistiller can now be none, false, ghostscript, or xpdf. Validation checks for dependencies. This needs testing, but the xpdf option should produce the highest-quality output and small file sizes - DSD

**2006-01-10** For the usetex option, backend_ps now does all the LaTeX work in the os's temp directory - DSD

2006-1-10 Added checks for usetex dependencies. - DSD

2006-1-9 Released 0.86

2006-1-4 Changed to support numpy (new name for scipy_core) - TEO

2006-1-4 Added Mark's scaled axes patch for shared axis

2005-12-28 Added Chris Barker's build_wxagg patch - JDH

**2005-12-27** Altered numerix/scipy to support new scipy package structure - TEO

2005-12-20 Fixed Jame's Boyles date tick reversal problem - JDH

**2005-12-20** Added Jouni's rc patch to support lists of keys to set on - JDH

**2005-12-12** Updated pyparsing and mathtext for some speed enhancements (Thanks Paul McGuire) and minor fixes to scipy numerix and setup tools

**2005-12-12** Matplotlib data is now installed as package_data in the matplotlib module. This gets rid of checking the many possibilities in matplotlib._get_data_path() - CM

**2005-12-11** Support for setuptools/pkg_resources to build and use matplotlib as an egg. Still allows matplotlib to exist using a traditional distutils install. - ADS

**2005-12-03** Modified setup to build matplotlibrc based on compile time findings. It will set numerix in the order of scipy, numarray, Numeric depending on which are founds, and backend as in preference order GTKAgg, WXAgg, TkAgg, GTK, Agg, PS

**2005-12-03** Modified scipy patch to support Numeric, scipy and numarray Some work remains to be done because some of the scipy imports are broken if only the core is installed. e.g., apparently we need from scipy.basic.fftpack import * rather than from scipy.fftpack import *

**2005-12-03** Applied some fixes to Nicholas Young's nonuniform image patch

2005-12-01 Applied Alex Ontmakher hatch patch - PS only for now

2005-11-30 Added Rob McMullen's EMF patch

2005-11-30 Added Daishi's patch for scipy

2005-11-30 Fixed out of bounds draw markers segfault in agg

2005-11-28 Got TkAgg blitting working 100% (cross fingers) correctly. - CM

2005-11-27 Multiple changes in cm.py, colors.py, figure.py, image.py, contour.py, contour_demo.py; new_cm.py, examples/image_masked.py. 1) Separated the color table data from cm.py out into a new file, _cm.py, to make it easier to find the actual code in cm.py and to add new colormaps. Also added some line breaks to the color data dictionaries. Everything from _cm.py is imported by cm.py, so the split should be transparent. 2) Enabled automatic generation of a colormap from a list of colors in contour; see modified examples/contour_demo.py. 3) Support for imshow of a masked array, with the ability to specify colors (or no color at all) for masked regions, and for regions that are above or below the normally mapped region. See examples/image_masked.py.
4) In support of the above, added two new classes, ListedColormap, and no_norm, to colors.py, and modified the Colormap class to include common functionality. Added a clip kwarg to the normalize class. Reworked color handling in contour.py, especially in the ContourLabeller mixin. - EF

2005-11-25 Changed text.py to ensure color is hashable. EF

2005-11-16 Released 0.85
2005-11-16 Changed the default default linewidth in rc to 1.0

2005-11-16 Replaced agg_to_gtk_drawable with pure pygtk pixbuf code in backend gtkagg. When the equivalent is doe for blit, the agg extension code will no longer be needed

2005-11-16 Added a maxdict item to cbook to prevent caches from growing w/o bounds

2005-11-15 Fixed a colorup/colordown reversal bug in finance.py - Thanks Gilles

2005-11-15 Applied Jouni K Steppanen’s boxplot patch SF patch#1349997
  • JDH

2005-11-09 added axisbelow attr for Axes to determine whether ticks and such are above or below the actors

2005-11-08 Added Nicolas’ irregularly spaced image patch

2005-11-08 Deprecated HorizontalSpanSelector and replaced with SpanSelection that takes a third arg, direction. The new SpanSelector supports horizontal and vertical span selection, and the appropriate min/max is returned. - CM

2005-11-08 Added lineprops dialog for gtk

2005-11-03 Added FIFOBuffer class to mlab to support real time feeds and examples/fifo_buffer.py

2005-11-01 Contributed Nickolas Young’s patch for afm mathtext to support mathtext based upon the standard postscript Symbol font when psusetex = True.

2005-10-26 Added support for scatter legends - thanks John Gill

2005-10-20 Fixed image clipping bug that made some tex labels disappear. JDH

2005-10-14 Removed sqrt from dvipng 1.6 alpha channel mask.

2005-10-14 Added width kwarg to hist function

2005-10-10 Replaced all instances of os.rename with shutil.move

2005-10-05 Added Michael Brady’s ydate patch

2005-10-04 Added rkern’s texmanager patch

2005-09-25 contour.py modified to use a single ContourSet class that handles filled contours, line contours, and labels; added keyword arg (clip_ends) to contourf. Colorbar modified to work with new ContourSet object; if the ContourSet has lines rather than polygons, the colorbar will follow suit. Fixed a bug introduced in 0.84, in which contourf(...,colors=...) was broken - EF

2005-09-19 Released 0.84
2005-09-14 **Added a new ’resize_event’ which triggers a callback with a**
backend.bases.ResizeEvent object - JDH

2005-09-14 font_manager.py: removed chkfontpath from x11FontDirectory() - SC

2005-09-14 **Factored out auto date locator/formatter factory code into**
matplotlib.date.date_ticker_factory; applies John Bryne’s quiver patch.

2005-09-13 Added Mark’s axes positions history patch #1286915

2005-09-09 **Added support for auto canvas resizing with**
fig.set_figsize_inches(9,5,forward=True) # inches OR fig.resize(400,300) # pixels

2005-09-07 **figure.py: update Figure.draw() to use the updated**
renderer.draw_image() so that examples/figimage_demo.py works again. examples/stock_demo.py: remove data_clipping (which no longer exists) - SC

2005-09-06 Added Eric’s tick.direction patch: in or out in rc

2005-09-06 Added Martin’s rectangle selector widget

2005-09-04 **Fixed a logic err in text.py that was preventing rgxsuper from matching** - JDH

2005-08-29 Committed Ken’s wx blit patch #1275002

2005-08-26 **colorbar modifications - now uses contourf instead of imshow so**
that colors used by contourf are displayed correctly. Added two new keyword args (cspaceing and clabels) that are only relevant for ContourMappable images - JSWHIT

2005-08-24 Fixed a PS image bug reported by Darren - JDH

2005-08-23 colors.py: change hex2color() to accept unicode strings as well as
normal strings. Use isinstance() instead of types.IntType etc - SC

2005-08-16 removed data_clipping line and rc property - JDH

2005-08-22 backend_svg.py: **Remove redundant “x=0.0 y=0.0” from svg element.**
Increase svg version from 1.0 to 1.1. Add viewBox attribute to svg element to allow SVG
documents to scale-to-fit into an arbitrary viewport - SC

2005-08-16 Added Eric’s dot marker patch - JDH

2005-08-08 Added blitting/animation for TkAgg - CM

2005-08-05 Fixed duplicate tickline bug - JDH

2005-08-05 **Fixed a GTK animation bug that cropped up when doing animations in**
gtk//gtkagg canvases that had widgets packed above them

2005-08-05 Added Clovis Goldemberg patch to the tk save dialog

2005-08-04 **Removed origin kwarg from backend.draw_image. origin is**
handled entirely by the frontend now.

2005-07-03 Fixed a bug related to TeX commands in backend_ps

2005-08-03 Fixed SVG images to respect upper and lower origins.

2005-08-03 Added flipud method to image and removed it from to_str.

2005-07-29 **Modified figure.figaspect to take an array or number; modified back-**
end_svg to write utf-8 - JDH

2005-07-30 backend_svg.py: **embed png image files in svg rather than linking to**
a separate png file, fixes bug #1245306 (thanks to Norbert Nemec for the patch) - SC
2005-07-29 Released 0.83.2

2005-07-27 Applied SF patch 1242648: minor rounding error in IndexDateFormatter in dates.py

2005-07-27 Applied SF patch 1244732: Scale axis such that circle looks like circle - JDH

2005-07-29 Improved message reporting in texmanager and backend_ps - DSD

2005-07-28 backend_gtk.py: update FigureCanvasGTK.draw() (needed due to the recent expose_event() change) so that examples/anim.py works in the usual way - SC

2005-07-26 Added new widgets Cursor and HorizontalSpanSelector to matplotlib.widgets. See examples/widgets/cursor.py and examples/widgets/span_selector.py - JDH

2005-07-26 added draw event to mpl event hierarchy - triggered on figure.draw

2005-07-26 backend_gtk.py: allow ‘f’ key to toggle window fullscreen mode

2005-07-26 backend_svg.py: write “<.../>” elements all on one line and remove surplus spaces - SC

2005-07-25 backend_svg.py: simplify code by deleting GraphicsContextSVG and RendererSVG.new_gc(), and moving the gc.get_capstyle() code into RendererSVG._get_gc_props_svg() - SC

2005-07-24 backend_gtk.py: call FigureCanvasBase.motion_notify_event() on all motion-notify-events, not just ones where a modifier key or button has been pressed (fixes bug report from Niklas Volbers) - SC

2005-07-24 backend_gtk.py: modify print_figure() use own pixmap, fixing problems where print_figure() overwrites the display pixmap. return False from all button/key etc events - to allow the event to propagate further - SC

2005-07-23 backend_gtk.py: change expose_event from using set_back_pixmap(); clear() to draw_drawable() - SC

2005-07-23 backend_gtk.py: removed pygtk.require() matplotlib/_init__.py: delete ‘FROZEN’ and ‘McPLError’ which are no longer used - SC

2005-07-22 backend_gtk.py: removed pygtk.require() - SC

2005-07-21 backend_svg.py: Remove unused imports. Remove methods doc strings which just duplicate the docs from backend_bases.py. Rename draw_mathtext to _draw_mathtext. - SC

2005-07-17 examples/embedding_in_gtk3.py: new example demonstrating placing a FigureCanvas in a gtk.ScrolledWindow - SC

2005-07-14 Fixed a Windows related bug (#1238412) in texmanager - DSD

2005-07-11 Fixed color kwarg bug, setting color=1 or 0 caused an exception - DSD

2005-07-07 Added Eric’s MA set_xdata Line2D fix - JDH

2005-07-06 Made HOME/.matplotlib the new config dir where the matplotlibrc file, the ttf.cache, and the tex.cache live. The new default filenames in .matplotlib have no leading dot and are not hidden. e.g., the new names are matplotlibrc tex.cache ttffont.cache. This is how ipython does it so it must be right. If old files are found, a warning is issued and they are moved to the new location. Also fixed texmanager to put
Matplotlib, Release 3.1.1

all files, including temp files in ~/.matplotlib/tex.cache, which allows you to usetex in non-writable dirs.

2005-07-05 Fixed bug #1231611 in subplots adjust layout. The problem was that the text caching mechanism was not using the transformation affine in the key. - JDH

2005-07-05 Fixed default backend import problem when using API (SF bug #1209354 - see API_CHANGES for more info - JDH

2005-07-04 backend_gtk.py: require PyGTK version 2.0.0 or higher - SC

2005-06-30 setupext.py: added numarray_inc_dirs for building against numarray when not installed in standard location - ADS

2005-06-27 backend_svg.py: write figure width, height as int, not float. Update to fix some of the pychecker warnings - SC

2005-06-23 Updated examples/agg_test.py to demonstrate curved paths and fills - JDH

2005-06-21 Moved some texmanager and backend_agg tex caching to class level rather than instance level - JDH

2005-06-20 setupext.py: fix problem where _nc_backend_gdk is installed to the wrong directory - SC

2005-06-19 Added 10.4 support for CocoaAgg. - CM

2005-06-18 Move Figure.get_width_height() to FigureCanvasBase and return int instead of float. - SC

2005-06-18 Applied Ted Drain’s QtAgg patch: 1) Changed the toolbar to be a horizontal bar of push buttons instead of a QToolbar and updated the layout algorithms in the main window accordingly. This eliminates the ability to drag and drop the toolbar and detach it from the window. 2) Updated the resize algorithm in the main window to show the correct size for the plot widget as requested. This works almost correctly right now. It looks to me like the final size of the widget is off by the border of the main window but I haven’t figured out a way to get that information yet. We could just add a small margin to the new size but that seems a little hacky. 3) Changed the x/y location label to be in the toolbar like the Tk backend instead of as a status line at the bottom of the widget. 4) Changed the toolbar pixmaps to use the ppm files instead of the png files. I noticed that the Tk backend buttons looked much nicer and it uses the ppm files so I switched them.

2005-06-17 Modified the gtk backend to not queue mouse motion events. This allows for live updates when dragging a slider. - CM

2005-06-17 Added starter CocoaAgg backend. Only works on OS 10.3 for now and requires PyObjC. (10.4 is high priority) - CM

2005-06-17 Upgraded pyparsing and applied Paul McGuire’s suggestions for speeding things up. This more than doubles the speed of mathtext in my simple tests. JDH

2005-06-16 Applied David Cooke’s subplot make_key patch

2005-06-15 0.82 released

2005-06-15 Added subplot config tool to GTK* backends - note you must now import the NavigationToolbar2 from your backend of choice rather than from backend_gtk because it needs to know about the backend specific canvas
- see examples/embedding_in_gtk2.py. Ditto for wx backend - see examples/embedding_in_wxagg.py

2005-06-15 backend_cairo.py: updated to use pycairo 0.5.0 - SC

2005-06-14 Wrote some GUI neutral widgets (Button, Slider, RadioButtons, CheckButtons) in matplotlib.widgets. See examples/widgets/*.py - JDH

2005-06-14 Exposed subplot parameters as rc vars and as the fig SubplotParams instance subplotpars. See figure.SubplotParams, figure.Figure.subplots_adjust and the pylab method subplots adjust and examples/subplots_adjust.py. Also added a GUI neutral widget for adjusting subplots, see examples/subplot_toolbar.py - JDH

2005-06-13 Exposed cap and join style for lines with new rc params and line properties

lines.dash_joinstyle : miter # miter|round|bevel lines.dash_capstyle : butt # butt|round|projecting lines.solid_joinstyle : miter # miter|round|bevel lines.solid_capstyle : projecting # butt|round|projecting

2005-06-13 Added kwargs to Axes init

2005-06-13 Applied Baptiste’s tick patch - JDH

2005-06-13 Fixed rc alias ‘l’ bug reported by Fernando by removing aliases for main-level rc options. - JDH

2005-06-10 Fixed bug #1217637 in ticker.py - DSD

2005-06-07 Fixed a bug in texmanager.py: .aux files not being removed - DSD

2005-06-08 Added Sean Richard’s hist binning fix - see API_CHANGES - JDH

2005-06-07 Fixed a bug in texmanager.py: .aux files not being removed

• DSD

2005-06-07 matplotlib-0.81 released

2005-06-06 Added autoscale_on prop to axes

2005-06-06 Added Nick’s picker “among” patch - JDH

2005-06-05 Fixed a TeX/LaTeX font discrepancy in backend_ps. - DSD

2005-06-05 Added a ps.distill option in rc settings. If True, postscript output will be distilled using ghostscript, which should trim the file size and allow it to load more quickly. Hopefully this will address the issue of large ps files due to font definitions. Tested with gnu-ghostscript-8.16. - DSD

2005-06-03 Improved support for tex handling of text in backend_ps. - DSD

2005-06-03 Added rc options to render text with tex or latex, and to select the latex font package. - DSD

2005-06-03 Fixed a bug in ticker.py causing a ZeroDivisionError

2005-06-02 backend_gtk.py remove DBL_BUFFER, add line to expose_event to try to fix pygtk 2.6 redraw problem - SC

2005-06-01 The default behavior of ScalarFormatter now renders scientific notation and large numerical offsets in a label at the end of the axis. - DSD
2005-06-01 Added Nicholas’ frombyte image patch - JDH
2005-05-31 Added vertical TeX support for agg - JDH
2005-05-31 Applied Eric’s cntr patch - JDH

**2005-05-27** Finally found the pesky agg bug (which Maxim was kind enough to fix within hours) that was causing a segfault in the win32 cached marker drawing. Now windows users can get the enormouse performance benefits of caced markers w/o those occasional pesy screenshots. - JDH

**2005-05-27** Got win32 build system working again, using a more recent version of gtk and pygtk in the win32 build, gtk 2.6 from [http://www.gimp.org/~tml/gimp/win32/downloads.html](http://www.gimp.org/~tml/gimp/win32/downloads.html) (you will also need libpng12.dll to use these). I haven’t tested whether this binary build of mpl for win32 will work with older gtk runtimes, so you may need to upgrade.

**2005-05-27** Fixed bug where 2nd wxapp could be started if using wxagg backend. - ADS

2005-05-26 Added Daishi text with dash patch – see examples/dashtick.py

**2005-05-26** Moved backend latex functionality into backend_ps. If text.usetex=True, the PostScript backend will use LaTeX to generate the .ps or .eps file. Ghostscript is required for eps output. - DSD

2005-05-24 Fixed alignment and color issues in latex backend. - DSD

**2005-05-21** Fixed raster problem for small rasters with dvipng - looks like it was a premultiplied alpha problem - JDH

**2005-05-20** Added linewidth and faceted kwarg to scatter to control edgewidth and color. Also added autolegend patch to inspect line segments.

2005-05-18 Added Orsay and JPL qt fixes - JDH

**2005-05-17** Added a psfrag latex backend – some alignment issues need to be worked out. Run with -dLaTeX and a .tex file and *.eps file are generated. latex and dvips the generated latex file to get ps output. Note xdvii *does not work, you must generate ps.- JDH

**2005-05-13** Added Florent Rougon’s Axis set_label1 patch

2005-05-17 pcolor optimization, fixed bug in previous pcolor patch - JSWHIT

2005-05-16 Added support for masked arrays in pcolor - JSWHIT

**2005-05-12** Started work on TeX text for antigrain using pngdvi - see examples/tex demo.py and the new module matplotlib.texmanager. Rotated text not supported and rendering small glyps is not working right yet. BUt large fontsizes and/or high dpi saved figs work great.

**2005-05-10** New image resize options interpolation options. New values for the interp kwarg are

See help(imshow) for details, particularly the interpolation, filternorm and filterrad kwargs

2005-05-10 Applied Eric’s contour mem leak fixes - JDH
2005-05-10 Extended python agg wrapper and started implementing backend_agg2, an agg renderer based on the python wrapper. This will be more flexible and easier to extend than the current backend_agg. See also examples/agg_test.py - JDH

2005-05-09 Added Marcin’s no legend patch to exclude lines from the autolegend builder

plot(x, y, label='nolegend')

2005-05-05 Upgraded to agg23

2005-05-05 Added newscalarformatter_demo.py to examples. -DSD

2005-05-04 Added NewScalarFormatter. Improved formatting of ticklabels, scientific notation, and the ability to plot large large numbers with small ranges, by determining a numerical offset. See ticker.NewScalarFormatter for more details. -DSD

2005-05-03 Added the option to specify a delimiter in pylab.load -DSD

2005-04-28 Added Darren’s line collection example

2005-04-28 Fixed aa property in agg - JDH

2005-04-27 Set postscript page size in .matplotlibrc - DSD

2005-04-26 Added embedding in qt example. - JDH

2005-04-14 Applied Michael Brady’s qt backend patch: 1) fix a bug where keyboard input was grabbed by the figure and not released 2) turn on cursor changes 3) clean up a typo and commented-out print statement. - JDH

2005-04-14 Applied Eric Firing’s masked data lines patch and contour patch. Support for masked arrays has been added to the plot command and to the Line2D object. Only the valid points are plotted. A “valid only” kwarg was added to the get_xdata() and get_ydata() methods of Line2D; by default it is False, so that the original data arrays are returned. Setting it to True returns the plottable points. - see examples/masked_demo.py - JDH

2005-04-13 Applied Tim Leslie’s arrow key event handling patch - JDH

0.80 released

2005-04-11 Applied a variant of rick’s xlim/ylim/axis patch. These functions now take kwargs to let you selectively alter only the min or max if desired. e.g., xlim(xmin=2) or axis(ymax=3). They always return the new lim. - JDH

2005-04-11 Incorporated Werner’s wx patch - wx backend should be compatible with wxpython2.4 and recent versions of 2.5. Some early versions of wxpython 2.5 will not work because there was a temporary change in the dc API that was rolled back to make it 2.4 compliant

2005-04-11 modified tkagg show so that new figure window pops up on call to figure

2005-04-11 fixed wxapp init bug

2005-04-02 updated backend_ps.draw_lines, draw_markers for use with the new API - DSD

2005-04-01 Added editable polygon example

2005-03-31 0.74 released
2005-03-30 Fixed and added checks for floating point inaccuracy in ticker.Base - DSD

2005-03-30 updated ellipse definition in backend_ps.py to address bug #1122041 - DSD

2005-03-29 Added unicode support for Agg and PS - JDH

2005-03-28 Added Jarrod’s svg patch for text - JDH

2005-03-28 Added Ludal’s arrow and quiver patch - JDH

2005-03-28 Added label kwarg to Axes to facilitate forcing the creation of new Axes with otherwise identical attributes

2005-03-28 Applied boxplot and OSX font search patches

2005-03-27 Added ft2font NULL check to fix Japanese font bug - JDH

2005-03-27 Added sprint legend patch plus John Gill’s tests and fix - see examples/legend_auto.py - JDH

2005-03-19 0.73.1 released

2005-03-19 Reverted wxapp handling because it crashed win32 - JDH

2005-03-18 Add .number attribute to figure objects returned by figure() - FP

2005-03-18 0.73 released

2005-03-16 Fixed labelsep bug

2005-03-16 Applied Darren’s ticker fix for small ranges - JDH

2005-03-16 Fixed tick on horiz colorbar - JDH

2005-03-16 Added Japanese winreg patch - JDH

2005-03-15 backend_gtkagg.py: changed to use double buffering, this fixes the problem reported Joachim Berdal Haga - “Parts of plot lagging from previous frame in animation”. Tested with anim.py and it makes no noticable difference to performance (23.7 before, 23.6 after) - SC

2005-03-14 add src/_backend_gdk.c extension to provide a substitute function for pixbuf.get_pixels_array(). Currently pixbuf.get_pixels_array() only works with Numeric, and then only works if pygtk has been compiled with Numeric support. The change provides a function pixbuf.get_pixels_array() which works with Numeric and numarray and is always available. It means that backend_gtk should be able to display images and mathtext in all circumstances. - SC

2005-03-11 Upgraded CXX to 5.3.1

2005-03-10 remove GraphicsContextPS.set_linestyle() and GraphicsContextSVG.set_linestyle() since they do no more than the base class GraphicsContext.set_linestyle() - SC

2005-03-09 Refactored contour functionality into dedicated module

2005-03-09 Added Eric’s contourf updates and Nadia’s clabel functionality

2005-03-09 Moved colorbar to figure.Figure to expose it for API developers

7.1. List of changes to Matplotlib prior to 2015
• JDH

2005-03-09 backend_cairo.py: implemented draw_markers() - SC

2005-03-09 cbook.py: only use enumerate() (the python version) if the builtin version is not available. Add new function ‘izip’ which is set to itertools.izip if available and the python equivalent if not available. - SC

2005-03-07 backend_gdk.py: remove PIXELS_PER_INCH from points_to_pixels(), but still use it to adjust font sizes. This allows the GTK version of line_styles.py to more closely match GTKAgg, previously the markers were being drawn too large. - SC

2005-03-01 Added Eric’s contourf routines

2005-03-01 Added start of proper agg SWIG wrapper. I would like to expose agg functionality directly at the user level and this module will serve that purpose eventually, and will hopefully take over most of the functionality of the current _image and _backend_agg modules. - JDH

2005-02-28 Fixed polyfit / polyval to convert input args to float arrays - JDH

2005-02-25 Add experimental feature to backend_gdk.py to enable/disable double buffering (DBL_BUFFER=True/False) - SC

2005-02-24 colors.py change ColorConverter.to_rgb() so it always returns rgb (and not rgbα), allow names keys to be cached, change the exception raised from Run-timeError to ValueError (like hex2color()) hex2color() use a regular expression to check the color string is valid - SC

2005-02-23 Added rc param ps.useafm so backend ps can use native afm fonts or truetype. afme breaks mathtext but causes much smaller font sizes and may result in images that display better in some contexts (e.g., pdfs incorporated into latex docs viewed in acrobat reader). I would like to extend this approach to allow the user to use truetype only for mathtext, which should be easy.

2005-02-23 Used sequence protocol rather than tuple in agg collection drawing routines for greater flexibility - JDH

2005-02-22 0.72.1 released

2005-02-21 fixed linestyles for collections - contour now dashes for levels <0

2005-02-21 fixed ps color bug - JDH

2005-02-15 fixed missing qt file

2005-02-15 banished error_msg and report_error. Internal backend methods like error_msg_gtk are preserved. backend writers, check your backends, and diff against 0.72 to make sure I did the right thing! - JDH

2005-02-14 Added enthought traits to matplotlib tree - JDH

2005-02-14 0.72 released

2005-02-14 fix bug in cbook alltrue() and onetrue() - SC

2005-02-11 updated qtagg backend from Ted - JDH
2005-02-11 matshow fixes for figure numbering, return value and docs - FP
2005-02-09 new zorder example for fine control in zorder_demo.py - FP

**2005-02-09 backend renderer draw_lines now has transform in backend, as in draw_markers; use numerix in _backend_agg, added small line optimization to agg**

2005-02-09 subplot now deletes axes that it overlaps

2005-02-08 Added transparent support for gzipped files in load/save - Fernando Perez (FP from now on).

2005-02-08 Small optimizations in PS backend. They may have a big impact for large plots, otherwise they don’t hurt - FP

2005-02-08 Added transparent support for gzipped files in load/save - Fernando Perez (FP from now on).

2005-02-07 Added newstyle path drawing for markers - only implemented in agg currently - JDH

2005-02-05 Some superscript text optimizations for ticking log plots

2005-02-05 Added some default key press events to pylab figures: ‘g’ toggles grid - JDH

2005-02-05 Added some support for handling log switching for lines that have non-pos data - JDH

2005-02-04 Added Nadia’s contour patch - contour now has matlab compatible syntax; this also fixed an unequal sized contour array bug - JDH

2005-02-04 Modified GTK backends to allow the FigureCanvas to be resized smaller than its original size - SC

2005-02-02 Fixed a bug in dates mx2num - JDH

2005-02-02 Incorporated Fernando’s matshow - JDH

2005-02-01 Added Fernando’s figure num patch, including experimental support for pylab backend switching, LineCOllection.color warns, savefig now a figure method, fixed a close(fig) bug - JDH

2005-01-31 updated datalim in contour - JDH

2005-01-30 Added backend_qtagg.py provided by Sigve Tjora - SC

2005-01-28 Added tk.inspect rc param to .matplotlibrc. IDLE users should set tk.pythoninspect:True and interactive:True and backend:TkAgg

2005-01-27 Added support for shared x or y axes. See examples/shared_axis_demo.py and examples/ganged_plots.py

2005-01-26 Added Lee’s patch for missing symbols leq and LEFTbracket to _math-text_data - JDH

2005-01-26 Added Baptiste’s two scales patch - see help(twinx) in the pylab interface for more info. See also examples/two_scales.py

2005-01-24 Fixed a mathtext parser bug that prevented font changes in sub/superscripts - JDH

---

7.1. List of changes to Matplotlib prior to 2015
2005-01-24 Fixed contour to work w/ interactive changes in colormaps, clim, etc - JDH

2005-01-21 matplotlib-0.71 released
2005-01-21 Refactored numerix to solve vexing namespace issues - JDH
2005-01-21 Applied Nadia’s contour bug fix - JDH

2005-01-20 Made some changes to the contour routine - particularly region=1 seems to fix a lot of the zigzag strangeness. Added colormaps as default for contour - JDH

2005-01-19 Restored builtin names which were overridden (min, max, abs, round, and sum) in pylab. This is a potentially significant change for those who were relying on an array version of those functions that previously overrode builtin function names. - ADS

2005-01-18 Added accents to mathtext: hat, breve, grave, bar, acute, tilde, vec, dot, ddot. All of them have the same syntax, e.g., to make an overbar you do bar{o} or to make an o umlaut you do ddot{o}. The shortcuts are also provided, e.g., "o ’e ‘e ~n .x ^y - JDH

2005-01-18 Pluged image resize memory leaks - JDH
2005-01-18 Fixed some mathtext parser problems relating to superscripts

2005-01-17 Fixed a yticklabel problem for colorbars under change of clim - JDH

2005-01-17 Cleaned up Destroy handling in wx reducing memleak/fig from approx 800k to approx 6k - JDH

2005-01-17 Added kappa to latex_to_bakoma - JDH
2005-01-15 Support arbitrary colorbar axes and horizontal colorbars - JDH

2005-01-15 Fixed colormap number of colors bug so that the colorbar has the same discretization as the image - JDH

2005-01-15 Added Nadia’s x,y contour fix - JDH

2005-01-15 backend_cairo: added PDF support which requires pycairo 0.1.4. Its not usable yet, but is ready for when the Cairo PDF backend matures - SC

2005-01-15 Added Nadia’s x,y contour fix

2005-01-12 Fixed set clip_on bug in artist - JDH
2005-01-11 Reverted pythoninspect in tkagg - JDH

2005-01-09 Fixed a backend_bases event bug caused when an event is triggered when location is None - JDH

2005-01-07 Add patch from Stephen Walton to fix bug in pylab.load() when the % character is included in a comment. - ADS

2005-01-07 Added markerscale attribute to Legend class. This allows the marker size in the legend to be adjusted relative to that in the plot. - ADS

2005-01-06 Add patch from Ben Vanhaeren to make the FigureManagerGTK vbox a public attribute - SC
2004-12-30 Release 0.70

2004-12-28 Added coord location to key press and added a examples/picker_demo.py

2004-12-28 Fixed coords notification in wx toolbar - JDH

2004-12-28 Moved connection and disconnection event handling to the FigureCanvasBase. Backends now only need to connect one time for each of the button press, button release and key press/release functions. The base class deals with callbacks and multiple connections. This fixes flakiness on some backends (tk, wx) in the presence of multiple connections and/or disconnect - JDH

2004-12-27 Fixed PS mathtext bug where color was not set - Jochen please verify correct - JDH

2004-12-27 Added Shadow class and added shadow kwarg to legend and pie for shadow effect - JDH

2004-12-27 Added pie charts and new example/pie_demo.py

2004-12-23 Fixed an agg text rotation alignment bug, fixed some text kwarg processing bugs, and added examples/text_rotation.py to explain and demonstrate how text rotations and alignment work in matplotlib. - JDH

2004-12-22 0.65.1 released - JDH

2004-12-22 Fixed colorbar bug which caused colorbar not to respond to changes in colormap in some instances - JDH

2004-12-22 Refactored NavigationToolbar in tkagg to support app embedding, init now takes (canvas, window) rather than (canvas, figman) - JDH

2004-12-21 Refactored axes and subplot management - removed add_subplot and add_axes from the FigureManager. Classic toolbar updates are done via an observer pattern on the figure using add_axobserver. Figure now maintains the axes stack (for gca) and supports axes deletion. Ported changes to GTK, Tk, Wx, and FLTK. Please test! Added delaxes - JDH

2004-12-21 Lots of image optimizations - 4x performance boost over 0.65 JDH

2004-12-20 Fixed a figimage bug where the axes is shown and modified tkagg to move the destroy binding into the show method.

2004-12-18 Minor refactoring of NavigationToolbar2 to support embedding in an application - JDH

2004-12-14 Added linestyle to collections (currently broken) - JDH

2004-12-14 Applied Nadia’s setupext patch to fix libstdc++ link problem with contour and solaris - JDH

2004-12-14 A number of pychecker inspired fixes, including removal of True and False from chook which I erroneously thought was needed for python2.2 - JDH

2004-12-14 Finished porting doc strings for set introspection. Used silent_list for many get funcs that return lists. JDH

2004-12-13 dates.py: removed all timezone() calls, except for UTC - SC
2004-12-13 0.65 released - JDH

2004-12-13 colors.py: rgb2hex(), hex2color() made simpler (and faster), also
rgb2hex() - added round() instead of integer truncation hex2color() - changed 256.0
divisor to 255.0, so now ‘#ffffff’ becomes (1.0,1.0,1.0) not (0.996,0.996,0.996) - SC

2004-12-11 Added ion and ioff to pylab interface - JDH

2004-12-11 backend_template.py: delete FigureCanvasTemplate.realize() - most
backends don’t use it and its no longer needed

backend_ps.py, backend_svg.py: delete show() and draw_if_interactive() - they are not
needed for image backends

backend_svg.py: write direct to file instead of StringIO - SC

2004-12-10 Added zorder to control drawing order of lines, patches and
text in axes. See examples/zoder_demo.py - JDH

2004-12-10 Fixed colorbar bug with scatter - JDH

2004-12-10 Added Nadia Dencheva <dencheva@stsci.edu> contour code - JDH

2004-12-10 backend_cairo.py: got mathtext working - SC

2004-12-09 Added Norm Peterson’s svg clipping patch

2004-12-09 Added Matthew Newville’s wx printing patch

2004-12-09 Migrated matlab to pylab - JDH

2004-12-09 backend_gtk.py: split into two parts

• backend_gdk.py - an image backend
• backend_gtk.py - A GUI backend that uses GDK - SC

2004-12-08 backend_gtk.py: remove quit_after_print_xvfb(*args), show_xvfb(),
Dialog_MeasureTool(gtk.Dialog) one month after sending mail to matplotlib-users
asking if anyone still uses these functions - SC

2004-12-02 backend_bases.py, backend_template.py: updated some of the method
documentation to make them consistent with each other - SC

2004-12-04 Fixed multiple bindings per event for TkAgg mpl_connect and
mpl_disconnect. Added a “test_disconnect” command line parameter to coords_demo.py
JTm

2004-12-04 Fixed some legend bugs JDH

2004-11-30 Added over command for oneoff over plots. e.g., over(plot, x, y, lw=2).
Works with any plot function.

2004-11-30 Added bbox property to text - JDH

2004-11-29 Zoom to rect now respect reversed axes limits (for both linear and log
axes). - GL

2004-11-29 Added the over command to the matlab interface. over allows you to add
an overlay plot regardless of hold state. - JDH

2004-11-25 Added Printf to mplutils for printf style format string
(should help write better exceptions)

2004-11-24 IMAGE_FORMAT: remove from agg and gtkagg backends as its no longer
used - SC
2004-11-23 Added matplotlib compatible set and get introspection. See set_and_get.py

2004-11-23 applied Norbert’s patched and exposed legend configuration to kwargs - JDH

2004-11-23 backend_gtk.py: added a default exception handler - SC

2004-11-18 backend_gtk.py: change so that the backend knows about all image formats and does not need to use IMAGE_FORMAT in other backends - SC

2004-11-18 Fixed some report_error bugs in string interpolation as reported on SF bug tracker - JDH

2004-11-17 backend_gtkcairo.py: change so all print_figure() calls render using Cairo and get saved using backend_gtk.print_figure() - SC

2004-11-13 backend_cairo.py: Discovered the magic number (96) required for Cairo PS plots to come out the right size. Restored Cairo PS output and added support for landscape mode - SC

2004-11-13 Added ishold - JDH

2004-11-12 Added many new matlab colormaps - autumn bone cool copper flag gray hot hsv jet pink prism spring summer winter - PG

2004-11-11 greatly simplify the emitted postscript code - JV

2004-11-12 Added new plotting functions spy, spy2 for sparse matrix visualization - JDH

2004-11-11 Added rgrids, thetragrids for customizing the grid locations and labels for polar plots - JDH

2004-11-11 make the Gtk backends build without an X-server connection - JV

2004-11-10 matplotlib/__init__.py: Added FROZEN to signal we are running under py2exe (or similar) - is used by backend_gtk.py - SC

2004-11-09 backend_gtk.py: Made fix suggested by maffew@cat.org.au to prevent problems when py2exe calls pygtk.require(). - SC

2004-11-09 backend_cairo.py: Added support for printing to a fileobject. Disabled cairo PS output which is not working correctly. - SC

2004-11-08 matplotlib-0.64 released

2004-11-04 Changed -dbackend processing to only use known backends, so we don’t clobber other non-matplotlib uses of -d, like -debug.

2004-11-04 backend_agg.py: added IMAGE_FORMAT to list the formats that the backend can save to. backend_gtkagg.py: added support for saving JPG files by using the GTK backend - SC

2004-10-31 backend_cairo.py: now produces png and ps files (although the figure sizing needs some work). pycairo did not wrap all the necessary functions, so I wrapped them myself, they are included in the backend_cairo.py doc string. - SC

2004-10-31 backend_ps.py: clean up the generated PostScript code, use the PostScript stack to hold intermediate values instead of storing them in the dictionary. - JV

7.1. List of changes to Matplotlib prior to 2015
2004-10-30 backend_ps.py, ft2font.cpp, ft2font.h: fix the position of text in the PostScript output. The new FT2Font method get_descent gives the distance between the lower edge of the bounding box and the baseline of a string. In backend_ps the text is shifted upwards by this amount. - JV

2004-10-30 backend_ps.py: clean up the code a lot. Change the PostScript output to be more DSC compliant. All definitions for the generated PostScript are now in a PostScript dictionary ‘mpldict’. Moved the long comment about drawing ellipses from the PostScript output into a Python comment. - JV

2004-10-30 backend_gtk.py: removed FigureCanvasGTK.realize() as its no longer needed. Merged ColorManager into GraphicsContext backend_bases.py: For set_capstyle/joinstyle() only set cap or joinstyle if there is no error. - SC

2004-10-30 backend_gtk.py: tidied up print_figure() and removed some of the dependency on widget events - SC

2004-10-28 backend_cairo.py: The renderer is complete except for mathtext, draw_image() and clipping. gtkcairo works reasonably well. cairo does not yet create any files since I can’t figure how to set the ‘target surface’, I don’t think pycairo wraps the required functions - SC

2004-10-28 backend_gtk.py: Improved the save dialog (GTK 2.4 only) so it presents the user with a menu of supported image formats - SC

2004-10-28 backend_svg.py: change print_figure() to restore original face/edge color
2004-10-28 backend_ps.py: change print_figure() to ensure original face/edge colors are restored even if there’s an IOError - SC

2004-10-27 Applied Norbert’s errorbar patch to support barsabove kwarg
2004-10-27 Applied Norbert’s legend patch to support None handles

2004-10-27 Added two more backends: backend_cairo.py, backend_gtkcairo.py
They are not complete yet, currently backend_gtkcairo just renders polygons, rectangles and lines - SC

2004-10-21 Added polar axes and plots - JDH

2004-10-20 Fixed corrcoef bug exposed by corrcoef(X) where X is matrix

- JDH

2004-10-19 Added kwarg support to xticks and yticks to set ticklabel text properties - thanks to T. Edward Whalen for the suggestion

2004-10-19 Added support for PIL images in imshow(), image.py - ADS

2004-10-19 Re-worked exception handling in _image.py and _transforms.py to avoid masking problems with shared libraries. - JTM

2004-10-16 Streamlined the matlab interface wrapper, removed the noplot option to hist - just use mlab.hist instead.

2004-09-30 Added Andrew Dalke’s strftime code to extend the range of dates supported by the DateFormatter - JDH

2004-09-30 Added barh - JDH

2004-09-30 Removed fallback to alternate array package from numerix so that ImportErrors are easier to debug. JTM

2004-09-30 Add GTK+ 2.4 support for the message in the toolbar. SC
2004-09-30 Made some changes to support python22 - lots of doc fixes. - JDH
2004-09-29 Added a Verbose class for reporting - JDH

2004-09-28 Released 0.63.0

2004-09-28 Added save to file object for agg - see examples/print_stdout.py
2004-09-24 Reorganized all py code to lib subdir

2004-09-24 Fixed axes resize image edge effects on interpolation - required upgrade to agg22 which fixed an agg bug related to this problem
2004-09-20 Added toolbar2 message display for backend_tkagg. JTM

2004-09-17 Added coords formatter attributes. These must be callable, and return a string for the x or y data. These will be used to format the x and y data for the coords box. Default is the axis major formatter. e.g.:

```python
# format the coords message box
def price(x): return '$%1.2f' % x
ax.format_xdata = DateFormatter('%Y-%m-%d')
ax.format_ydata = price
```

2004-09-17 Total rewrite of dates handling to use python datetime with num2date, date2num and drange. pytz for timezone handling, dateutils for sophisticated ticking. date ranges from 0001-9999 are supported. rrules allow arbitrary date ticking. examples/date_demo*.py converted to show new usage. new example examples/date_demo_rrule.py shows how to use rrules in date plots. The date locators are much more general and almost all of them have different constructors. See matplotlib.dates for more info.

2004-09-15 Applied Fernando's backend__init__ patch to support easier backend maintenance. Added his numutils to mlab. JDH

2004-09-16 Re-designated all files in matplotlib/images as binary and w/o keyword substitution using "cvs admin -kb *.svg ...". See binary files in "info cvs" under Linux. This was messing up builds from CVS on windows since CVS was doing if -> cr/lf and keyword substitution on the bitmaps. - JTM

2004-09-15 Modified setup to build array-package-specific extensions for those extensions which are array-aware. Setup builds extensions automatically for either Numeric, numarray, or both, depending on what you have installed. Python proxy modules for the array-aware extensions import the version optimized for numarray or Numeric determined by numerix. - JTM

2004-09-15 Moved definitions of infinity from mlab to numerix to avoid divide by zero warnings for numarray - JTM

2004-09-09 Added axhline, axvline, axhspan and axvspan

2004-08-30 matplotlib 0.62.4 released

2004-08-30 Fixed a multiple images with different extent bug, Fixed markerfacecolor as RGB tuple

2004-08-27 Mathtext now more than 5x faster. Thanks to Paul McGuire for fixes both to pyparsing and to the matplotlib grammar! mathtext broken on python2.2

2004-08-25 Exposed Darren’s and Greg’s log ticking and formatting options to semilogx and friends
2004-08-23 Fixed grid w/o args to toggle grid state - JDH
2004-08-11 Added Gregory’s log patches for major and minor ticking
2004-08-18 Some pixel edge effects fixes for images
2004-08-18 Fixed TTF files reads in backend_ps on win32.

2004-08-18 **Added base and subs properties for logscale plots, user modifiable using**

set_[x,y]scale('log',base=b,subs=[mt1,mt2,...]) - GL

2004-08-18 **fixed a bug exposed by trying to find the HOME dir on win32** thanks to

Alan Issac for pointing to the light - JDH
2004-08-18 fixed errorbar bug in setting ecolor - JDH
2004-08-12 Added Darren Dale’s exponential ticking patch
2004-08-11 Added Gregory’s fltkagg backend

2004-08-09 matplotlib-0.61.0 released

**2004-08-08 backend_gtk.py: get rid of the final PyGTK deprecation warning by**

replacing gtkOptionMenu with gtkMenu in the 2.4 version of the classic toolbar.

**2004-08-06 Added Tk zoom to rect rectangle, proper idle drawing, and keybinding** - JDH
2004-08-05 Updated installing.html and INSTALL - JDH
2004-08-01 backend_gtk.py: move all drawing code into the expose_event()
2004-07-28 Added Greg’s toolbar2 and backend_*agg patches - JDH

**2004-07-28 Added image.imread with support for loading png into numerix arrays**
2004-07-28 **Added key modifiers to events - implemented dynamic updates and rubber banding for interactive pan/zoom** - JDH
2004-07-27 **did a readthrough of SVG, replacing all the string additions with string interps for efficiency, fixed some layout problems, added font and image support (through external pngs)** - JDH

**2004-07-25 backend_gtk.py: modify toolbar2 to make it easier to support GTK+ 2.4. Add GTK+ 2.4 toolbar support.** - SC
2004-07-24 backend_gtk.py: Simplified classic toolbar creation - SC
2004-07-24 **Added images/matplotlib.svg to be used when GTK+ windows are minimised** - SC
2004-07-22 **Added right mouse click zoom for NavigationToolbar2 panning mode.** - JTM
2004-07-22 **Added NavigationToolbar2 support to backend_tkagg.** Minor tweak to backend_bases. - JTM
2004-07-22 **Incorporated Gergory’s renderer cache and buffer object cache** - JDH

2004-07-22 **Backend_gtk.py: Added support for GtkFileChooser, changed FileSelection/FileChooser so that only one instance pops up, and made them both modal.** - SC
2004-07-21 Applied backend_agg memory leak patch from hayden -
  jocallo@online.no. Found and fixed a leak in binary operations on transforms. Moral of
the story: never incref where you meant to decref! Fixed several leaks in ft2font: moral
of story: almost always return Py::asObject over Py::Object - JDH

2004-07-21 Fixed a to string memory allocation bug in agg and image
  modules - JDH
2004-07-21 Added mpl_connect and mpl_disconnect to matlab interface - JDH
2004-07-21 Added beginnings of users_guide to CVS - JDH
2004-07-20 ported toolbar2 to wx
2004-07-20 upgraded to agg21 - JDH
2004-07-20 Added new icons for toolbar2 - JDH

2004-07-19 Added vertical mathtext for *Agg and GTK - thanks Jim
  Benson! - JDH
2004-07-16 Added ps/eps/svg savefig options to wx and gtk - JDH
2004-07-15 Fixed python framework tk finder in setupext.py - JDH

2004-07-14 Fixed layer images demo which was broken by the 07/12 image
  extent fixes - JDH
2004-07-13 Modified line collections to handle arbitrary length
  segments for each
  line segment. - JDH
2004-07-13 Fixed problems with image extent and origin - set_image_extent
deprecated. Use imshow(blah, blah, extent=(xmin, xmax, ymin, ymax) instead - JDH
2004-07-12 Added prototype for new navbar with codified event
  handling. Use
  mpl_connect rather than connect for matplotlib event handling. toolbar style
determined by rc toolbar param. backend status: gtk: prototype, wx: in progress, tk: not
  started - JDH

  • SC
2004-07-10 Added embedding_in_wx3 example - ADS
2004-07-09 Added dynamic_image_wxagg to examples - ADS
2004-07-09 added support for embedding TrueType fonts in PS files - PEB
2004-07-09 fixed a sfnt bug exposed if font cache is not built

2004-07-09 added default arg None to matplotlib.matlab grid command to
  toggle
  current grid state

2004-07-08 0.60.2 released
2004-07-08 fixed a mathtext bug for ‘6’
2004-07-08 added some numarray bug workarounds

2004-07-07 0.60 released
2004-07-07 Fixed a bug in dynamic_demo_wx

2004-07-07 backend_gtk.py: raise SystemExit immediately if
  ‘import pygtk’ fails - SC
2004-07-05 Added new mathtext commands over{sym1}{sym2} and under{sym1}{sym2}

2004-07-05 Unified image and patch collections colormapping and scaling args. Updated docstrings for all - JDH

2004-07-05 Fixed a figure legend bug and added examples/figlegend_demo.py - JDH

2004-07-01 Fixed a memory leak in image and agg to string methods

2004-06-25 Fixed fonts_demo spacing problems and added a kwargs version of the fonts_demo_fonts Demo_kws.py - JDH

2004-06-25 finance.py: handle case when urlopen() fails - SC

2004-06-24 Support for multiple images on axes and figure, with blending. Support for upper and lower image origins. clim, jet and gray functions in matlab interface operate on current image - JDH

2004-06-23 ported code to Perry’s new colormap and norm scheme. Added new rc attributes image.aspect, image.interpolation, image.cmap, image.lut, image.origin

2004-06-20 backend_gtk.py: replace gtk.TRUE/FALSE with True/False. simplified _make_axis_menu(). - SC

2004-06-19 anim_tk.py: Updated to use TkAgg by default (not GTK) backend_gtk.py: Added `_` in front of private widget creation functions - SC

2004-06-17 backend_gtk.py: Create a GC once in realise(), not every time draw() is called. - SC

2004-06-16 Added new py2exe FAQ entry and added frozen support in get_data_path for py2exe - JDH

2004-06-16 Removed GTKGD, which was always just a proof-of-concept backend - JDH

2004-06-16 backend_gtk.py updates to replace deprecated functions
gtk.mainquit(), gtk.mainloop(). Update NavigationToolbar to use the new GtkTool- bar API - SC

2004-06-15 removed set_default_font from font manager to unify font customization using the new function rc. See API CHANGES for more info. The examples fonts Demo.py and fonts Demo_kws.py are ported to the new API - JDH

2004-06-15 Improved (yet again!) axis scaling to properly handle singleton plots - JDH

2004-06-15 Restored the old FigureCanvasGTK.draw() - SC

2004-06-11 More memory leak fixes in transforms and ft2font - JDH

2004-06-11 Eliminated numerix .numerix file and environment variable NUMERIX. Fixed bug which prevented command line overrides: --numarray or --numeric. - JTM

2004-06-10 Added rc configuration function rc; deferred all rc param setting until object creation time; added new rc attrs: lines.markerfacecolor, lines.markeredgewidth, lines.markeredgewidth, patch.linewidth, patch.facecolor, patch.edgecolor, patch.antialiased; see examples/customize_rc.py for usage - JDH

2004-06-09 0.54.2 released
2004-06-08 Rewrote ft2font using CXX as part of general memory leak fixes; also fixed transform memory leaks - JDH
2004-06-07 Fixed several problems with log ticks and scaling - JDH
2004-06-07 Fixed width/height issues for images - JDH
2004-06-03 Fixed draw_if_interactive bug for semilogx;
2004-06-02 Fixed text clipping to clip to axes - JDH
2004-06-02 Fixed leading newline text and multiple newline text - JDH
2004-06-02 Fixed plot date to return lines - JDH
2004-06-01 Fixed plot to work with x or y having shape N,1 or 1,N - JDH
2004-05-31 Added renderer markeredgewidth attribute of Line2D. - ADS
2004-05-29 Fixed tick label clipping to work with navigation.

2004-05-28 Added renderer grouping commands to support groups in SVG/PS. - JDH
2004-05-28 Fixed, this time I really mean it, the singleton plot plot([0]) scaling bug; Fixed Flavio’s shape = N,1 bug - JDH
2004-05-28 added colorbar - JDH
2004-05-28 Made some changes to the matplotlib.colors.Colormap to properly support clim - JDH

2004-05-27 0.54.1 released
2004-05-27 Lots of small bug fixes: rotated text at negative angles, errorbar capsize and autoscaling, right tick label position, gtkagg on win98, alpha of figure background, singleton plots - JDH
2004-05-26 Added Gary’s errorbar stuff and made some fixes for length one plots and constant data plots - JDH
2004-05-25 Tweaked TkAgg backend so that canvas.draw() works more like the other backends. Fixed a bug resulting in 2 draws per figure manager show(). - JTM

2004-05-19 0.54 released
2004-05-18 Added newline separated text with rotations to text.Text layout - JDH
2004-05-16 Added fast pcolor using PolyCollections. - JDH
2004-05-14 Added fast polygon collections - changed scatter to use them. Added multiple symbols to scatter. 10x speedup on large scatters using *Agg and 5X speedup for ps. - JDH
2004-05-14 On second thought... created an “nx” namespace in numerix which maps type names onto typecodes the same way for both numarray and Numeric. This undoes my previous change immediately below. To get a typename for Int16 useable in a Numeric extension: say nx.Int16. - JTM
2004-05-15 Rewrote transformation class in extension code, simplified all the artist constructors - JDH
2004-05-14 Modified the type definitions in the numarray side of numerix so that they are Numeric typecodes and can be used with Numeric complex extensions. The original numarray types were renamed to type<old_name>. - JTM

2004-05-06 Gary Ruben sent me a bevy of new plot symbols and markers. See matplotlib.matlab.plot - JDH

2004-05-06 Total rewrite of mathtext - factored ft2font stuff out of layout engine and defined abstract class for font handling to lay groundwork for ps mathtext. Rewrote parser and made layout engine much more precise. Fixed all the layout hacks. Added spacing commands / and hspace. Added composite chars and defined angstrom. - JDH

2004-05-05 Refactored text instances out of backend; aligned text with arbitrary rotations is now supported - JDH

2004-05-05 Added a Matrix capability for numarray to numerix. JTM

2004-05-04 Updated whats_new.html.template to use dictionary and template loop, added anchors for all versions and items; updated goals.txt to use those for links. PG

2004-05-04 Added fonts_demo.py to backend_driver, and AFM and TTF font caches to font_manager.py - PEB

2004-05-03 Redid goals.html.template to use a goals.txt file that has a pseudo restructured text organization. PG

2004-05-03 Removed the close buttons on all GUIs and added the python #! bang line to the examples following Steve Chaplin’s advice on matplotlib dev

2004-04-29 Added CXX and rewrote backend_agg using it; tracked down and fixed agg memory leak - JDH

2004-04-29 Added stem plot command - JDH

2004-04-28 Fixed PS scaling and centering bug - JDH

2004-04-26 Fixed errorbar autoscale problem - JDH

2004-04-22 Fixed copy tick attribute bug, fixed singular datalim ticker bug; fixed mathtext fontsize interactive bug. - JDH

2004-04-21 Added calls to draw_if_interactive to axes(), legend(), and pcolor(). - JTM

2004-04-21 matplotlib 0.53 release

2004-04-19 Fixed vertical alignment bug in PS backend - JDH

2004-04-17 Added support for two scales on the "same axes" with tick different ticking and labeling left right or top bottom. See examples/two_scales.py - JDH

2004-04-17 Added default dirs as list rather than single dir in setupext.py - JDH

2004-04-16 Fixed wx exception swallowing bug (and there was much rejoicing!) - JDH

2004-04-16 Added new ticker locator a formatter, fixed default font return - JDH

2004-04-16 Added get_name method to FontProperties class. Fixed font lookup in GTK and WX backends. - PEB
2004-04-16 Added get- and set_fontstyle mmethods. - PEB
2004-04-10 Mathtext fixes: scaling with dpi, - JDH
2004-04-09 Improved font detection algorithm. - PEB
2004-04-09 Move deprecation warnings from text.py to __init__.py - PEB
2004-04-09 Added default font customization - JDH
2004-04-08 Fixed viewlim set problem on axes and axis. - JDH
2004-04-07 Added validate_comma_sep_str and font properties parameters to __init__. Removed font families and added rcParams to FontProperties __init__ arguments in font_manager. Added default font property parameters to .matplotlibrc file with descriptions. Added deprecation warnings to the get_ - and set_fontXXX methods of the Text object. - PEB
2004-04-06 Added load and save commands for ASCII data - JDH
2004-04-05 Improved font caching by not reading AFM fonts until needed. Added better documentation. Changed the behaviour of the get_family, set_family, and set_name methods of FontProperties. - PEB
2004-04-05 Added WXAgg backend - JDH
2004-04-04 Improved font caching in backend_agg with changes to font_manager - JDH
2004-03-29 Fixed fontdicts and kwargs to work with new font manager - JDH

This is the Old, stale, never used changelog

2002-12-10 - Added a TODO file and CHANGELOG. Lots to do - get crackin’!

- Fixed y zoom tool bug
- Adopted a compromise fix for the y data clipping problem. The problem was that for solid lines, the y data clipping (as opposed to the gc clipping) caused artifactual horizontal solid lines near the ylim boundaries. I did a 5% offset hack in Axes set_xlim functions which helped, but didn’t cure the problem for very high gain y zooms. So I disabled y data clipping for connected lines. If you need extensive y clipping, either plot(y,x) because x data clipping is always enabled, or change the _set_clip code to ‘if 1’ as indicated in the lines.py src. See _set_clip in lines.py and set_xlim in figure.py for more information.

2002-12-11 - Added a measurement dialog to the figure window to measure axes position and the delta x delta y with a left mouse drag. These defaults can be overridden by deriving from Figure and overriding button_press_event, button_release_event, and motion_notify_event, and _dialog_measure_tool.

- Fixed the navigation dialog so you can check the axes the navigation buttons apply to.

2003-04-23 Released matplotlib v0.1

2003-04-24 Added a new line style PixelLine2D which is the plots the markers as pixels (as small as possible) with format symbol ‘,’ Added a new class Patch with derived classes Rectangle, RegularPolygon and Circle
2003-04-25 Implemented new functions errorbar, scatter and hist

   Added a new line type ‘|’ which is a vline. syntax is plot(x, Y, ‘|’) where y.shape = len(x),2 and each row gives the ymin,ymax for the respective values of x. Previously I had implemented vlines as a list of lines, but I needed the efficiency of the numeric clipping for large numbers of vlines outside the viewport, so I wrote a dedicated class Vline2D which derives from Line2D

2003-05-01

   Fixed ytick bug where grid and tick show outside axis viewport with gc clip

2003-05-14

   Added new ways to specify colors 1) matlab format string 2) html-style hex string, 3) rgb tuple. See examples/color_demo.py

2003-05-28

   Changed figure rendering to draw form a pixmap to reduce flicker. See examples/system_monitor.py for an example where the plot is continuously updated w/o flicker. This example is meant to simulate a system monitor that shows free CPU, RAM, etc...

2003-08-04

   Added Jon Anderson’s GTK shell, which doesn’t require pygtk to have threading built-in and looks nice!

2003-08-25

   Fixed deprecation warnings for python2.3 and pygtk-1.99.18

2003-08-26

   Added figure text with new example examples/figtext.py

2003-08-27

   Fixed bugs in figure text with font override dictionairies and fig text that was placed outside the window bounding box

2003-09-1 thru 2003-09-15

   Added a postscript and a GD module backend

2003-09-16

   Fixed font scaling and point scaling so circles, squares, etc on lines will scale with DPI as will fonts. Font scaling is not fully implemented on the gtk backend because I have not figured out how to scale fonts to arbitrary sizes with GTK

2003-09-17

   Fixed figure text bug which crashed X windows on long figure text extending beyond display area. This was, I believe, due to the vestigial erase functionality that was no longer needed since I began rendering to a pixmap

2003-09-30 Added legend

2003-10-01 Fixed bug when colors are specified with rgb tuple or hex string.

2003-10-21 Andrew Straw provided some legend code which I modified and incorporated. Thanks Andrew!
2003-10-27 **Fixed a bug in axis.get_view_distance that affected zoom in versus out** with interactive scrolling, and a bug in the axis text reset system that prevented the text from being redrawn on an interactive gtk view lim set with the widget

Fixed a bug in that prevented the manual setting of ticklabel strings from working properly

2003-11-02 - **Do a nearest neighbor color pick on GD when allocate fails**

2003-11-02

- Added pcolor plot
- Added MRI example
- Fixed bug that screwed up label position if xticks or yticks were empty
- added nearest neighbor color picker when GD max colors exceeded
- fixed figure background color bug in GD backend

2003-11-10 - 2003-11-11

- major refactoring.
  - Ticks (with labels, lines and grid) handled by dedicated class
  - Artist now know bounding box and dpi
  - Bounding boxes and transforms handled by dedicated classes
  - legend in dedicated class. Does a better job of alignment and bordering. Can be initialized with specific line instances. See examples/legend_demo2.py

2003-11-14 Fixed legend positioning bug and added new position args

2003-11-16 Finished porting GD to new axes API

2003-11-20 - add TM for matlab on website and in docs

2003-11-20 - make a nice errorbar and scatter screenshot

2003-11-20 - **auto line style cycling for multiple line types** broken

2003-11-18 (using inkrect) :logical rect too big on gtk backend

2003-11-18 **ticks don’t reach edge of axes in gtk mode** - rounding error?

2003-11-20 - port Gary’s errorbar code to new API before 0.40

2003-11-20 - **problem with stale_set_font. legend axes box** doesn’t resize on save in GTK backend - see htdocs legend_demo.py

2003-11-21 - make a dash-dot dict for the GC

2003-12-15 - fix install path bug

---

7.2 **New in matplotlib 0.98.4**

---

Table of Contents

- New in matplotlib 0.98.4
It’s been four months since the last matplotlib release, and there are a lot of new features and bug-fixes.

Thanks to Charlie Moad for testing and preparing the source release, including binaries for OS X and Windows for python 2.4 and 2.5 (2.6 and 3.0 will not be available until numpy is available on those releases). Thanks to the many developers who contributed to this release, with contributions from Jae-Joon Lee, Michael Droettboom, Ryan May, Eric Firing, Manuel Metz, Jouni K. Seppänen, Jeff Whitaker, Darren Dale, David Kaplan, Michiel de Hoon and many others who submitted patches

7.2.1 Legend enhancements

Jae-Joon has rewritten the legend class, and added support for multiple columns and rows, as well as fancy box drawing. See legend() and matplotlib.legend.Legend.

Fig. 1: Whats New 98 4 Legend

7.2.2 Fancy annotations and arrows

Jae-Joon has added lots of support to annotations for drawing fancy boxes and connectors in annotations. See annotate() and BoxStyle, ArrowStyle, and ConnectionStyle.
7.2.3 Native OS X backend

Michiel de Hoon has provided a native Mac OSX backend that is almost completely implemented in C. The backend can therefore use Quartz directly and, depending on the application, can be orders of magnitude faster than the existing backends. In addition, no third-party libraries are needed other than Python and NumPy. The backend is interactive from the usual terminal application on Mac using regular Python. It hasn’t been tested with ipython yet, but in principle it should work there as well. Set ‘backend : macosx’ in your matplotlibrc file, or run your script with:

```
> python myfile.py -dmacosx
```

7.2.4 psd amplitude scaling

Ryan May did a lot of work to rationalize the amplitude scaling of `psd()` and friends. See /gallery/lines_bars_and_markers/psd_demo. The changes should increase MATLAB compatibility and increase scaling options.

7.2.5 Fill between

Added a `fill_between()` function to make it easier to do shaded region plots in the presence of masked data. You can pass an x array and a `ylower` and `yupper` array to fill between, and an optional `where` argument which is a logical mask where you want to do the filling.
7.2.6 Lots more

Here are the 0.98.4 notes from the CHANGELOG:

- Added mdehoon's native macosx backend from sf patch 2179017 - JDH

- Removed the prints in the set_*style commands. Return the list of pretty-printed strings instead - JDH

- Some of the changes Michael made to improve the output of the property tables in the rest docs broke or made difficult to use some of the interactive doc helpers, e.g., setp and getp. Having all the rest markup in the ipython shell also confused the docstrings. I added a new rc param docstring.harcopy, to format the docstrings differently for hardcopy and other use. The ArtistInspector could use a little refactoring now since there is duplication of effort between the rest out put and the non-rest output - JDH

- Updated spectral methods (psd, csd, etc.) to scale one-sided densities by a factor of 2 and, optionally, scale all densities by the sampling frequency. This gives better MATLAB compatibility. -RM

- Fixed alignment of ticks in colorbars. -MGD

- drop the deprecated "new" keyword of np.histogram() for numpy 1.2 or later. -JL

- Fixed a bug in svg backend that new_figure_manager() ignores keywords arguments such as figsize, etc. -JL

- Fixed a bug that the handlelength of the new legend class set too short when numpoints=1 -JL

- Added support for data with units (e.g., dates) to
Axes.fill_between. -RM

Added fancybox keyword to legend. Also applied some changes for better look, including baseline adjustment of the multiline texts so that it is center aligned. -JJL

The transmuter classes in the patches.py are reorganized as subclasses of the Style classes. A few more box and arrow styles are added. -JJL

Fixed a bug in the new legend class that didn't allowed a tuple of coordinate values as loc. -JJL

Improve checks for external dependencies, using subprocess (instead of deprecated popen+) and distutils (for version checking) - DSD

Reimplementation of the legend which supports baseline alignment, multi-column, and expand mode. - J JL

Fixed histogram autoscaling bug when bins or range are given explicitly (fixes Debian bug 503148) - MM

Added rcParam axes.unicode_minus which allows plain hyphen for minus when False - JDH

Added scatterpoints support in Legend. patch by Erik Tollerud - J JL

Fix crash in log ticking. - MGD

Added static helper method BrokenHBarCollection.span_where and Axes/pyplot method fill_between. See examples/pylab/fill_between.py - JDH

Add x_isdata and y_isdata attributes to Artist instances, and use them to determine whether either or both coordinates are used when updating dataLim. This is used to fix autoscaling problems that had been triggered by axhline, axhspan, axvline, axvspan. - EF

Update the psd(), csd(), cohere(), and specgram() methods of Axes and the csd() cohere(), and specgram() functions in mlab to be in sync with the changes to psd(). In fact, under the hood, these all call the same core to do computations. - RM

Add 'pad_to' and 'sides' parameters to mlab.psd() to allow controlling of zero padding and returning of negative frequency components, respectively. These are added in a way that does not change the API. - RM

Fix handling of c kwarg by scatter; generalize is_string_like to accept numpy and numpy.ma string array scalars. - RM and EF

(continues on next page)
Fix a possible EINTR problem in dviread, which might help when saving pdf files from the qt backend - JKS

Fix bug with zoom to rectangle and twin axes - MGD

Added Jae Joon's fancy arrow, box and annotation enhancements -- see examples/pylab_examples/annotation_demo2.py

Autoscaling is now supported with shared axes - EF

Fixed exception in dviread that happened with Minion - JKS

set_xlim, ylim now return a copy of the viewlim array to avoid modify inplace surprises

Added image thumbnail generating function
matplotlib.image.thumbnail. See examples/misc/image_thumbnail.py - JDH

Applied scatleg patch based on ideas and work by Erik Tollerud and Jae-Joon Lee. - MM

Fixed bug in pdf backend: if you pass a file object for output instead of a filename, e.g., in a wep app, we now flush the object at the end. - JKS

Add path simplification support to paths with gaps. - EF

Fix problem with AFM files that don't specify the font's full name or family name. - JKS

Added 'scilimits' kwarg to Axes.ticklabel_format() method, for easy access to the set_powerlimits method of the major ScalarFormatter. - EF

Experimental new kwarg borderpad to replace pad in legend, based on suggestion by Jae-Joon Lee. - EF

Allow spy to ignore zero values in sparse arrays, based on patch by Tony Yu. Also fixed plot to handle empty data arrays, and fixed handling of markers in figlegend. - EF

Introduce drawstyles for lines. Transparently split linestyles like 'steps--' into drawstyle 'steps' and linestyle '--'. Legends always use drawstyle 'default'. - MM

Fixed quiver and quiverkey bugs (failure to scale properly when resizing) and added additional methods for determining the arrow angles - EF

Fix polar interpolation to handle negative values of theta - MGD

(continues on next page)
Reorganized cbook and mlab methods related to numerical calculations that have little to do with the goals of those two modules into a separate module numerical_methods.py. Also, added ability to select points and stop point selection with keyboard in ginput and manual contour labeling code. Finally, fixed contour labeling bug. - DMK

Fix backtick in Postscript output. - MGD

[ 2089958 ] Path simplification for vector output backends
Leverage the simplification code exposed through path_to_polygons to simplify certain well-behaved paths in the vector backends (PDF, PS and SVG). "path.simplify" must be set to True in matplotlibrc for this to work. - MGD

Add "filled" kwarg to Path.intersects_path and Path.intersects_bbox. - MGD

Changed full arrows slightly to avoid an xpdf rendering problem reported by Friedrich Hagedorn. - JKS

Fix conversion of quadratic to cubic Bezier curves in PDF and PS backends. Patch by Jae-Joon Lee. - JKS

Added 5-point star marker to plot command q- EF

Fix hatching in PS backend - MGD

Fix log with base 2 - MGD

Added support for bilinear interpolation in NonUniformImage; patch by Gregory Lielens. - EF

Added support for multiple histograms with data of different length - MM

Fix step plots with log scale - MGD

Fix masked arrays with markers in non-Agg backends - MGD

Fix clip_on kwarg so it actually works correctly - MGD

Fix locale problems in SVG backend - MGD

fix quiver so masked values are not plotted - JSW

improve interactive pan/zoom in qt4 backend on windows - DSD

Fix more bugs in NaN/inf handling. In particular, path simplification (which does not handle NaNs or infs) will be turned off automatically when infs or NaNs are present. Also masked
arrays are now converted to arrays with NaNs for consistent handling of masks and NaNs - MGD and EF

Added support for arbitrary rasterization resolutions to the SVG backend. - MW

7.3 New in matplotlib 0.99

Table of Contents

- New in matplotlib 0.99
  - New documentation
  - mplot3d
  - axes grid toolkit
  - Axis spine placement

7.3.1 New documentation

Jae-Joon Lee has written two new guides Legend guide and Advanced Annotation. Michael Sarahan has written Image tutorial. John Hunter has written two new tutorials on working with paths and transformations: Path Tutorial and Transformations Tutorial.

7.3.2 mplot3d

Reinier Heeres has ported John Porter’s mplot3d over to the new matplotlib transformations framework, and it is now available as a toolkit mpl_toolkits.mplot3d (which now comes standard with all mpl installs). See mplot3d-examples-index and Getting started

7.3.3 axes grid toolkit

Jae-Joon Lee has added a new toolkit to ease displaying multiple images in matplotlib, as well as some support for curvilinear grids to support the world coordinate system. The toolkit is included standard with all new mpl installs. See axes_grid1-examples-index, axisartist-examples-index, What is axes_grid1 toolkit? and axisartist

7.3.4 Axis spine placement

Andrew Straw has added the ability to place “axis spines” - the lines that denote the data limits - in various arbitrary locations. No longer are your axis lines constrained to be a simple rectangle around the figure - you can turn on or off left, bottom, right and top, as well as “detach” the spine to offset it away from the data. See /gallery/ticks_and_spines/spine_placement_demo and matplotlib.spines.Spine.
Fig. 4: Whats New 99 Mplot3d

Fig. 5: Whats New 99 Axes Grid

Fig. 6: Whats New 99 Spines
7.4 New in matplotlib 1.0

Table of Contents

- New in matplotlib 1.0
  - HTML5/Canvas backend
  - Sophisticated subplot grid layout
  - Easy pythonic subplots
  - Contour fixes and triplot
  - Multiple calls to show supported
  - Mplot3d graphs can be embedded in arbitrary axes
  - Tick_params
  - Lots of performance and feature enhancements
  - Much improved software carpentry
  - Bugfix marathon

7.4.1 HTML5/Canvas backend

Simon Ratcliffe and Ludwig Schwardt have released an HTML5/Canvas backend for matplotlib. The backend is almost feature complete, and they have done a lot of work comparing their html5 rendered images with our core renderer Agg. The backend features client/server interactive navigation of matplotlib figures in an html5 compliant browser.

7.4.2 Sophisticated subplot grid layout

Jae-Joon Lee has written gridspec, a new module for doing complex subplot layouts, featuring row and column spans and more. See Customizing Figure Layouts Using GridSpec and Other Functions for a tutorial overview.

7.4.3 Easy pythonic subplots

Fernando Perez got tired of all the boilerplate code needed to create a figure and multiple subplots when using the matplotlib API, and wrote a subplots() helper function. Basic usage allows you to create the figure and an array of subplots with numpy indexing (starts with 0). e.g.:

```python
fig, axarr = plt.subplots(2, 2)
axarr[0,0].plot([1,2,3])  # upper, left
```

See /gallery/subplots_axes_and_figures/subplot_demo for several code examples.
7.4.4 Contour fixes and and triplot

Ian Thomas has fixed a long-standing bug that has vexed our most talented developers for years. `contourf()` now handles interior masked regions, and the boundaries of line and filled contours coincide.

Additionally, he has contributed a new module `tri` and helper function `triplot()` for creating and plotting unstructured triangular grids.

7.4.5 multiple calls to show supported

A long standing request is to support multiple calls to `show()`. This has been difficult because it is hard to get consistent behavior across operating systems, user interface toolkits and versions. Eric Firing has done a lot of work on rationalizing show across backends, with the desired behavior to make show raise all newly created figures and block execution until they are closed. Repeated calls to show should raise newly created figures since the last call. Eric has done a lot of testing on the user interface toolkits and versions and platforms he has
access to, but it is not possible to test them all, so please report problems to the mailing list and bug tracker.

7.4.6 mplot3d graphs can be embedded in arbitrary axes

You can now place an mplot3d graph into an arbitrary axes location, supporting mixing of 2D and 3D graphs in the same figure, and/or multiple 3D graphs in a single figure, using the "projection" keyword argument to add_axes or add_subplot. Thanks Ben Root.

![Fig. 9: Whats New 1 Subplot3d](image)

7.4.7 tick_params

Eric Firing wrote tick_params, a convenience method for changing the appearance of ticks and tick labels. See pyplot function `tick_params()` and associated Axes method `tick_params()`.

7.4.8 Lots of performance and feature enhancements

- Faster magnification of large images, and the ability to zoom in to a single pixel
- Local installs of documentation work better
- Improved "widgets" – mouse grabbing is supported
- More accurate snapping of lines to pixel boundaries
- More consistent handling of color, particularly the alpha channel, throughout the API

7.4.9 Much improved software carpentry

The matplotlib trunk is probably in as good a shape as it has ever been, thanks to improved software carpentry. We now have a buildbot which runs a suite of nose regression tests on every svn commit, auto-generating a set of images and comparing them against a set of
known-goods, sending emails to developers on failures with a pixel-by-pixel image comparison. Releases and release bugfixes happen in branches, allowing active new feature development to happen in the trunk while keeping the release branches stable. Thanks to Andrew Straw, Michael Droettboom and other matplotlib developers for the heavy lifting.

7.4.10 Bugfix marathon

Eric Firing went on a bug fixing and closing marathon, closing over 100 bugs on the bug tracker with help from Jae-Joon Lee, Michael Droettboom, Christoph Gohlke and Michiel de Hoon.

7.5 New in matplotlib 1.1

Table of Contents

- New in matplotlib 1.1
  - Sankey Diagrams
  - Animation
  - Tight Layout
  - PyQt4, PySide, and IPython
  - Legend
  - mplot3d
  - Numerix support removed
  - Markers
  - Other improvements

Note: matplotlib 1.1 supports Python 2.4 to 2.7

7.5.1 Sankey Diagrams

Kevin Davies has extended Yannick Copin’s original Sankey example into a module (sankey) and provided new examples (/gallery/specialty_plots/sankey basics, /gallery/specialty_plots/sankey links, /gallery/specialty_plots/sankey rankine).

7.5.2 Animation

Ryan May has written a backend-independent framework for creating animated figures. The animation module is intended to replace the backend-specific examples formerly in the
Fig. 10: Sankey Rankine
examples-index listings. Examples using the new framework are in animation-examples-index; see the entrancing double pendulum <gallery/animation/double_pendulum_sgskip.py> which uses matplotlib.animation.Animation.save() to create the movie below.

This should be considered as a beta release of the framework; please try it and provide feedback.

7.5.3 Tight Layout

A frequent issue raised by users of matplotlib is the lack of a layout engine to nicely space out elements of the plots. While matplotlib still adheres to the philosophy of giving users complete control over the placement of plot elements, Jae-Joon Lee created the tight_layout module and introduced a new command tight_layout() to address the most common layout issues.

7.5. New in matplotlib 1.1
The usage of this functionality can be as simple as

```python
plt.tight_layout()
```

and it will adjust the spacing between subplots so that the axis labels do not overlap with neighboring subplots. A *Tight Layout guide* has been created to show how to use this new tool.

### 7.5.4 PyQt4, PySide, and IPython

Gerald Storer made the Qt4 backend compatible with PySide as well as PyQt4. At present, however, PySide does not support the PyOS_InputHook mechanism for handling gui events while waiting for text input, so it cannot be used with the new version 0.11 of IPython. Until this feature appears in PySide, IPython users should use the PyQt4 wrapper for QT4, which remains the matplotlib default.

An `rcParam` entry, “backend.qt4”, has been added to allow users to select PyQt4, PyQt4v2, or PySide. The latter two use the Version 2 Qt API. In most cases, users can ignore this `rcParam` variable; it is available to aid in testing, and to provide control for users who are embedding matplotlib in a PyQt4 or PySide app.

### 7.5.5 Legend

Jae-Joon Lee has improved plot legends. First, legends for complex plots such as `stem()` plots will now display correctly. Second, the ‘best’ placement of a legend has been improved in the presence of NANs.

See the *Legend guide* for more detailed explanation and examples.

![Legend Demo4](image)

**Fig. 11: Legend Demo4**

### 7.5.6 mplot3d

In continuing the efforts to make 3D plotting in matplotlib just as easy as 2D plotting, Ben Root has made several improvements to the `mplot3d` module.
• Axes3D has been improved to bring the class towards feature-parity with regular Axes objects
• Documentation for Getting started was significantly expanded
• Axis labels and orientation improved
• Most 3D plotting functions now support empty inputs
• Ticker offset display added:

![Fig. 12: Offset](image)

• contourf() gains zdir and offset kwargs. You can now do this:

![Fig. 13: Contourf3d 2](image)

7.5.7 Numerix support removed

After more than two years of deprecation warnings, Numerix support has now been completely removed from matplotlib.
7.5.8 Markers

The list of available markers for `plot()` and `scatter()` has now been merged. While they were mostly similar, some markers existed for one function, but not the other. This merge did result in a conflict for the ‘d’ diamond marker. Now, ‘d’ will be interpreted to always mean “thin” diamond while ‘D’ will mean “regular” diamond.

Thanks to Michael Droettboom for this effort.

7.5.9 Other improvements

- Unit support for polar axes and `arrow()`
- `PolarAxes` gains getters and setters for “theta_direction”, and “theta_offset” to allow for theta to go in either the clock-wise or counter-clockwise direction and to specify where zero degrees should be placed. `set_theta_zero_location()` is an added convenience function.
- Fixed error in argument handling for tri-functions such as `tripcolor()`
- `axes.labelweight` parameter added to `rcParams`.
- For `imshow()`, `interpolation=‘nearest’` will now always perform an interpolation. A “none” option has been added to indicate no interpolation at all.
- An error in the Hammer projection has been fixed.
- `clabel` for `contour()` now accepts a callable. Thanks to Daniel Hyams for the original patch.
- Jae-Joon Lee added the `HBox` and `VBox` classes.
- Christoph Gohlke reduced memory usage in `imshow()`.
- `scatter()` now accepts empty inputs.
- The behavior for ‘symlog’ scale has been fixed, but this may result in some minor changes to existing plots. This work was refined by ssyr.
- Peter Butterworth added named figure support to `figure()`.
- Michiel de Hoon has modified the MacOSX backend to make its interactive behavior consistent with the other backends.
- Pim Schellart added a new colormap called “cubehelix”. Sameer Grover also added a colormap called “coolwarm”. See it and all other colormaps here.
- Many bug fixes and documentation improvements.

7.6 New in matplotlib 1.2
- PGF/TikZ backend
- Locator interface
- Tri-Surface Plots
- Control the lengths of colorbar extensions
- Figures are picklable
- Set default bounding box in matplotlibrc
- New Boxplot Functionality
- New RC parameter functionality
- Streamplot
- New hist functionality
- Updated shipped dependencies
- Face-centred colors in tripcolor plots
- Hatching patterns in filled contour plots, with legends
- Known issues in the matplotlib 1.2 release

**Note:** matplotlib 1.2 supports Python 2.6, 2.7, and 3.1

### 7.6.1 Python 3.x support

Matplotlib 1.2 is the first version to support Python 3.x, specifically Python 3.1 and 3.2. To make this happen in a reasonable way, we also had to drop support for Python versions earlier than 2.6.

This work was done by Michael Droettboom, the Cape Town Python Users’ Group, many others and supported financially in part by the SAGE project.

The following GUI backends work under Python 3.x: Gtk3Cairo, Qt4Agg, TkAgg and MacOSX. The other GUI backends do not yet have adequate bindings for Python 3.x, but continue to work on Python 2.6 and 2.7, particularly the Qt and QtAgg backends (which have been deprecated). The non-GUI backends, such as PDF, PS and SVG, work on both Python 2.x and 3.x.

Features that depend on the Python Imaging Library, such as JPEG handling, do not work, since the version of PIL for Python 3.x is not sufficiently mature.

### 7.6.2 PGF/TikZ backend

Peter Würtz wrote a backend that allows matplotlib to export figures as drawing commands for LaTeX. These can be processed by PdLaTeX, XeLaTeX or LuaLaTeX using the PGF/TikZ package. Usage examples and documentation are found in *Typesetting With XeLaTeX/LuaLaTeX*. 

7.6. New in matplotlib 1.2
7.6.3 Locator interface

Philip Elson exposed the intelligence behind the tick Locator classes with a simple interface. For instance, to get no more than 5 sensible steps which span the values 10 and 19.5:

```python
>>> import matplotlib.ticker as mticker
>>> locator = mticker.MaxNLocator(nbins=5)
>>> print(locator.tick_values(10, 19.5))
```

7.6.4 Tri-Surface Plots

Damon McDougall added a new plotting method for the mplot3d toolkit called plot_trisurf().

![Fig. 14: Trisurf3d](image)
7.6.5 Control the lengths of colorbar extensions

Andrew Dawson added a new keyword argument `extendfrac` to `colorbar()` to control the length of minimum and maximum colorbar extensions.

7.6.6 Figures are picklable

Philip Elson added an experimental feature to make figures picklable for quick and easy short-term storage of plots. Pickle files are not designed for long term storage, are unsupported when restoring a pickle saved in another matplotlib version and are insecure when restoring a pickle from an untrusted source. Having said this, they are useful for short term storage for later modification inside matplotlib.

7.6.7 Set default bounding box in matplotlibrc

Two new defaults are available in the matplotlibrc configuration file: `savefig.bbox`, which can be set to 'standard' or 'tight', and `savefig.pad_inches`, which controls the bounding box padding.
7.6.8 New Boxplot Functionality

Users can now incorporate their own methods for computing the median and its confidence intervals into the `boxplot()` method. For every column of data passed to boxplot, the user can specify an accompanying median and confidence interval.

![Boxplot Demo3](image)

Fig. 15: Boxplot Demo3

7.6.9 New RC parameter functionality

Matthew Emmett added a function and a context manager to help manage RC parameters: `rc_file()` and `rc_context`. To load RC parameters from a file:

```python
>>> mpl.rc_file('mplrc')
```

To temporarily use RC parameters:

```python
>>> with mpl.rc_context(fname='mplrc', rc={'text.usetex': True}):
    ...
```

7.6.10 Streamplot

Tom Flannaghan and Tony Yu have added a new `streamplot()` function to plot the streamlines of a vector field. This has been a long-requested feature and complements the existing `quiver()` function for plotting vector fields. In addition to simply plotting the streamlines of the vector field, `streamplot()` allows users to map the colors and/or line widths of the streamlines to a separate parameter, such as the speed or local intensity of the vector field.
Fig. 16: Plot Streamplot
7.6.11 New hist functionality

Nic Eggert added a new stacked kwarg to `hist()` that allows creation of stacked histograms using any of the histogram types. Previously, this functionality was only available by using the barstacked histogram type. Now, when `stacked=True` is passed to the function, any of the histogram types can be stacked. The barstacked histogram type retains its previous functionality for backwards compatibility.

7.6.12 Updated shipped dependencies

The following dependencies that ship with matplotlib and are optionally installed alongside it have been updated:

- `pytz` 2012d
- `dateutil` 1.5 on Python 2.x, and 2.1 on Python 3.x

7.6.13 Face-centred colors in tripcolor plots

Ian Thomas extended `tripcolor()` to allow one color value to be specified for each triangular face rather than for each point in a triangulation.

![Fig. 17: Tripcolor Demo](image)

7.6.14 Hatching patterns in filled contour plots, with legends

Phil Elson added support for hatching to `contourf()`, together with the ability to use a legend to identify contoured ranges.

7.6.15 Known issues in the matplotlib 1.2 release

- When using the Qt4Agg backend with IPython 0.11 or later, the save dialog will not display. This should be fixed in a future version of IPython.
7.7 New in matplotlib 1.2.2

Table of Contents

- New in matplotlib 1.2.2
  - Improved collections
  - Multiple images on same axes are correctly transparent

7.7.1 Improved collections

The individual items of a collection may now have different alpha values and be rendered correctly. This also fixes a bug where collections were always filled in the PDF backend.

7.7.2 Multiple images on same axes are correctly transparent

When putting multiple images onto the same axes, the background color of the axes will now show through correctly.

7.8 New in matplotlib 1.3

Table of Contents

- New in matplotlib 1.3
  - New in 1.3.1
  - New plotting features
- Updated Axes3D.contour methods
- Drawing
- Text
- Configuration (rcParams)
- Backends
- Documentation and examples
- Infrastructure

**Note:** matplotlib 1.3 supports Python 2.6, 2.7, 3.2, and 3.3

### 7.8.1 New in 1.3.1

1.3.1 is a bugfix release, primarily dealing with improved setup and handling of dependencies, and correcting and enhancing the documentation.

The following changes were made in 1.3.1 since 1.3.0.

#### Enhancements

- Added a context manager for creating multi-page pdfs (see `matplotlib.backends.backend_pdf.PdfPages`).
- The WebAgg backend should now have lower latency over heterogeneous Internet connections.

#### Bug fixes

- Histogram plots now contain the endline.
- Fixes to the Molleweide projection.
- Handling recent fonts from Microsoft and Macintosh-style fonts with non-ascii metadata is improved.
- Hatching of fill between plots now works correctly in the PDF backend.
- Tight bounding box support now works in the PGF backend.
- Transparent figures now display correctly in the Qt4Agg backend.
- Drawing lines from one subplot to another now works.
- Unit handling on masked arrays has been improved.

#### Setup and dependencies

- Now works with any version of pyparsing 1.5.6 or later, without displaying hundreds of warnings.
• Now works with 64-bit versions of Ghostscript on MS-Windows.
• When installing from source into an environment without Numpy, Numpy will first be downloaded and built and then used to build matplotlib.
• Externally installed backends are now always imported using a fully-qualified path to the module.
• Works with newer version of wxPython.
• Can now build with a PyCXX installed globally on the system from source.
• Better detection of Gtk3 dependencies.

Testing

• Tests should now work in non-English locales.
• PEP8 conformance tests now report on locations of issues.

7.8.2 New plotting features

xkcd-style sketch plotting

To give your plots a sense of authority that they may be missing, Michael Droettboom (inspired by the work of many others in PR #1329) has added an xkcd-style sketch plotting mode. To use it, simply call matplotlib.pyplot.xkcd() before creating your plot. For really fine control, it is also possible to modify each artist’s sketch parameters individually with matplotlib.artist.Artist.set_sketch_params().

Fig. 19: xkcd

7.8.3 Updated Axes3D.contour methods

Damon McDougall updated the tricontour() and tricontourf() methods to allow 3D contour plots on arbitrary unstructured user-specified triangulations.
New eventplot plot type

Todd Jennings added a eventplot() function to create multiple rows or columns of identical line segments.

As part of this feature, there is a new EventCollection class that allows for plotting and manipulating rows or columns of identical line segments.

Triangular grid interpolation

Geoffroy Billotey and Ian Thomas added classes to perform interpolation within triangular grids: (LinearTriInterpolator and CubicTriInterpolator) and a utility class to find the triangles in which points lie (TrapezoidMapTriFinder). A helper class to perform mesh refinement and smooth contouring was also added (UniformTriRefiner). Finally, a class implementing some basic tools for triangular mesh improvement was added (TriAnalyzer).
Baselines for stackplot

Till Stensitzki added non-zero baselines to `stackplot()`. They may be symmetric or weighted.

Rectangular colorbar extensions

Andrew Dawson added a new keyword argument `extendrect` to `colorbar()` to optionally make colorbar extensions rectangular instead of triangular.

More robust boxplots

Paul Hobson provided a fix to the `boxplot()` method that prevent whiskers from being drawn inside the box for oddly distributed data sets.
Calling subplot() without arguments

A call to `subplot()` without any arguments now acts the same as `subplot(111)` or `subplot(1,1,1)` – it creates one axes for the whole figure. This was already the behavior for both `axes()` and `subplots()`, and now this consistency is shared with `subplot()`.

### 7.8.4 Drawing

**Independent alpha values for face and edge colors**

Wes Campagne modified how `Patch` objects are drawn such that (for backends supporting transparency) you can set different alpha values for faces and edges, by specifying their colors in RGBA format. Note that if you set the alpha attribute for the patch object (e.g. using `set_alpha()` or the alpha keyword argument), that value will override the alpha components set in both the face and edge colors.

**Path effects on lines**

Thanks to Jae-Joon Lee, path effects now also work on plot lines.

![PathEffect Demo](image)

**Fig. 24: Patheffect Demo**

**Easier creation of colormap and normalizer for levels with colors**

Phil Elson added the `matplotlib.colors.from_levels_and_colors()` function to easily create a colormap and normalizer for representation of discrete colors for plot types such as `matplotlib.pyplot.pcolormesh()`, with a similar interface to that of `contourf()`.

**Full control of the background color**

Wes Campagne and Phil Elson fixed the Agg backend such that PNGs are now saved with the correct background color when `fig.patch.get_alpha()` is not 1.

**Improved bbox_inches="tight" functionality**

Passing `bbox_inches="tight"` through to `plt.save()` now takes into account all artists on a figure - this was previously not the case and led to several corner cases which did not function as expected.
Initialize a rotated rectangle

Damon McDougall extended the Rectangle constructor to accept an angle kwarg, specifying the rotation of a rectangle in degrees.

7.8.5 Text

Anchored text support

The svg and pgf backends are now able to save text alignment information to their output formats. This allows to edit text elements in saved figures, using Inkscape for example, while preserving their intended position. For svg please note that you’ll have to disable the default text-to-path conversion (mpl.rc('svg', fonttype='none')).

Better vertical text alignment and multi-line text

The vertical alignment of text is now consistent across backends. You may see small differences in text placement, particularly with rotated text.

If you are using a custom backend, note that the draw_text renderer method is now passed the location of the baseline, not the location of the bottom of the text bounding box.

Multi-line text will now leave enough room for the height of very tall or very low text, such as superscripts and subscripts.

Left and right side axes titles

Andrew Dawson added the ability to add axes titles flush with the left and right sides of the top of the axes using a new keyword argument loc to title().

Improved manual contour plot label positioning

Brian Mattern modified the manual contour plot label positioning code to interpolate along line segments and find the actual closest point on a contour to the requested position. Previously, the closest path vertex was used, which, in the case of straight contours was sometimes quite distant from the requested location. Much more precise label positioning is now possible.

7.8.6 Configuration (rcParams)

Quickly find rcParams

Phil Elson made it easier to search for rcParameters by passing a valid regular expression to matplotlib.RcParams.find_all(). matplotlib.RcParams now also has a pretty repr and str representation so that search results are printed prettily:
axes.xmargin and axes.ymargin added to rcParams

rcParam values (axes.xmargin and axes.ymargin) were added to configure the default margins used. Previously they were hard-coded to default to 0, default value of both rcParam values is 0.

Changes to font rcParams

The font.* rcParams now affect only text objects created after the rcParam has been set, and will not retroactively affect already existing text objects. This brings their behavior in line with most other rcParams.

savefig.jpeg_quality added to rcParams

rcParam value savefig.jpeg_quality was added so that the user can configure the default quality used when a figure is written as a JPEG. The default quality is 95; previously, the default quality was 75. This change minimizes the artifacting inherent in JPEG images, particularly with images that have sharp changes in color as plots often do.

7.8.7 Backends

WebAgg backend

Michael Droettboom, Phil Elson and others have developed a new backend, WebAgg, to display figures in a web browser. It works with animations as well as being fully interactive.
Future versions of matplotlib will integrate this backend with the IPython notebook for a fully web browser based plotting frontend.

**Remember save directory**

Martin Spacek made the save figure dialog remember the last directory saved to. The default is configurable with the new `savefig.directory` rcParam in `matplotlibrc`.

### 7.8.8 Documentation and examples

**Numpydoc docstrings**

Nelle Varoquaux has started an ongoing project to convert matplotlib’s docstrings to numpydoc format. See [MEP10](#) for more information.

**Example reorganization**

Tony Yu has begun work reorganizing the examples into more meaningful categories. The new gallery page is the fruit of this ongoing work. See [MEP12](#) for more information.
Examples now use subplots()

For the sake of brevity and clarity, most of the examples now use the newer `subplots()`, which creates a figure and one (or multiple) axes object(s) in one call. The old way involved a call to `figure()`, followed by one (or multiple) `subplot()` calls.

7.8.9 Infrastructure

Housecleaning

A number of features that were deprecated in 1.2 or earlier, or have not been in a working state for a long time have been removed. Highlights include removing the Qt version 3 backends, and the FltkAgg and Emf backends. See Changes in 1.3.x for a complete list.

New setup script

matplotlib 1.3 includes an entirely rewritten setup script. We now ship fewer dependencies with the tarballs and installers themselves. Notably, pytz, dateutil, pyparsing and six are no longer included with matplotlib. You can either install them manually first, or let pip install them as dependencies along with matplotlib. It is now possible to not include certain subcomponents, such as the unit test data, in the install. See setup.cfg.template for more information.

XDG base directory support

On Linux, matplotlib now uses the XDG base directory specification to find the matplotlibrc configuration file. matplotlibrc should now be kept in config/matplotlib, rather than matplotlib. If your configuration is found in the old location, it will still be used, but a warning will be displayed.

Catch opening too many figures using pyplot

Figures created through pyplot.figure are retained until they are explicitly closed. It is therefore common for new users of matplotlib to run out of memory when creating a large series of figures in a loop without closing them.

matplotlib will now display a `RuntimeWarning` when too many figures have been opened at once. By default, this is displayed for 20 or more figures, but the exact number may be controlled using the `figure.max_open_warning` rcParam.

7.9 New in matplotlib 1.4

Thomas A. Caswell served as the release manager for the 1.4 release.
• New in matplotlib 1.4
  - New colormap
  - The nbagg backend
  - New plotting features
  - Date handling
  - Configuration (rcParams)
  - style package added
  - Backends
  - Text
  - Sphinx extensions
  - Legend and PathEffects documentation
  - Widgets
  - GAE integration

Note: matplotlib 1.4 supports Python 2.6, 2.7, 3.3, and 3.4

7.9.1 New colormap

In heatmaps, a green-to-red spectrum is often used to indicate intensity of activity, but this can be problematic for the red/green colorblind. A new, colorblind-friendly colormap is now available at matplotlib.cm.Wistia. This colormap maintains the red/green symbolism while achieving deuteranopic legibility through brightness variations. See here for more information.

7.9.2 The nbagg backend

Phil Elson added a new backend, named “nbagg”, which enables interactive figures in a live IPython notebook session. The backend makes use of the infrastructure developed for the webagg backend, which itself gives standalone server backed interactive figures in the browser, however nbagg does not require a dedicated matplotlib server as all communications are handled through the IPython Comm machinery.

As with other backends nbagg can be enabled inside the IPython notebook with:

```python
import matplotlib
matplotlib.use('nbagg')
```

Once figures are created and then subsequently shown, they will placed in an interactive widget inside the notebook allowing panning and zooming in the same way as any other matplotlib backend. Because figures require a connection to the IPython notebook server for their interactivity, once the notebook is saved, each figure will be rendered as a static image - thus allowing non-interactive viewing of figures on services such as nbviewer.
7.9.3 New plotting features

Power-law normalization

Ben Gamari added a power-law normalization method, PowerNorm. This class maps a range of values to the interval [0,1] with power-law scaling with the exponent provided by the constructor’s gamma argument. Power law normalization can be useful for, e.g., emphasizing small populations in a histogram.

Fully customizable boxplots

Paul Hobson overhauled the boxplot() method such that it is now completely customizable in terms of the styles and positions of the individual artists. Under the hood, boxplot() relies on a new function (boxplot_stats()), which accepts any data structure currently compatible with boxplot(), and returns a list of dictionaries containing the positions for each element of the boxplots. Then a second method, bxp() is called to draw the boxplots based on the stats.

The boxplot() function can be used as before to generate boxplots from data in one step. But now the user has the flexibility to generate the statistics independently, or to modify the output of boxplot_stats() prior to plotting with bxp().

Lastly, each artist (e.g., the box, outliers, cap, notches) can now be toggled on or off and their styles can be passed in through individual kargs. See the examples: gallery/statistics/boxplot and gallery/statistics/bxp

Added a bool kwarg, manage_xticks, which if False disables the management of the ticks and limits on the x-axis by bxp().

Support for datetime axes in 2d plots

Andrew Dawson added support for datetime axes to contour(), contourf(), pcolormesh() and pcolor().

Support for additional spectrum types

Todd Jennings added support for new types of frequency spectrum plots: magnitude_spectrum(), phase_spectrum(), and angle_spectrum(), as well as corresponding functions in mlab.

He also added these spectrum types to specgram(), as well as adding support for linear scaling there (in addition to the existing dB scaling). Support for additional spectrum types was also added to specgram().

He also increased the performance for all of these functions and plot types.

Support for detrending and windowing 2D arrays in mlab

Todd Jennings added support for 2D arrays in the detrend_mean(), detrend_none(), and detrend(), as well as adding apply_window() which support windowing 2D arrays.
Support for strides in mlab

Todd Jennings added some functions to mlab to make it easier to use numpy strides to create memory-efficient 2D arrays. This includes `stride_repeat()`, which repeats an array to create a 2D array, and `stride_windows()`, which uses a moving window to create a 2D array from a 1D array.

Formatter for new-style formatting strings

Added `FormatStrFormatterNewStyle` which does the same job as `FormatStrFormatter`, but accepts new-style formatting strings instead of printf-style formatting strings.

Consistent grid sizes in streamplots

`streamplot()` uses a base grid size of 30x30 for both `density=1` and `density=(1, 1)`. Previously a grid size of 30x30 was used for `density=1`, but a grid size of 25x25 was used for `density=(1, 1)`.

Get a list of all tick labels (major and minor)

Added the kwarg ‘which’ to `get_xticklabels()`, `get_yticklabels()` and `get_ticklabels()`. ‘which’ can be ‘major’, ‘minor’, or ‘both’ select which ticks to return, like `set_ticks_position()`. If ‘which’ is `None` then the old behaviour (controlled by the bool `minor`).

Separate horizontal/vertical axes padding support in ImageGrid

The kwarg ‘axes_pad’ to `mpl_toolkits.axes_grid1.ImageGrid` can now be a tuple if separate horizontal/vertical padding is needed. This is supposed to be very helpful when you have a labelled legend next to every subplot and you need to make some space for legend’s labels.

Support for skewed transformations

The `Affine2D` gained additional methods `skew` and `skew_deg` to create skewed transformations. Additionally, matplotlib internals were cleaned up to support using such transforms in `Axes`. This transform is important for some plot types, specifically the Skew-T used in meteorology.

Support for specifying properties of wedge and text in pie charts.

Added the kwargs ‘wedgeprops’ and ‘textprops’ to `pie()` to accept properties for wedge and text objects in a pie. For example, one can specify `wedgeprops = {'linewidth':3}` to specify the width of the borders of the wedges in the pie. For more properties that the user can specify, look at the docs for the wedge and text objects.

Fixed the direction of errorbar upper/lower limits

Larry Bradley fixed the `errorbar()` method such that the upper and lower limits (`lolims`, `uplims`, `xlolims`, `xuplims`) now point in the correct direction.
More consistent add-object API for Axes

Added the Axes method `add_image` to put image handling on a par with artists, collections, containers, lines, patches, and tables.

Violin Plots

Per Parker, Gregory Kelsie, Adam Ortiz, Kevin Chan, Geoffrey Lee, Deokjae Donald Seo, and Taesu Terry Lim added a basic implementation for violin plots. Violin plots can be used to represent the distribution of sample data. They are similar to box plots, but use a kernel density estimation function to present a smooth approximation of the data sample used. The added features are:

- `violin()` - Renders a violin plot from a collection of statistics.
- `violin_stats()` - Produces a collection of statistics suitable for rendering a violin plot.
- `violinplot()` - Creates a violin plot from a set of sample data. This method makes use of `violin_stats()` to process the input data, and `violin_stats()` to do the actual rendering. Users are also free to modify or replace the output of `violin_stats()` in order to customize the violin plots to their liking.

This feature was implemented for a software engineering course at the University of Toronto, Scarborough, run in Winter 2014 by Anya Taflovich.

More `markevery` options to show only a subset of markers

Rohan Walker extended the `markevery` property in `Line2D`. You can now specify a subset of markers to show with an int, slice object, numpy fancy indexing, or float. Using a float shows markers at approximately equal display-coordinate-distances along the line.
Added size related functions to specialized Collections

Added the `get_size` and `set_size` functions to control the size of elements of specialized collections (AsteriskPolygonCollection BrokenBarHCollection CircleCollection PathCollection PolyCollection RegularPolyCollection StarPolygonCollection).

Fixed the mouse coordinates giving the wrong theta value in Polar graph

Added code to `transform_non_affine()` to ensure that the calculated theta value was between the range of 0 and 2 * pi since the problem was that the value can become negative after applying the direction and rotation to the theta calculation.

Simple quiver plot for mplot3d toolkit

A team of students in an Engineering Large Software Systems course, taught by Prof. Anya Tafliovich at the University of Toronto, implemented a simple version of a quiver plot in 3D space for the mplot3d toolkit as one of their term project. This feature is documented in `quiver()`. The team members are: Ryan Steve D’Souza, Victor B, xbtsw, Yang Wang, David, Caradec Bisesar and Vlad Vassilovski.

Fig. 26: Quiver3d

polar-plot r-tick locations

Added the ability to control the angular position of the r-tick labels on a polar plot via `set_rlabel_position()`.

7.9.4 Date handling

n-d array support for date conversion

Andrew Dawson added support for n-d array handling to `matplotlib.dates.num2date()`, `matplotlib.dates.date2num()` and `matplotlib.dates.datestr2num()`. Support is also added to the unit conversion interfaces `matplotlib.dates.DateConverter` and `matplotlib.units.Registry`. 
### 7.9.5 Configuration (rcParams)

**savefig.transparent added**

Controls whether figures are saved with a transparent background by default. Previously `savefig` always defaulted to a non-transparent background.

**axes.titleweight**

Added rcParam to control the weight of the title

**axes.formatter.useoffset added**

Controls the default value of `useOffset` in `ScalarFormatter`. If `True` and the data range is much smaller than the data average, then an offset will be determined such that the tick labels are meaningful. If `False` then the full number will be formatted in all conditions.

**nbagg.transparent added**

Controls whether nbagg figures have a transparent background. `nbagg.transparent` is `True` by default.

**XDG compliance**

Matplotlib now looks for configuration files (both rcparams and style) in XDG compliant locations.

### 7.9.6 style package added

You can now easily switch between different styles using the new `style` package:

```py
>>> from matplotlib import style
>>> style.use('dark_background')
```

Subsequent plots will use updated colors, sizes, etc. To list all available styles, use:

```py
>>> print style.available
```

You can add your own custom `<style name>.mplstyle` files to `~/.matplotlib/stylelib` or call use with a URL pointing to a file with `matplotlibrc` settings.

*Note that this is an experimental feature*, and the interface may change as users test out this new feature.
7.9.7 Backends

Qt5 backend

Martin Fitzpatrick and Tom Badran implemented a Qt5 backend. The differences in namespace locations between Qt4 and Qt5 was dealt with by shimming Qt4 to look like Qt5, thus the Qt5 implementation is the primary implementation. Backwards compatibility for Qt4 is maintained by wrapping the Qt5 implementation.

The Qt5Agg backend currently does not work with IPython’s %matplotlib magic.

The 1.4.0 release has a known bug where the toolbar is broken. This can be fixed by:

```
cd path/to/installed/matplotlib
wget https://github.com/matplotlib/matplotlib/pull/3322.diff
# unix2dos 3322.diff (if on windows to fix line endings)
patch -p2 < 3322.diff
```

Qt4 backend

Rudolf Höfler changed the appearance of the subplottool. All sliders are vertically arranged now, buttons for tight layout and reset were added. Furthermore, the subplottool is now implemented as a modal dialog. It was previously a QMainWindow, leaving the SPT open if one closed the plot window.

In the figure options dialog one can now choose to (re-)generate a simple automatic legend. Any explicitly set legend entries will be lost, but changes to the curves’ label, linestyle, et cetera will now be updated in the legend.

Interactive performance of the Qt4 backend has been dramatically improved under windows.
The mapping of key-signals from Qt to values matplotlib understands was greatly improved (For both Qt4 and Qt5).

Cairo backends

The Cairo backends are now able to use the cairocffi bindings which are more actively maintained than the pycairo bindings.

Gtk3Agg backend

The Gtk3Agg backend now works on Python 3.x, if the cairocffi bindings are installed.

PDF backend

Added context manager for saving to multi-page PDFs.
7.9.8 Text

Text URLs supported by SVG backend

The `svg` backend will now render `Text` objects' url as a link in output SVGs. This allows one to make clickable text in saved figures using the url kwarg of the `Text` class.

Anchored sizebar font

Added the `fontproperties` kwarg to `AnchoredSizeBar` to control the font properties.

7.9.9 Sphinx extensions

The `:context:` directive in the `plot_directive` Sphinx extension can now accept an optional `reset` setting, which will cause the context to be reset. This allows more than one distinct context to be present in documentation. To enable this option, use `:context: reset` instead of `:context:` any time you want to reset the context.

7.9.10 Legend and PathEffects documentation

The `Legend` guide and `Path effects guide` have both been updated to better reflect the full potential of each of these powerful features.

7.9.11 Widgets

Span Selector

Added an option `span_stays` to the `SpanSelector` which makes the selector rectangle stay on the axes after you release the mouse.

7.9.12 GAE integration

Matplotlib will now run on google app engine.

7.10 New in matplotlib 1.5

**Table of Contents**

- New in matplotlib 1.5
  - Interactive OO usage
  - Working with labeled data like pandas DataFrames
  - Added `axes.prop_cycle` key to `rcParams`
Interactive OO usage

All Artists now keep track of if their internal state has been changed but not reflected in the display (‘stale’) by a call to draw. It is thus possible to pragmatically determine if a given Figure needs to be re-drawn in an interactive session.

To facilitate interactive usage a draw_all method has been added to pyplot which will redraw all of the figures which are ‘stale’.

To make this convenient for interactive use matplotlib now registers a function either with IPython’s ‘post_execute’ event or with the displayhook in the standard python REPL to automatically call plt.draw_all just before control is returned to the REPL. This ensures that the draw command is deferred and only called once.

The upshot of this is that for interactive backends (including %matplotlib notebook) in interactive mode (with plt.ion())

```python
import matplotlib.pyplot as plt
fig, ax = plt.subplots()
ln, = ax.plot([0, 1, 4, 9, 16])
plt.show()
ln.set_color('g')
```

will automatically update the plot to be green. Any subsequent modifications to the Artist objects will do likewise.

This is the first step of a larger consolidation and simplification of the pyplot internals.

Note: matplotlib 1.5 supports Python 2.7, 3.4, and 3.5
7.10.2 Working with labeled data like pandas DataFrames

Plot methods which take arrays as inputs can now also work with labeled data and unpack such data.

This means that the following two examples produce the same plot:

Example

```python
df = pandas.DataFrame({'var1':[1,2,3,4,5,6], 'var2':[1,2,3,4,5,6]})
plt.plot(df['var1'], df['var2'])
```

Example

```python
plt.plot('var1', 'var2', data=df)
```

This works for most plotting methods, which expect arrays/sequences as inputs. data can be anything which supports `__getitem__` (dict, pandas.DataFrame, h5py, ...) to access array like values with string keys.

In addition to this, some other changes were made, which makes working with labeled data (ex pandas.Series) easier:

- For plotting methods with label keyword argument, one of the data inputs is designated as the label source. If the user does not supply a label that value object will be introspected for a label, currently by looking for a name attribute. If the value object does not have a name attribute but was specified by as a key into the data kwarg, then the key is used. In the above examples, this results in an implicit label="var2" for both cases.
- `plot()` now uses the index of a Series instead of `np.arange(len(y))`, if no x argument is supplied.

7.10.3 Added axes.prop_cycle key to rcParams

This is a more generic form of the now-deprecated `axes.color_cycle` param. Now, we can cycle more than just colors, but also linestyles, hatches, and just about any other artist property. Cycler notation is used for defining property cycles. Adding cyclers together will be like you are `zip()`-ing together two or more property cycles together:

```python
axes.prop_cycle: cycler('color', 'rgb') + cycler('lw', [1, 2, 3])
```

You can even multiply cyclers, which is like using `itertools.product()` on two or more property cycles. Remember to use parentheses if writing a multi-line `prop_cycle` parameter.

7.10.4 New Colormaps

All four of the colormaps proposed as the new default are available as 'viridis' (the new default in 2.0), 'magma', 'plasma', and 'inferno'

7.10.5 Styles

Several new styles have been added, including many styles from the Seaborn project. Additionally, in order to prep for the upcoming 2.0 style-change release, a 'classic' and 'default'
Fig. 27: Color Cycle

viridis

magma

plasma

inferno
style has been added. For this release, the ‘default’ and ‘classic’ styles are identical. By using them now in your scripts, you can help ensure a smooth transition during future upgrades of matplotlib, so that you can upgrade to the snazzy new defaults when you are ready!

```python
import matplotlib.style
matplotlib.style.use('classic')
```

The ‘default’ style will give you matplotlib's latest plotting styles:

```python
matplotlib.style.use('default')
```

### 7.10.6 Backends

**New backend selection**

The environment variable `MPLBACKEND` can now be used to set the matplotlib backend.

**wx backend has been updated**

The wx backend can now be used with both wxPython classic and Phoenix. wxPython classic has to be at least version 2.8.12 and works on Python 2.x. As of May 2015 no official release of wxPython Phoenix is available but a current snapshot will work on Python 2.7+ and 3.4+.

If you have multiple versions of wxPython installed, then the user code is responsible setting the wxPython version. How to do this is explained in the comment at the beginning of the example `examples/user_interfaces/embedding_in_wx2.py`.

### 7.10.7 Configuration (rcParams)

Some parameters have been added, others have been improved.
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>(x, y)</code>axis.labelpad</td>
<td><code>mplot3d</code> now respects these parameters</td>
</tr>
<tr>
<td>axes.labelpad</td>
<td>Default space between the axis and the label</td>
</tr>
<tr>
<td>errorbar.capsize</td>
<td>Default length of end caps on error bars</td>
</tr>
<tr>
<td><code>(x, y)</code>tick.minor.visible</td>
<td>Default visibility of minor x/y ticks</td>
</tr>
<tr>
<td>legend.framealpha</td>
<td>Default transparency of the legend frame box</td>
</tr>
<tr>
<td>legend.facecolor</td>
<td>Default facecolor of legend frame box (or 'inherit' from axes.facecolor)</td>
</tr>
<tr>
<td>legend.edgcolor</td>
<td>Default edgecolor of legend frame box (or 'inherit' from axes.edgecolor)</td>
</tr>
<tr>
<td>figure.titlesize</td>
<td>Default font size for figure suptitles</td>
</tr>
<tr>
<td>figure.titleweight</td>
<td>Default font weight for figure suptitles</td>
</tr>
<tr>
<td>image.composite_image</td>
<td>Whether a vector graphics backend should composite several images into a single image or not when saving. Useful when needing to edit the files further in Inkscape or other programs.</td>
</tr>
<tr>
<td>markers.fillstyle</td>
<td>Default fillstyle of markers. Possible values are 'full' (the default), 'left', 'right', 'bottom', 'top' and 'none'</td>
</tr>
<tr>
<td>toolbar</td>
<td>Added 'toolmanager' as a valid value, enabling the experimental ToolManager feature.</td>
</tr>
</tbody>
</table>

#### 7.10.8 Widgets

**Active state of Selectors**

All selectors now implement `set_active` and `get_active` methods (also called when accessing the `active` property) to properly update and query whether they are active.

Moved `ignore`, `set_active`, and `get_active` methods to base class `Widget`

Pushes up duplicate methods in child class to parent class to avoid duplication of code.

**Adds enable/disable feature to MultiCursor**

A MultiCursor object can be disabled (and enabled) after it has been created without destroying the object. Example:

```python
multi_cursor.active = False
```
Improved RectangleSelector and new EllipseSelector Widget

Adds an interactive keyword which enables visible handles for manipulating the shape after it has been drawn.

Adds keyboard modifiers for:

- Moving the existing shape (default key = 'space')
- Make the shape square (default ‘shift’)
- Make the initial point the center of the shape (default ‘control’)
- Square and center can be combined

Allow Artists to Display Pixel Data in Cursor

Adds get_pixel_data and format_pixel_data methods to artists which can be used to add zdata to the cursor display in the status bar. Also adds an implementation for Images.

7.10.9 New plotting features

Auto-wrapping Text

Added the keyword argument "wrap" to Text, which automatically breaks long lines of text when being drawn. Works for any rotated text, different modes of alignment, and for text that are either labels or titles. This breaks at the Figure, not Axes edge.

Contour plot corner masking

Ian Thomas rewrote the C++ code that calculates contours to add support for corner masking. This is controlled by a new keyword argument corner_mask in the functions contour() and contourf(). The previous behaviour, which is now obtained using corner_mask=False, was for a single masked point to completely mask out all four quads touching that point. The new behaviour, obtained using corner_mask=True, only masks the corners of those quads touching the point; any triangular corners comprising three unmasked points are contoured as usual. If the corner_mask keyword argument is not specified, the default value is taken from rcParams.

 Mostly unified linestyles for Line2D, Patch and Collection

The handling of linestyles for Lines, Patches and Collections has been unified. Now they all support defining linestyles with short symbols, like "--", as well as with full names, like "dashed". Also the definition using a dash pattern ((0., [3., 3.])) is supported for all methods using Line2D, Patch or Collection.

Legend marker order

Added ability to place the label before the marker in a legend box with markerfirst keyword
This is a really long string that should be wrapped so that it does not go outside the figure.

Fig. 28: Contour Corner Mask
Support for legend for PolyCollection and stackplot

Added a `legend_handler` for `PolyCollection` as well as a `labels` argument to `stackplot()`.

Support for alternate pivots in mplot3d quiver plot

Added a `pivot` kwarg to `quiver()` that controls the pivot point around which the quiver line rotates. This also determines the placement of the arrow head along the quiver line.

Logit Scale

Added support for the ‘logit’ axis scale, a nonlinear transformation

\[ x \rightarrow \log_{10}(x/(1-x)) \]

for data between 0 and 1 excluded.

Add step kwargs to fill_between

Added `step` kwarg to `Axes.fill_between` to allow to fill between lines drawn using the ‘step’ draw style. The values of `step` match those of the `where` kwarg of `Axes.step`. The asymmetry of the kwarg names is not ideal, but `Axes.fill_between` already has a `where` kwarg.

This is particularly useful for plotting pre-binned histograms.

![Filled Step Plot](Fig. 29: Filled Step)

Square Plot

Implemented square plots feature as a new parameter in the axis function. When argument ‘square’ is specified, equal scaling is set, and the limits are set such that `xmax-xmin == ymax-ymin.`
Updated figimage to take optional resize parameter

Added the ability to plot simple 2D-Array using `plt.figimage(X, resize=True)`. This is useful for plotting simple 2D-Array without the Axes or whitespacing around the image.

Updated Figure.savefig() can now use figure’s dpi

Added support to save the figure with the same dpi as the figure on the screen using `dpi='figure'`.

Example:

```python
f = plt.figure(dpi=25)  # dpi set to 25
S = plt.scatter([1,2,3],[4,5,6])
f.savefig('output.png', dpi='figure')  # output savefig dpi set to 25 (same as figure)
```

Updated Table to control edge visibility

Added the ability to toggle the visibility of lines in Tables. Functionality added to the pyplot. `table()` factory function under the keyword argument “edges”. Values can be the strings “open”, “closed”, “horizontal”, “vertical” or combinations of the letters “L”, “R”, “T”, “B” which represent left, right, top, and bottom respectively.

Example:
table(..., edges="open")  # No line visible
table(..., edges="closed")  # All lines visible
table(..., edges="horizontal")  # Only top and bottom lines visible
table(..., edges="LT")  # Only left and top lines visible.

**Zero r/cstride support in plot_wireframe**

Adam Hughes added support to mplot3d’s plot_wireframe to draw only row or column line plots.

![Plot bar and barh with labels](image)

**Plot bar and barh with labels**

Added kwarg "tick_label" to bar and barh to support plotting bar graphs with a text label for each bar.

**Added center and frame kwargs to pie**

These control where the center of the pie graph are and if the Axes frame is shown.
Fixed 3D filled contour plot polygon rendering

Certain cases of 3D filled contour plots that produce polygons with multiple holes produced improper rendering due to a loss of path information between PolyCollection and Poly3DCollection. A function `set_verts_and_codes()` was added to allow path information to be retained for proper rendering.

Dense colorbars are rasterized

Vector file formats (pdf, ps, svg) are efficient for many types of plot element, but for some they can yield excessive file size and even rendering artifacts, depending on the renderer used for screen display. This is a problem for colorbars that show a large number of shades, as is most commonly the case. Now, if a colorbar is showing 50 or more colors, it will be rasterized in vector backends.

DateFormatter strftime

`strftime` method will format a `datetime.datetime` object with the format string passed to the formatter’s constructor. This method accepts datetimes with years before 1900, unlike `datetime.datetime.strftime()`.
Artist-level \{get,set\}\_usetex for text

Add \{get,set\}\_usetex methods to \texttt{Text} objects which allow artist-level control of LaTeX rendering vs the internal mathtex rendering.

\texttt{ax.remove()} works as expected

As with artists added to an \texttt{Axes}, \texttt{Axes} objects can be removed from their figure via \texttt{remove()}.

API Consistency fix within Locators set\_params() function

\texttt{set\_params()} function, which sets parameters within a \texttt{Locator} type instance, is now available to all \texttt{Locator} types. The implementation also prevents unsafe usage by strictly defining the parameters that a user can set.

To use, call \texttt{set\_params()} on a \texttt{Locator} instance with desired arguments:

```python
loc = matplotlib.ticker.LogLocator()
# Set given attributes for loc.
loc.set_params(numticks=8, numdecs=8, subs=[2.0], base=8)
# The below will error, as there is no such parameter for LogLocator
# named foo
# loc.set_params(foo='bar')
```

Date Locators

Date Locators (derived from \texttt{DateLocator}) now implement the \texttt{tick\_values()} method. This is expected of all Locators derived from \texttt{Locator}.

The Date Locators can now be used easily without creating axes

```python
from datetime import datetime
from matplotlib.dates import YearLocator
t0 = datetime(2002, 10, 9, 12, 10)
tf = datetime(2005, 10, 9, 12, 15)
loc = YearLocator()
values = loc.tick\_values(t0, tf)
```

OffsetBoxes now support clipping

Artists draw onto objects of type OffsetBox through DrawingArea and TextArea. The TextArea calculates the required space for the text and so the text is always within the bounds, for this nothing has changed.

However, DrawingArea acts as a parent for zero or more Artists that draw on it and may do so beyond the bounds. Now child Artists can be clipped to the bounds of the DrawingArea.
OffsetBoxes now considered by tight_layout

When `tight_layout()` or `Figure.tight_layout()` or `GridSpec.tight_layout()` is called, OffsetBoxes that are anchored outside the axes will not get chopped out. The OffsetBoxes will also not get overlapped by other axes in case of multiple subplots.

Per-page pdf notes in multi-page pdfs (PdfPages)

Add a new method `attach_note()` to the PdfPages class, allowing the attachment of simple text notes to pages in a multi-page pdf of figures. The new note is visible in the list of pdf annotations in a viewer that has this facility (Adobe Reader, OSX Preview, Skim, etc.). Per default the note itself is kept off-page to prevent it to appear in print-outs.

PdfPages.attach_note needs to be called before `savefig()` in order to be added to the correct figure.

Updated fignum_exists to take figure name

Added the ability to check the existence of a figure using its name instead of just the figure number. Example:

```python
figure('figure')
fignum_exists('figure') #true
```

7.10.10 ToolManager

Federico Ariza wrote the new `ToolManager` that comes as replacement for `NavigationToolbar2`.

ToolManager offers a new way of looking at the user interactions with the figures. Before we had the `NavigationToolbar2` with its own tools like `zoom/pan/home/save/...` and also we had the shortcuts like `yscale/grid/quit/...` ToolManager relocate all those actions as `Tools` (located in `backend_tools`), and defines a way to access/trigger/reconfigure them.

The Toolbars are replaced for ToolContainers that are just GUI interfaces to trigger the tools. But don’t worry the default backends include a ToolContainer called `toolbar`.

**Note:** At the moment, we release this primarily for feedback purposes and should be treated as experimental until further notice as API changes will occur. For the moment the ToolManager works only with the GTK3 and Tk backends. Make sure you use one of those. Port for the rest of the backends is comming soon.

To activate the ToolManager include the following at the top of your file

```python
>>> matplotlib.rcParams['toolbar'] = 'toolmanager'
```

Interact with the ToolContainer

The most important feature is the ability to easily reconfigure the ToolContainer (aka toolbar). For example, if we want to remove the "forward" button we would just do.
>>> fig.canvas.manager.toolmanager.remove_tool('forward')

Now if you want to programmatically trigger the “home” button

>>> fig.canvas.manager.toolmanager.trigger_tool('home')

**New Tools for ToolManager**

It is possible to add new tools to the ToolManager

A very simple tool that prints “You’re awesome” would be:

```python
from matplotlib.backend_tools import ToolBase
class AwesomeTool(ToolBase):
    def trigger(self, *args, **kwargs):
        print("You're awesome")
```

To add this tool to ToolManager

>>> fig.canvas.manager.toolmanager.add_tool('Awesome', AwesomeTool)

If we want to add a shortcut ("d") for the tool

>>> fig.canvas.manager.toolmanager.update_keymap('Awesome', 'd')

To add it to the toolbar inside the group ‘foo’

>>> fig.canvas.manager.toolbar.add_tool('Awesome', 'foo')

There is a second class of tools, “Toggleable Tools”, this are almost the same as our basic tools, just that belong to a group, and are mutually exclusive inside that group. For tools derived from ToolToggleBase there are two basic methods enable and disable that are called automatically whenever it is toggled.

A full example is located in /gallery/user_interfaces/toolmanager_sgskip

**7.10.11 cbook.is_sequence_of_strings recognizes string objects**

This is primarily how pandas stores a sequence of strings

```python
import pandas as pd
import matplotlib.cbook as cbook

a = np.array(['a', 'b', 'c'])
print(cbook.is_sequence_of_strings(a)) # True

a = np.array(['a', 'b', 'c'], dtype=object)
print(cbook.is_sequence_of_strings(a)) # True

s = pd.Series(['a', 'b', 'c'])
print(cbook.is_sequence_of_strings(s)) # True
```

Previously, the last two prints returned false.
**7.10.12 New close-figs argument for plot directive**

Matplotlib has a sphinx extension `plot_directive` that creates plots for inclusion in sphinx documents. Matplotlib 1.5 adds a new option to the plot directive - `close-figs` - that closes any previous figure windows before creating the plots. This can help avoid some surprising duplicates of plots when using `plot_directive`.

**7.10.13 Support for URL string arguments to imread**

The `imread()` function now accepts URL strings that point to remote PNG files. This circumvents the generation of a HTTPResponse object directly.

**7.10.14 Display hook for animations in the IPython notebook**

`Animation` instances gained a `_repr_html_` method to support inline display of animations in the notebook. The method used to display is controlled by the `animation.html` rc parameter, which currently supports values of `none` and `html5`. `none` is the default, performing no display. `html5` converts the animation to an h264 encoded video, which is embedded directly in the notebook.

Users not wishing to use the `_repr_html_` display hook can also manually call the `to_html5_video` method to get the HTML and display using IPython’s HTML display class:

```python
from IPython.display import HTML
HTML(anim.to_html5_video())
```

**7.10.15 Prefixed pkg-config for building**

Handling of `pkg-config` has been fixed in so far as it is now possible to set it using the environment variable `PKG_CONFIG`. This is important if your toolchain is prefixed. This is done in a similar way as setting `CC` or `CXX` before building. An example follows.

```bash
export PKG_CONFIG=x86_64-pc-linux-gnu-pkg-config
```

**7.11 New in matplotlib 2.0**

**Note:** matplotlib 2.0 supports Python 2.7, and 3.4+

**7.11.1 Default style changes**

The major changes in v2.0 are related to overhauling the default styles.
Changes to the default style

The most important changes in matplotlib 2.0 are the changes to the default style. While it is impossible to select the best default for all cases, these are designed to work well in the most common cases.

A ‘classic’ style sheet is provided so reverting to the 1.x default values is a single line of python

```python
import matplotlib
import matplotlib as mpl
mpl.style.use('classic')
```

See *The matplotlibrc file* for details about how to persistently and selectively revert many of these changes.

Colors, color cycles, and color maps

Colors in default property cycle

The colors in the default property cycle have been changed from ['b', 'g', 'r', 'c', 'm', 'y', 'k'] to the category10 color palette used by Vega and d3 originally developed at Tableau.

In addition to changing the colors, an additional method to specify colors was added. Previously, the default colors were the single character short-hand notations for red, green, blue, cyan, magenta, yellow, and black. This made them easy to type and usable in the abbreviated style string in plot, however the new default colors are only specified via hex values.

To access these colors outside of the property cycling the notation for colors 'CN', where N takes values 0-9, was added to denote the first 10 colors in mpl.rcParams['axes.prop_cycle']

See Specifying Colors for more details.

To restore the old color cycle use

```python
from cycler import cycler
mpl.rcParams['axes.prop_cycle'] = cycler(color='bgrcmyk')
```

or set
axes.prop_cycle : cycler('color', 'bgrcmyk')

in your matplotlibrc file.

**Colormap**

The new default color map used by matplotlib.cm.ScalarMappable instances is 'viridis' (aka option D).

For an introduction to color theory and how 'viridis' was generated watch Nathaniel Smith and Stéfan van der Walt’s talk from SciPy2015. See here for many more details about the other alternatives and the tools used to create the color map. For details on all of the color maps available in matplotlib see Choosing Colormaps in Matplotlib.

The previous default can be restored using

```python
mpl.rcParams['image.cmap'] = 'jet'
```

or setting

```python
image.cmap : 'jet'
```

in your matplotlibrc file; however this is strongly discouraged.

**Interactive figures**

The default interactive figure background color has changed from grey to white, which matches the default background color used when saving.

The previous defaults can be restored by

```python
mpl.rcParams['figure.facecolor'] = '0.75'
```

or by setting
figure.facecolor : '0.75'

in your matplotlibrc file.

Grid lines

The default style of grid lines was changed from black dashed lines to thicker solid light grey lines.

The previous default can be restored by using:

```python
mpl.rcParams['grid.color'] = 'k'
mpl.rcParams['grid.linestyle'] = ':'
mpl.rcParams['grid.linewidth'] = 0.5
```

or by setting:

```bash
grid.color : k # grid color
grid.linestyle : : # dotted
grid.linewidth : 0.5 # in points
```

in your matplotlibrc file.

Figure size, font size, and screen dpi

The default dpi used for on-screen display was changed from 80 dpi to 100 dpi, the same as the default dpi for saving files. Due to this change, the on-screen display is now more what-you-see-is-what-you-get for saved files. To keep the figure the same size in terms of pixels, in order to maintain approximately the same size on the screen, the default figure size was reduced from 8x6 inches to 6.4x4.8 inches. As a consequence of this the default font sizes used for the title, tick labels, and axes labels were reduced to maintain their size relative to the overall size of the figure. By default the dpi of the saved image is now the dpi of the Figure instance being saved.
This will have consequences if you are trying to match text in a figure directly with external text.

The previous defaults can be restored by

```python
mpl.rcParams['figure.figsize'] = [8.0, 6.0]
mpl.rcParams['figure.dpi'] = 80
mpl.rcParams['savefig.dpi'] = 100

mpl.rcParams['font.size'] = 12
mpl.rcParams['legend.fontsize'] = 'large'
mpl.rcParams['figure.titlesize'] = 'medium'
```

or by setting:

```python
figure.figsize : [8.0, 6.0]
figure.dpi : 80
savefig.dpi : 100

font.size : 12.0
legend.fontsize : 'large'
figure.titlesize : 'medium'
```

In your `matplotlibrc` file.

In addition, the `forward` kwarg to `set_size_inches` now defaults to `True` to improve the interactive experience. Backend canvases that adjust the size of their bound `matplotlib.figure.Figure` must pass `forward=False` to avoid circular behavior. This default is not configurable.

### Plotting functions

**scatter**

The following changes were made to the default behavior of `scatter`

- The default size of the elements in a scatter plot is now based on the rcParam `lines.markersize` so it is consistent with `plot(x, y, 'o')`. The old value was 20, and the new value is 36 ($6^2$).
- Scatter markers no longer have a black edge.
- If the color of the markers is not specified it will follow the property cycle, pulling from the 'patches' cycle on the `Axes`. The classic default behavior of `scatter` can only be recovered through `mpl.style.use('classic')`. The marker size can be recovered via

```python
mpl.rcParams['lines.markersize'] = np.sqrt(20)
```

however, this will also affect the default marker size of `plot`. To recover the classic behavior on a per-call basis pass the following kwargs:

```python
classic_kwargs = {'s': 20, 'edgecolors': 'k', 'c': 'b'}
```
The following changes were made to the default behavior of `plot`:

- the default linewidth increased from 1 to 1.5
- the dash patterns associated with ‘--’, ‘:’, and ‘.-’ have changed
- the dash patterns now scale with line width

The previous defaults can be restored by setting:

```python
mpl.rcParams['lines.linewidth'] = 1.0
mpl.rcParams['lines.dashed_pattern'] = [6, 6]
mpl.rcParams['lines.dashdot_pattern'] = [3, 5, 1, 5]
```
or by setting:

```python
mpl.rcParams['lines.dotted_pattern'] = [1, 3]
mpl.rcParams['lines.scale_dashes'] = False
```

or by setting:

```python
lines.linewidth : 1.0
lines.dashed_pattern : 6, 6
lines.dashdot_pattern : 3, 5, 1, 5
lines.dotted_pattern : 1, 3
lines.scale_dashes: False
```

in your `matplotlibrc` file.

**errorbar**

By default, caps on the ends of errorbars are not present.

This also changes the return value of `errorbar()` as the list of ‘caplines’ will be empty by default.

The previous defaults can be restored by setting:

```python
mpl.rcParams['errorbar.capsize'] = 3
```

or by setting:

```python
errorbar.capsize : 3
```

in your `matplotlibrc` file.
Previously, boxplots were composed of a mish-mash of styles that were, for better for worse, inherited from Matlab. Most of the elements were blue, but the medians were red. The fliers (outliers) were black plus-symbols (+) and the whiskers were dashed lines, which created ambiguity if the (solid and black) caps were not drawn.

For the new defaults, everything is black except for the median and mean lines (if drawn), which are set to the first two elements of the current color cycle. Also, the default flier markers are now hollow circles, which maintain the ability of the plus-symbols to overlap without obscuring data too much.

The previous defaults can be restored by setting:

```python
mpl.rcParams['boxplot.flierprops.color'] = 'k'
mpl.rcParams['boxplot.flierprops.marker'] = '+'
mpl.rcParams['boxplot.flierprops.markerfacecolor'] = 'none'
mpl.rcParams['boxplot.flierprops.markeredgecolor'] = 'k'
mpl.rcParams['boxplot.boxprops.color'] = 'b'
mpl.rcParams['boxplot.whiskerprops.color'] = 'b'
mpl.rcParams['boxplot.whiskerprops.linestyle'] = '--'
mpl.rcParams['boxplot.medianprops.color'] = 'r'
mpl.rcParams['boxplot.meanprops.color'] = 'r'
mpl.rcParams['boxplot.meanprops.marker'] = '^'
mpl.rcParams['boxplot.meanprops.markeredgecolor'] = 'r'
mpl.rcParams['boxplot.meanprops.markerfacecolor'] = 'k'
```
or by setting:

```python
mpl.rcParams['boxplot.meanprops.markersize'] = 6
mpl.rcParams['boxplot.meanprops.linestyle'] = '--'
mpl.rcParams['boxplot.meanprops.linewidth'] = 1.0
```

in your `matplotlibrc` file.

`fill_between` and `fill_betweenx` both follow the patch color cycle.

If the facecolor is set via the `facecolors` or `color` keyword argument, then the color is not cycled.

To restore the previous behavior, explicitly pass the keyword argument `facecolors='C0'` to the method call.
Patch edges and color

Most artists drawn with a patch (`~matplotlib.axes.Axes.bar`, `~matplotlib.axes.Axes.pie`, etc) no longer have a black edge by default. The default face color is now `'C0' instead of `'b'`.

The previous defaults can be restored by setting:

```python
mpl.rcParams['patch.force_edgecolor'] = True
gp.rcParams['patch.facecolor'] = 'b'
```

or by setting:

```python
patch.facecolor : b
patch.force_edgecolor : True
```

in your `matplotlibrc` file.
hexbin

The default value of the `linecolor` kwarg for `hexbin` has changed from 'none' to 'face'. If 'none' is now supplied, no line edges are drawn around the hexagons.

bar and barh

The default value of the `align` kwarg for both `bar` and `barh` is changed from 'edge' to 'center'. To restore the previous behavior explicitly pass the keyword argument `align='edge'` to the method call.

Hatching

The color of the lines in the hatch is now determined by

- If an edge color is explicitly set, use that for the hatch color
- If the edge color is not explicitly set, use `rcParam['hatch.color']` which is looked up at artist creation time.
The width of the lines in a hatch pattern is now configurable by the `rcParams` `hatch.linewidth`, which defaults to 1 point. The old behavior for the line width was different depending on backend:

- PDF: 0.1 pt
- SVG: 1.0 pt
- PS: 1 px
- Agg: 1 px

The old line width behavior can not be restored across all backends simultaneously, but can be restored for a single backend by setting:

```python
mpl.rcParams['hatch.linewidth'] = 0.1  # previous pdf hatch linewidth
mpl.rcParams['hatch.linewidth'] = 1.0  # previous svg hatch linewidth
```

The behavior of the PS and Agg backends was DPI dependent, thus:

```python
mpl.rcParams['figure.dpi'] = dpi
mpl.rcParams['savefig.dpi'] = dpi  # or leave as default 'figure'
mpl.rcParams['hatch.linewidth'] = 1.0 / dpi  # previous ps and Agg hatch linewidth
```

There is no direct API level control of the hatch color or linewidth.

Hatching patterns are now rendered at a consistent density, regardless of DPI. Formerly, high DPI figures would be more dense than the default, and low DPI figures would be less dense. This old behavior cannot be directly restored, but the density may be increased by repeating the hatch specifier.

## Fonts

### Normal text

The default font has changed from “Bitstream Vera Sans” to “DejaVu Sans”. DejaVu Sans has additional international and math characters, but otherwise has the same appearance as Bitstream Vera Sans. Latin, Greek, Cyrillic, Armenian, Georgian, Hebrew, and Arabic are all supported (but right-to-left rendering is still not handled by matplotlib). In addition, DejaVu contains a sub-set of emoji symbols.

See the DejaVu Sans PDF sample for full coverage.

### Math text

The default math font when using the built-in math rendering engine (mathtext) has changed from “Computer Modern” (i.e. LaTeX-like) to “DejaVu Sans”. This change has no effect if the TeX backend is used (i.e. `text.usetex` is `True`).

To revert to the old behavior set the:

```python
mpl.rcParams['mathtext.fontset'] = 'cm'
mpl.rcParams['mathtext.rm'] = 'serif'
```

or set:
Диаграмма со смайликами

classic

\[
\int_0^\infty dx
\]
in your matplotlibrc file.
This rcParam is consulted when the text is drawn, not when the artist is created. Thus all mathtext on a given canvas will use the same fontset.

**Legends**

- By default, the number of points displayed in a legend is now 1.
- The default legend location is 'best', so the legend will be automatically placed in a location to minimize overlap with data.
- The legend defaults now include rounded corners, a lighter boundary, and partially transparent boundary and background.

The previous defaults can be restored by setting:

```python
mpl.rcParams['legend.fancybox'] = False
mpl.rcParams['legend.loc'] = 'upper right'
mpl.rcParams['legend.numpoints'] = 2
mpl.rcParams['legend.fontsize'] = 'large'
mpl.rcParams['legend.framealpha'] = None
mpl.rcParams['legend.scatterpoints'] = 3
mpl.rcParams['legend.edgecolor'] = 'inherit'
```

or by setting:

```python
legend.fancybox : False
legend.loc : upper right
legend.numpoints : 2 # the number of points in the legend line
legend.fontsize : large
```

(continues on next page)
in your matplotlibrc file.

**Image**

**Interpolation**

The default interpolation method for `imshow` is now 'nearest' and by default it resamples the data (both up and down sampling) before color mapping.

To restore the previous behavior set:

```python
mpl.rcParams['image.interpolation'] = 'bilinear
mpl.rcParams['image.resample'] = False
```

or set:

```python
image.interpolation : bilinear   # see help(imshow) for options
image.resample : False
```

in your matplotlibrc file.

**Colormapping pipeline**

Previously, the input data was normalized, then color mapped, and then resampled to the resolution required for the screen. This meant that the final resampling was being done in color space. Because the color maps are not generally linear in RGB space, colors not in the
The input data is now normalized, then resampled to the correct resolution (in normalized dataspace), and then color mapped to RGB space. This ensures that only colors from the color map appear in the final image. (If your viewer subsequently resamples the image, the artifact may reappear.)

The previous behavior cannot be restored.

**Shading**

- The default shading mode for light source shading, in `matplotlib.colors.LightSource.shade`, is now `overlay`. Formerly, it was `hsv`.

**Plot layout**

**Auto limits**

The previous auto-scaling behavior was to find ‘nice’ round numbers as view limits that enclosed the data limits, but this could produce bad plots if the data happened to fall on a vertical or horizontal line near the chosen ‘round number’ limit. The new default sets the view limits to 5% wider than the data range.

The size of the padding in the x and y directions is controlled by the `axes.xmargin` and `axes.ymargin` rcParams respectively. Whether the view limits should be ‘round numbers’ is controlled by the `axes.autolimit_mode` rcParam. In the original ‘round_number’ mode, the view limits coincide with ticks.

The previous default can be restored by using:
Z-order

• Ticks and grids are now plotted above solid elements such as filled contours, but below lines. To return to the previous behavior of plotting ticks and grids above lines, set:

    mpl.rcParams['axes.axisbelow'] = False

Ticks

Direction

To reduce the collision of tick marks with data, the default ticks now point outward by default. In addition, ticks are now drawn only on the bottom and left spines to prevent a porcupine appearance, and for a cleaner separation between subplots.

To restore the previous behavior set:

    mpl.rcParams['xtick.direction'] = 'in'
    mpl.rcParams['ytick.direction'] = 'in'

(continues on next page)
Chapter 7. Previous What’s New
or set:

```python
xtick.top: True
xtick.direction: in

ytick.right: True
ytick.direction: in
```

in your `matplotlibrc` file.

**Number of ticks**

The default *Locator* used for the x and y axis is *AutoLocator* which tries to find, up to some maximum number, 'nicely' spaced ticks. The locator now includes an algorithm to estimate the maximum number of ticks that will leave room for the tick labels. By default it also ensures that there are at least two ticks visible.

![Graph showing classic and v2.0 tick configurations](image)

There is no way, other than using `mpl.style.use('classic')`, to restore the previous behavior as the default. On an axis-by-axis basis you may either control the existing locator via:

```python
ax.xaxis.get_major_locator().set_params(nbins=9, steps=[1, 2, 5, 10])
```

or create a new *MaxNLocator*:

```python
import matplotlib.ticker as mticker
ax.set_major_locator(mticker.MaxNLocator(nbins=9, steps=[1, 2, 5, 10]))
```

The algorithm used by *MaxNLocator* has been improved, and this may change the choice of tick locations in some cases. This also affects *AutoLocator*, which uses *MaxNLocator* internally.
For a log-scaled axis the default locator is the \texttt{LogLocator}. Previously the maximum number of ticks was set to 15, and could not be changed. Now there is a \texttt{numticks} kwarg for setting the maximum to any integer value, to the string ‘auto’, or to its default value of None which is equivalent to ‘auto’. With the ‘auto’ setting the maximum number will be no larger than 9, and will be reduced depending on the length of the axis in units of the tick font size. As in the case of the \texttt{AutoLocator}, the heuristic algorithm reduces the incidence of overlapping tick labels but does not prevent it.

\textbf{Tick label formatting}

\texttt{LogFormatter} labeling of minor ticks

Minor ticks on a log axis are now labeled when the axis view limits span a range less than or equal to the interval between two major ticks. See \texttt{LogFormatter} for details. The minor tick labeling is turned off when using \texttt{mpl.style.use('classic')}, but cannot be controlled independently via \texttt{rcParams}.

\texttt{ScalarFormatter} tick label formatting with offsets

With the default of \texttt{rcParams['axes.formatter.useoffset'] = True}, an offset will be used when it will save 4 or more digits. This can be controlled with the new \texttt{rcParam, axes.formatter.offset_threshold}. To restore the previous behavior of using an offset to save 2 or more digits, use \texttt{rcParams['axes.formatter.offset_threshold'] = 2}.

\texttt{AutoDateFormatter} format strings

The default date formats are now all based on ISO format, i.e., with the slowest-moving value first. The date formatters are configurable through the \texttt{date.autoformatter.* rcParams}. 
Threshold (tick interval >= than) | rcParam | classic | v2.0
---|---|---|---
365 days | 'date.autoformatter.year' | '%Y' | '%Y'
30 days | 'date.autoformatter.month' | '%b %Y' | '%Y-%m'
1 day | 'date.autoformatter.day' | '%b %d %Y' | '%Y-%m-%d'
1 hour | 'date.autoformatter.hour' | '%H:%M:%S' | '%H:%M'
1 minute | 'date.autoformatter.minute' | '%H:%M:%S.%f' | '%H:%M:%S'
1 second | 'date.autoformatter.second' | '%H:%M:%S.%f' | '%H:%M:%S'
1 microsecond | 'date.autoformatter.microsecond' | '%H:%M:%S.%f' | '%H:%M:%S.%f'

Python’s `%x` and `%X` date formats may be of particular interest to format dates based on the current locale.

The previous default can be restored by:

```python
mpl.rcParams['date.autoformatter.year'] = '%Y'
mpl.rcParams['date.autoformatter.month'] = '%b %Y'
mpl.rcParams['date.autoformatter.day'] = '%b %d %Y'
mpl.rcParams['date.autoformatter.hour'] = '%H:%M:%S'
mpl.rcParams['date.autoformatter.minute'] = '%H:%M:%S.%f'
mpl.rcParams['date.autoformatter.second'] = '%H:%M:%S.%f'
mpl.rcParams['date.autoformatter.microsecond'] = '%H:%M:%S.%f'
```

or setting

```python
date.autoformatter.year = '%Y'
date.autoformatter.month = '%b %Y'
date.autoformatter.day = '%b %d %Y'
date.autoformatter.hour = '%H:%M:%S'
date.autoformatter.minute = '%H:%M:%S.%f'
```

(continues on next page)
in your matplotlibrc file.

mplot3d

• mplot3d now obeys some style-related rcParams, rather than using hard-coded defaults. These include:
  - xtick.major.width
  - ytick.major.width
  - xtick.color
  - ytick.color
  - axes.linewidth
  - axes.edgecolor
  - grid.color
  - grid.linewidth
  - grid.linestyle

7.11.2 Improved color conversion API and RGBA support

The colors gained a new color conversion API with full support for the alpha channel. The main public functions are is_color_like(), matplotlib.colors.to_rgba(), matplotlib.colors.to_rgba_array() and to_hex(). RGBA quadruplets are encoded in hex format as #rrggbbaa. A side benefit is that the Qt options editor now allows setting the alpha channel of the artists as well.

7.11.3 New Configuration (rcParams)

New rcparams added
Parameter | Description
--- | ---
`date.autoformatter.year` | format string for 'year' scale dates
`date.autoformatter.month` | format string for 'month' scale dates
`date.autoformatter.day` | format string for 'day' scale dates
`date.autoformatter.hour` | format string for 'hour' scale times
`date.autoformatter.minute` | format string for 'minute' scale times
`date.autoformatter.second` | format string for 'second' scale times
`date.autoformatter.microsecond` | format string for 'microsecond' scale times
`scatter.marker` | default marker for scatter plot
`svg.hashsalt` | see note
`xtick.top, xtick.minor.top, xtick.major.top, xtick.bottom, xtick.minor.bottom, xtick.major.bottom, ytick.left, ytick.minor.left, ytick.major.left, ytick.right, ytick.minor.right, ytick.major.right` | Control where major and minor ticks are drawn. The global values are added with the corresponding major/minor values.
`hist.bins` | The default number of bins to use in `hist`. This can be an `int`, a list of floats, or 'auto' if numpy >= 1.11 is installed.
`lines.scale_dashes` | Whether the line dash patterns should scale with linewidth.
`axes.formatter.offset_threshold` | Minimum number of digits saved in tick labels that triggers using an offset.

**Added** `svg.hashsalt` key to `rcParams`

If `svg.hashsalt` is `None` (which it is by default), the svg backend uses `uuid4` to generate the hash salt. If it is not `None`, it must be a string that is used as the hash salt instead of `uuid4`. This allows for deterministic SVG output.

**Removed the** `svg.image_noscale` `rcParam`

As a result of the extensive changes to image handling, the `svg.image_noscale` `rcParam` has been removed. The same functionality may be achieved by setting `interpolation='none'` on individual images or globally using the `image.interpolation` `rcParam`.

### 7.11.4 Qualitative colormaps

ColorBrewer’s “qualitative” colormaps ("Accent", "Dark2", "Paired", "Pastel1", "Pastel2", "Set1", "Set2", "Set3") were intended for discrete categorical data, with no implication of value, and therefore have been converted to `ListedColormap` instead of `LinearSegmentedColormap`, so the colors will no longer be interpolated and they can be used for choropleths, labeled image features, etc.
7.11.5 Axis offset label now responds to labelcolor

Axis offset labels are now colored the same as axis tick markers when labelcolor is altered.

7.11.6 Improved offset text choice

The default offset-text choice was changed to only use significant digits that are common to all ticks (e.g. 1231..1239 -> 1230, instead of 1231), except when they straddle a relatively large multiple of a power of ten, in which case that multiple is chosen (e.g. 1999..2001->2000).

7.11.7 Style parameter blacklist

In order to prevent unexpected consequences from using a style, style files are no longer able to set parameters that affect things unrelated to style. These parameters include:

- interactive
- backend
- backend.qt4
- webagg.port
- webagg.port_retries
- webagg.open_in_browser
- backend_fallback
- toolbar
- timezone
- datapath
- figure.max_open_warning
- savefig.directory
- tk.window_focus
- docstring.hardcopy

7.11.8 Change in default font

The default font used by matplotlib in text has been changed to DejaVu Sans and DejaVu Serif for the sans-serif and serif families, respectively. The DejaVu font family is based on the previous matplotlib default –Bitstream Vera– but includes a much wider range of characters.

The default mathtext font has been changed from Computer Modern to the DejaVu family to maintain consistency with regular text. Two new options for the mathtext.fontset configuration parameter have been added: dejavusans (default) and dejavuserif. Both of these options use DejaVu glyphs whenever possible and fall back to STIX symbols when a glyph is not found in DejaVu. To return to the previous behavior, set the rcParam mathtext.fontset to cm.

7.11.9 Faster text rendering

Rendering text in the Agg backend is now less fuzzy and about 20% faster to draw.

7.11.10 Improvements for the Qt figure options editor

Various usability improvements were implemented for the Qt figure options editor, among which:

- Line style entries are now sorted without duplicates.
- The colormap and normalization limits can now be set for images.
- Line edits for floating values now display only as many digits as necessary to avoid precision loss. An important bug was also fixed regarding input validation using Qt5 and a locale where the decimal separator is ",".
• The axes selector now uses shorter, more user-friendly names for axes, and does not crash if there are no axes.
• Line and image entries using the default labels ("_lineX", "_imageX") are now sorted numerically even when there are more than 10 entries.

7.11.11 Improved image support

Prior to version 2.0, matplotlib resampled images by first applying the color map and then resizing the result. Since the resampling was performed on the colored image, this introduced colors in the output image that didn’t actually exist in the color map. Now, images are resampled first (and entirely in floating-point, if the input image is floating-point), and then the color map is applied.

In order to make this important change, the image handling code was almost entirely rewritten. As a side effect, image resampling uses less memory and fewer datatype conversions than before.

The experimental private feature where one could “skew” an image by setting the private member _image_skew_coordinate has been removed. Instead, images will obey the transform of the axes on which they are drawn.

Non-linear scales on image plots

`imshow()` now draws data at the requested points in data space after the application of non-linear scales.

The image on the left demonstrates the new, correct behavior. The old behavior can be recreated using `pcolormesh()` as demonstrated on the right.

This can be understood by analogy to plotting a histogram with linearly spaced bins with a logarithmic x-axis. Equal sized bins will be displayed as wider for small x and narrower for large x.

7.11. New in matplotlib 2.0
7.11.12 Support for HiDPI (Retina) displays in the NbAgg and WebAgg backends

The NbAgg and WebAgg backends will now use the full resolution of your high-pixel-density display.

7.11.13 Change in the default animation codec

The default animation codec has been changed from mpeg4 to h264, which is more efficient. It can be set via the animation.codec rcParam.

7.11.14 Deprecated support for mencoder in animation

The use of mencoder for writing video files with mpl is problematic; switching to ffmpeg is strongly advised. All support for mencoder will be removed in version 2.2.

7.11.15 Boxplot Zorder Keyword Argument

The zorder parameter now exists for boxplot(). This allows the zorder of a boxplot to be set in the plotting function call.

```python
boxplot(np.arange(10), zorder=10)
```

7.11.16 Filled + and x markers

New fillable plus and x markers have been added. See the markers module and marker reference examples.

7.11.17 rcount and ccount for plot_surface()

As of v2.0, mplot3d’s plot_surface() now accepts rcount and ccount arguments for controlling the sampling of the input data for plotting. These arguments specify the maximum number of evenly spaced samples to take from the input data. These arguments are also the new default sampling method for the function, and is considered a style change.

The old rstride and cstride arguments, which specified the size of the evenly spaced samples, become the default when ‘classic’ mode is invoked, and are still available for use. There are no plans for deprecating these arguments.

7.11.18 Streamplot Zorder Keyword Argument Changes

The zorder parameter for streamplot() now has default value of None instead of 2. If None is given as zorder, streamplot() has a default zorder of matplotlib.lines.Line2D.zorder.
7.11.19 Extension to `matplotlib.backend_bases.GraphicsContextBase`

To support standardizing hatch behavior across the backends we ship the `matplotlib.backend_bases.GraphicsContextBase.get_hatch_color` method as added to `matplotlib.backend_bases.GraphicsContextBase`. This is only used during the render process in the backends we ship so will not break any third-party backends.

If you maintain a third-party backend which extends `GraphicsContextBase` this method is now available to you and should be used to color hatch patterns.

7.12 New in Matplotlib 2.1.0

7.12.1 Documentation

The examples have been migrated to use `sphinx gallery`. This allows better mixing of prose and code in the examples, provides links to download the examples as both a Python script and a Jupyter notebook, and improves the thumbnail galleries. The examples have been re-organized into `Tutorials` and a gallery.

Many docstrings and examples have been clarified and improved.

7.12.2 New features

String categorical values

All plotting functions now support string categorical values as input. For example:

```python
data = {'apples': 10, 'oranges': 15, 'lemons': 5, 'limes': 20}
fig, ax = plt.subplots()
ax.bar(data.keys(), data.values(), color='lightgray')
```

Interactive JS widgets for animation

Jake Vanderplas’ JSAnimation package has been merged into Matplotlib. This adds to Matplotlib the `HTMLWriter` class for generating a JavaScript HTML animation, suitable for the IPython notebook. This can be activated by default by setting the `animation.html` rc parameter to `jshtml`. One can also call the `to_jshtml` method to manually convert an animation. This can be displayed using IPython’s `HTML` display class:

```python
from IPython.display import HTML
HTML(animation.to_jshtml())
```

The `HTMLWriter` class can also be used to generate an HTML file by asking for the `html` writer.

Enhancements to polar plot

The polar axes transforms have been greatly re-factored to allow for more customization of view limits and tick labelling. Additional options for view limits allow for creating an annulus, a sector, or some combination of the two.
The `set_rorigin()` method may be used to provide an offset to the minimum plotting radius, producing an annulus.

The `set_theta_zero_location()` method now has an optional `offset` argument. This argument may be used to further specify the zero location based on the given anchor point.

The `set_thetamin()` and `set_thetamax()` methods may be used to limit the range of angles plotted, producing sectors of a circle.

Previous releases allowed plots containing negative radii for which the negative values are simply used as labels, and the real radius is shifted by the configured minimum. This release also allows negative radii to be used for grids and ticks, which were previously silently ignored.

Radial ticks have been modified to be parallel to the circular grid line, and angular ticks have been modified to be parallel to the grid line. It may also be useful to rotate tick labels to match the boundary. Calling `ax.tick_params(rotation='auto')` will enable the new behavior: radial tick labels will be parallel to the circular grid line, and angular tick labels will be perpendicular to the grid line (i.e., parallel to the outer boundary). Additionally, tick labels now obey the padding settings that previously only worked on Cartesian plots. Consequently, the `frac` argument to `PolarAxes.set_thetagrids` is no longer applied. Tick padding can be modified with the `pad` argument to `Axes.tick_params` or `Axis.set_tick_params`.

---

Chapter 7. Previous What’s New
Fig. 30: Polar Offset Demo

Fig. 31: Polar Sector Demo
Figure class now has subplots method

The `Figure` class now has a `subplots()` method which behaves the same as `pyplot.subplots()` but on an existing figure.

Metadata savefig keyword argument

`savefig()` now accepts `metadata` as a keyword argument. It can be used to store key/value pairs in the image metadata.

- ‘png’ with Agg backend
- ‘pdf’ with PDF backend (see `writeInfoDict()` for a list of supported keywords)
- ‘eps’ and ‘ps’ with PS backend (only ‘Creator’ key is accepted)

```python
plt.savefig('test.png', metadata={'Software': 'My awesome software'})
```

Busy Cursor

The interactive GUI backends will now change the cursor to busy when Matplotlib is rendering the canvas.

PolygonSelector

A `PolygonSelector` class has been added to `matplotlib.widgets`. See /gallery/widgets/polygon_selector_demo for details.

Added `matplotlib.ticker.PercentFormatter`

The new `PercentFormatter` formatter has some nice features like being able to convert from arbitrary data scales to percents, a customizable percent symbol and either automatic or manual control over the decimal points.

Reproducible PS, PDF and SVG output

The `SOURCE_DATE_EPOCH` environment variable can now be used to set the timestamp value in the PS and PDF outputs. See source date epoch.

Alternatively, calling `savefig` with `metadata={'CreationDate': None}` will omit the timestamp altogether for the PDF backend.

The reproducibility of the output from the PS and PDF backends has so far been tested using various plot elements but only default values of options such as `ps,pdf.fonttype` that can affect the output at a low level, and not with the mathtext or usetex features. When Matplotlib calls external tools (such as PS distillers or LaTeX) their versions need to be kept constant for reproducibility, and they may add sources of nondeterminism outside the control of Matplotlib.

For SVG output, the `svg.hashsalt` rc parameter has been added in an earlier release. This parameter changes some random identifiers in the SVG file to be deterministic. The downside
of this setting is that if more than one file is generated using deterministic identifiers and they end up as parts of one larger document, the identifiers can collide and cause the different parts to affect each other.

These features are now enabled in the tests for the PDF and SVG backends, so most test output files (but not all of them) are now deterministic.

**Orthographic projection for mplot3d**

Axes3D now accepts `proj_type` keyword argument and has a method `set_proj_type()`. The default option is 'persp' as before, and supplying 'ortho' enables orthographic view.

Compare the z-axis which is vertical in orthographic view, but slightly skewed in the perspective view.

```python
import numpy as np
import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d import Axes3D

fig = plt.figure(figsize=(4, 6))
ax1 = fig.add_subplot(2, 1, 1, projection='3d')
ax1.set_proj_type('persp')
ax1.set_title('Perspective (default)')

ax2 = fig.add_subplot(2, 1, 2, projection='3d')
ax2.set_proj_type('ortho')
ax2.set_title('Orthographic')

plt.show()
```

**Voxels function for mplot3d**

Axes3D now has a `voxels` method, for visualizing boolean 3D data. Uses could include plotting a sparse 3D heat map, or visualizing a volumetric model.

### 7.12.3 Improvements

**CheckButtons widget get_status function**

A `get_status()` method has been added to the `matplotlib.widgets.CheckButtons` class. This `get_status` method allows user to query the status (True/False) of all of the buttons in the CheckButtons object.

**Add fill_bar argument to AnchoredSizeBar**

The `mpl_toolkits` class `AnchoredSizeBar` now has an additional `fill_bar` argument, which makes the size bar a solid rectangle instead of just drawing the border of the rectangle. The default is `None`, and whether or not the bar will be filled by default depends on the value of `size_vertical`. If `size_vertical` is nonzero, `fill_bar` will be set to True. If `size_vertical` is zero then `fill_bar`
will be set to False. If you wish to override this default behavior, set fill_bar to True or False to unconditionally always or never use a filled patch rectangle for the size bar.

```python
import matplotlib.pyplot as plt
from mpl_toolkits.axes_grid1.anchored_artists import AnchoredSizeBar

fig, ax = plt.subplots(figsize=(3, 3))

bar0 = AnchoredSizeBar(ax.transData, 0.3, 'unfilled', loc='lower left',
                        frameon=False, size_vertical=0.05, fill_bar=False)
ax.add_artist(bar0)

bar1 = AnchoredSizeBar(ax.transData, 0.3, 'filled', loc='lower right',
                        frameon=False, size_vertical=0.05, fill_bar=True)
ax.add_artist(bar1)

plt.show()
```

**Annotation can use a default arrow style**

Annotations now use the default arrow style when setting `arrowprops={}`, rather than no arrow (the new behavior actually matches the documentation).

**Barbs and Quiver Support Dates**

When using the `quiver()` and `barbs()` plotting methods, it is now possible to pass dates, just like for other methods like `plot()`. This also allows these functions to handle values that need unit-conversion applied.
Hexbin default line color

The default `linecolor` keyword argument for `hexbin()` is now 'face', and supplying 'none' now prevents lines from being drawn around the hexagons.

Figure.legend() can be called without arguments

Calling `Figure.legend()` can now be done with no arguments. In this case a legend will be created that contains all the artists on all the axes contained within the figure.

Multiple legend keys for legend entries

A legend entry can now contain more than one legend key. The extended `HandlerTuple` class now accepts two parameters: `ndivide` divides the legend area in the specified number of sections; `pad` changes the padding between the legend keys.

New parameter clear for `figure()`

When the pyplot’s function `figure()` is called with a `num` parameter, a new window is only created if no existing window with the same value exists. A new bool parameter `clear` was added for explicitly clearing its existing contents. This is particularly useful when utilized in interactive sessions. Since `subplots()` also accepts keyword arguments from `figure()`, it can also be used there:

```python
import matplotlib.pyplot as plt

fig0 = plt.figure(num=1)
fig0.suptitle("A fancy plot")
print("fig0.texts: ", [t.get_text() for t in fig0.texts])
```

(continues on next page)
Fig. 33: Multiple Legend Keys

Specify minimum value to format as scalar for LogFormatterMathtext

LogFormatterMathtext now includes the option to specify a minimum value exponent to format as a scalar (i.e., 0.001 instead of $10^{-3}$).

New quiverkey angle keyword argument

Plotting a `quiverkey()` now admits the `angle` keyword argument, which sets the angle at which to draw the key arrow.
Colormap reversed method

The methods `matplotlib.colors.LinearSegmentedColormap.reversed()` and `matplotlib.colors.ListedColormap.reversed()` return a reversed instance of the Colormap. This implements a way for any Colormap to be reversed.

**Artist.setp (and pyplot.setp) accept a file argument**

The argument is keyword-only. It allows an output file other than `sys.stdout` to be specified. It works exactly like the `file` argument to `print`.

**streamplot streamline generation more configurable**

The starting point, direction, and length of the stream lines can now be configured. This allows to follow the vector field for a longer time and can enhance the visibility of the flow pattern in some use cases.

**Axis.set_tick_params now responds to rotation**

Bulk setting of tick label rotation is now possible via `tick_params()` using the `rotation` keyword.

```python
ax.tick_params(which='both', rotation=90)
```

**Ticklabels are turned off instead of being invisible**

Internally, the Tick’s `label1On()` attribute is now used to hide tick labels instead of setting the visibility on the tick label objects. This improves overall performance and fixes some issues. As a consequence, in case those labels ought to be shown, `tick_params()` needs to be used, e.g.

```python
ax.tick_params(labelbottom=True)
```

**Shading in 3D bar plots**

A new `shade` parameter has been added the 3D `bar` plotting method. The default behavior remains to shade the bars, but now users have the option of setting `shade` to `False`.

```python
import numpy as np
import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d import Axes3D

x = np.arange(2)
y = np.arange(3)
x2d, y2d = np.meshgrid(x, y)
x, y = x2d.ravel(), y2d.ravel()
z = np.zeros_like(x)
dz = x + y
```

(continues on next page)
fig = plt.figure(figsize=(4, 6))
ax1 = fig.add_subplot(2, 1, 1, projection='3d')
ax1.bar3d(x, y, z, 1, 1, dz, shade=True)
ax1.set_title('Shading On')

ax2 = fig.add_subplot(2, 1, 2, projection='3d')
ax2.bar3d(x, y, z, 1, 1, dz, shade=False)
ax2.set_title('Shading Off')

plt.show()
New which Parameter for `autofmt_xdate`

A `which` parameter now exists for the method `autofmt_xdate()`. This allows a user to format major, minor or both tick labels selectively. The default behavior will rotate and align the major tick labels.

```python
fig.autofmt_xdate(bottom=0.2, rotation=30, ha='right', which='minor')
```

New Figure Parameter for `subplot2grid`

A `fig` parameter now exists for the function `subplot2grid()`. This allows a user to specify the figure where the subplots will be created. If `fig` is `None` (default) then the method will use the current figure retrieved by `gcf()`.

```python
subplot2grid(shape, loc, rowspan=1, colspan=1, fig=myfig)
```

Interpolation in `fill_betweenx`

The `interpolate` parameter now exists for the method `fill_betweenx()`. This allows a user to interpolate the data and fill the areas in the crossover points, similarly to `fill_between()`.

New keyword argument `sep` for `EngFormatter`

A new `sep` keyword argument has been added to `EngFormatter` and provides a means to define the string that will be used between the value and its unit. The default string is " ", which preserves the former behavior. Additionally, the separator is now present between the value and its unit even in the absence of SI prefix. There was formerly a bug that was causing strings like "3.14V" to be returned instead of the expected "3.14 V" (with the default behavior).

Extend MATPLOTLIBRC behavior

The environmental variable can now specify the full file path or the path to a directory containing a `matplotlibrc` file.

density kwarg to `hist`

The `hist()` method now prefers `density` to `normed` to control if the histogram should be normalized, following a change upstream to NumPy. This will reduce confusion as the behavior has always been that the integral of the histogram is 1 (rather than sum or maximum value).

7.12.4 Internals

New `TransformedPatchPath` caching object

A newly added `TransformedPatchPath` provides a means to transform a `Patch` into a `Path` via a `Transform` while caching the resulting path. If neither the patch nor the transform have changed, a cached copy of the path is returned.
This class differs from the older \texttt{TransformedPath} in that it is able to refresh itself based on the underlying patch while the older class uses an immutable path.

**Abstract base class for movie writers**

The new \texttt{AbstractMovieWriter} class defines the API required by a class that is to be used as the writer in the \texttt{matplotlib.animation.Animation.save()} method. The existing \texttt{MovieWriter} class now derives from the new abstract base class.

**Stricter validation of line style rcParams**

The validation of rcParams that are related to line styles (\texttt{lines.linestyle}, \texttt{boxplot.*.linestyle}, \texttt{grid.linestyle} and \texttt{contour.negative_linestyle}) now effectively checks that the values are valid line styles. Strings like ‘dashed’ or ‘--’ are accepted, as well as even-length sequences of on-off ink like [1, 1.65]. In this latter case, the offset value is handled internally and should not be provided by the user.

The new validation scheme replaces the former one used for the \texttt{contour.negative_linestyle} rcParams, that was limited to 'solid' and 'dashed' line styles.

The validation is case-insensitive. The following are now valid:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{grid.linestyle}</td>
<td>(1, 3)</td>
<td>loosely dotted grid lines</td>
</tr>
<tr>
<td>\texttt{contour.negative_linestyle}</td>
<td>dashdot</td>
<td>previously only solid or dashed</td>
</tr>
</tbody>
</table>

**pytest**

The automated tests have been switched from \texttt{nose} to \texttt{pytest}.

### 7.12.5 Performance

**Path simplification updates**

Line simplification controlled by the \texttt{path.simplify} and \texttt{path.simplify_threshold} parameters has been improved. You should notice better rendering performance when plotting large amounts of data (as long as the above parameters are set accordingly). Only the line segment portion of paths will be simplified – if you are also drawing markers and experiencing problems with rendering speed, you should consider using the \texttt{markevery} option to \texttt{plot}. See the \texttt{Performance} section in the usage tutorial for more information.

The simplification works by iteratively merging line segments into a single vector until the next line segment’s perpendicular distance to the vector (measured in display-coordinate space) is greater than the \texttt{path.simplify_threshold} parameter. Thus, higher values of \texttt{path.simplify_threshold} result in quicker rendering times. If you are plotting just to explore data and not for publication quality, pixel perfect plots, then a value of 1.0 can be safely used. If you want to make sure your plot reflects your data exactly, then you should set \texttt{path.simplify} to false and/or \texttt{path.simplify_threshold} to 0. Matplotlib currently defaults to a conservative value of 1/9, smaller values are unlikely to cause any visible differences in your plots.
Implement `intersects_bbox` in C++

`intersects_bbox()` has been implemented in C++ which improves the performance of automatically placing the legend.

## 7.13 New in Matplotlib 2.2

### 7.13.1 Constrained Layout Manager

**Warning:** Constrained Layout is **experimental**. The behaviour and API are subject to change, or the whole functionality may be removed without a deprecation period.

A new method to automatically decide spacing between subplots and their organizing `GridSpec` instances has been added. It is meant to replace the venerable `tight_layout` method. It is invoked via a new `constrained_layout=True` kwarg to `Figure` or `subplots`.

There are new `rcParams` for this package, and spacing can be more finely tuned with the new `set_constrained_layout_pads`.

Features include:

- Automatic spacing for subplots with a fixed-size padding in inches around subplots and all their decorators, and space between as a fraction of subplot size between subplots.
- Spacing for `suptitle`, and colorbars that are attached to more than one axes.
- Nested `GridSpec` layouts using `GridSpecFromSubplotSpec`.

For more details and capabilities please see the new tutorial: *Constrained Layout Guide*

Note the new API to access this:

**New `plt.figure` and `plt.subplots` kwarg: `constrained_layout`**

`figure()` and `subplots()` can now be called with `constrained_layout=True` kwarg to enable `constrained_layout`.

**New `ax.set_position` behaviour**

`set_position()` now makes the specified axis no longer responsive to `constrained_layout`, consistent with the idea that the user wants to place an axis manually.

Internally, this means that old `ax.set_position` calls inside the library are changed to private `ax._set_position` calls so that `constrained_layout` will still work with these axes.
New figure kwarg for GridSpec

In order to facilitate constrained_layout, GridSpec now accepts a figure keyword. This is backwards compatible, in that not supplying this will simply cause constrained_layout to not operate on the subplots organized by this GridSpec instance. Routines that use GridSpec (e.g. fig.subplots) have been modified to pass the figure to GridSpec.

7.13.2 xlabels and ylabels can now be automatically aligned

Subplot axes ylabels can be misaligned horizontally if the tick labels are very different widths. The same can happen to xlabels if the ticklabels are rotated on one subplot (for instance). The new methods on the Figure class: Figure.align_xlabels and Figure.align_ylabels will now align these labels horizontally or vertically. If the user only wants to align some axes, a list of axes can be passed. If no list is passed, the algorithm looks at all the labels on the figure.

Only labels that have the same subplot locations are aligned. i.e. the ylabels are aligned only if the subplots are in the same column of the subplot layout.

Alignment is persistent and automatic after these are called.

A convenience wrapper Figure.align_labels calls both functions at once.

7.13.3 Axes legends now included in tight_bbox

Legends created via ax.legend can sometimes overspill the limits of the axis. Tools like fig.tight_layout() and fig.savefig(bbox_inches='tight') would clip these legends. A change was made to include them in the tight calculations.

7.13.4 Cividis colormap

A new dark blue/yellow colormap named ‘cividis’ was added. Like viridis, cividis is perceptually uniform and colorblind friendly. However, cividis also goes a step further: not only
is it usable by colorblind users, it should actually look effectively identical to colorblind and non-colorblind users. For more details see Nuñez J, Anderton C, and Renslow R: “Optimizing colormaps with consideration for color vision deficiency to enable accurate interpretation of scientific data”.

7.13.5 New style colorblind-friendly color cycle

A new style defining a color cycle has been added, tableau-colorblind10, to provide another option for colorblind-friendly plots. A demonstration of this new style can be found in the reference of style sheets. To load this color cycle in place of the default one:

```python
import matplotlib.pyplot as plt
plt.style.use('tableau-colorblind10')
```

7.13.6 Support for numpy.datetime64

Matplotlib has supported `datetime.datetime` dates for a long time in `matplotlib.dates`. We now support `numpy.datetime64` dates as well. Anywhere that `datetime.datetime` could be used, `numpy.datetime64` can be used. eg:

```python
time = np.arange('2005-02-01', '2005-02-02', dtype='datetime64[h]')
plt.plot(time)
```
7.13.7 Writing animations with Pillow

It is now possible to use Pillow as an animation writer. Supported output formats are currently gif (Pillow>=3.4) and webp (Pillow>=5.0). Use e.g. as

```python
from __future__ import division

from matplotlib import pyplot as plt
from matplotlib.animation import FuncAnimation, PillowWriter

fig, ax = plt.subplots()
line, = plt.plot([0, 1])

def animate(i):
    line.set_ydata([0, i / 20])
    return [line]

anim = FuncAnimation(fig, animate, 20, blit=True)
anim.save("movie.gif", writer=PillowWriter(fps=24))
plt.show()
```

7.13.8 Slider UI widget can snap to discrete values

The slider UI widget can take the optional argument `valstep`. Doing so forces the slider to take on only discrete values, starting from `valmin` and counting up to `valmax` with steps of size `valstep`.

If `closedmax==True`, then the slider will snap to `valmax` as well.

7.13.9 capstyle and joinstyle attributes added to Collection

The Collection class now has customizable `capstyle` and `joinstyle` attributes. This allows the user for example to set the `capstyle` of errorbars.

7.13.10 pad kwarg added to ax.set_title

The method `axes.set_title` now has a `pad` kwarg, that specifies the distance from the top of an axes to where the title is drawn. The units of `pad` is points, and the default is the value of the (already-existing) `rcParams['axes.titlepad']`.

7.13.11 Comparison of 2 colors in Matplotlib

As the colors in Matplotlib can be specified with a wide variety of ways, the `matplotlib.colors.same_color` method has been added which checks if two `colors` are the same.
7.13.12 Autoscaling a polar plot snaps to the origin

Setting the limits automatically in a polar plot now snaps the radial limit to zero if the automatic limit is nearby. This means plotting from zero doesn’t automatically scale to include small negative values on the radial axis.

The limits can still be set manually in the usual way using `set_ylim`.

7.13.13 PathLike support

On Python 3.6+, `savefig`, `imsave`, `imread`, and animation writers now accept `os.PathLike`s as input.

7.13.14 `Axes.tick_params` can set gridline properties

Tick objects hold gridlines as well as the tick mark and its label. `Axis.set_tick_params`, `Axes.tick_params` and `pyplot.tick_params` now have keyword arguments ‘grid_color’, ‘grid_alpha’, ‘grid_linewidth’, and ‘grid_linestyle’ for overriding the defaults in `rcParams`: ‘grid.color’, etc.

7.13.15 `Axes.imshow` clips RGB values to the valid range

When `Axes.imshow` is passed an RGB or RGBA value with out-of-range values, it now logs a warning and clips them to the valid range. The old behaviour, wrapping back in to the range, often hid outliers and made interpreting RGB images unreliable.

7.13.16 Properties in `matplotlibrc` to place xaxis and yaxis tick labels

Introducing four new boolean properties in `matplotlibrc` for default positions of xaxis and yaxis tick labels, namely, `xtick.labeltop`, `xtick.labelbottom`, `ytick.labelright`, and `ytick.labelleft`. These can also be changed in `rcParams`.

7.13.17 PGI bindings for gtk3

The GTK3 backends can now use `PGI` instead of `PyGObject`. PGI is a fairly incomplete binding for GObject, thus its use is not recommended; its main benefit is its availability on Travis (thus allowing CI testing for the gtk3agg and gtk3cairo backends).

The binding selection rules are as follows: - if `gi` has already been imported, use it; else - if `pgi` has already been imported, use it; else - if `gi` can be imported, use it; else - if `pgi` can be imported, use it; else - error out.

Thus, to force usage of PGI when both bindings are installed, import it first.

7.13.18 Cairo rendering for Qt, WX, and Tk canvases

The new `Qt4Cairo`, `Qt5Cairo`, `WXCairo`, and `TkCairo` backends allow Qt, Wx, and Tk canvases to use Cairo rendering instead of Agg.
### 7.13.19 Added support for QT in new ToolManager

Now it is possible to use the ToolManager with Qt5 For example

```python
import matplotlib
matplotlib.use('QT5AGG') matplotlib.rcParams['toolbar'] = 'toolmanager' import matplotlib.pyplot as plt plt.plot([1,2,3]) plt.show()
```

Treat the new Tool classes experimental for now, the API will likely change and perhaps the rcParam as well

The main example examples/user_interfaces/toolmanager_sgskip.py shows more details, just adjust the header to use QT instead of GTK3

### 7.13.20 TkAgg backend reworked to support PyPy

PyPy can now plot using the TkAgg backend, supported on PyPy 5.9 and greater (both PyPy for python 2.7 and PyPy for python 3.5).

### 7.13.21 Python logging library used for debug output

Matplotlib has in the past (sporadically) used an internal verbose-output reporter. This version converts those calls to using the standard python logging library.

Support for the old rcParams verbose.level and verbose.fileo is dropped.

The command-line options --verbose-helpful and --verbose-debug are still accepted, but deprecated. They are now equivalent to setting logging.INFO and logging.DEBUG.

The logger's root name is matplotlib and can be accessed from programs as:

```python
import logging
mlog = logging.getLogger('matplotlib')
```

Instructions for basic usage are in Troubleshooting and for developers in Contributing.

### 7.13.22 Improved repr for Transforms

Transforms now indent their reprs in a more legible manner:

```python
In [1]: 1, = plt.plot([]); 1.get_transform()
Out[1]:
```

(continues on next page)
TransformWrapper(
    BlendedAffine2D(
        IdentityTransform(),
        IdentityTransform()))),
BboxTransformTo(
    TransformedBbox(
        Bbox(x0=0.125, y0=0.10999999999999999, x1=0.9, y1=0.88),
        BboxTransformTo(
            TransformedBbox(
                Bbox(x0=0.0, y0=0.0, x1=6.4, y1=4.8),
                Affine2D(
                    [[ 100. 0. 0.]
                    [ 0. 100. 0.]
                    [ 0. 0. 1.]]))))))

7.14 New in Matplotlib 3.0

7.14.1 Improved default backend selection

The default backend no longer must be set as part of the build process. Instead, at run time, the builtin backends are tried in sequence until one of them imports.

Headless linux servers (identified by the DISPLAY env not being defined) will not select a GUI backend.

7.14.2 Cyclic colormaps

Two new colormaps named ‘twilight’ and ‘twilight_shifted’ have been added. These colormaps start and end on the same color, and have two symmetric halves with equal lightness, but diverging color. Since they wrap around, they are a good choice for cyclic data such as phase angles, compass directions, or time of day. Like viridis and cividis, twilight is perceptually uniform and colorblind friendly.

7.14.3 Ability to scale axis by a fixed order of magnitude

To scale an axis by a fixed order of magnitude, set the scilimits argument of Axes.ticklabel_format to the same (non-zero) lower and upper limits. Say to scale the y axis by a million (1e6), use

```python
ax.ticklabel_format(style='sci', scilimits=(6, 6), axis='y')
```

The behavior of scilimits=(0, 0) is unchanged. With this setting, Matplotlib will adjust the order of magnitude depending on the axis values, rather than keeping it fixed. Previously, setting scilimits=(m, m) was equivalent to setting scilimits=(0, 0).
7.14.4 Add AnchoredDirectionArrows feature to mpl_toolkits

A new mpl_toolkits class AnchoredDirectionArrows draws a pair of orthogonal arrows to indicate directions on a 2D plot. A minimal working example takes in the transformation object for the coordinate system (typically ax.transAxes), and arrow labels. There are several optional parameters that can be used to alter layout. For example, the arrow pairs can be rotated and the color can be changed. By default the labels and arrows have the same color, but the class may also pass arguments for customizing arrow and text layout, these are passed to matplotlib.text.TextPath and matplotlib.patches.FancyArrowPatch. Location, length and width for both arrow tail and head can be adjusted, the the direction arrows and labels can have a frame. Padding and separation parameters can be adjusted.

7.14.5 Add minorticks_on()/off() methods for colorbar

A new method colorbar.Colobar.minorticks_on() has been added to correctly display minor ticks on a colorbar. This method doesn't allow the minor ticks to extend into the regions beyond vmin and vmax when the extend kwarg (used while creating the colorbar) is set to 'both', 'max' or 'min'. A complementary method colorbar.Colobar.minorticks_off() has also been added to remove the minor ticks on the colorbar.

7.14.6 Colorbar ticks can now be automatic

The number of ticks placed on colorbars was previously appropriate for a large colorbar, but looked bad if the colorbar was made smaller (i.e. via the shrink kwarg). This has been changed so that the number of ticks is now responsive to how large the colorbar is.

7.14.7 Don't automatically rename duplicate file names

Previously, when saving a figure to a file using the GUI's save dialog box, if the default filename (based on the figure window title) already existed on disk, Matplotlib would append a suffix (e.g. Figure_1-1.png), preventing the dialog from prompting to overwrite the file. This behaviour has been removed. Now if the file name exists on disk, the user is prompted whether or not to overwrite it. This eliminates guesswork, and allows intentional overwriting, especially when the figure name has been manually set using figure.Figure.canvas.set_window_title().

7.14.8 Legend now has a title_fontsize kwarg (and rcParam)

The title for a Figure.legend and Axes.legend can now have its fontsize set via the title_fontsize kwarg. There is also a new rcParams["legend.title_fontsize"]. Both default to None, which means the legend title will have the same fontsize as the axes default fontsize (not the legend fontsize, set by the fontsize kwarg or rcParams["legend.fontsize"]).

7.14.9 Support for axes.prop_cycle property markevery in rcParams

The Matplotlib rcParams settings object now supports configuration of the attribute axes.prop_cycle with cyclers using the markevery Line2D object property. An example of this feature is provided at /gallery/lines_bars_and_markers/markevery_prop_cycle.
7.14.10 Multipage PDF support for pgf backend

The pgf backend now also supports multipage PDF files.

```python
from matplotlib.backends.backend_pdf import PdfPages
import matplotlib.pyplot as plt

with PdfPages('multipage.pdf') as pdf:
    # page 1
    plt.plot([2, 1, 3])
    pdf.savefig()

    # page 2
    plt.plot([3, 1, 2])
    pdf.savefig()
```

7.14.11 Pie charts are now circular by default

We acknowledge that the majority of people do not like egg-shaped pies. Therefore, an axes to which a pie chart is plotted will be set to have equal aspect ratio by default. This ensures that the pie appears circular independent on the axes size or units. To revert to the previous behaviour set the axes’ aspect ratio to automatic by using `ax.set_aspect("auto")` or `plt.axis("auto")`.

7.14.12 Add `ax.get_gridspec` to `SubplotBase`

New method `SubplotBase.get_gridspec` is added so that users can easily get the gridspec that went into making an axes:

```python
import matplotlib.pyplot as plt

fig, axs = plt.subplots(3, 2)
gs = axs[0, -1].get_gridspec()

# remove the last column
for ax in axs[:, -1].flatten():
    ax.remove()

# make a subplot in last column that spans rows.
ax = fig.add_subplot(gs[:, -1])
plt.show()
```

7.14.13 Axes titles will no longer overlap xaxis

Previously an axes title had to be moved manually if an xaxis overlapped (usually when the xaxis was put on the top of the axes). Now, the title will be automatically moved above the xaxis and its decorators (including the xlabel) if they are at the top.
If desired, the title can still be placed manually. There is a slight kludge; the algorithm checks if the y-position of the title is 1.0 (the default), and moves if it is. If the user places the title in the default location (i.e. `ax.title.set_position(0.5, 1.0)`), the title will still be moved above the xaxis. If the user wants to avoid this, they can specify a number that is close (i.e. `ax.title.set_position(0.5, 1.01)`) and the title will not be moved via this algorithm.

### 7.14.14 New convenience methods for GridSpec

There are new convenience methods for `gridspec.GridSpec` and `gridspec.GridSpecFromSubplotSpec`. Instead of the former we can now call `Figure.add_gridspec` and for the latter `SubplotSpec.subgridspec`.

```python
import matplotlib.pyplot as plt

fig = plt.figure()
gs0 = fig.add_gridspec(3, 1)
ax1 = fig.add_subplot(gs0[0])
ax2 = fig.add_subplot(gs0[1])
gssub = gs0[2].subgridspec(1, 3)
for i in range(3):
    fig.add_subplot(gssub[0, i])
```

### 7.14.15 Figure has an add_artist method

A method `add_artist` has been added to the `Figure` class, which allows artists to be added directly to a figure. E.g.

```python
circ = plt.Circle((.7, .5), .05)
fig.add_artist(circ)
```

In case the added artist has no transform set previously, it will be set to the figure transform (`fig.transFigure`). This new method may be useful for adding artists to figures without axes or to easily position static elements in figure coordinates.

### 7.14.16 :math: directive renamed to :mathmpl:

The :math: rst role provided by `matplotlib.sphinxext.mathmpl` has been renamed to :mathmpl: to avoid conflicting with the :math: role that Sphinx 1.8 provides by default. (:mathmpl: uses Matplotlib to render math expressions to images embedded in html, whereas Sphinx uses MathJax.)

When using Sphinx<1.8, both names (:math: and :mathmpl:) remain available for backcompatibility.

### 7.15 What’s new in Matplotlib 3.1

For a list of all of the issues and pull requests since the last revision, see the *GitHub Stats*. 
Table of Contents

- What’s new in Matplotlib 3.1
  - New Features
    * ConciseDateFormatter
    * Secondary x/y Axis support
    * FuncScale for arbitrary axes scales
    * Legend for scatter
    * Matplotlib no longer requires framework app build on MacOSX backend
  - Figure, FigureCanvas, and Backends
    * Figure.frameon is now a direct proxy for the Figure patch visibility state
    * pil_kwargs argument added to savefig
    * Add inaxes method to FigureCanvasBase
    * cairo backend defaults to pycairo instead of cairocffi
  - Axes and Artists
    * axes_grid1 and axisartist Axes no longer draw spines twice
    * Return type of ArtistInspector.get_aliases changed
    * ConnectionPatch accepts arbitrary transforms
    * mplot3d Line3D now allows {set,get}_data_3d
    * Axes3D.voxels now shades the resulting voxels
  - Axis and Ticks
    * Added Axis.get_inverted and Axis.set_inverted
    * Adjust default minor tick spacing
    * EngFormatter now accepts useTeX, useMathText as keyword only arguments
  - Animation and Interactivity
    * Support for forward/backward mouse buttons
    * progress_callback argument to save()
    * Add cache_frame_data keyword-only argument into animation.FuncAnimation
    * Endless Looping GIFs with PillowWriter
    * Adjusted matplotlib.widgets.Slider to have vertical orientation
    * Improved formatting of image values under cursor when a colorbar is present
    * MouseEvent button attribute is now an IntEnum
  - Configuration, Install, and Development
    * The MATPLOTLIBRC environment variable can now point to any “file” path
    * Allow LaTeX code pgf.preamble and text.latex.preamble in MATPLOTLIBRC file
    * New logging API
7.15.1 New Features

ConciseDateFormatter

The automatic date formatter used by default can be quite verbose. A new formatter can be accessed that tries to make the tick labels appropriately concise.

![Concise Date Formatter](image)

Secondary x/y Axis support

A new method provides the ability to add a second axis to an existing axes via `Axes.secondary_xaxis` and `Axes.secondary_yaxis`. See /gallery/subplots_axes_and_figures/secondary_axis for examples.

FuncScale for arbitrary axes scales

A new `FuncScale` class was added (and `FuncTransform`) to allow the user to have arbitrary scale transformations without having to write a new subclass of `ScaleBase`. This can be accessed by:
where `forward` and `inverse` are callables that return the scale transform and its inverse. See the last example in /gallery/scales/scales.

**Legend for scatter**

A new method for creating legends for scatter plots has been introduced. Previously, in order to obtain a legend for a `scatter()` plot, one could either plot several scatters, each with an individual label, or create proxy artists to show in the legend manually. Now, `PathCollection` provides a method `legend_elements()` to obtain the handles and labels for a scatter plot in an automated way. This makes creating a legend for a scatter plot as easy as An example can be found in automatedlegendcreation.

**Matplotlib no longer requires framework app build on MacOSX backend**

Previous versions of matplotlib required a Framework build of python to work. The app type was updated to no longer require this, so the MacOSX backend should work with non-framework python.

This also adds support for the MacOSX backend for PyPy3.

**7.15.2 Figure, FigureCanvas, and Backends**

**Figure.frameon is now a direct proxy for the Figure patch visibility state**

Accessing `Figure.frameon` (including via `get_frameon` and `set_frameon` now directly forwards to the visibility of the underlying Rectangle artist (`Figure.patch.get_frameon`, `Figure.patch.set_frameon`).
Matplotlib uses Pillow to handle saving to the JPEG and TIFF formats. The `savefig()` function gained a `pil_kwargs` keyword argument, which can be used to forward arguments to Pillow’s `pillow.Image.save()`.

The `pil_kwargs` argument can also be used when saving to PNG. In that case, Matplotlib also uses Pillow’s `pillow.Image.save()` instead of going through its own built-in PNG support.

**Add `inaxes` method to `FigureCanvasBase`**

The `FigureCanvasBase` class has now an `inaxes` method to check whether a point is in an axes and returns the topmost axes, else None.

**cairo backend defaults to `pycairo` instead of `cairocffi`**

This leads to faster import/runtime performance in some cases. The backend will fall back to `cairocffi` in case `pycairo` isn’t available.

### 7.15.3 Axes and Artists
axes_grid1 and axisartist Axes no longer draw spines twice

Previously, spines of axes_grid1 and axisartist Axes would be drawn twice, leading to a "bold" appearance. This is no longer the case.

Return type of ArtistInspector.get_aliases changed

ArtistInspector.get_aliases previously returned the set of aliases as {fullname: {alias1: None, alias2: None, ...}}. The dict-to-None mapping was used to simulate a set in earlier versions of Python. It has now been replaced by a set, i.e. {fullname: {alias1, alias2, ...}}. This value is also stored in ArtistInspector.aliasd, which has likewise changed.

ConnectionPatch accepts arbitrary transforms

Alternatively to strings like "data" or "axes fraction" ConnectionPatch now accepts any Transform as input for the coordsA and coordsB argument. This allows to draw lines between points defined in different user defined coordinate systems. Also see the Connect Simple01 example.

mpl3d Line3D now allows {set.get}_data_3d

Lines created with the 3d projection in mpl3d can now access the data using get_data_3d() which returns a tuple of array_likes containing the (x, y, z) data. The equivalent set_data_3d can be used to modify the data of an existing Line3D.

Axes3D.voxels now shades the resulting voxels

The voxels() method now takes a shade parameter that defaults to True. This shades faces based on their orientation, behaving just like the matching parameters to trisurf() and bar3d(). The plot below shows how this affects the output.

7.15.4 Axis and Ticks

Added Axis.get_inverted and Axis.set_inverted

The Axis.get_inverted and Axis.set_inverted methods query and set whether the axis uses "inverted" orientation (i.e. increasing to the left for the x-axis and to the bottom for the y-axis).

They perform tasks similar to Axes.xaxis_inverted, Axes.yaxis_inverted, Axes.invert_xaxis, and Axes.invert_yaxis, with the specific difference that Axes..set_inverted makes it easier to set the invertedness of an axis regardless of whether it had previously been inverted before.

Adjust default minor tick spacing

Default minor tick spacing was changed from 0.625 to 0.5 for major ticks spaced 2.5 units apart.
EngFormatter now accepts useTex, useMatheText as keyword only arguments

A public API has been added to EngFormatter to control how the numbers in the ticklabels will be rendered. By default, useMatheText evaluates to rcParams["axes.formatter.use_mathtext"] and useTex evaluates to rcParams["text.useTex"].

If either is True then the numbers will be encapsulated by $ signs. When using TeX this implies that the numbers will be shown in TeX’s math font. When using mathtext, the $ signs around numbers will ensure unicode rendering (as implied by mathtext). This will make sure that the minus signs in the ticks are rendered as the unicode=minus (U+2212) when using mathtext (without relying on the fix_minus method).

7.15.5 Animation and Interactivity

Support for forward/backward mouse buttons

Figure managers now support a button_press event for mouse buttons, similar to the key_press events. This allows binding actions to mouse buttons (see MouseButton) The first application of this mechanism is support of forward/backward mouse buttons in figures created with the Qt5 backend.

progress_callback argument to save()

The method Animation.save gained an optional progress_callback argument to notify the saving progress.

Add cache_frame_data keyword-only argument into animation.FuncAnimation

matplotlib.animation.FuncAnimation has been caching frame data by default; however, this caching is not ideal in certain cases e.g. When FuncAnimation needs to be only drawn(not
saved) interactively and memory required by frame data is quite large. By adding `cache_frame_data` keyword-only argument, users can now disable this caching; thereby, this new argument provides a fix for issue #8528.

**Endless Looping GIFs with PillowWriter**

We acknowledge that most people want to watch a gif more than once. Saving an animation as a gif with PillowWriter now produces an endless looping gif.

**Adjusted `matplotlib.widgets.Slider` to have vertical orientation**

The `matplotlib.widgets.Slider` widget now takes an optional argument `orientation` which indicates the direction ('horizontal' or 'vertical') that the slider should take.

**Improved formatting of image values under cursor when a colorbar is present**

When a colorbar is present, its formatter is now used to format the image values under the mouse cursor in the status bar. For example, for an image displaying the values 10,000 and 10,001, the statusbar will now (using default settings) display the values as `10000` and `10001`), whereas both values were previously displayed as `1e+04`.

**MouseEvent button attribute is now an IntEnum**

The `button` attribute of `MouseEvent` instances can take the values None, 1 (left button), 2 (middle button), 3 (right button), ”up” (scroll), and ”down” (scroll). For better legibility, the 1, 2, and 3 values are now represented using the `IntEnum` class `matplotlib.backend_bases.MouseButton`, with the values `MouseButton.LEFT` (== 1), `MouseButton.MIDDLE` (== 2), and `MouseButton.RIGHT` (== 3).

**7.15.6 Configuration, Install, and Development**

**The MATPLOTLIBRC environment variable can now point to any "file" path**

This includes device files; in particular, on Unix systems, one can set `MATPLOTLIBRC` to `/dev/null` to ignore the user’s matplotlibrc file and fall back to Matplotlib’s defaults.

As a reminder, if `MATPLOTLIBRC` points to a directory, Matplotlib will try to load the matplotlibrc file from `$MATPLOTLIBRC/matplotlibrc`.

**Allow LaTeX code `pgf.preamble` and `text.latex.preamble` in MATPLOTLIBRC file**

Previously, the rc file keys `rcParams["pgf.preamble"]` and `rcParams["text.latex.preamble"]` were parsed using commas as separators. This would break valid LaTeX code, such as:

\usepackage[protrusion=true, expansion=false]{microtype}

The parsing has been modified to pass the complete line to the LaTeX system, keeping all commas. Passing a list of strings from within a Python script still works as it used to.
New logging API

`matplotlib.set_loglevel` / `pyplot.set_loglevel` can be called to display more (or less) detailed logging output.
Matplotlib only uses BSD compatible code, and its license is based on the PSF license. See the Open Source Initiative licenses page for details on individual licenses. Non-BSD compatible licenses (e.g., LGPL) are acceptable in matplotlib toolkits. For a discussion of the motivations behind the licencing choice, see Licenses.

8.1 Copyright Policy

John Hunter began matplotlib around 2003. Since shortly before his passing in 2012, Michael Droettboom has been the lead maintainer of matplotlib, but, as has always been the case, matplotlib is the work of many.

Prior to July of 2013, and the 1.3.0 release, the copyright of the source code was held by John Hunter. As of July 2013, and the 1.3.0 release, matplotlib has moved to a shared copyright model.

matplotlib uses a shared copyright model. Each contributor maintains copyright over their contributions to matplotlib. But, it is important to note that these contributions are typically only changes to the repositories. Thus, the matplotlib source code, in its entirety, is not the copyright of any single person or institution. Instead, it is the collective copyright of the entire matplotlib Development Team. If individual contributors want to maintain a record of what changes/contributions they have specific copyright on, they should indicate their copyright in the commit message of the change, when they commit the change to one of the matplotlib repositories.

The Matplotlib Development Team is the set of all contributors to the matplotlib project. A full list can be obtained from the git version control logs.

8.2 License agreement for matplotlib 3.1.1

1. This LICENSE AGREEMENT is between the Matplotlib Development Team (“MDT”), and the Individual or Organization (“Licensee”) accessing and otherwise using matplotlib software in source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, MDT hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use matplotlib 3.1.1 alone or in any derivative version, provided, however, that MDT’s License Agreement and MDT’s notice of copyright, i.e., “Copyright (c) 2012-2013 Matplotlib Development Team;
All Rights Reserved” are retained in matplotlib 3.1.1 alone or in any derivative version prepared by Licensee.

3. In the event Licensee prepares a derivative work that is based on or incorporates matplotlib 3.1.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to matplotlib 3.1.1.

4. MDT is making matplotlib 3.1.1 available to Licensee on an “AS IS” basis. MDT MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED. BY WAY OF EXAMPLE, BUT NOT LIMITATION, MDT MAKES NO AND DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF MATPLOTLIB 3.1.1 WILL NOT INFRINGE ANY THIRD PARTY RIGHTS.

5. MDT SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF MATPLOTLIB 3.1.1 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING MATPLOTLIB 3.1.1, OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material breach of its terms and conditions.

7. Nothing in this License Agreement shall be deemed to create any relationship of agency, partnership, or joint venture between MDT and Licensee. This License Agreement does not grant permission to use MDT trademarks or trade name in a trademark sense to endorse or promote products or services of Licensee, or any third party.

8. By copying, installing or otherwise using matplotlib 3.1.1, Licensee agrees to be bound by the terms and conditions of this License Agreement.

8.3 License agreement for matplotlib versions prior to 1.3.0

1. This LICENSE AGREEMENT is between John D. Hunter (“JDH”), and the Individual or Organization (“Licensee”) accessing and otherwise using matplotlib software in source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, JDH hereby grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce, analyze, test, perform and/or display publicly, prepare derivative works, distribute, and otherwise use matplotlib 3.1.1 alone or in any derivative version, provided, however, that JDH’s License Agreement and JDH’s notice of copyright, i.e., “Copyright (c) 2002-2009 John D. Hunter; All Rights Reserved” are retained in matplotlib 3.1.1 alone or in any derivative version prepared by Licensee.

3. In the event Licensee prepares a derivative work that is based on or incorporates matplotlib 3.1.1 or any part thereof, and wants to make the derivative work available to others as provided herein, then Licensee hereby agrees to include in any such work a brief summary of the changes made to matplotlib 3.1.1.

Matplotlib was written by John D. Hunter, with contributions from an ever-increasing number of users and developers. The current lead developer is Thomas A. Caswell; they are assisted by many active developers.

The following is a list of contributors extracted from the git revision control history of the project:

Élie Gouzien, Андрей Парамонов

Some earlier contributors not included above are (with apologies to any we have missed):

Charles Twardy, Gary Ruben, John Gill, David Moore, Paul Barrett, Jared Wahlstrand, Jim Benson, Paul Mcguire, Andrew Dalke, Nadia Dencheva, Baptiste Carvello, Sigve Tjoraand, Ted Drain, James Amundson, Daishi Harada, Nicolas Young, Paul Kienzle, John Porter, and Jonathon Taylor.

Thanks to Tony Yu for the original logo design.

We also thank all who have reported bugs, commented on proposed changes, or otherwise contributed to Matplotlib’s development and usefulness.
Part II

The Matplotlib FAQ

10.1 Report a compilation problem

See Getting help.

10.2 Matplotlib compiled fine, but nothing shows up when I use it

The first thing to try is a clean install and see if that helps. If not, the best way to test your install is by running a script, rather than working interactively from a python shell or an integrated development environment such as IDLE which add additional complexities. Open up a UNIX shell or a DOS command prompt and run, for example:

```
python -c "from pylab import *; plot(); show()" --verbose-helpful
```

This will give you additional information about which backends Matplotlib is loading, version information, and more. At this point you might want to make sure you understand Matplotlib’s
configuration process, governed by the matplotlibrc configuration file which contains instructions within and the concept of the Matplotlib backend.

If you are still having trouble, see Getting help.

10.3 How to completely remove Matplotlib

Occasionally, problems with Matplotlib can be solved with a clean installation of the package. In order to fully remove an installed Matplotlib:

1. Delete the caches from your Matplotlib configuration directory.
2. Delete any Matplotlib directories or eggs from your installation directory.

10.4 Linux Notes

To install Matplotlib at the system-level, we recommend that you use your distribution’s package manager. This will guarantee that Matplotlib’s dependencies will be installed as well.

If, for some reason, you cannot use the package manager, you may use the wheels available on PyPI:

```
python -mpip install matplotlib
```

or build Matplotlib from source.

10.5 OSX Notes

10.5.1 Which python for OSX?

Apple ships OSX with its own Python, in /usr/bin/python, and its own copy of Matplotlib. Unfortunately, the way Apple currently installs its own copies of NumPy, Scipy and Matplotlib means that these packages are difficult to upgrade (see system python packages). For that reason we strongly suggest that you install a fresh version of Python and use that as the basis for installing libraries such as NumPy and Matplotlib. One convenient way to install Matplotlib with other useful Python software is to use one of the excellent Python scientific software collections that are now available:

- Anaconda from Continuum Analytics
- Canopy from Enthought

These collections include Python itself and a wide range of libraries; if you need a library that is not available from the collection, you can install it yourself using standard methods such as pip. Continuum and Enthought offer their own installation support for these collections; see the Ananconda and Canopy web pages for more information.

Other options for a fresh Python install are the standard installer from python.org, or installing Python using a general OSX package management system such as homebrew or macports. Power users on OSX will likely want one of homebrew or macports on their system to install open source software packages, but it is perfectly possible to use these systems with another source for your Python binary, such as Anaconda, Canopy or Python.org Python.
10.5.2 Installing OSX binary wheels

If you are using Python from https://www.python.org, Homebrew, or Macports, then you can use the standard pip installer to install Matplotlib binaries in the form of wheels.

pip is installed by default with python.org and Homebrew Python, but needs to be manually installed on Macports with

```
sudo port install py36-pip
```

Once pip is installed, you can install Matplotlib and all its dependencies with from the Terminal.app command line:

```
python3 -mpip install matplotlib
```

(sudo python3.6 ... on Macports).

You might also want to install IPython or the Jupyter notebook (python3 -mpip install ipython notebook).

**pip problems**

If you get errors with pip trying to run a compiler like gcc or clang, then the first thing to try is to install xcode and retry the install. If that does not work, then check Getting help.

10.5.3 Checking your installation

The new version of Matplotlib should now be on your Python “path”. Check this at the Terminal.app command line:

```
python3 -c 'import matplotlib; print(matplotlib.__version__, matplotlib.__file__)
```

You should see something like

```
3.0.0 /Library/Frameworks/Python.framework/Versions/3.6/lib/python3.6/site-packages/...matplotlib/__init__.py
```

where 3.0.0 is the Matplotlib version you just installed, and the path following depends on whether you are using Python.org Python, Homebrew or Macports. If you see another version, or you get an error like

```
Traceback (most recent call last):
  File "<string>", line 1, in <module>
ImportError: No module named matplotlib
```

then check that the Python binary is the one you expected by running

```
which python3
```

If you get a result like /usr/bin/python..., then you are getting the Python installed with OSX, which is probably not what you want. Try closing and restarting Terminal.app before running the check again. If that doesn’t fix the problem, depending on which Python you wanted to use, consider reinstalling Python.org Python, or check your homebrew or macports setup.
Remember that the disk image installer only works for Python.org Python, and will not get picked up by other Pythons. If all these fail, please let us know.

### 10.6 Install from source

Clone the main source using one of:

```bash
git clone git@github.com:matplotlib/matplotlib.git
```

or:

```bash
git clone git://github.com/matplotlib/matplotlib.git
```

and build and install as usual with:

```bash
cd matplotlib
python -mpip install .
```

**Note:** If you are on Debian/Ubuntu, you can get all the dependencies required to build Matplotlib with:

```bash
sudo apt-get build-dep python-matplotlib
```

If you are on Fedora/RedHat, you can get all the dependencies required to build Matplotlib by first installing `yum-builddep` and then running:

```bash
su -c 'yum-builddep python-matplotlib'
```

This does not build Matplotlib, but it does get all of the build dependencies, which will make building from source easier.

If you want to be able to follow the development branch as it changes just replace the last step with:

```bash
python -mpip install -e .
```

This creates links and installs the command line script in the appropriate places.

**Note:** OSX users please see the *Building on macOS* guide.

Windows users please see the *Building on Windows* guide.

Then, if you want to update your Matplotlib at any time, just do:

```bash
git pull
```

When you run `git pull`, if the output shows that only Python files have been updated, you are all set. If C files have changed, you need to run `pip install -e .` again to compile them.

There is more information on *using git* in the developer docs.

    * Clickable images for HTML
11.1 Plotting: howto

11.1.1 Plot numpy.datetime64 values

As of Matplotlib 2.2, numpy.datetime64 objects are handled the same way as datetime.datetime objects.

If you prefer the pandas converters and locators, you can register their converter with the matplotlib.units module:

```python
from pandas.tseries import converter as pdtc
pdtc.register()
```

If you only want to use the pandas converter for datetime64 values:

```python
from pandas.tseries import converter as pdtc
import matplotlib.units as munits
import numpy as np

munits.registry[np.datetime64] = pdtc.DatetimeConverter()
```

11.1.2 Find all objects in a figure of a certain type

Every Matplotlib artist (see Artist tutorial) has a method called `findobj()` that can be used to recursively search the artist for any artists it may contain that meet some criteria (e.g., match all `Line2D` instances or match some arbitrary filter function). For example, the following snippet finds every object in the figure which has a `set_color` property and makes the object blue:

```python
def myfunc(x):
    return hasattr(x, 'set_color')

for o in fig.findobj(myfunc):
    o.set_color('blue')
```

You can also filter on class instances:

```python
import matplotlib.text as text
for o in fig.findobj(text.Text):
    o.set_fontstyle('italic')
```

11.1.3 How to prevent ticklabels from having an offset

The default formatter will use an offset to reduce the length of the ticklabels. To turn this feature off on a per-axis basis:
11.1.4 Save transparent figures

The `savefig()` command has a keyword argument `transparent` which, if ‘True’, will make the figure and axes backgrounds transparent when saving, but will not affect the displayed image on the screen.

If you need finer grained control, e.g., you do not want full transparency or you want to affect the screen displayed version as well, you can set the alpha properties directly. The figure has a `Rectangle` instance called `patch` and the axes has a `Rectangle` instance called `patch`. You can set any property on them directly (`facecolor`, `edgecolor`, `linewidth`, `linestyle`, `alpha`). e.g.:

```python
fig = plt.figure()
fig.patch.set_alpha(0.5)
ax = fig.add_subplot(111)
ax.patch.set_alpha(0.5)
```

If you need all the figure elements to be transparent, there is currently no global alpha setting, but you can set the alpha channel on individual elements, e.g.:

```python
ax.plot(x, y, alpha=0.5)
ax.set_xlabel('volts', alpha=0.5)
```

11.1.5 Save multiple plots to one pdf file

Many image file formats can only have one image per file, but some formats support multi-page files. Currently only the pdf backend has support for this. To make a multi-page pdf file, first initialize the file:

```python
from matplotlib.backends.backend_pdf import PdfPages
pp = PdfPages('multipage.pdf')
```

You can give the `PdfPages` object to `savefig()`, but you have to specify the format:

```python
plt.savefig(pp, format='pdf')
```

An easier way is to call `PdfPages.savefig`:

```python
pp.savefig()
```

Finally, the multipage pdf object has to be closed:

```python
pp.close()
```

The same can be done using the pgf backend:

```python
from matplotlib.backends.backend_pdf import PdfPages
```
11.1.6 Move the edge of an axes to make room for tick labels

For subplots, you can control the default spacing on the left, right, bottom, and top as well as the horizontal and vertical spacing between multiple rows and columns using the `matplotlib.figure.Figure.subplots_adjust()` method (in pyplot it is `subplots_adjust()`). For example, to move the bottom of the subplots up to make room for some rotated x tick labels:

```python
fig = plt.figure()
fig.subplots_adjust(bottom=0.2)
ax = fig.add_subplot(111)
```

You can control the defaults for these parameters in your `matplotlibrc` file; see `Customizing Matplotlib with style sheets and rcParams`. For example, to make the above setting permanent, you would set:

```python
figure.subplot.bottom : 0.2  # the bottom of the subplots of the figure
```

The other parameters you can configure are, with their defaults

- `left = 0.125` the left side of the subplots of the figure
- `right = 0.9` the right side of the subplots of the figure
- `bottom = 0.1` the bottom of the subplots of the figure
- `top = 0.9` the top of the subplots of the figure
- `wspace = 0.2` the amount of width reserved for space between subplots, expressed as a fraction of the average axis width
- `hspace = 0.2` the amount of height reserved for space between subplots, expressed as a fraction of the average axis height

If you want additional control, you can create an `Axes` using the `axes()` command (or equivalently the `add_axes()` method), which allows you to specify the location explicitly:

```python
ax = fig.add_axes([left, bottom, width, height])
```

where all values are in fractional (0 to 1) coordinates. See /gallery/subplots_axes_and_figures/axes_demo for an example of placing axes manually.

11.1.7 Automatically make room for tick labels

**Note:** This is now easier to handle than ever before. Calling `tight_layout()` can fix many common layout issues. See the `Tight Layout guide`.

The information below is kept here in case it is useful for other purposes.

In most use cases, it is enough to simply change the subplots adjust parameters as described in Move the edge of an axes to make room for tick labels. But in some cases, you don’t know ahead of time what your tick labels will be, or how large they will be (data and labels outside your control may be being fed into your graphing application), and you may need to automatically adjust your subplot parameters based on the size of the tick labels. Any `Text` instance can report its extent in window coordinates (a negative x coordinate is outside the window), but there is a rub.
The `RendererBase` instance, which is used to calculate the text size, is not known until the figure is drawn (`draw()`). After the window is drawn and the text instance knows its renderer, you can call `get_window_extent()`. One way to solve this chicken and egg problem is to wait until the figure is drawn by connecting (`mpl_connect()`) to the "on_draw" signal (`DrawEvent`) and get the window extent there, and then do something with it, e.g., move the left of the canvas over; see Event handling and picking.

Here is an example that gets a bounding box in relative figure coordinates (0..1) of each of the labels and uses it to move the left of the subplots over so that the tick labels fit in the figure:

![Figure 1: Auto Subplots Adjust](image)

### 11.1.8 Configure the tick widths

Wherever possible, it is recommended to use the `tick_params()` or `set_tick_params()` methods to modify tick properties:

```python
import matplotlib.pyplot as plt

fig, ax = plt.subplots()
ax.plot(range(10))
ax.tick_params(width=10)
plt.show()
```

For more control of tick properties that are not provided by the above methods, it is important to know that in Matplotlib, the ticks are markers. All `Line2D` objects support a line (solid, dashed, etc) and a marker (circle, square, tick). The tick width is controlled by the "markeredgewidth" property, so the above effect can also be achieved by:

```python
import matplotlib.pyplot as plt

fig, ax = plt.subplots()
ax.plot(range(10))
```

(continues on next page)
for line in ax.get_xticklines() + ax.get_yticklines():
    line.set_markeredgewidth(10)
plt.show()

The other properties that control the tick marker, and all markers, are markerfacecolor, markeredgecolor, markeredgewidth, markersize. For more information on configuring ticks, see Axis containers and Tick containers.

### 11.1.9 Align my ylabels across multiple subplots

If you have multiple subplots over one another, and the y data have different scales, you can often get ylabels that do not align vertically across the multiple subplots, which can be unattractive. By default, Matplotlib positions the x location of the ylabel so that it does not overlap any of the y ticks. You can override this default behavior by specifying the coordinates of the label. The example below shows the default behavior in the left subplots, and the manual setting in the right subplots.

![Fig. 2: Align Ylabels](image)

### 11.1.10 Skip dates where there is no data

When plotting time series, e.g., financial time series, one often wants to leave out days on which there is no data, e.g., weekends. By passing in dates on the x-axis, you get large horizontal gaps on periods when there is not data. The solution is to pass in some proxy x-data, e.g., evenly sampled indices, and then use a custom formatter to format these as dates. The example below shows how to use an 'index formatter' to achieve the desired plot:

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.mlab as mlab
import matplotlib.ticker as ticker

r = mlab.csv2rec('..data/aapl.csv')
```
r.sort()
r = r[-30:]  # get the last 30 days

N = len(r)
ind = np.arange(N)  # the evenly spaced plot indices

def format_date(x, pos=None):
    thisind = np.clip(int(x+0.5), 0, N-1)
    return r.date[thisind].strftime('%Y-%m-%d')

fig = plt.figure()
ax = fig.add_subplot(111)
ax.plot(ind, r.adj_close, 'o-')
ax.xaxis.set_major_formatter(ticker.FuncFormatter(format_date))
fig.autofmt_xdate()
plt.show()

11.1.11 Control the depth of plot elements

Within an axes, the order that the various lines, markers, text, collections, etc appear is determined by the set_zorder() property. The default order is patches, lines, text, with collections of lines and collections of patches appearing at the same level as regular lines and patches, respectively:

```python
line, = ax.plot(x, y, zorder=10)
```

You can also use the Axes property set_axisbelow() to control whether the grid lines are placed above or below your other plot elements.

11.1.12 Make the aspect ratio for plots equal

The Axes property set_aspect() controls the aspect ratio of the axes. You can set it to be 'auto', 'equal', or some ratio which controls the ratio:

```python
ax = fig.add_subplot(111, aspect='equal')
```

11.1.13 Multiple y-axis scales

A frequent request is to have two scales for the left and right y-axis, which is possible using twinx() (more than two scales are not currently supported, though it is on the wish list). This works pretty well, though there are some quirks when you are trying to interactively pan and zoom, because both scales do not get the signals.

The approach uses twinx() (and its sister twiny()) to use 2 different axes, turning the axes rectangular frame off on the 2nd axes to keep it from obscuring the first, and manually setting the tick locs and labels as desired. You can use separate matplotlib.ticker formatters and locators as desired because the two axes are independent.

11.1. Plotting: howto
11.1.14 Generate images without having a window appear

Simply do not call `show`, and directly save the figure to the desired format:

```python
import matplotlib.pyplot as plt
plt.plot([1, 2, 3])
plt.savefig('myfig.png')
```

See also:

`Matplotlib in a web application server` for information about running matplotlib inside of a web application.

11.1.15 Use `show()`

When you want to view your plots on your display, the user interface backend will need to start the GUI mainloop. This is what `show()` does. It tells Matplotlib to raise all of the figure windows created so far and start the mainloop. Because this mainloop is blocking by default (i.e., script execution is paused), you should only call this once per script, at the end. Script execution is resumed after the last window is closed. Therefore, if you are using Matplotlib to generate only images and do not want a user interface window, you do not need to call `show` (see `Generate images without having a window appear` and `What is a backend`?).

**Note:** Because closing a figure window invokes the destruction of its plotting elements, you
should call `savefig()` before calling `show` if you wish to save the figure as well as view it.

New in version v1.0.0: `show` now starts the GUI mainloop only if it isn’t already running. Therefore, multiple calls to `show` are now allowed.

Having `show` block further execution of the script or the python interpreter depends on whether Matplotlib is set for interactive mode or not. In non-interactive mode (the default setting), execution is paused until the last figure window is closed. In interactive mode, the execution is not paused, which allows you to create additional figures (but the script won’t finish until the last figure window is closed).

**Note:** Support for interactive/non-interactive mode depends upon the backend. Until version 1.0.0 (and subsequent fixes for 1.0.1), the behavior of the interactive mode was not consistent across backends. As of v1.0.1, only the macosx backend differs from other backends because it does not support non-interactive mode.

Because it is expensive to draw, you typically will not want Matplotlib to redraw a figure many times in a script such as the following:

```python
plot([1,2,3])  # draw here ?
xlabel('time') # and here ?
ylabel('volts') # and here ?
title('a simple plot') # and here ?
show()
```

However, it is **possible** to force Matplotlib to draw after every command, which might be what you want when working interactively at the python console (see Using matplotlib in a python shell), but in a script you want to defer all drawing until the call to `show`. This is especially important for complex figures that take some time to draw. `show()` is designed to tell Matplotlib that you’re all done issuing commands and you want to draw the figure now.

**Note:** `show()` should typically only be called at most once per script and it should be the last line of your script. At that point, the GUI takes control of the interpreter. If you want to force a figure draw, use `draw()` instead.

Many users are frustrated by `show` because they want it to be a blocking call that raises the figure, pauses the script until they close the figure, and then allow the script to continue running until the next figure is created and the next show is made. Something like this:

```python
# WARNING : illustrating how NOT to use show
for i in range(10):
    # make figure i
    show()
```

This is not what show does and unfortunately, because doing blocking calls across user interfaces can be tricky, is currently unsupported, though we have made significant progress towards supporting blocking events.

New in version v1.0.0: As noted earlier, this restriction has been relaxed to allow multiple calls to `show`. In most backends, you can now expect to be able to create new figures and raise them in a subsequent call to `show` after closing the figures from a previous call to `show`. 
11.1.16 Interpreting box plots and violin plots

Tukey’s box plots (Robert McGill, John W. Tukey and Wayne A. Larsen: “The American Statistician” Vol. 32, No. 1, Feb., 1978, pp. 12-16) are statistical plots that provide useful information about the data distribution such as skewness. However, bar plots with error bars are still the common standard in most scientific literature, and thus, the interpretation of box plots can be challenging for the unfamiliar reader. The figure below illustrates the different visual features of a box plot.

Violin plots are closely related to box plots but add useful information such as the distribution of the sample data (density trace). Violin plots were added in Matplotlib 1.4.

11.1.17 Working with threads

Matplotlib is not thread-safe: in fact, there are known race conditions that affect certain artists. Hence, if you work with threads, it is your responsibility to set up the proper locks to serialize access to Matplotlib artists.

Note that (for the case where you are working with an interactive backend) most GUI back-ends require being run from the main thread as well.

11.2 Contributing: howto

11.2.1 Request a new feature

Is there a feature you wish Matplotlib had? Then ask! The best way to get started is to email the developer mailing list for discussion. This is an open source project developed primarily in the contributors free time, so there is no guarantee that your feature will be added. The best way to get the feature you need added is to contribute it yourself.
11.2.2 Reporting a bug or submitting a patch

The development of Matplotlib is organized through github. If you would like to report a bug or submit a patch please use that interface.

To report a bug create an issue on github (this requires having a github account). Please include a Short, Self Contained, Correct (Compilable), Example demonstrating what the bug is. Including a clear, easy to test example makes it easy for the developers to evaluate the bug. Expect that the bug reports will be a conversation. If you do not want to register with github, please email bug reports to the mailing list.

The easiest way to submit patches to Matplotlib is through pull requests on github. Please see the The Matplotlib Developers’ Guide for the details.

11.2.3 Contribute to Matplotlib documentation

Matplotlib is a big library, which is used in many ways, and the documentation has only scratched the surface of everything it can do. So far, the place most people have learned all these features are through studying the examples (Search examples), which is a recommended and great way to learn, but it would be nice to have more official narrative documentation guiding people through all the dark corners. This is where you come in.

There is a good chance you know more about Matplotlib usage in some areas, the stuff you do every day, than many of the core developers who wrote most of the documentation. Just pulled your hair out compiling Matplotlib for Windows? Write a FAQ or a section for the Installation page. Are you a digital signal processing wizard? Write a tutorial on the signal analysis plotting functions like xcorr(), psd() and specgram(). Do you use Matplotlib with django or other popular web application servers? Write a FAQ or tutorial and we’ll find a place for it in the User’s Guide. And so on... I think you get the idea.

Matplotlib is documented using the sphinx extensions to restructured text (ReST). sphinx is an extensible python framework for documentation projects which generates HTML and PDF, and is pretty easy to write; you can see the source for this document or any page on this site by clicking on the Show Source link at the end of the page in the sidebar.

The sphinx website is a good resource for learning sphinx, but we have put together a cheat-sheet at Writing documentation which shows you how to get started, and outlines the Matplotlib conventions and extensions, e.g., for including plots directly from external code in your documents.

Once your documentation contributions are working (and hopefully tested by actually building the docs) you can submit them as a patch against git. See Install git and Reporting a bug or submitting a patch. Looking for something to do? Search for TODO or look at the open issues on github.

11.3 Matplotlib in a web application server

In general, the simplest solution when using Matplotlib in a web server is to completely avoid using pyplot (pyplot maintains references to the opened figures to make show work, but this will cause memory leaks unless the figures are properly closed). Since Matplotlib 3.1, one can directly create figures using the Figure constructor and save them to in-memory buffers. The following example uses Flask, but other frameworks work similarly:
import base64
from io import BytesIO

from flask import Flask
from matplotlib.figure import Figure

app = Flask(__name__)

@app.route("/")
def hello():
    # Generate the figure **without using pyplot**.
    fig = Figure()
    ax = fig.subplots()
    ax.plot([1, 2])
    # Save it to a temporary buffer.
    buf = BytesIO()
    fig.savefig(buf, format="png")
    # Embed the result in the html output.
    data = base64.b64encode(buf.getbuffer()).decode("ascii")
    return f"<img src='data:image/png;base64,{data}'>"

When using Matplotlib versions older than 3.1, it is necessary to explicitly instantiate an Agg canvas; see e.g. /gallery/user_interfaces/canvasagg.

11.3.1 Clickable images for HTML

Andrew Dalke of Dalke Scientific has written a nice article on how to make html click maps with Matplotlib agg PNGs. We would also like to add this functionality to SVG. If you are interested in contributing to these efforts that would be great.

11.4 Search examples

The nearly 300 code examples-index included with the Matplotlib source distribution are full-text searchable from the search page, but sometimes when you search, you get a lot of results from the The object-oriented API or other documentation that you may not be interested in if you just want to find a complete, free-standing, working piece of example code. To facilitate example searches, we have tagged every code example page with the keyword codex for code example which shouldn’t appear anywhere else on this site except in the FAQ. So if you want to search for an example that uses an ellipse, search for codex ellipse.

TROUBLESHOOTING

Contents

• Troubleshooting
  - Obtaining Matplotlib version
  - matplotlib install location
  - matplotlib configuration and cache directory locations
  - Getting help
  - Problems with recent git versions

12.1 Obtaining Matplotlib version

To find out your Matplotlib version number, import it and print the \_version\_ attribute:

```python
>>> import matplotlib
>>> matplotlib.__version__
'0.98.0'
```

12.2 matplotlib install location

You can find what directory Matplotlib is installed in by importing it and printing the \_file\_ attribute:

```python
>>> import matplotlib
>>> matplotlib.__file__
'/home/jdhunter/dev/lib64/python2.5/site-packages/matplotlib/__init__.pyc'
```

12.3 matplotlib configuration and cache directory locations

Each user has a Matplotlib configuration directory which may contain a \matplotlibrc file. To locate your matplotlib/ configuration directory, use matplotlib.get_configdir():

```python
```
On unix-like systems, this directory is generally located in your HOME directory under the config/ directory.

In addition, users have a cache directory. On unix-like systems, this is separate from the configuration directory by default. To locate your .cache/ directory, use matplotlib.get_cachedir():

```python
>>> import matplotlib as mpl
>>> mpl.get_cachedir()
'/home/darren/.cache/matplotlib'
```

On windows, both the config directory and the cache directory are the same and are in your Documents and Settings or Users directory by default:

```python
>>> import matplotlib as mpl
>>> mpl.get_configdir()
'C:\Documents and Settings\jdhunter\.matplotlib'
>>> mpl.get_cachedir()
'C:\Documents and Settings\jdhunter\.matplotlib'
```

If you would like to use a different configuration directory, you can do so by specifying the location in your MPLCONFIGDIR environment variable – see Setting environment variables in Linux and OS-X. Note that MPLCONFIGDIR sets the location of both the configuration directory and the cache directory.

### 12.4 Getting help

There are a number of good resources for getting help with Matplotlib. There is a good chance your question has already been asked:

- The mailing list archive.
- Github issues.
- Stackoverflow questions tagged matplotlib.

If you are unable to find an answer to your question through search, please provide the following information in your e-mail to the mailing list:

- Your operating system (Linux/UNIX users: post the output of `uname -a`).
- Matplotlib version:

  ```
  python -c "import matplotlib; print matplotlib.__version__"
  ```

- Where you obtained Matplotlib (e.g., your Linux distribution’s packages, Github, PyPi, or Anaconda or Enthought Canopy).
- Any customizations to your `matplotlibrc` file (see Customizing Matplotlib with style sheets and rcParams).
• If the problem is reproducible, please try to provide a minimal, standalone Python script that demonstrates the problem. This is the critical step. If you can't post a piece of code that we can run and reproduce your error, the chances of getting help are significantly diminished. Very often, the mere act of trying to minimize your code to the smallest bit that produces the error will help you find a bug in your code that is causing the problem.

• Matplotlib provides debugging information through the logging library, and a helper function to set the logging level: one can call

```
plt.set_loglevel("info")  # or "debug" for more info
```

to obtain this debugging information.

Standard functions from the logging module are also applicable; e.g. one could call `logging.basicConfig(level="DEBUG")` even before importing Matplotlib (this is in particular necessary to get the logging info emitted during Matplotlib’s import), or attach a custom handler to the “matplotlib” logger. This may be useful if you use a custom logging configuration.

If you compiled Matplotlib yourself, please also provide:

• any changes you have made to setup.py or setupext.py.

• the output of:

```
rm -rf build
python setup.py build
```

The beginning of the build output contains lots of details about your platform that are useful for the Matplotlib developers to diagnose your problem.

• your compiler version – e.g., gcc --version.

Including this information in your first e-mail to the mailing list will save a lot of time.

You will likely get a faster response writing to the mailing list than filing a bug in the bug tracker. Most developers check the bug tracker only periodically. If your problem has been determined to be a bug and can not be quickly solved, you may be asked to file a bug in the tracker so the issue doesn’t get lost.

### 12.5 Problems with recent git versions

First make sure you have a clean build and install (see *How to completely remove Matplotlib*), get the latest git update, install it and run a simple test script in debug mode:

```
rm -rf /path/to/site-packages/matplotlib*/
git clean -xdf
git pull
python -mpip install -v . > build.out
python examples/pylab_examples/simple_plot.py --verbose-debug > run.out
```

and post build.out and run.out to the matplotlib-devel mailing list (please do not post git problems to the users list).

Of course, you will want to clearly describe your problem, what you are expecting and what you are getting, but often a clean build and install will help. See also Getting help.
13.1 Setting environment variables in Linux and OS-X

To list the current value of $PYTHONPATH$, which may be empty, try:

```
echo $PYTHONPATH
```

The procedure for setting environment variables in depends on what your default shell is. 
$BASH$ seems to be the most common, but $CSH$ is also common. You should be able to determine which by running at the command prompt:
13.1.1 BASH/KSH

To create a new environment variable:

```bash
export PYTHONPATH=~/.Python
```

To prepend to an existing environment variable:

```bash
export PATH=~/.bin:${PATH}
```

The search order may be important to you, do you want `~/.bin` to be searched first or last? To append to an existing environment variable:

```bash
export PATH=${PATH}:~/.bin
```

To make your changes available in the future, add the commands to your `~/.bashrc` file.

13.1.2 CSH/TCSH

To create a new environment variable:

```csh
setenv PYTHONPATH ~/.Python
```

To prepend to an existing environment variable:

```csh
setenv PATH ~/.bin:${PATH}
```

The search order may be important to you, do you want `~/.bin` to be searched first or last? To append to an existing environment variable:

```csh
setenv PATH ${PATH}:~/.bin
```

To make your changes available in the future, add the commands to your `~/.cshrc` file.

13.2 Setting environment variables in windows

Open the Control Panel (Start → Control Panel), start the System program. Click the Advanced tab and select the Environment Variables button. You can edit or add to the User Variables.
WORKING WITH MATPLOTLIB IN VIRTUAL ENVIRONMENTS

While Matplotlib itself runs fine in a virtual environment (venv), some of the GUI frameworks that Matplotlib uses for interactive figures are tricky to install in a venv. Everything below assumes some familiarity with the Matplotlib backends as found in What is a backend?.

If you only use the IPython and Jupyter Notebook’s inline and notebook backends, or non-interactive backends, you should not have any issues and can ignore everything below.

Likewise, the Tk framework (TkAgg backend) does not require any external dependencies and is normally always available. On certain Linux distributions, a package named python-tk (or similar) needs to be installed.

Otherwise, the situation (at the time of writing) is as follows:

<table>
<thead>
<tr>
<th>framework</th>
<th>bindings</th>
<th>pip-installable?</th>
<th>conda or conda-fg-e-installable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Qt5</td>
<td>PyQt5</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>Qt5</td>
<td>PySide2</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>Qt4</td>
<td>PyQt4</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>Qt4</td>
<td>PySide</td>
<td>OSX and Windows</td>
<td>yes</td>
</tr>
<tr>
<td>GTK3</td>
<td>PyGObject</td>
<td>yes(^1)</td>
<td>Linux and OSX</td>
</tr>
<tr>
<td>wxWidgets</td>
<td>wxPython</td>
<td>yes(^2)</td>
<td>yes</td>
</tr>
</tbody>
</table>

For cases where the framework is not installable in a venv, it needs to be installed in the global (system) site-packages, and then made available from within the venv. This can be achieved by either of the following methods (in all cases, the system-wide Python and the venv Python must be of the same version):

- vext allows controlled access from within the venv to specific system-wide packages. A specific package needs to be installed for each framework, e.g. vext.pyqt5, etc. It is recommended to use vext>=0.7.0 as earlier versions misconfigure the logging system.

- Using the --system-site-packages option when creating an environment adds all system-wide packages to the virtual environment. However, this breaks the isolation between the virtual environment and the system install. Among other issues it results in hard to debug problems with system packages shadowing the environment packages. If you use virtualenv (rather than the stdlib’s venv) together with virtualenvwrapper, this can be toggled with the toggleglobalsitepackages command.

---

\(^1\) No wheels available, see https://pygobject.readthedocs.io/en/latest/devguide/dev_environ.html for build instructions.

\(^2\) OSX and Windows wheels available on PyPI. Linux wheels available but not on PyPI, see https://wxpython.org/pages/downloads/.
Part III

API Overview
API CHANGES

If updating Matplotlib breaks your scripts, this list may help you figure out what caused the breakage and how to fix it by updating your code.

For API changes in older versions see

15.1 Old API Changes

15.1.1 Changes for 0.40

- Artist
  * __init__ takes a DPI instance and a Bound2D instance which is the bounding box of the artist in display coords
  * get_window_extent returns a Bound2D instance
  * set_size is removed; replaced by bbox and dpi
  * the clip_gc method is removed. Artists now clip themselves with their box
  * added _clipOn boolean attribute. If True, gc clip to bbox.

- AxisTextBase
  * Initialized with a transx, transy which are Transform instances
  * set_drawing_area removed
  * get_left_right and get_top_bottom are replaced by get_window_extent

- Line2D Patches now take transx, transy
  * Initialized with a transx, transy which are Transform instances

- Patches
  * Initialized with a transx, transy which are Transform instances

- FigureBase attributes dpi is a DPI instance rather than scalar and new attribute bbox is a Bound2D in display coords, and I got rid of the left, width, height, etc... attributes. These are now accessible as, for example, bbox.x.min is left, bbox.x.interval() is width, bbox.y.max is top, etc...

- GcfBase attribute pagesize renamed to figsize

- Axes

(continues on next page)
- removed figbg attribute
- added fig instance to __init__
- resizing is handled by figure call to resize.

- Subplot
  - added fig instance to __init__

- Renderer methods for patches now take gcEdge and gcFace instances.
  gcFace=None takes the place of filled=False

- True and False symbols provided by cbook in a python2.3 compatible way

- new module transforms supplies Bound1D, Bound2D and Transform instances and more

- Changes to the MATLAB helpers API

  * _matlab_helpers.GcfBase is renamed by Gcf. Backends no longer need to derive from this class. Instead, they provide a factory function new_figure_manager(num, figsize, dpi). The destroy method of the GcfDerived from the backends is moved to the derived FigureManager.

  * FigureManagerBase moved to backend_bases

  * Gcf.get_all_figwins renamed to Gcf.get_all_fig_managers

Jeremy:

Make sure to self._reset = False in AxisTextWX._set_font. This was something missing in my backend code.

15.1.2 Changes for 0.42

* Refactoring AxisText to be backend independent. Text drawing and get_window_extent functionality will be moved to the Renderer.

* backend_bases.AxisTextBase is now text.Text module

* All the erase and reset functionality removed from AxisText - not needed with double buffered drawing. Ditto with state change. Text instances have a get_prop_tup method that returns a hashable tuple of text properties which you can use to see if text props have changed, e.g., by caching a font or layout instance in a dict with the prop tup as a key -- see RendererGTK.get_pango_layout in backend_gtk for an example.

* Text._get_xy_display renamed Text.get_xy_display

(continues on next page)
* Artist set_renderer and wash_brushes methods removed

* Moved Legend class from matplotlib.axes into matplotlib.legend

* Moved Tick, XTick, YTick, Axis, XAxis, YAxis from matplotlib.axes to matplotlib.axis

* moved process_text_args to matplotlib.text

* After getting Text handled in a backend independent fashion, the import process is much cleaner since there are no longer cyclic dependencies

* matplotlib.matlab._get_current_fig_manager renamed to matplotlib.matlab.get_current_fig_manager to allow user access to the GUI window attribute, e.g., figManager.window for GTK and figManager.frame for wx

15.1.3 Changes for 0.50

* refactored Figure class so it is no longer backend dependent. FigureCanvasBackend takes over the backend specific duties of the Figure. matplotlib.backend_bases.FigureBase moved to matplotlib.figure.Figure.

* backends must implement FigureCanvasBackend (the thing that controls the figure and handles the events if any) and FigureManagerBackend (wraps the canvas and the window for MATLAB interface). FigureCanvasBase implements a backend switching mechanism

* Figure is now an Artist (like everything else in the figure) and is totally backend independent

* GDFONTPATH renamed to TTFPATH

* backend faceColor argument changed to rgbFace

* colormap stuff moved to colors.py

* arg_to_rgb in backend_bases moved to class ColorConverter in colors.py

* GD users must upgrade to gd-2.0.22 and gdmodule-0.52 since new gd features (clipping, antialiased lines) are now used.

* Renderer must implement points_to_pixels

Migrating code:
MATLAB interface:

The only API change for those using the MATLAB interface is in how you call figure redraws for dynamically updating figures. In the old API, you did

```python
fig.draw()
```

In the new API, you do

```python
manager = get_current_fig_manager()
manager.canvas.draw()
```

See the examples system_monitor.py, dynamic_demo.py, and anim.py

API

There is one important API change for application developers. Figure instances used subclass GUI widgets that enabled them to be placed directly into figures. e.g., FigureGTK subclassed gtk.DrawingArea. Now the Figure class is independent of the backend, and FigureCanvas takes over the functionality formerly handled by Figure. In order to include figures into your apps, you now need to do, for example

```python
# gtk example
fig = Figure(figsize=(5,4), dpi=100)
canvas = FigureCanvasGTK(fig)  # a gtk.DrawingArea
canvas.show()
vbox.pack_start(canvas)
```

If you use the NavigationToolbar, this in now initialized with a FigureCanvas, not a Figure. The examples embedding_in_gtk.py, embedding_in_gtk2.py, and mpl_with_glade.py all reflect the new API so use these as a guide.

All prior calls to

```python
figure.draw() and
figure.print_figure(args)
```

should now be

```python
canvas.draw() and
canvas.print_figure(args)
```

Apologies for the inconvenience. This refactorization brings significant more freedom in developing matplotlib and should bring better plotting capabilities, so I hope the inconvenience is worth it.
15.1.4 Changes for 0.54

MATLAB interface

dpi

Several of the backends used a PIXELS_PER_INCH hack that I added to try and make images render consistently across backends. This just complicated matters. So you may find that some font sizes and line widths appear different than before. Apologies for the inconvenience. You should set the dpi to an accurate value for your screen to get true sizes.

pcolor and scatter

There are two changes to the MATLAB interface API, both involving the patch drawing commands. For efficiency, pcolor and scatter have been rewritten to use polygon collections, which are a new set of objects from matplotlib.collections designed to enable efficient handling of large collections of objects. These new collections make it possible to build large scatter plots or pcolor plots with no loops at the python level, and are significantly faster than their predecessors. The original pcolor and scatter functions are retained as pcolor_classic and scatter_classic.

The return value from pcolor is a PolyCollection. Most of the properties that are available on rectangles or other patches are also available on PolyCollections, e.g., you can say:

```
c = scatter(blah, blah)
c.set_linewidth(1.0)
c.set_facecolor('r')
c.set_alpha(0.5)
```

or:

```
c = scatter(blah, blah)
set(c, 'linewidth', 1.0, 'facecolor', 'r', 'alpha', 0.5)
```

Because the collection is a single object, you no longer need to loop over the return value of scatter or pcolor to set properties for the entire list.

If you want the different elements of a collection to vary on a property, e.g., to have different line widths, see matplotlib.collections for a discussion on how to set the properties as a sequence.

For scatter, the size argument is now in points^2 (the area of the symbol in points) as in MATLAB and is not in data coords as before. Using sizes in data coords caused several problems. So you will need to adjust your size arguments accordingly or use scatter_classic.

mathtext spacing

For reasons not clear to me (and which I’ll eventually fix) spacing no longer works in font groups. However, I added three new spacing commands which compensate for this ” (regular space), '/' (small space) and ‘hspace{frac}’ where frac is a fraction of fontsize in points. You will need to quote spaces in font strings, is:
Object interface - Application programmers

Autoscaling

The x and y axis instances no longer have autoscale view. These are handled by axes.autoscale_view

Axes creation

You should not instantiate your own Axes any more using the OO API. Rather, create a Figure as before and in place of:

```python
f = Figure(figsize=(5,4), dpi=100)
a = Subplot(f, 111)
f.add_axis(a)
```

use:

```python
f = Figure(figsize=(5,4), dpi=100)
a = f.add_subplot(111)
```

That is, add_axis no longer exists and is replaced by:

- add_axes(rect, axisbg=defaultcolor, frameon=True)
- add_subplot(num, axisbg=defaultcolor, frameon=True)

Artist methods

If you define your own Artists, you need to rename the _draw method to draw

Bounding boxes

matplotlib.transforms.Bound2D is replaced by matplotlib.transforms.Bbox. If you want to construct a bbox from left, bottom, width, height (the signature for Bound2D), use matplotlib.transforms.lbwh_to_bbox, as in

```python
bbox = clickBBox = lbwh_to_bbox(left, bottom, width, height)
```

The Bbox has a different API than the Bound2D. e.g., if you want to get the width and height of the bbox

- **OLD::** width = fig.bbox.x.interval() height = fig.bbox.y.interval()
- **New::** width = fig.bbox.width() height = fig.bbox.height()
Object constructors

You no longer pass the bbox, dpi, or transforms to the various Artist constructors. The old way or creating lines and rectangles was cumbersome because you had to pass so many attributes to the Line2D and Rectangle classes not related directly to the geometry and properties of the object. Now default values are added to the object when you call axes.add_line or axes.add_patch, so they are hidden from the user.

If you want to define a custom transformation on these objects, call o.set_transform(trans) where trans is a Transformation instance.

In prior versions of you wanted to add a custom line in data coords, you would have to do

```python
l = Line2D(dpi, bbox, x, y, color = color, transx = transx, transy = transy, )
```

now all you need is

```python
l = Line2D(x, y, color=color)
```

and the axes will set the transformation for you (unless you have set your own already, in which case it will eave it unchanged)

Transformations

The entire transformation architecture has been rewritten. Previously the x and y transformations where stored in the xaxis and yaxis instances. The problem with this approach is it only allows for separable transforms (where the x and y transformations don’t depend on one another). But for cases like polar, they do. Now transformations operate on x,y together. There is a new base class matplotlib.transforms.Transformation and two concrete implementations, matplotlib.transforms.SeparableTransformation and matplotlib.transforms.Affine. The SeparableTransformation is constructed with the bounding box of the input (this determines the rectangular coordinate system of the input, i.e., the x and y view limits), the bounding box of the display, and possibly nonlinear transformations of x and y. The 2 most frequently used transformations, data coordinates -> display and axes coordinates -> display are available as ax.transData and ax.transAxes. See alignment_demo.py which uses axes coords.

Also, the transformations should be much faster now, for two reasons

- they are written entirely in extension code
- because they operate on x and y together, they can do the entire transformation in one loop. Earlier I did something along the lines of:

```python
xt = sx*func(x) + tx
yt = sy*func(y) + ty
```

Although this was done in numerix, it still involves 6 length(x) for-loops (the multiply, add, and function evaluation each for x and y). Now all of that is done in a single pass.

If you are using transformations and bounding boxes to get the cursor position in data coordinates, the method calls are a little different now. See the updated examples/coords_demo.py which shows you how to do this.
Likewise, if you are using the artist bounding boxes to pick items on the canvas with the GUI, the bbox methods are somewhat different. You will need to see the updated examples/object_picker.py.

See unit/transforms_unit.py for many examples using the new transformations.

15.1.5 Changes for 0.54.3

removed the set_default_font / get_default_font scheme from the font_manager to unify customization of font defaults with the rest of the rc scheme. See examples/font_properties_demo.py and help(rc) in matplotlib.matlab.

15.1.6 Changes for 0.60

ColormapJet and Grayscale are deprecated. For backwards compatibility, they can be obtained either by doing

```python
from matplotlib.cm import ColormapJet
```
or

```python
from matplotlib.matlab import *
```

They are replaced by cm.jet and cm.grey

15.1.7 Changes for 0.61

canvas.connect is now deprecated for event handling. use mpl_connect and mpl_disconnect instead. The callback signature is func(event) rather than func(widget, event)

15.1.8 Changes for 0.63

Dates are now represented internally as float days since 0001-01-01, UTC.

All date tickers and formatters are now in matplotlib.dates, rather than matplotlib.tickers

converters have been abolished from all functions and classes. num2date and date2num are now the converter functions for all date plots

Most of the date tick locators have a different meaning in their constructors. In the prior implementation, the first argument was a

(continues on next page)
base and multiples of the base were ticked. e.g.,

    HourLocator(5)  # old: tick every 5 minutes

In the new implementation, the explicit points you want to tick are provided as a number or sequence

    HourLocator(range(0,5,61))  # new: tick every 5 minutes

This gives much greater flexibility. I have tried to make the default constructors (no args) behave similarly, where possible.

Note that YearLocator still works under the base/multiple scheme. The difference between the YearLocator and the other locators is that years are not recurrent.

Financial functions:

    matplotlib.finance.quotes_historical_yahoo(ticker, date1, date2)

date1, date2 are now datetime instances. Return value is a list of quotes where the quote time is a float - days since gregorian start, as returned by date2num

    See examples/finance_demo.py for example usage of new API

15.1.9 Changes for 0.65

mpl_connect and mpl_disconnect in the MATLAB interface renamed to connect and disconnect

Did away with the text methods for angle since they were ambiguous. fontangle could mean fontstyle (oblique, etc) or the rotation of the text. Use style and rotation instead.

15.1.10 Changes for 0.65.1

removed add_axes and add_subplot from backend_bases. Use figure.add_axes and add_subplot instead. The figure now manages the current axes with gca and sca for get and set current axes. If you have code you are porting which called, e.g., figmanager.add_axes, you can now simply do figmanager.canvas.figure.add_axes.
15.1.11 Changes for 0.70

MplEvent factored into a base class Event and derived classes
MouseEvent and KeyEvent

Removed definct set_measurement in wx toolbar

15.1.12 Changes for 0.71

Significant numerix namespace changes, introduced to resolve
namespace clashes between python built-ins and mlab names.
Refactored numerix to maintain separate modules, rather than
folding all these names into a single namespace. See the following
mailing list threads for more information and background

OLD usage

from matplotlib.numerix import array, mean, fft

NEW usage

from matplotlib.numerix import array
from matplotlib.numerix.mlab import mean
from matplotlib.numerix.fft import fft

numerix dir structure mirrors numarray (though it is an incomplete
implementation)

numerix
numerix/mlab
numerix/linear_algebra
numerix/fft
numerix/random_array

but of course you can use 'numerix : Numeric' and still get the
symbols.

pylab still imports most of the symbols from Numerix, MLab, fft,
etc, but is more cautious. For names that clash with python names
(min, max, sum), pylab keeps the builtins and provides the numeric
versions with an a* prefix, e.g., (amin, amax, asum)
15.1.13 Changes for 0.72

- Line2D, Text, and Patch copy_properties renamed update_from and moved into artist base class
- LineCollections.color renamed to LineCollections.set_color for consistency with set/get introspection mechanism,
- pylab figure now defaults to num=None, which creates a new figure with a guaranteed unique number
- contour method syntax changed - now it is MATLAB compatible
  
  unchanged: contour(Z)
  old: contour(Z, x=Y, y=Y)
  new: contour(X, Y, Z)

  see http://matplotlib.sf.net/matplotlib.pylab.html#-contour

- Increased the default resolution for save command.
- Renamed the base attribute of the ticker classes to _base to avoid conflict with the base method. Sitt for subs
- subs=none now does autosubbing in the tick locator.
- New subplots that overlap old will delete the old axes. If you do not want this behavior, use fig.add_subplot or the axes command

15.1.14 Changes for 0.73

- Removed deprecated ColormapJet and friends
- Removed all error handling from the verbose object
- figure num of zero is now allowed

15.1.15 Changes for 0.80

- xlim/ylim/axis always return the new limits regardless of arguments. They now take kwargs which allow you to selectively change the upper or lower limits while leaving unnamed limits unchanged. See help(xlim) for example
15.1.16 Changes for 0.81

- pylab and artist "set" functions renamed to setp to avoid clash with python2.4 built-in set. Current version will issue a deprecation warning which will be removed in future versions.

- imshow interpolation arguments changes for advanced interpolation schemes. See help imshow, particularly the interpolation, filternorm and filterrad kwargs.

- Support for masked arrays has been added to the plot command and to the Line2D object. Only the valid points are plotted. A "valid_only" kwarg was added to the get_xdata() and get_ydata() methods of Line2D; by default it is False, so that the original data arrays are returned. Setting it to True returns the plottable points.

- contour changes:

  Masked arrays: contour and contourf now accept masked arrays as the variable to be contoured. Masking works correctly for contour, but a bug remains to be fixed before it will work for contourf. The "badmask" kwarg has been removed from both functions.

  Level argument changes:

  Old version: a list of levels as one of the positional arguments specified the lower bound of each filled region; the upper bound of the last region was taken as a very large number. Hence, it was not possible to specify that z values between 0 and 1, for example, be filled, and that values outside that range remain unfilled.

  New version: a list of N levels is taken as specifying the boundaries of N-1 z ranges. Now the user has more control over what is colored and what is not. Repeated calls to contourf (with different colormaps or color specifications, for example) can be used to color different ranges of z. Values of z outside an expected range are left uncolored.

  Example:
  Old: contourf(z, [0, 1, 2]) would yield 3 regions: 0-1, 1-2, and >2.
  New: it would yield 2 regions: 0-1, 1-2. If the same 3 regions were desired, the equivalent list of levels would be [0, 1, 2, 1e38].

15.1.17 Changes for 0.82

- toolbar import change in GTKAgg, GTKCairo and WXAgg

(continues on next page)
- Added subplot config tool to GTK* backends -- note you must now import the NavigationToolbar2 from your backend of choice rather than from backend_gtk because it needs to know about the backend specific canvas -- see examples/embedding_in_gtk2.py. Ditto for wx backend -- see examples/embedding_in_wxagg.py

- hist bin change

Sean Richards notes there was a problem in the way we created the binning for histogram, which made the last bin underrepresented. From his post:

I see that hist uses the linspace function to create the bins and then uses searchsorted to put the values in their correct bin. That's all good but I am confused over the use of linspace for the bin creation. I wouldn't have thought that it does what is needed, to quote the docstring it creates a "Linear spaced array from min to max". For it to work correctly shouldn't the values in the bins array be the same bound for each bin? (i.e. each value should be the lower bound of a bin). To provide the correct bins for hist would it not be something like

```python
def bins(xmin, xmax, N):
    if N==1: return xmax
    dx = (xmax-xmin)/N # instead of N-1
    return xmin + dx*arange(N)
```

This suggestion is implemented in 0.81. My test script with these changes does not reveal any bias in the binning

```python
from matplotlib.numerix.mlab import randn, rand, zeros, Float
from matplotlib.mlab import hist, mean

Nbins = 50
Ntests = 200
results = zeros((Ntests, Nbins), typecode=Float)
for i in range(Ntests):
    print 'computing', i
    x = rand(10000)
    n, bins = hist(x, Nbins)
    results[i] = n
    print mean(results)
```

15.1.18 Changes for 0.83

- Made HOME/.matplotlib the new config dir where the matplotlibrc file, the ttf.cache, and the tex.cache live. The new default
filenames in .matplotlib have no leading dot and are not hidden. e.g., the new names are matplotlibrc, tex.cache, and ttffont.cache. This is how ipython does it so it must be right.

If old files are found, a warning is issued and they are moved to the new location.

- backends/__init__.py no longer imports new_figure_manager, draw_if_interactive and show from the default backend, but puts these imports into a call to pylab_setup. Also, the Toolbar is no longer imported from WX/WXAgg. New usage:

```python
from backends import pylab_setup
new_figure_manager, draw_if_interactive, show = pylab_setup()
```

- Moved Figure.get_width_height() to FigureCanvasBase. It now returns int instead of float.

### 15.1.19 Changes for 0.84

Unified argument handling between hlines and vlines. Both now take optionally a fmt argument (as in plot) and a keyword args that can be passed onto Line2D.

Removed all references to "data clipping" in rc and lines.py since these were not used and not optimized. I'm sure they'll be resurrected later with a better implementation when needed.

'set' removed - no more deprecation warnings. Use 'setp' instead.

Backend developers: Added flipud method to image and removed it from to_str. Removed origin kwarg from backend.draw_image. origin is handled entirely by the frontend now.

### 15.1.20 Changes for 0.85

Made xtick and ytick separate props in rc

made pos=None the default for tick formatters rather than 0 to indicate "not supplied"

Removed "feature" of minor ticks which prevents them from overlapping major ticks. Often you want major and minor ticks at the same place, and can offset the major ticks with the pad. This could be made configurable

Changed the internal structure of contour.py to a more OO style. Calls to contour or contourf in axes.py or pylab.py now return (continues on next page)
a ContourSet object which contains references to the LineCollections or PolyCollections created by the call, as well as the configuration variables that were used. The ContourSet object is a "mappable" if a colormap was used.

Added a clip_ends kwarg to contourf. From the docstring:

* clip_ends = True
  * If False, the limits for color scaling are set to the minimum and maximum contour levels.
  * True (default) clips the scaling limits. Example:
    * if the contour boundaries are $V = [-100, 2, 1, 0, 1, 2, 100]$, then the scaling limits will be $[-100, 100]$ if clip_ends is False, and $[-3, 3]$ if clip_ends is True.

Added kwargs linewidths, antialiased, and nchunk to contourf. These are experimental; see the docstring.

Changed Figure.colorbar():

kw argument order changed;

  * if mappable arg is a non-filled ContourSet, colorbar() shows lines instead if hof polygons.
  * if mappable arg is a filled ContourSet with clip_ends=True, the endpoints are not labelled, so as to give the correct impression of open-endedness.

Changed LineCollection.get_linewidths to get_linewidth, for consistency.

15.1.21 Changes for 0.86

Matplotlib data is installed into the matplotlib module. This is similar to package_data. This should get rid of having to check for many possibilities in _get_data_path(). The MATPLOTLIBDATA env key is still checked first to allow for flexibility.

1) Separated the color table data from cm.py out into a new file, _cm.py, to make it easier to find the actual code in cm.py and to add new colormaps. Everything from _cm.py is imported by cm.py, so the split should be transparent.

2) Enabled automatic generation of a colormap from a list of colors in contour; see modified examples/contour_demo.py.

3) Support for imshow of a masked array, with the ability to specify colors (or no color at all) for masked regions, and for regions that are above or below the normally mapped region. See examples/image_masked.py.

4) In support of the above, added two new classes, ListedColormap, and no_norm, to colors.py, and modified...
the Colormap class to include common functionality. Added a clip kwarg to the normalize class.

15.1.22 Changes for 0.87.7

Completely reworked the annotations API because I found the old API cumbersome. The new design is much more legible and easy to read. See matplotlib.text.Annotation and examples/annotation_demo.py

markeredgecolor and markerfacecolor cannot be configured in matplotlibrc any more. Instead, markers are generally colored automatically based on the color of the line, unless marker colors are explicitly set as kwargs - NN

Changed default comment character for load to '#' - JDH

math_parse_s_ft2font_svg from mathtext.py & mathtext2.py now returns width, height, svg_elements. svg_elements is an instance of Bunch (cmbook.py) and has the attributes svg_glyphs and svg_lines, which are both lists.

Renderer.draw_arc now takes an additional parameter, rotation. It specifies to draw the artist rotated in degrees anti-clockwise. It was added for rotated ellipses.

Renamed Figure.set_figsizes_inches to Figure.set_size_inches to better match the get method, Figure.get_size_inches.

Removed the copy_bbox_transform from transforms.py; added shallowcopy methods to all transforms. All transforms already had deepcopy methods.

FigureManager.resize(width, height): resize the window specified in pixels

barh: x and y args have been renamed to width and bottom respectively, and their order has been swapped to maintain a (position, value) order.

bar and barh: now accept kwarg 'edgecolor'.

bar and barh: The left, height, width and bottom args can now all be scalars or sequences; see docstring.

barh: now defaults to edge aligned instead of center aligned bars

bar, barh and hist: Added a keyword arg 'align' that controls between edge or center bar alignment.
Collections: PolyCollection and LineCollection now accept vertices or segments either in the original form \([(x,y), (x,y), ...]\) or as a 2D numerix array, with X as the first column and Y as the second. Contour and quiver output the numerix form. The transforms methods Bbox.update() and Transformation.seq_xy_tups() now accept either form.

Collections: LineCollection is now a ScalarMappable like PolyCollection, etc.

Specifying a grayscale color as a float is deprecated; use a string instead, e.g., 0.75 -> '0.75'.

Collections: initializers now accept any mpl color arg, or sequence of such args; previously only a sequence of rgba tuples was accepted.

Colorbar: completely new version and api; see docstring. The original version is still accessible as colorbar_classic, but is deprecated.

Contourf: "extend" kwarg replaces "clip_ends"; see docstring. Masked array support added to pcolormesh.

Modified aspect-ratio handling:
- Removed aspect kwarg from imshow
- Axes methods:
  - set_aspect(self, aspect, adjustable=None, anchor=None)
  - set_adjustable(self, adjustable)
  - set_anchor(self, anchor)
- Pylab interface:
  - axis('image')

Backend developers: ft2font's load_char now takes a flags argument, which you can OR together from the LOAD_XXX constants.

### 15.1.23 Changes for 0.90.0

All artists now implement a "pick" method which users should not call. Rather, set the "picker" property of any artist you want to pick on (the epsilon distance in points for a hit test) and register with the "pick_event" callback. See examples/pick_event_demo.py for details.

Bar, barh, and hist have "log" binary kwarg: log=True sets the ordinate to a log scale.

Boxplot can handle a list of vectors instead of just
an array, so vectors can have different lengths.

Plot can handle 2-D x and/or y; it plots the columns.

Added linewidth kwarg to bar and barh.

Made the default Artist._transform None (rather than invoking identity_transform for each artist only to have it overridden later). Use artist.get_transform() rather than artist._transform, even in derived classes, so that the default transform will be created lazily as needed.

New LogNorm subclass of Normalize added to colors.py. All Normalize subclasses have new inverse() method, and the __call__() method has a new clip kwarg.

Changed class names in colors.py to match convention: normalize -> Normalize, no_norm -> NoNorm. Old names are still available for now.

Removed obsolete pcolor_classic command and method.

Removed lineprops and markerprops from the Annotation code and replaced them with an arrow configurable with kwarg arrowprops. See examples/annotation_demo.py - JDH

15.1.24 Changes for 0.90.1

The file dviread.py has a (very limited and fragile) dvi reader for usetex support. The API might change in the future so don’t depend on it yet.

Removed deprecated support for a float value as a gray-scale; now it must be a string, like '0.5'. Added alpha kwarg to ColorConverter.to_rgba_list.

New method set_bounds(vmin, vmax) for formatters, locators sets the viewInterval and dataInterval from floats.

Removed deprecated colorbar_classic.

Line2D.get_xdata and get_ydata valid_only=False kwarg is replaced by orig=True. When True, it returns the original data, otherwise the processed data (masked, converted)

Some modifications to the units interface.
units.ConversionInterface.tickers renamed to units.ConversionInterface.axisinfo and it now returns a units.AxisInfo object rather than a tuple. This will make it easier to add axis info functionality (e.g., I added a default label
Axes.errorbar uses Axes.vlines and Axes.hlines to draw its error limits in the vertical and horizontal direction. As you'll see in the changes below, these functions now return a LineCollection rather than a list of lines. The new return signature for errorbar is ylins, caplines, errorcollections where errorcollections is a xerrcollection, yerrcollection

Axes.vlines and Axes.hlines now create and returns a LineCollection, not a list of lines. This is much faster. The kwarg signature has changed, so consult the docs

MaxNLocator accepts a new Boolean kwarg ('integer') to force ticks to integer locations.

Commands that pass an argument to the Text constructor or to Text.set_text() now accept any object that can be converted with '%s'. This affects xlabel(), title(), etc.

Barh now takes a **kwargs dict instead of most of the old arguments. This helps ensure that bar and barh are kept in sync, but as a side effect you can no longer pass e.g., color as a positional argument.

ft2font.get_charmap() now returns a dict that maps character codes to glyph indices (until now it was reversed)

Moved data files into lib/matplotlib so that setuptools' develop mode works. Re-organized the mpl-data layout so that this source structure is maintained in the installation. (i.e., the 'fonts' and 'images' sub-directories are maintained in site-packages.). Suggest removing site-packages/matplotlib/mpl-data and ~/.matplotlib/ttffont.cache before installing

### 15.1.25 Changes for 0.91.0

- Changed cbook.is_file_like() to cbook.is_writable_file_like() and corrected behavior.
- Added ax kwarg to pyplot.colorbar() and Figure.colorbar() so that one can specify the axes object from which space for the colorbar is to be taken, if one does not want to make the colorbar axes manually.
- Changed cbook.reversed() so it yields a tuple rather than a (index, tuple). This agrees with the python reversed builtin, and cbook only defines reversed if python doesn’t provide the builtin.
- Made skiprows=1 the default on csv2rec()
- The gd and paint backends have been deleted.
• The errorbar method and function now accept additional kwargs so that upper and lower limits can be indicated by capping the bar with a caret instead of a straight line segment.

• The `matplotlib.dviread` file now has a parser for files like psfonts.map and pdftex.map, to map TeX font names to external files.

• The file `matplotlib.type1font` contains a new class for Type 1 fonts. Currently it simply reads pfa and pfb format files and stores the data in a way that is suitable for embedding in pdf files. In the future the class might actually parse the font to allow e.g., subsetting.

• `matplotlib.FT2Font` now supports `FT_Attach_File()`. In practice this can be used to read an afm file in addition to a pfa/pfb file, to get metrics and kerning information for a Type 1 font.

• The `AFM` class now supports querying CapHeight and stem widths. The `get_name_char` method now has an isord kwarg like `get_width_char`.

• Changed `pcolor()` default to shading='flat'; but as noted now in the docstring, it is preferable to simply use the edgecolor kwarg.

• The `mathtext` font commands (`\cal`, `\rm`, `\it`, `\tt`) now behave as TeX does: they are in effect until the next font change command or the end of the grouping. Therefore uses of `$\cal{R}$` should be changed to `$\cal{R}$`. Alternatively, you may use the new LaTeX-style font commands (`\mathcal`, `\mathrm`, `\mathit`, `\mathtt`) which do affect the following group, e.g., `$\mathcal{R}$`.

• Text creation commands have a new default linespacing and a new `linespacing` kwarg, which is a multiple of the maximum vertical extent of a line of ordinary text. The default is 1.2; `linespacing=2` would be like ordinary double spacing, for example.

• Changed default kwarg in `matplotlib.colors.Normalize.__init__()` to `clip=False`; clipping silently defeats the purpose of the special over, under, and bad values in the colormap, thereby leading to unexpected behavior. The new default should reduce such surprises.

• Made the `emit` property of `set_xlim()` and `set_ylim()` True by default; removed the Axes custom callback handling into a ‘callbacks’ attribute which is a CallbackRegistry instance. This now supports the ‘xlim_changed’ and ‘ylim_changed’ Axes events.

### 15.1.26 Changes for 0.91.2

• For `csv2rec()`, checkrows=0 is the new default indicating all rows will be checked for type inference

• A warning is issued when an image is drawn on log-scaled axes, since it will not log-scale the image data.

• Moved `rec2gtk()` to `matplotlib.toolkits.gtktools`

• Moved `rec2excel()` to `matplotlib.toolkits.exceltools`

• Removed, dead/experimental ExampleInfo, Namespace and Importer code from `matplotlib.__init__`

### 15.1.27 Changes for 0.98.0

• `matplotlib.image.imread()` now no longer always returns RGBA data—if the image is luminance or RGB, it will return a MxN or MxNx3 array if possible. Also uint8 is no longer
always forced to float.

- New axes function and Axes method provide control over the plot color cycle: `matplotlib.axes.set_default_color_cycle()` and `matplotlib.axes.Axes.set_color_cycle()`.

- Matplotlib now requires Python 2.4, so `matplotlib.cbook` will no longer provide `set`, `enumerate()`, `reversed()` or `izip()` compatibility functions.

- In Numpy 1.0, bins are specified by the left edges only. The axes method `matplotlib.axes.Axes.hist()` now uses future Numpy 1.3 semantics for histograms. Providing `binedges`, the last value gives the upper-right edge now, which was implicitly set to +infinity in Numpy 1.0. This also means that the last bin doesn’t contain upper outliers any more by default.

- New axes method and pyplot function, `hexbin()`, is an alternative to `scatter()` for large datasets. It makes something like a `pcolor()` of a 2-D histogram, but uses hexagonal bins.

- New kwarg, `symmetric`, in `matplotlib.ticker.MaxNLocator` allows one require an axis to be centered around zero.

- Toolkits must now be imported from `mpl_toolkits` (not `matplotlib.toolkits`)

**Notes about the transforms refactoring**

A major new feature of the 0.98 series is a more flexible and extensible transformation infrastructure, written in Python/Numpy rather than a custom C extension.

The primary goal of this refactoring was to make it easier to extend matplotlib to support new kinds of projections. This is mostly an internal improvement, and the possible user-visible changes it allows are yet to come.

See `matplotlib.transforms` for a description of the design of the new transformation framework.

For efficiency, many of these functions return views into Numpy arrays. This means that if you hold on to a reference to them, their contents may change. If you want to store a snapshot of their current values, use the Numpy array method `copy()`.

The view intervals are now stored only in one place - in the `matplotlib.axes.Axes` instance, not in the locator instances as well. This means locators must get their limits from their `matplotlib.axis.Axis`, which in turn looks up its limits from the `Axes`. If a locator is used temporarily and not assigned to an Axis or Axes, (e.g., in `matplotlib.contour`), a dummy axis must be created to store its bounds. Call `matplotlib.ticker.Locator.create_dummy_axis()` to do so.

The functionality of `Pbox` has been merged with `Bbox`. Its methods now all return copies rather than modifying in place.

The following lists many of the simple changes necessary to update code from the old transformation framework to the new one. In particular, methods that return a copy are named with a verb in the past tense, whereas methods that alter an object in place are named with a verb in the present tense.
### matplotlib.transforms

</tr>
</tbody>
</table>

¹ The Bbox is bound by the points (x0, y0) to (x1, y1) and there is no defined order to these points, that is, x0 is not necessarily the left edge of the box. To get the left edge of the Bbox, use the read-only property xmin.

² The Matplotlib axes class now has a method `get_position()` which returns the position of the axis in the figure.

³ The Matplotlib axes class now has a method `set_position()` which sets the position of the axis in the figure.
The Polar class has moved to `matplotlib.projections.polar`.

</tr>
</tbody>
</table>

---

2 `matplotlib.axes.Axes.get_position()` used to return a list of points, now it returns a `matplotlib.transforms.Bbox` instance.
3 `matplotlib.axes.Axes.set_position()` now accepts either four scalars or a `matplotlib.transforms.Bbox` instance.
4 Since the refactoring allows for more than two scale types (‘log’ or ‘linear’), it no longer makes sense to have a toggle. `Axes.toggle_log_linear()` has been removed.
5 `matplotlib.artist.Artist.set_clip_path()` now accepts a `matplotlib.path.Path` instance and a `matplotlib.transforms.Transform` that will be applied to the path immediately before clipping.
6 Linestyles are now treated like all other collection attributes, i.e. a single value or multiple values may be provided.
Matplotlib, Release 3.1.1

**RendererBase**

New methods:

- `draw_path(self, gc, path, transform, rgbFace)`
- `draw_markers(self, gc, marker_path, marker_trans, path, trans, rgbFace)`
- `draw_path_collection(self, master_transform, cliprect, clippath, clippath_trans, paths, all_transforms, offsets, offsetTrans, facecolors, edgecolors, linewidths, linestyles, antialiaseds) [optional]`

Changed methods:

- `draw_image(self, x, y, im, bbox)` is now `draw_image(self, x, y, im, bbox, clippath, clippath_trans)`

Removed methods:

- `draw_arc`
- `draw_line_collection`
- `draw_line`
- `draw_lines`
- `draw_point`
- `draw_quad_mesh`
- `draw_poly_collection`
- `draw_polygon`
- `draw_rectangle`
- `draw_regpoly_collection`

---

7 `matplotlib.backend_bases.GraphicsContext.get_clip_path()` returns a tuple of the form `(path, affine_transform)`, where `path` is a `matplotlib.path.Path` instance and `affine_transform` is a `matplotlib.transforms.Affine2D` instance.

8 `matplotlib.backend_bases.GraphicsContext.set_clip_path()` now only accepts a `matplotlib.transforms.TransformedPath` instance.
15.1.28 Changes for 0.98.1

- Removed broken `matplotlib.axes3d` support and replaced it with a non-implemented error pointing to 0.91.x

15.1.29 Changes for 0.98.x

- `psd()`, `csd()`, and `cohere()` will now automatically wrap negative frequency components to the beginning of the returned arrays. This is much more sensible behavior and makes them consistent with `specgram()`. The previous behavior was more of an oversight than a design decision.
- Added new keyword parameters `nonposx`, `nonposy` to `matplotlib.axes.Axes` methods that set log scale parameters. The default is still to mask out non-positive values, but the kwargs accept ‘clip’, which causes non-positive values to be replaced with a very small positive value.
- Added new `matplotlib.pyplot.fignum_exists()` and `matplotlib.pyplot.get_fignums()`; they merely expose information that had been hidden in `matplotlib._pylab_helpers`.
- Deprecated numerix package.
- Added new `matplotlib.image.imsave()` and exposed it to the `matplotlib.pyplot` interface.
- Remove support for pyExcelerator in exceltools – use xlwt instead
- Changed the defaults of `acorr` and `xcorr` to use `usevlines=True`, `maxlags=10` and `normed=True` since these are the best defaults
- Following keyword parameters for `matplotlib.label.Label` are now deprecated and new set of parameters are introduced. The new parameters are given as a fraction of the font-size. Also, `scatteryoffsets`, `fancybox` and `columnspacing` are added as keyword parameters.

<table>

<td>borderaxespad</td>
</tr>
</tbody>
</table>

- Removed the configobj and experimental traits rc support
- Modified `matplotlib.mlab.psd()`, `matplotlib.mlab.csd()`, `matplotlib.mlab.cohere()`, and `matplotlib.mlab.specgram()` to scale one-sided densities by a factor of 2. Also, optionally scale the densities by the sampling frequency, which gives true values of densities that can be integrated by the returned frequency values. This also gives better MATLAB compatibility. The corresponding `matplotlib.azes.Axes` methods and `matplotlib.pyplot` functions were updated as well.
- Font lookup now uses a nearest-neighbor approach rather than an exact match. Some fonts may be different in plots, but should be closer to what was requested.
• `matplotlib.afm.AFM.get_fullname()` and `matplotlib.afm.AFM.get_familyname()` no longer raise an exception if the AFM file does not specify these optional attributes, but returns a guess based on the required FontName attribute.

• Changed precision kwarg in `matplotlib.pyplot.spy()`; default is 0, and the string value ‘present’ is used for sparse arrays only to show filled locations.

• `matplotlib.collections.EllipseCollection` added.

• Added angles kwarg to `matplotlib.pyplot.quiver()` for more flexible specification of the arrow angles.

• Deprecated (raise `NotImplementedError`) all the mlab2 functions from `matplotlib.mlab` out of concern that some of them were not clean room implementations.

• Methods `matplotlib.collections.Collection.get_offsets()` and `matplotlib.collections.Collection.set_offsets()` added to `Collection` base class.

• `matplotlib.figure.Figure.figurePatch` renamed `matplotlib.figure.Figure.patch`; `matplotlib.axes.Axes.axesPatch` renamed `matplotlib.axes.Axes.patch`; `matplotlib.axes.Axes.axesFrame` renamed `matplotlib.axes.Axes.frame`. `matplotlib.axes.Axes.get_frame()`, which returns `matplotlib.axes.Axes.patch.Axes.patch`, is deprecated.

• Changes in the `matplotlib.contour.ContourLabeler` attributes (`matplotlib.pyplot.clabel()` function) so that they all have a form like `.labelAttribute`. The three attributes that are most likely to be used by end users, `.cl`, `.cl_xy` and `.cl_cvalues` have been maintained for the moment (in addition to their renamed versions), but they are deprecated and will eventually be removed.

• Moved several functions in `matplotlib.mlab` and `matplotlib.cbook` into a separate module `matplotlib.numerical_methods` because they were unrelated to the initial purpose of mlab or cbook and appeared more coherent elsewhere.

15.1.30 Changes in 0.99

• `pylab` no longer provides a load and save function. These are available in `mplib.mlab`, or you can use `numpy.loadtxt` and `numpy.savetxt` for text files, or `np.save` and `np.load` for binary numpy arrays.

• User-generated colormaps can now be added to the set recognized by `matplotlib.cm.get_cmap()`. Colormaps can be made the default and applied to the current image using `matplotlib.pyplot.set_cmap()`.

• Changed `use_mrecords` default to False in `mlab.csv2rec` since this is partially broken.

• Axes instances no longer have a “frame” attribute. Instead, use the new “spines” attribute. Spines is a dictionary where the keys are the names of the spines (e.g., ‘left’, ‘right’ and so on) and the values are the artists that draw the spines. For normal (rectilinear) axes, these artists are Line2D instances. For other axes (such as polar axes), these artists may be Patch instances.

• Polar plots no longer accept a resolution kwarg. Instead, each Path must specify its own number of interpolation steps. This is unlikely to be a user-visible change – if interpolation of data is required, that should be done before passing it to `Matplotlib`. 
15.1.31 Changes beyond 0.99.x

- The default behavior of `matplotlib.axes.Axes.set_xlim()`, `matplotlib.axes.Axes.set_ylim()`, and `matplotlib.axes.Axes.axis()`, and their corresponding pyplot functions, has been changed: when view limits are set explicitly with one of these methods, autoscaling is turned off for the matching axis. A new `auto` kwarg is available to control this behavior. The limit kwargs have been renamed to `left` and `right` instead of `xmin` and `xmax`, and `bottom` and `top` instead of `ymin` and `ymax`. The old names may still be used, however.

- There are five new Axes methods with corresponding pyplot functions to facilitate autoscaling, tick location, and tick label formatting, and the general appearance of ticks and tick labels:
  - `matplotlib.axes.Axes.autoscale()` turns autoscaling on or off, and applies it.
  - `matplotlib.axes.Axes.margins()` sets margins used to autoscale the `matplotlib.axes.Axes.viewLim` based on the `matplotlib.axes.Axes.dataLim`.
  - `matplotlib.axes.Axes.locator_params()` allows one to adjust axes locator parameters such as `nbins`.
  - `matplotlib.axes.Axes.ticklabel_format()` is a convenience method for controlling the `matplotlib.ticker.ScalarFormatter` that is used by default with linear axes.
  - `matplotlib.axes.Axes.tick_params()` controls direction, size, visibility, and color of ticks and their labels.

- The `matplotlib.axes.Axes.bar()` method accepts a `error_kw` kwarg; it is a dictionary of kwargs to be passed to the errorbar function.

- The `matplotlib.axes.Axes.hist()` `color` kwarg now accepts a sequence of color specs to match a sequence of datasets.

- The `EllipseCollection` has been changed in two ways:
  - There is a new `units` option, ‘xy’, that scales the ellipse with the data units. This matches the :class:`~matplotlib.patches.Ellipse` scaling.
  - The `height` and `width` kwargs have been changed to specify the height and width, again for consistency with `Ellipse`, and to better match their names; previously they specified the half-height and half-width.

- There is a new rc parameter `axes.color_cycle`, and the color cycle is now independent of the rc parameter `lines.color`. `matplotlib.Axes.set_default_color_cycle()` is deprecated.

- You can now print several figures to one pdf file and modify the document information dictionary of a pdf file. See the docstrings of the class `matplotlib.backends.backend_pdf.PdfPages` for more information.

- Removed `configobj` and `enthought.traits` packages, which are only required by the experimental traited config and are somewhat out of date. If needed, install them independently.

- The new rc parameter `savefig.extension` sets the filename extension that is used by `matplotlib.figure.Figure.savefig()` if its `fname` argument lacks an extension.

- In an effort to simplify the backend API, all clipping rectangles and paths are now passed in using `GraphicsContext` objects, even on collections and images. Therefore:
draw_path_collection(self, master_transform, cliprect, clippath,
    clippath_trans, paths, all_transforms, offsets,
    offsetTrans, facecolors, edgecolors, linewidths,
    linestyles, antialiaseds, urls)

# is now
draw_path_collection(self, gc, master_transform, paths, all_transforms,
    offsets, offsetTrans, facecolors, edgecolors,
    linewidths, linestyles, antialiaseds, urls)

draw_quad_mesh(self, master_transform, cliprect, clippath,
    clippath_trans, meshWidth, meshHeight, coordinates,
    offsets, offsetTrans, facecolors, antialiased,
    showedges)

# is now
draw_quad_mesh(self, gc, master_transform, meshWidth, meshHeight,
    coordinates, offsets, offsetTrans, facecolors,
    antialiased, showedges)

draw_image(self, x, y, im, bbox, clippath=None, clippath_trans=None)

# is now
draw_image(self, gc, x, y, im)

• There are four new Axes methods with corresponding pyplot functions that deal with unstructured triangular grids:
  - `matplotlib.axes.Axes.tricontour()` draws contour lines on a triangular grid.
  - `matplotlib.axes.Axes.tricontourf()` draws filled contours on a triangular grid.
  - `matplotlib.axes.Axes.tripcolor()` draws a pseudocolor plot on a triangular grid.
  - `matplotlib.axes.Axes.triplot()` draws a triangular grid as lines and/or markers.

15.1.32 Changes in 1.1.x

• Added new `matplotlib.sankey.Sankey` for generating Sankey diagrams.

• In `imshow()`, setting `interpolation` to 'nearest' will now always mean that the nearest-neighbor interpolation is performed. If you want the no-op interpolation to be performed, choose 'none'.

• There were errors in how the tri-functions were handling input parameters that had to be fixed. If your tri-plots are not working correctly anymore, or you were working around apparent mistakes, please see issue #203 in the github tracker. When in doubt, use `kwargs`.

• The 'symlog' scale had some bad behavior in previous versions. This has now been fixed and users should now be able to use it without frustrations. The fixes did result in some
minor changes in appearance for some users who may have been depending on the bad behavior.

• There is now a common set of markers for all plotting functions. Previously, some markers existed only for `scatter()` or just for `plot()`. This is now no longer the case. This merge did result in a conflict. The string ‘d’ now means “thin diamond” while ‘D’ will mean “regular diamond”.

15.1.33 Changes in 1.2.x

• The classic option of the rc parameter `toolbar` is deprecated and will be removed in the next release.

• The `isvector()` method has been removed since it is no longer functional.

• The `rasterization_zorder` property on `Axes` a zorder below which artists are rasterized. This has defaulted to -30000.0, but it now defaults to `None`, meaning no artists will be rasterized. In order to rasterize artists below a given zorder value, `set_rasterization_zorder` must be explicitly called.

• In `scatter()`, and `scatter`, when specifying a marker using a tuple, the angle is now specified in degrees, not radians.

• Using `twinx()` or `twiny()` no longer overrides the current locaters and formatters on the axes.

• In `contourf()`, the handling of the `extend` kwarg has changed. Formerly, the extended ranges were mapped after to 0, 1 after being normed, so that they always corresponded to the extreme values of the colormap. Now they are mapped outside this range so that they correspond to the special colormap values determined by the `set_under()` and `set_over()` methods, which default to the colormap end points.

• The new rc parameter `savefig.format` replaces `cairo.format` and `savefig.extension`, and sets the default file format used by `matplotlib.figure.Figure.savefig()`.

• In `pie()` and `pie()`, one can now set the radius of the pie; setting the `radius` to ‘None’ (the default value), will result in a pie with a radius of 1 as before.

• Use of `projection_factory()` is now deprecated in favour of axes class identification using `process_projection_requirements()` followed by direct axes class invocation (at the time of writing, functions which do this are: `add_axes()`, `add_subplot()` and `gca()`). Therefore:

```python
key = figure._make_key(*args, **kwargs)
is_polar = kwargs.pop('polar', False)
projection = kwargs.pop('projection', None)
if is_polar:
    if projection is not None and projection != 'polar':
        raise ValueError('polar and projection args are inconsistent')
    projection = 'polar'
ax = projection_factory(projection, self, rect, **kwargs)
key = self._make_key(*args, **kwargs)

# is now

projection_class, kwargs, key = 
    process_projection_requirements(self, *args, **kwargs)
ax = projection_class(self, rect, **kwargs)
```
This change means that third party objects can expose themselves as Matplotlib axes by providing a `_as_mpl_axes` method. See Developer’s guide for creating scales and transformations for more detail.

- A new keyword `extendfrac` in `colorbar()` and `ColorbarBase` allows one to control the size of the triangular minimum and maximum extensions on colorbars.

- A new keyword `capthick` in `errorbar()` has been added as an intuitive alias to the `markeredgewidth` and `mew` keyword arguments, which indirectly controlled the thickness of the caps on the errorbars. For backwards compatibility, specifying either of the original keyword arguments will override any value provided by `capthick`.

- Transform subclassing behaviour is now subtly changed. If your transform implements a non-affine transformation, then it should override the `transform_non_affine` method, rather than the generic `transform` method. Previously transforms would define `transform` and then copy the method into `transform_non_affine`:

```python
class MyTransform(mtrans.Transform):
    def transform(self, xy):
        ...
    transform_non_affine = transform
```

This approach will no longer function correctly and should be changed to:

```python
class MyTransform(mtrans.Transform):
    def transform_non_affine(self, xy):
        ...
```

- Artists no longer have `x_isdata` or `y_isdata` attributes; instead any artist’s transform can be interrogated with `artist_instance.get_transform().contains_branch(ax.transData)`.

- Lines added to an axes now take into account their transform when updating the data and view limits. This means transforms can now be used as a pre-transform. For instance:

```python
>>> import matplotlib.pyplot as plt
>>> import matplotlib.transforms as mtrans
>>> ax = plt.axes()
>>> ax.plot(range(10), transform=mtrans.Affine2D().scale(10) + ax.transData)
>>> print(ax.viewLim)
Bbox('array([[ 0., 0.], [ 90., 90.]])')
```

- One can now easily get a transform which goes from one transform’s coordinate system to another, in an optimized way, using the new subtract method on a transform. For instance, to go from data coordinates to axes coordinates:

```python
>>> import matplotlib.pyplot as plt
>>> ax = plt.axes()
>>> data2ax = ax.transData - ax.transAxes
>>> print(ax.transData.depth, ax.transAxes.depth)
3, 1
>>> print(data2ax.depth)
2
```

for versions before 1.2 this could only be achieved in a sub-optimal way, using `ax.transData + ax.transAxes.inverted()` (depth is a new concept, but had it existed it would return 4 for this example).
• `twinx` and `twiny` now return an instance of `SubplotBase` if parent axes is an instance of `SubplotBase`.

• All Qt3-based backends are now deprecated due to the lack of py3k bindings. Qt and QtAgg backends will continue to work in v1.2.x for py2.6 and py2.7. It is anticipated that the Qt3 support will be completely removed for the next release.

• `ColorConverter`, `Colormap` and `Normalize` now subclasses `object`

• `ContourSet` instances no longer have a `transform` attribute. Instead, access the transform with the `get_transform` method.

15.1.34 Changes in 1.3.x

Changes in 1.3.1

It is rare that we make an API change in a bugfix release, however, for 1.3.1 since 1.3.0 the following change was made:

• `text.Text.cached` (used to cache font objects) has been made into a private variable. Among the obvious encapsulation benefit, this removes this confusing-looking member from the documentation.

• The method `hist()` now always returns bin occupancies as an array of type `float`. Previously, it was sometimes an array of type `int`, depending on the call.

Code removal

• The following items that were deprecated in version 1.2 or earlier have now been removed completely.

  - The Qt 3.x backends (qt and qtagg) have been removed in favor of the Qt 4.x backends (qt4 and qt4agg).
  - The FltkAgg and Emf backends have been removed.
  - The `matplotlib.nxutils` module has been removed. Use the functionality on `matplotlib.path.Path.contains_point` and friends instead.
  - The following kwargs to the `legend` function have been renamed:
    * `pad` -> `borderpad`
    * `labelsep` -> `labelspacing`
    * `handlelen` -> `handlelength`
    * `handletextsep` -> `handletextpad`
    * `axespad` -> `borderaxespad`

  Related to this, the following rcParams have been removed:
    * `legend.pad`, `legend.labelsep`, `legend.handlelen`, `legend.handletextsep` and `legend.axespad`

  - For the `hist` function, instead of `width`, use `rwidth` (relative width).
- On patches.Circle, the resolution kwarg has been removed. For a circle made up of line segments, use patches.CirclePolygon.

- The printing functions in the Wx backend have been removed due to the burden of keeping them up-to-date.

- mlab.liaunov has been removed.

- mlab.save, mlab.load, pylab.save and pylab.load have been removed. We recommend using numpy.savetxt and numpy.loadtxt instead.

- widgets.HorizontalSpanSelector has been removed. Use widgets.SpanSelector instead.

Code deprecation

- The CocoaAgg backend has been deprecated, with the possibility for deletion or resurrection in a future release.

- The top-level functions in matplotlib.path that are implemented in C++ were never meant to be public. Instead, users should use the Pythonic wrappers for them in the path.Path and collections.Collection classes. Use the following mapping to update your code:
  - point_in_path -> path.Path.contains_point
  - get_path_extents -> path.Path.get_extents
  - point_in_path_collection -> collection.Collection.contains
  - path_in_path -> path.Path.contains_path
  - path_intersects_path -> path.Path.intersects_path
  - convert_path_to_polygons -> path.Path.to_polygons
  - cleanup_path -> path.Path.cleaned
  - points_in_path -> path.Path.contains_points
  - clip_path_to_rect -> path.Path.clip_to_bbox

- matplotlib.colors.normalize and matplotlib.colors.no_norm have been deprecated in favour of matplotlib.colors.Normalize and matplotlib.colors.NoNorm respectively.

- The ScalarMappable class’ set_colorbar is now deprecated. Instead, the matplotlib.cm.ScalarMappable.colorbar attribute should be used. In previous Matplotlib versions this attribute was an undocumented tuple of (colorbar_instance, colorbar_axes) but is now just colorbar_instance. To get the colorbar axes it is possible to just use the az attribute on a colorbar instance.

- The mpl module is now deprecated. Those who relied on this module should transition to simply using import matplotlib as mpl.

Code changes

- Patch now fully supports using RGBA values for its facecolor and edgecolor attributes, which enables faces and edges to have different alpha values. If the Patch object’s alpha attribute is set to anything other than None, that value will override any alpha-channel
value in both the face and edge colors. Previously, if Patch had alpha=None, the alpha component of edgecolor would be applied to both the edge and face.

- The optional isRGB argument to set_foreground() (and the other GraphicsContext classes that descend from it) has been renamed to isRGBA, and should now only be set to True if the fg color argument is known to be an RGBA tuple.

- For Patch, the capstyle used is now butt, to be consistent with the default for most other objects, and to avoid problems with non-solid linestyle appearing solid when using a large linewidth. Previously, Patch used capstyle='projecting'.

- Path objects can now be marked as readonly by passing readonly=True to its constructor. The built-in path singletons, obtained through Path.unit* class methods return readonly paths. If you have code that modified these, you will need to make a deepcopy first, using either:

```python
import copy
path = copy.deepcopy(Path.unit_circle())

# or
path = Path.unit_circle().deepcopy()
```

Deep copying a Path always creates an editable (i.e. non-readonly) Path.

- The list at Path.NUM_VERTICES was replaced by a dictionary mapping Path codes to the number of expected vertices at NUM_VERTICES_FOR_CODE.

- To support XKCD style plots, the matplotlib.path.cleanup_path() method’s signature was updated to require a sketch argument. Users of matplotlib.path.cleanup_path() are encouraged to use the new cleaned() Path method.

- Data limits on a plot now start from a state of having “null” limits, rather than limits in the range (0, 1). This has an effect on artists that only control limits in one direction, such as axvline and axhline, since their limits will not longer also include the range (0, 1). This fixes some problems where the computed limits would be dependent on the order in which artists were added to the axes.

- Fixed a bug in setting the position for the right/top spine with data position type. Previously, it would draw the right or top spine at +1 data offset.

- In FancyArrow, the default arrow head width, head_width, has been made larger to produce a visible arrow head. The new value of this kwarg is head_width = 20 * width.

- It is now possible to provide number of levels + 1 colors in the case of extend='both' for contourf (or just number of levels colors for an extend value min or max) such that the resulting colormap’s set_under and set_over are defined appropriately. Any other number of colors will continue to behave as before (if more colors are provided than levels, the colors will be unused). A similar change has been applied to contour, where extend='both' would expect number of levels + 2 colors.

- A new keyword extendrect in colorbar() and ColorbarBase allows one to control the shape of colorbar extensions.

- The extension of MultiCursor to both vertical (default) and/or horizontal cursor implied that self.line is replaced by self.vline for vertical cursors lines and self.hline is added for the horizontal cursors lines.

- On POSIX platforms, the report_memory() function raises NotImplementedError instead of OSError if the ps command cannot be run.
• The `matplotlib.cbook.check_output()` function has been moved to `matplotlib.compat.subprocess()`.

Configuration and rcParams

• On Linux, the user-specific `matplotlibrc` configuration file is now located in `config/matplotlib/matplotlibrc` to conform to the XDG Base Directory Specification.
• The `font.*` rcParams now affect only text objects created after the rcParam has been set, and will not retroactively affect already existing text objects. This brings their behavior in line with most other rcParams.
• Removed call of `grid()` in `plotfile()`. To draw the axes grid, set the `axes.grid` rcParam to `True`, or explicitly call `grid()`.

15.1.35 Changes in 1.4.x

Code changes

• A major refactoring of the axes module was made. The axes module has been split into smaller modules:
  – the `_base` module, which contains a new private `_AxesBase` class. This class contains all methods except plotting and labelling methods.
  – the `axes` module, which contains the Axes class. This class inherits from `_AxesBase`, and contains all plotting and labelling methods.
  – the `_subplot` module, with all the classes concerning subplotting.

There are a couple of things that do not exists in the axes module’s namespace anymore. If you use them, you need to import them from their original location:

- `math` -> `import math`
- `ma` -> `from numpy import ma`
- `cbook` -> `from matplotlib import cbook`
- `docstring` -> `from matplotlib import docstring`
- `is_sequence_of_strings` -> `from matplotlib.cbook import is_sequence_of_strings`
- `is_string_like` -> `from matplotlib.cbook import is_string_like`
- `iterable` -> `from matplotlib.cbook import iterable`
- `itertools` -> `import itertools`
- `martist` -> `from matplotlib import artist as martist`
- `matplotlib` -> `import matplotlib`
- `mcoll` -> `from matplotlib.collections import mcoll`
- `mcolors` -> `from matplotlib.colors import mcolors`
- `mcontour` -> `from matplotlib.contour import mcontour`
- `mpatches` -> `from matplotlib.patches import mpatches`
- `mpath` -> `from matplotlib import path as mpath`
• `mquiver` -> from `matplotlib` import `quiver` as `mquiver`
• `mstack` -> from `matplotlib` import `stack` as `mstack`
• `mstream` -> from `matplotlib` import `stream` as `mstream`
• `mtable` -> from `matplotlib` import `table` as `mtable`

As part of the refactoring to enable Qt5 support, the module `matplotlib.backends.qt4_compat` was renamed to `matplotlib.qt_compat`. `qt4_compat` is deprecated in 1.4 and will be removed in 1.5.

• The `errorbar()` method has been changed such that the upper and lower limits (`lolims`, `uplims`, `xlolims`, `xuplims`) now point in the correct direction.

• The `fmt` kwarg for `plot()` defaults.

• A bug has been fixed in the path effects rendering of fonts, which now means that the font size is consistent with non-path effect fonts. See [https://github.com/matplotlib/matplotlib/issues/2889](https://github.com/matplotlib/matplotlib/issues/2889) for more detail.

• The Sphinx extensions `ipython_directive` and `ipython_console_highlighting` have been moved to the IPython project itself. While they remain in Matplotlib for this release, they have been deprecated. Update your extensions in `conf.py` to point to `IPython.sphinxext.ipython_directive` instead of `matplotlib.sphinxext.ipython_directive`.

• In finance, almost all functions have been deprecated and replaced with a pair of functions name `_ochl` and `_ohlc`. The former is the ‘open-close-high-low’ order of quotes used previously in this module, and the latter is the ‘open-high-low-close’ order that is standard in finance.

• For consistency the `face_alpha` keyword to `matplotlib.patheffects.SimplePatchShadow` has been deprecated in favour of the `alpha` keyword. Similarly, the keyword `offset_xy` is now named `offset` across all `_Base` has been renamed to `matplotlib.patheffects.AbstractPathEffect`. `matplotlib.patheffect.ProxyRenderer` has been renamed to `matplotlib.patheffects.PathEffectRenderer` and is now a full `RendererBase` subclass.

• The artist used to draw the outline of a colorbar has been changed from a `matplotlib.lines.Line2D` to `matplotlib.patches.Polygon`, thus `colorbar.ColorbarBase.outline` is now a `matplotlib.patches.Polygon` object.

• The legend handler interface has changed from a callable, to any object which implements the `legend_artists` method (a deprecation phase will see this interface be maintained for v1.4). See [Legend guide](#) for further details. Further legend changes include:
  - `matplotlib.axes.Axes._get_legend_handles()` now returns a generator of handles, rather than a list.
  - The `legend()` function’s “loc” positional argument has been deprecated. Use the “loc” keyword instead.

• The `rcParams` `savefig.transparent` has been added to control default transparency when saving figures.

• Slightly refactored the `Annotation` family. The text location in `Annotation` is now handled entirely handled by the underlying `Text` object so `set_position` works as expected. The attributes `xytext` and `textcoords` have been deprecated in favor of `xyann` and `anncoords` so that `Annotation` and `AnnotationBbox` can share a common sensibly named api for getting/setting the location of the text or box.
  - `xyann` -> set the location of the annotation
  - `xy` -> set where the arrow points to
- `anncoords` -> set the units of the annotation location
- `xycoords` -> set the units of the point location
- `set_position()` -> Annotation only set location of annotation

- `matplotlib.mlab.specgram`, `matplotlib.mlab.psd`, `matplotlib.mlab.csd`, `matplotlib.mlab.cohere`, `matplotlib.mlab.cohere_pairs`, `matplotlib.pyplot.specgram`, `matplotlib.pyplot.psd`, `matplotlib.pyplot.csd`, and `matplotlib.pyplot.cohere` now raise `ValueError` where they previously raised `AssertionError`.

- For `matplotlib.mlab.psd`, `matplotlib.mlab.csd`, `matplotlib.mlab.cohere`, `matplotlib.mlab.cohere_pairs`, `matplotlib.pyplot.specgram`, `matplotlib.pyplot.psd`, `matplotlib.pyplot.csd`, and `matplotlib.pyplot.cohere`, in cases where a shape (n, 1) array is returned, this is now converted to a (n, ) array. Previously, (n, m) arrays were averaged to an (n, ) array, but (n, 1) arrays were returned unchanged. This change makes the dimensions consistent in both cases.

- Added the `rcParam axes.formatter.useoffset` to control the default value of `useOffset` in `ticker.ScalarFormatter`

- Added `Formatter` sub-class `StrMethodFormatter` which does the exact same thing as `FormatStrFormatter`, but for new-style formatting strings.

- Deprecated `matplotlib.testing.image_util` and the only function within, `matplotlib.testing.image_util.autocontrast`. These will be removed completely in v1.5.0.

- The `fmt` argument of `plot_date()` has been changed from `bo` to just `o`, so color cycling can happen by default.

- Removed the class `FigureManagerQTAgg` and deprecated `NavigationToolbar2QTAgg` which will be removed in 1.5.

- Removed formerly public (non-prefixed) attributes `rect` and `drawRect` from `FigureCanvasQTAgg`; they were always an implementation detail of the (preserved) `drawRectangle()` function.

- The function signatures of `tight_bbox.adjust_bbox` and `tight_bbox.process_figure_for_rasterizing` have been changed. A new `fixed_dpi` parameter allows for overriding the `figure.dpi` setting instead of trying to deduce the intended behaviour from the file format.

- Added support for horizontal/vertical axes padding to `mpl_toolkits.axes_grid1.ImageGrid` — argument `axes_pad` can now be tuple-like if separate axis padding is required. The original behavior is preserved.

- Added support for skewed transforms to `matplotlib.transforms.Affine2D`, which can be created using the `skew` and `skew_deg` methods.

- Added clockwise parameter to control sectors direction in `axes.pie`

- In `matplotlib.lines.Line2D` the `markevery` functionality has been extended. Previously an integer start-index and stride-length could be specified using either a two-element-list or a two-element-tuple. Now this can only be done using a two-element-tuple. If a two-element-list is used then it will be treated as numpy fancy indexing and only the two markers corresponding to the given indexes will be shown.

- Removed `prop` kwarg from `mpl_toolkits.axes_grid1.anchored_artists.AnchoredSizeBar` call. It was passed through to the base-class `__init__` and is only used for setting padding. Now `fontproperties` (which is what is really used to set the font properties of `AnchoredSizeBar`) is passed through in place of `prop`. If `fontproperties` is not passed
Matplotlib, Release 3.1.1

in, but prop is, then prop is used inplace of fontproperties. If both are passed in, prop is
silently ignored.

- The use of the index 0 in plt.subplot and related commands is deprecated. Due to a lack
  of validation calling plt.subplots(2, 2, 0) does not raise an exception, but puts an axes
  in the _last_ position. This is due to the indexing in subplot being 1-based (to mirror
  MATLAB) so before indexing into the GridSpec object used to determine where the axes
  should go, 1 is subtracted off. Passing in 0 results in passing -1 to GridSpec which results
  in getting the last position back. Even though this behavior is clearly wrong and not
  intended, we are going through a deprecation cycle in an abundance of caution that any
  users are exploiting this ‘feature’. The use of 0 as an index will raise a warning in 1.4
  and an exception in 1.5.

- Clipping is now off by default on offset boxes.

- Matplotlib now uses a less-aggressive call to gc.collect(1) when closing figures to avoid
  major delays with large numbers of user objects in memory.

- The default clip value of all pie artists now defaults to False.

Code removal

- Removed mlab.levypdf. The code raised a numpy error (and has for a long time) and was
  not the standard form of the Levy distribution. scipy.stats.levy should be used instead

15.1.36 Changes in 1.5.0

Code Changes

Reversed matplotlib.cbook.ls_mapper, added ls_mapper_r

Formerly, matplotlib.cbook.ls_mapper was a dictionary with the long-form line-style names
("solid") as keys and the short forms ("-" ) as values. This long-to-short mapping is now done
by ls_mapper_r, and the short-to-long mapping is done by the ls_mapper.

Prevent moving artists between Axes, Property-ify Artist.axes, deprecate Artist.{get,set}_axes

This was done to prevent an Artist that is already associated with an Axes from being
moved/added to a different Axes. This was never supported as it causes havoc with the trans-
form stack. The apparent support for this (as it did not raise an exception) was the source of
multiple bug reports and questions on SO.

For almost all use-cases, the assignment of the axes to an artist should be taken care of by
the axes as part of the Axes.add_* method, hence the deprecation of {get,set}_axes.

Removing the set_axes method will also remove the ‘axes’ line from the ACCEPTS kwarg
Tables (assuming that the removal date gets here before that gets overhauled).

Tightened input validation on ‘pivot’ kwarg to quiver

Tightened validation so that only {‘tip’, ‘tail’, ‘mid’, and ‘middle’} (but any capitalization)
are valid values for the ‘pivot’ kwarg in the Quiver.__init__ (and hence Axes.quiver and plt.
quiver which both fully delegate to Quiver). Previously any input matching ‘mid.*’ would be interpreted as ‘middle’, ‘tip.*’ as ‘tip’ and any string not matching one of those patterns as ‘tail’.

The value of Quiver.pivot is normalized to be in the set {‘tip’, ‘tail’, ‘middle’} in Quiver.__init__.

**Reordered Axes.get_children**

The artist order returned by Axes.get_children did not match the one used by Axes.draw. They now use the same order, as Axes.draw now calls Axes.get_children.

**Changed behaviour of contour plots**

The default behaviour of contour() and contourf() when using a masked array is now determined by the new keyword argument corner_mask, or if this is not specified then the new rcParam contour.corner_mask instead. The new default behaviour is equivalent to using corner_mask=True; the previous behaviour can be obtained using corner_mask=False or by changing the rcParam. The example [http://matplotlib.org/examples/pylab_examples/contour_corner_mask.html](http://matplotlib.org/examples/pylab_examples/contour_corner_mask.html) demonstrates the difference. Use of the old contouring algorithm, which is obtained with corner_mask='legacy', is now deprecated.

Contour labels may now appear in different places than in earlier versions of Matplotlib.

In addition, the keyword argument nchunk now applies to contour() as well as contourf(), and it subdivides the domain into subdomains of exactly nchunk by nchunk quads, whereas previously it was only roughly nchunk by nchunk quads.

The C/C++ object that performs contour calculations used to be stored in the public attribute QuadContourSet.Cntr, but is now stored in a private attribute and should not be accessed by end users.

**Added set_params function to all Locator types**

This was a bug fix targeted at making the api for Locators more consistent.

In the old behavior, only locators of type MaxNLocator have set_params() defined, causing its use on any other Locator to raise an AttributeError (aside: set_params(args) is a function that sets the parameters of a Locator instance to be as specified within args). The fix involves moving set_params() to the Locator class such that all subtypes will have this function defined. Since each of the Locator subtypes have their own modifiable parameters, a universal set_params() in Locator isn’t ideal. Instead, a default no-operation function that raises a warning is implemented in Locator. Subtypes extending Locator will then override with their own implementations. Subtypes that do not have a need for set_params() will fall back onto their parent’s implementation, which raises a warning as intended.

In the new behavior, Locator instances will not raise an AttributeError when set_params() is called. For Locators that do not implement set_params(), the default implementation in Locator is used.
Disallow None as x or y value in `ax.plot`

Do not allow None as a valid input for the x or y args in `ax.plot`. This may break some user code, but this was never officially supported (ex documented) and allowing None objects through can lead to confusing exceptions downstream.

To create an empty line use

```python
ln1, = ax.plot([], [], ...)  
ln2, = ax.plot([], ...)  
```

In either case to update the data in the `Line2D` object you must update both the x and y data.

**Removed args and kwargs from `MicrosecondLocator.__call__`**

The call signature of `__call__()` has changed from `__call__(self, *args, **kwargs)` to `__call__(self)`. This is consistent with the superclass `Locator` and also all the other Locators derived from this superclass.

**No ValueError for the MicrosecondLocator and YearLocator**

The `MicrosecondLocator` and `YearLocator` objects when called will return an empty list if the axes have no data or the view has no interval. Previously, they raised a `ValueError`. This is consistent with all the Date Locators.

**'OffsetBox.DrawingArea' respects the 'clip' keyword argument**

The call signature was `OffsetBox.DrawingArea(..., clip=True)` but nothing was done with the `clip` argument. The object did not do any clipping regardless of that parameter. Now the object can and does clip the child Artists if they are set to be clipped.

You can turn off the clipping on a per-child basis using `child.set_clip_on(False)`.

**Add salt to clipPath id**

Add salt to the hash used to determine the id of the `clipPath` nodes. This is to avoid conflicts when two svg documents with the same clip path are included in the same document (see https://github.com/ipython/ipython/issues/8133 and https://github.com/matplotlib/matplotlib/issues/4349 ), however this means that the svg output is no longer deterministic if the same figure is saved twice. It is not expected that this will affect any users as the current ids are generated from an md5 hash of properties of the clip path and any user would have a very difficult time anticipating the value of the id.

**Changed snap threshold for circle markers to inf**

When drawing circle markers above some marker size (previously 6.0) the path used to generate the marker was snapped to pixel centers. However, this ends up distorting the marker away from a circle. By setting the snap threshold to inf snapping is never done on circles. This change broke several tests, but is an improvement.
**Preserve units with Text position**

Previously the ‘get_position’ method on Text would strip away unit information even though the units were still present. There was no inherent need to do this, so it has been changed so that unit data (if present) will be preserved. Essentially a call to ‘get_position’ will return the exact value from a call to ‘set_position’.

If you wish to get the old behaviour, then you can use the new method called ‘get_unitless_position’.

**New API for custom Axes view changes**

Interactive pan and zoom were previously implemented using a Cartesian-specific algorithm that was not necessarily applicable to custom Axes. Three new private methods, _get_view(), _set_view(), and _set_view_from_bbox(), allow for custom Axes classes to override the pan and zoom algorithms. Implementors of custom Axes who override these methods may provide suitable behaviour for both pan and zoom as well as the view navigation buttons on the interactive toolbars.

**MathTex visual changes**

The spacing commands in mathtext have been changed to more closely match vanilla TeX.

**Improved spacing in mathtext**

The extra space that appeared after subscripts and superscripts has been removed.

**No annotation coordinates wrap**

In #2351 for 1.4.0 the behavior of ['axes points', 'axes pixel', 'figure points', 'figure pixel'] as coordinates was change to no longer wrap for negative values. In 1.4.3 this change was reverted for ‘axes points’ and ‘axes pixel’ and in addition caused ‘axes fraction’ to wrap. For 1.5 the behavior has been reverted to as it was in 1.4.0-1.4.2, no wrapping for any type of coordinate.

**Deprecation**

Deprecated GraphicsContextBase.set_graylevel

The GraphicsContextBase.set_graylevel function has been deprecated in 1.5 and will be removed in 1.6. It has been unused. The GraphicsContextBase.set_foreground could be used instead.
**deprecated idle_event**

The `idle_event` was broken or missing in most backends and causes spurious warnings in some cases, and its use in creating animations is now obsolete due to the animations module. Therefore code involving it has been removed from all but the wx backend (where it partially works), and its use is deprecated. The animations module may be used instead to create animations.

**color_cycle deprecated**

In light of the new property cycling feature, the Axes method `set_color_cycle` is now deprecated. Calling this method will replace the current property cycle with one that cycles just the given colors.

Similarly, the rc parameter `axes.color_cycle` is also deprecated in lieu of the new `axes.prop_cycle` parameter. Having both parameters in the same rc file is not recommended as the result cannot be predicted. For compatibility, setting `axes.color_cycle` will replace the cycler in `axes.prop_cycle` with a color cycle. Accessing `axes.color_cycle` will return just the color portion of the property cycle, if it exists.

Timeline for removal has not been set.

**Bundled jquery**

The version of jquery bundled with the webagg backend has been upgraded from 1.7.1 to 1.11.3. If you are using the version of jquery bundled with webagg you will need to update your html files as such

```
- <script src="_static/jquery/js/jquery-1.7.1.min.js"></script>
+ <script src="_static/jquery/js/jquery-1.11.3.min.js"></script>
```

**Code Removed**

**Removed Image from main namespace**

`Image` was imported from PIL/pillow to test if PIL is available, but there is no reason to keep `Image` in the namespace once the availability has been determined.

**Removed lod from Artist**

Removed the method `set_lod` and all references to the attribute `_lod` as the are not used anywhere else in the code base. It appears to be a feature stub that was never built out.

**Removed threading related classes from cbook**

The classes `Scheduler`, `Timeout`, and `Idle` were in cbook, but are not used internally. They appear to be a prototype for the idle event system which was not working and has recently been pulled out.
**Removed Lena images from sample_data**

The `lena.png` and `lena.jpg` images have been removed from Matplotlib’s sample_data directory. The images are also no longer available from `matplotlib.cbook.get_sample_data`. We suggest using `matplotlib.cbook.get_sample_data('grace_hopper.png')` or `matplotlib.cbook.get_sample_data('grace_hopper.jpg')` instead.

**Legend**

Removed handling of `loc` as a positional argument to `Legend`

**Legend handlers**

Remove code to allow legend handlers to be callable. They must now implement a method `legend_artist`.

**Axis**

Removed method `set_scale`. This is now handled via a private method which should not be used directly by users. It is called via `Axes.set_{x,y}scale` which takes care of ensuring the related changes are also made to the Axes object.

**finance.py**

Removed functions with ambiguous argument order from `finance.py`

**Annotation**

Removed `textcoords` and `xytext` proprieties from Annotation objects.

**spinxext.ipython_*.py**

Both `ipython_console_highlighting` and `ipython_directive` have been moved to IPython. Change your import from `matplotlib.sphinxext.ipython_directive` to `IPython.sphinxext.ipython_directive` and from `matplotlib.sphinxext.ipython_directive` to `IPython.sphinxext.ipython_directive`

**LineCollection.color**

Deprecated in 2005, use `set_color`

**remove 'faceted' as a valid value for shading in tri.tripcolor**

Use `edgecolor` instead. Added validation on `shading` to only be valid values.
Remove faceted kwarg from scatter

Remove support for the faceted kwarg. This was deprecated in d48b34288e9651ff95c3b8a071ef5ac5cf50bae7 (2008-04-18!) and replaced by edgecolor.

Remove set_colorbar method from ScalarMappable

Remove set_colorbar method, use colorbar attribute directly.

patheffects.svg

• remove get_proxy_renderer method from AbstractPathEffect class
• remove patch_alpha and offset_xy from SimplePatchShadow

Remove testing.image_util.py

Contained only a no-longer used port of functionality from PIL

Remove mlab.FIFOServer

Not used internally and not part of core mission of mpl.

Remove mlab.prepca

Deprecated in 2009.

Remove NavigationToolbar2QTAgg

Added no functionality over the base NavigationToolbar2Qt

mpl.py

Remove the module matplotlib.mpl. Deprecated in 1.3 by PR #1670 and commit 78ce67d161625833cacff23cfe5d74920248c5b2

15.1.37 Changes in 1.5.2

Default Behavior Changes
Changed default autorange behavior in boxplots

Prior to v1.5.2, the whiskers of boxplots would extend to the minimum and maximum values if the quartiles were all equal (i.e., Q1 = median = Q3). This behavior has been disabled by default to restore consistency with other plotting packages.

To restore the old behavior, simply set autorange=True when calling plt.boxplot.

15.1.38 Changes in 1.5.3

ax.plot(..., marker=None) gives default marker

Prior to 1.5.3 kwargs passed to plot were handled in two parts - default kwargs generated internal to plot (such as the cycled styles) and user supplied kwargs. The internally generated kwargs were passed to the matplotlib.lines.Line2D.__init__ and the user kwargs were passed to ln.set(**kwargs) to update the artist after it was created. Now both sets of kwargs are merged and passed to __init__. This change was made to allow None to be passed in via the user kwargs to mean ‘do the default thing’ as is the convention throughout mpl rather than raising an exception.

Unlike most Line2D setter methods set_marker did accept None as a valid input which was mapped to ‘no marker’. Thus, by routing this marker=None through __init__ rather than set(, . . .) the meaning of ax.plot(..., marker=None) changed from ‘no markers’ to ‘default markers from rcparams’.

This is change is only evident if mpl.rcParams['lines.marker'] has a value other than 'None' (which is string 'None' which means ‘no marker’).

15.1.39 API Changes in 2.0.0

Deprecation and removal

Color of Axes

The axisbg and axisbgcolor properties on Axes have been deprecated in favor of facecolor.

GTK and GDK backends deprecated

The GDK and GTK backends have been deprecated. These obsolete backends allow figures to be rendered via the GDK API to files and GTK2 figures. They are untested and known to be broken, and their use has been discouraged for some time. Instead, use the GTKAgg and GTKCairo backends for rendering to GTK2 windows.

WX backend deprecated

The WX backend has been deprecated. It is untested, and its use has been discouraged for some time. Instead, use the WXAgg backend for rendering figures to WX windows.
CocoaAgg backend removed

The deprecated and not fully functional CocoaAgg backend has been removed.

round removed from TkAgg Backend

The TkAgg backend had its own implementation of the round function. This was unused internally and has been removed. Instead, use either the round builtin function or numpy.round.

'hold' functionality deprecated

The 'hold' keyword argument and all functions and methods related to it are deprecated, along with the axes.hold rcparsms entry. The behavior will remain consistent with the default hold=True state that has long been in place. Instead of using a function or keyword argument (hold=False) to change that behavior, explicitly clear the axes or figure as needed prior to subsequent plotting commands.

Artist.update has return value

The methods matplotlib.artist.Artist.set, matplotlibArtist.update, and the function matplotlib.artist.artist.set now use a common codepath to look up how to update the given artist properties (either using the setter methods or an attribute/property).

The behavior of matplotlib.Artist.update is slightly changed to return a list of the values returned from the setter methods to avoid changing the API of matplotlib.Artist.set and matplotlib.artist.artist.set.

The keys passed into matplotlib.Artist.update are now converted to lower case before being processed, to match the behavior of matplotlib.Artist.set and matplotlib.artist.artist.set. This should not break any user code because there are no set methods with capitals in their names, but this puts a constraint on naming properties in the future.

Legend initializers gain edgecolor and facecolor kwargs

The Legend background patch (or 'frame') can have its edgecolor and facecolor determined by the corresponding keyword arguments to the matplotlib.legend.Legend initializer, or to any of the methods or functions that call that initializer. If left to their default values of None, their values will be taken from matplotlib.rcParams. The previously-existing framealpha kwarg still controls the alpha transparency of the patch.

Qualitative colormaps

Colorbrewer's qualitative/discrete colormaps ("Accent", "Dark2", "Paired", "Pastel1", "Pastel2", "Set1", "Set2", "Set3") are now implemented as ListedColormap instead of LinearSegmentedColormap.

To use these for images where categories are specified as integers, for instance, use:

```python
plt.imshow(x, cmap='Dark2', norm=colors.NoNorm())
```
Change in the `draw_image` backend API

The `draw_image` method implemented by backends has changed its interface. This change is only relevant if the backend declares that it is able to transform images by returning `True` from `option_scale_image`. See the `draw_image` docstring for more information.

`matplotlib.ticker.LinearLocator` algorithm update

The `matplotlib.ticker.LinearLocator` is used to define the range and location of axis ticks when the user wants an exact number of ticks. `LinearLocator` thus differs from the default locator `MaxNLocator`, for which the user specifies a maximum number of intervals rather than a precise number of ticks.

The view range algorithm in `matplotlib.ticker.LinearLocator` has been changed so that more convenient tick locations are chosen. The new algorithm returns a plot view range that is a multiple of the user-requested number of ticks. This ensures tick marks will be located at whole integers more consistently. For example, when both y-axes of a “twinx” plot use `matplotlib.ticker.LinearLocator` with the same number of ticks, their y-tick locations and grid lines will coincide.

`matplotlib.ticker.LogLocator` gains numticks kwarg

The maximum number of ticks generated by the `LogLocator` can now be controlled explicitly via setting the new ‘numticks’ kwarg to an integer. By default the kwarg is None which internally sets it to the ‘auto’ string, triggering a new algorithm for adjusting the maximum according to the axis length relative to the ticklabel font size.

`matplotlib.ticker.LogFormatter`: two new kwargs

Previously, minor ticks on log-scaled axes were not labeled by default. An algorithm has been added to the `LogFormatter` to control the labeling of ticks between integer powers of the base. The algorithm uses two parameters supplied in a kwarg tuple named ‘minor_thresholds’. See the docstring for further explanation.

To improve support for axes using `SymmetricLogLocator`, a ‘linthresh’ kwarg was added.

New defaults for 3D quiver function in mpl_toolkits.mplot3d.axes3d.py

Matplotlib has both a 2D and a 3D `quiver` function. These changes affect only the 3D function and make the default behavior of the 3D function match the 2D version. There are two changes:

1) The 3D quiver function previously normalized the arrows to be the same length, which makes it unusable for situations where the arrows should be different lengths and does not match the behavior of the 2D function. This normalization behavior is now controlled with the `normalize` keyword, which defaults to False.

2) The `pivot` keyword now defaults to `tail` instead of `tip`. This was done in order to match the default behavior of the 2D quiver function.

To obtain the previous behavior with the 3D quiver function, one can call the function with
ax.quiver(x, y, z, u, v, w, normalize=True, pivot='tip')

where “ax” is an Axes3d object created with something like

```python
import mpl_toolkits.mplot3d.axes3d
ax = plt.subplot(111, projection='3d')
```

### Stale figure behavior

Attempting to draw the figure will now mark it as not stale (independent if the draw succeeds). This change is to prevent repeatedly trying to re-draw a figure which is raising an error on draw. The previous behavior would only mark a figure as not stale after a full re-draw succeeded.

### The spectral colormap is now nipy_spectral

The colormaps formerly known as spectral and spectral_r have been replaced by nipy_spectral and nipy_spectral_r since Matplotlib 1.3.0. Even though the colormap was deprecated in Matplotlib 1.3.0, it never raised a warning. As of Matplotlib 2.0.0, using the old names raises a deprecation warning. In the future, using the old names will raise an error.

### Default install no longer includes test images

To reduce the size of wheels and source installs, the tests and baseline images are no longer included by default.

To restore installing the tests and images, use a `setup.cfg` with

```ini
[packages]
tests = True
toolkits_tests = True
```

in the source directory at build/install time.

### 15.1.40 API Changes in 2.0.1

#### Extensions to matplotlib.backend_bases.GraphicsContextBase

To better support controlling the color of hatches, the method `matplotlib.backend_bases.GraphicsContextBase.set_hatch_color` was added to the expected API of GraphicsContext classes. Calls to this method are currently wrapped with a `try:...except AttributeError:` block to preserve back-compatibility with any third-party backends which do not extend `GraphicsContextBase`.

This value can be accessed in the backends via `matplotlib.backend_bases.GraphicsContextBase.get_hatch_color` (which was added in 2.0 see Extension to `matplotlib.backend_bases.GraphicsContextBase`) and should be used to color the hatches.

In the future there may also be `hatch_linewidth` and `hatch_density` related methods added. It is encouraged, but not required that third-party backends extend `GraphicsContextBase` to make adapting to these changes easier.
Matplotlib, Release 3.1.1

afm.get_fontconfig_fonts returns a list of paths and does not check for existence

afm.get_fontconfig_fonts used to return a set of paths encoded as a {key: 1, ...} dict, and checked for the existence of the paths. It now returns a list and dropped the existence check, as the same check is performed by the caller (afm.findSystemFonts) as well.

bar now returns rectangles of negative height or width if the corresponding input is negative

plt.bar used to normalize the coordinates of the rectangles that it created, to keep their height and width positives, even if the corresponding input was negative. This normalization has been removed to permit a simpler computation of the correct sticky_edges to use.

Do not clip line width when scaling dashes

The algorithm to scale dashes was changed to no longer clip the scaling factor: the dash patterns now continue to shrink at thin line widths. If the line width is smaller than the effective pixel size, this may result in dashed lines turning into solid gray-ish lines. This also required slightly tweaking the default patterns for ‘–’, ‘:’, and ‘.-’ so that with the default line width the final patterns would not change.

There is no way to restore the old behavior.

Deprecate ‘Vega’ color maps

The “Vega” colormaps are deprecated in Matplotlib 2.0.1 and will be removed in Matplotlib 2.2. Use the “tab” colormaps instead: “tab10”, “tab20”, “tab20b”, “tab20c”.

15.1.41 API Changes in 2.1.0

Default behavior of log scales changed to mask <= 0 values

Calling matplotlib.axes.Axes.set_xscale or matplotlib.axes.Axes.set_yscale now uses ‘mask’ as the default method to handle invalid values (as opposed to ‘clip’). This means that any values <= 0 on a log scale will not be shown.

Previously they were clipped to a very small number and shown.

matplotlib.cbook.CallbackRegistry.process() suppresses exceptions by default

Matplotlib uses instances of CallbackRegistry as a bridge between user input event from the GUI and user callbacks. Previously, any exceptions raised in a user call back would bubble out of the process method, which is typically in the GUI event loop. Most GUI frameworks simple print the traceback to the screen and continue as there is not always a clear method of getting the exception back to the user. However PyQt5 now exits the process when it receives an un-handled python exception in the event loop. Thus, process() now suppresses and prints tracebacks to stderr by default.

What process() does with exceptions is now user configurable via the exception_handler attribute and kwarg. To restore the previous behavior pass None.
A function which take and `Exception` as its only argument may also be passed

```python
def maybe_reraise(exc):
    if isinstance(exc, RuntimeError):
        pass
    else:
        raise exc
```

```python
cb = CallbackRegistry(exception_handler=maybe_reraise)
```

**Improved toggling of the axes grids**

The g key binding now switches the states of the x and y grids independently (by cycling through all four on/off combinations).

The new G key binding switches the states of the minor grids.

Both bindings are disabled if only a subset of the grid lines (in either direction) is visible, to avoid making irreversible changes to the figure.

**Ticklabels are turned off instead of being invisible**

Internally, the `Tick`’s `label1On()` attribute is now used to hide tick labels instead of setting the visibility on the tick label objects. This improves overall performance and fixes some issues. As a consequence, in case those labels ought to be shown, `tick_params()` needs to be used, e.g.

```python
ax.tick_params(labelbottom=True)
```

**Removal of warning on empty legends**

`plt.legend` used to issue a warning when no labeled artist could be found. This warning has been removed.

**More accurate legend autopositioning**

Automatic positioning of legends now prefers using the area surrounded by a `Line2D` rather than placing the legend over the line itself.

**Cleanup of stock sample data**

The sample data of stocks has been cleaned up to remove redundancies and increase portability. The `AAPL.dat.gz`, `INTC.dat.gz` and `aapl.csv` files have been removed entirely and will also no longer be available from `matplotlib.cbook.get_sample_data`. If a CSV file is required, we suggest using the `msft.csv` that continues to be shipped in the sample data. If a NumPy binary file is acceptable, we suggest using one of the following two new files. The `aapl.npy.gz` and `goog.npy` files have been replaced by `aapl.npz` and `goog.npz`, wherein the first column’s type
Matplotlib, Release 3.1.1

has changed from `datetime.date` to `np.datetime64` for better portability across Python versions. Note that Matplotlib does not fully support `np.datetime64` as yet.

**Updated qhull to 2015.2**

The version of qhull shipped with Matplotlib, which is used for Delaunay triangulation, has been updated from version 2012.1 to 2015.2.

**Improved Delaunay triangulations with large offsets**

Delaunay triangulations now deal with large x,y offsets in a better way. This can cause minor changes to any triangulations calculated using Matplotlib, i.e. any use of `matplotlib.tri.Triangulation` that requests that a Delaunay triangulation is calculated, which includes `matplotlib.pyplot.tricontour`, `matplotlib.pyplot.tricontourf`, `matplotlib.pyplot.tripcolor`, `matplotlib.pyplot.triplot`, `matplotlib.mlab.griddata` and `mpl_toolkits.mplot3d.axes3d.Axes3D.plot_trisurf`.

Use `backports.functools_lru_cache` instead of `functools32`

It's better maintained and more widely used (by pylint, jaraco, etc).

**cbook.is_numlike only performs an instance check**

`is_numlike()` now only checks that its argument is an instance of `(numbers.Number, np.Number)`. In particular, this means that arrays are now not num-like.

**Elliptical arcs now drawn between correct angles**

The `matplotlib.patches.Arc` patch is now correctly drawn between the given angles.

Previously a circular arc was drawn and then stretched into an ellipse, so the resulting arc did not lie between `theta1` and `theta2`.

**-d$backend no longer sets the backend**

It is no longer possible to set the backend by passing `-d$backend` at the command line. Use the `MPLBACKEND` environment variable instead.

**Path.intersects_bbox always treats the bounding box as filled**

Previously, when `Path.intersects_bbox` was called with `filled` set to `False`, it would treat both the path and the bounding box as unfilled. This behavior was not well documented and it is usually not the desired behavior, since bounding boxes are used to represent more complex shapes located inside the bounding box. This behavior has now been changed: when `filled` is `False`, the path will be treated as unfilled, but the bounding box is still treated as filled. The old behavior was arguably an implementation bug.
When `Path.intersects_bbox` is called with `filled` set to `True` (the default value), there is no change in behavior. For those rare cases where `Path.intersects_bbox` was called with `filled` set to `False` and where the old behavior is actually desired, the suggested workaround is to call `Path.intersects_path` with a rectangle as the path:

```python
from matplotlib.path import Path
from matplotlib.transforms import Bbox, BboxTransformTo
rect = Path.unit_rectangle().transformed(BboxTransformTo(bbox))
result = path.intersects_path(rect, filled=False)
```

**WX no longer calls generates IdleEvent events or calls idle_event**

Removed unused private method `_onIdle` from FigureCanvasWx.

The IdleEvent class and FigureCanvasBase.idle_event method will be removed in 2.2

**Correct scaling of magnitude_spectrum()**

The functions `matplotlib.mlab.magnitude_spectrum()` and `matplotlib.pyplot.magnitude_spectrum()` implicitly assumed the sum of windowing function values to be one. In Matplotlib and Numpy the standard windowing functions are scaled to have maximum value of one, which usually results in a sum of the order of n/2 for a n-point signal. Thus the amplitude scaling `magnitude_spectrum()` was off by that amount when using standard windowing functions (Bug 8417). Now the behavior is consistent with `matplotlib.pyplot.psd()` and `scipy.signal.welch()`. The following example demonstrates the new and old scaling:

```python
import matplotlib.pyplot as plt
import numpy as np

tau, n = 10, 1024  # 10 second signal with 1024 points
T = tau/n  # sampling interval
t = np.arange(n)*T

a = 4  # amplitude
x = a*np.sin(40*np.pi*t)  # 20 Hz sine with amplitude a

# New correct behavior: Amplitude at 20 Hz is a/2
plt.magnitude_spectrum(x, Fs=1/T, sides='onesided', scale='linear')

# Original behavior: Amplitude at 20 Hz is (a/2)*(n/2) for a Hanning window
w = np.hanning(n)  # default window is a Hanning window
plt.magnitude_spectrum(x*np.sum(w), Fs=1/T, sides='onesided', scale='linear')
```

**Change to signatures of bar() & barh()**

For 2.0 the default value of `*align*` changed to `'center'`. However this caused the signature of `bar()` and `barh()` to be misleading as the first parameters were still `left` and `bottom` respectively:

```python
bar(left, height, *, align='center', **kwargs)
barh(bottom, width, *, align='center', **kwargs)
```
Matplotlib, Release 3.1.1

despite behaving as the center in both cases. The methods now take *args, **kwargs as input
and are documented to have the primary signatures of:

```python
bar(x, height, *, align='center', **kwargs)
barh(y, width, *, align='center', **kwargs)
```

Passing `left` and `bottom` as keyword arguments to `bar()` and `barh()` respectively will warn. Support will be removed in Matplotlib 3.0.

**Font cache as json**

The font cache is now saved as json, rather than a pickle.

**Invalid (Non-finite) Axis Limit Error**

When using `set_xlim()` and `set_ylim()`, passing non-finite values now results in a `ValueError`. The previous behavior resulted in the limits being erroneously reset to `(-0.001, 0.001)`.

**scatter** and **Collection offsets are no longer implicitly flattened**

`Collection` (and thus both 2D `scatter` and 3D `scatter`) no longer implicitly flattens its offsets. As a consequence, `scatter`'s `x` and `y` arguments can no longer be 2+-dimensional arrays.

**Deprecations**

**GraphicsContextBase's linestyle property.**

The `GraphicsContextBase.get_linestyle` and `GraphicsContextBase.set_linestyle` methods, which had no effect, have been deprecated. All of the backends Matplotlib ships use `GraphicsContextBase.get_dashes` and `GraphicsContextBase.set_dashes` which are more general. Third-party backends should also migrate to the *_dashes methods.

**NavigationToolbar2.dynamic_update**

Use `draw_idle()` method on the Canvas instance instead.

**Testing**

`matplotlib.testing.noseclasses` is deprecated and will be removed in 2.3

**EngFormatter num arg as string**

Passing a string as `num` argument when calling an instance of `matplotlib.ticker.EngFormatter` is deprecated and will be removed in 2.3.
mpl_toolkits.axes_grid module

All functionally from mpl_toolkits.axes_grid can be found in either mpl_toolkits.axes_grid1 or mpl_toolkits.axisartist. Axes classes from mpl_toolkits.axes_grid based on Axis from mpl_toolkits.axisartist can be found in mpl_toolkits.axisartist.

Axes collision in Figure.add_axes

Adding an axes instance to a figure by using the same arguments as for a previous axes instance currently reuses the earlier instance. This behavior has been deprecated in Matplotlib 2.1. In a future version, a new instance will always be created and returned. Meanwhile, in such a situation, a deprecation warning is raised by AxesStack.

This warning can be suppressed, and the future behavior ensured, by passing a unique label to each axes instance. See the docstring of add_axes() for more information.

Additional details on the rationale behind this deprecation can be found in #7377 and #9024.

Former validators for contour.negative_linestyle

The former public validation functions validate_negative_linestyle and validate_negative_linestyle_legacy will be deprecated in 2.1 and may be removed in 2.3. There are no public functions to replace them.

cbook

Many unused or near-unused matplotlib.cbook functions and classes have been deprecated: converter, tostr, todatetime, todate, tofloat, toint, unique, is_string_like, is_sequence_of_strings, is_scalar, Sorter, Xlator, soundex, Null, dict_delall, RingBuffer, get_split_ind, wrap, get_recursive_filelist, pieces, exception_to_str, allequal, alltrue, onetrue, allpairs, finddir, reverse_dict, restrict_dict, issubclass_safe, recursive_remove, unmasked_index_ranges.

Code Removal

qt4_compat.py

Moved to qt_compat.py. Renamed because it now handles Qt5 as well.

Previously Deprecated methods

The GraphicsContextBase.set_graylevel, FigureCanvasBase.onHilite and mpl_toolkits.axes_grid1.mpl_axes.Axes.toggle_axisline methods have been removed.

The ArtistInspector.findobj method, which was never working due to the lack of a get_children method, has been removed.
The deprecated `point_in_path`, `get_path_extents`, `point_in_path_collection`, `path_intersects_path`, `convert_path_to_polygons`, `cleanup_path` and `clip_path_to_rect` functions in the `matplotlib.path` module have been removed. Their functionality remains exposed as methods on the `Path` class.

The deprecated `Artist.get_axes` and `Artist.set_axes` methods have been removed.

The `matplotlib.backends.backend_ps.seq_allequal` function has been removed. Use `np.array_equal` instead.

The deprecated `matplotlib.rcsetup.validate_maskedarray`, `matplotlib.rcsetup.deprecate_savefig_extension` and `matplotlib.rcsetup.validate_tkpythoninspect` functions, and associated `savefig.extension` and `tk.pythoninspect.rcparams` entries have been removed.

The kwarg `resolution` of `matplotlib.projections.polar.PolarAxes` has been removed. It has deprecation with no effect from version 0.98.x.

```python
Axes.set_aspect("normal")
```

Support for setting an Axes’s aspect to "normal" has been removed, in favor of the synonym "auto".

```python
shading kwarg to pcolor
```

The shading kwarg to `pcolor` has been removed. Set `edgecolors` appropriately instead.

### Functions removed from the `lines` module

The `matplotlib.lines` module no longer imports the `pts_to_prestep`, `pts_to_midstep` and `pts_to_poststep` functions from `matplotlib.cbook`.

### PDF backend functions

The methods `embedTeXFont` and `tex_font_mapping` of `matplotlib.backend_pdf.PdfFile` have been removed. It is unlikely that external users would have called these methods, which are related to the font system internal to the PDF backend.

`matplotlib.delaunay`

Remove the delaunay triangulation code which is now handled by Qhull via `matplotlib.tri`.

### 15.1.42 API Changes in 2.1.1

#### Default behavior of log scales reverted to clip $\leq 0$ values

The change in 2.1.0 to mask in logscale by default had more disruptive changes than anticipated and has been reverted, however the clipping is now done in a way that fixes the issues that motivated changing the default behavior to 'mask'.
As a side effect of this change, error bars which go negative now work as expected on log scales.

15.1.43 API Changes in 2.1.2

Figure.legend no longer checks for repeated lines to ignore

`matplotlib.Figure.legend` used to check if a line had the same label as an existing legend entry. If it also had the same line color or marker color legend didn’t add a new entry for that line. However, the list of conditions was incomplete, didn’t handle RGB tuples, didn’t handle linewidths or linestyles etc.

This logic did not exist in `Axes.legend`. It was included (erroneously) in Matplotlib 2.1.1 when the legend argument parsing was unified [#9324](https://github.com/matplotlib/matplotlib/pull/9324). This change removes that check in `Axes.legend` again to restore the old behavior.

This logic has also been dropped from `Figure.legend`, where it was previously undocumented. Repeated lines with the same label will now each have an entry in the legend. If you do not want the duplicate entries, don’t add a label to the line, or prepend the label with an underscore.

15.1.44 API Changes in 2.2.0

New dependency

`kiwisolver` is now a required dependency to support the new constrained_layout, see Constrained Layout Guide for more details.

Deprecations

Classes, functions, and methods

The unused and untested `Artist.onRemove` and `Artist.hitlist` methods have been deprecated.

The now unused `mlab.less_simple_linear_interpolation` function is deprecated.

The unused `ContourLabeler.get_real_label_width` method is deprecated.

The unused `FigureManagerBase.show_popup` method is deprecated. This introduced in e945059b327d42a99938b939a1be867fa023e7ba in 2005 but never built out into any of the backends.

`backend_tkagg.AxesMenu` is deprecated, as it has become unused since the removal of “classic” toolbars.

Changed function signatures

`kwarg fig` to `GridSpec.get_subplot_params` is deprecated, use `figure` instead.

Using `pyplot.axes` with an `Axes` as argument is deprecated. This sets the current axes, i.e. it has the same effect as `pyplot.sca`. For clarity `plt.sca(ax)` should be preferred over `plt.axes(ax)`.
Using strings instead of booleans to control grid and tick visibility is deprecated. Using "on", "off", "true", or "false" to control grid and tick visibility has been deprecated. Instead, use normal booleans (True/False) or boolean-likes. In the future, all non-empty strings may be interpreted as True.

When given 2D inputs with non-matching numbers of columns, \texttt{plot} currently cycles through the columns of the narrower input, until all the columns of the wider input have been plotted. This behavior is deprecated; in the future, only broadcasting (1 column to \textit{n} columns) will be performed.

\texttt{rcparams}

The \texttt{rcParams["backend.qt4"]} and \texttt{rcParams["backend.qt5"]} \texttt{rcParams} were deprecated in version 2.2. In order to force the use of a specific Qt binding, either import that binding first, or set the \texttt{QT_API} environment variable.

Deprecation of the \texttt{nbagg.transparent \texttt{rcParam}}. To control transparency of figure patches in the \texttt{nbagg} (or any other) backend, directly set \texttt{figure.patch.facecolor}, or the \texttt{figure.facecolor \texttt{rcParam}}.

\texttt{Deprecated Axis.unit_data}

Use \texttt{Axis.units} (which has long existed) instead.

\texttt{Removals}

\texttt{Function Signatures}

Contouring no longer supports legacy corner masking. The deprecated \texttt{ContourSet.vmin} and \texttt{ContourSet.vmax} properties have been removed.

Passing \texttt{None} instead of "none" as format to \texttt{errorbar} is no longer supported.

The \texttt{bgcolor} keyword argument to \texttt{Axes} has been removed.

\texttt{Modules, methods, and functions}

The \texttt{matplotlib.finance}, \texttt{mpl_toolkits.exceltools} and \texttt{mpl_toolkits.gtktools} modules have been removed. \texttt{matplotlib.finance} remains available at \url{https://github.com/matplotlib/mpl_finance}.

The \texttt{mpl_toolkits.mplot3d.art3d.iscolor} function has been removed.

The \texttt{Axes.get_axisbgcolor}, \texttt{Axes.set_axisbgcolor}, \texttt{Bbox.update_from_data}, \texttt{Bbox.update_datalim_numerix}, \texttt{MaxNLocator.bin_boundaries} methods have been removed.

\texttt{mencoder} can no longer be used to encode animations.

The unused \texttt{FONT_SCALE} and \texttt{fontd} attributes of the \texttt{RendererSVG} class have been removed.
color maps

The spectral colormap has been removed. The vega* colormaps, which were aliases for the tab* colormaps, have been removed.

rcparams

The following deprecated rcParams have been removed:

- axes.color_cycle (see axes.prop_cycle),
- legend.isaxes,
- svg.embed_char_paths (see svg.fonttype),
- text.fontstyle, text.fontangle, text.fontvariant, text.fontweight, text.fontsize (renamed to text.style, etc.),
- tick.size (renamed to tick.major.size).

Only accept string-like for Categorical input

Do not accept mixed string / float / int input, only strings are valid categoricals.

Removal of unused imports

Many unused imports were removed from the codebase. As a result, trying to import certain classes or functions from the “wrong” module (e.g. Figure from matplotlib.backends.backend_agg instead of matplotlib.figure) will now raise an ImportError.

Axes3D.get_xlim, get_ylim and get_zlim now return a tuple

They previously returned an array. Returning a tuple is consistent with the behavior for 2D axes.

Exception type changes

If MovieWriterRegistry can’t find the requested MovieWriter, a more helpful RuntimeError message is now raised instead of the previously raised KeyError.

auto_adjust_subplotpars now raises ValueError instead of RuntimeError when sizes of input lists don’t match

Figure.set_figwidth and Figure.set_figheight default forward to True

matplotlib.Figure.set_figwidth and matplotlib.Figure.set_figheight had the kwarg forward=False by default, but Figure.set_size_inches now defaults to forward=True. This makes these functions consistent.
Do not truncate svg sizes to nearest point

There is no reason to size the SVG output in integer points, change to outputting floats for the *height*, *width*, and *viewBox* attributes of the *svg* element.

Fonts sizes less than 1 pt are clipped to be 1 pt.

FreeType doesn’t allow fonts to get smaller than 1 pt, so all Agg backends were silently rounding up to 1 pt. PDF (other vector backends?) were letting us write fonts that were less than 1 pt, but they could not be placed properly because position information comes from FreeType. This change makes it so no backends can use fonts smaller than 1 pt, consistent with FreeType and ensuring more consistent results across backends.

Changes to Qt backend class MRO

To support both Agg and cairo rendering for Qt backends all of the non-Agg specific code previously in *backend_qt5agg.FigureCanvasQTAggBase* has been moved to *backend_qt5.FigureCanvasQT* so it can be shared with the cairo implementation. The *FigureCanvasQTAggBase.paintEvent()*, *FigureCanvasQTAggBase.blit()*, and *FigureCanvasQTAggBase.print_figure()* methods have moved to *FigureCanvasQTAgg.paintEvent()*, *FigureCanvasQTAgg.blit()*, and *FigureCanvasQTAgg.print_figure()* . The first two methods assume that the instance is also a *QWidget* so to use *FigureCanvasQTAggBase* it was required to multiple inherit from a *QWidget* sub-class.

Having moved all of its methods either up or down the class hierarchy *FigureCanvasQTAggBase* has been deprecated. To do this with out warning and to preserve as much API as possible, *backend_qt5.FigureCanvasQTAggBase* now inherits from *backend_qt5.FigureCanvasQTAgg*. The MRO for *FigureCanvasQTAgg* and *FigureCanvasQTAggBase* used to be

```python
[matplotlib.backends.backend_qt5agg.FigureCanvasQTAgg,
 matplotlib.backends.backend_qt5agg.FigureCanvasQTAggBase,
 matplotlib.backends.backend_agg.FigureCanvasAgg,
 matplotlib.backends.backend_qt5.FigureCanvasQT,
 PyQt5.QtWidgets.QWidget, 
 PyQt5.QtCore.QObject, 
 sip.wrapper, 
 PyQt5.QtGui.QPaintDevice, 
 sip.simplerwrapper, 
 matplotlib.backend_bases.FigureCanvasBase, 
 object]
```

and

```python
[matplotlib.backends.backend_qt5agg.FigureCanvasQTAggBase,
 matplotlib.backends.backend_agg.FigureCanvasAgg,
 matplotlib.backend_bases.FigureCanvasBase, 
 object]
```

respectively. They are now

```python
[matplotlib.backends.backend_qt5agg.FigureCanvasQTAgg, 
 matplotlib.backends.backend_agg.FigureCanvasAgg, 
 matplotlib.backend_bases.FigureCanvasBase, 
 object]
```
Axes.imshow clips RGB values to the valid range

When Axes.imshow is passed an RGB or RGBA value with out-of-range values, it now logs a warning and clips them to the valid range. The old behaviour, wrapping back in to the range, often hid outliers and made interpreting RGB images unreliable.

GTKAgg and GTKCairo backends deprecated

The GTKAgg and GTKCairo backends have been deprecated. These obsolete backends allow figures to be rendered via the GTK+ 2 toolkit. They are untested, known to be broken, will not work with Python 3, and their use has been discouraged for some time. Instead, use the GTK3Agg and GTK3Cairo backends for rendering to GTK+ 3 windows.

15.1.45 API Changes for 3.0.0

Drop support for python 2

Matplotlib 3 only supports python 3.5 and higher.

Changes to backend loading

Failure to load backend modules (macosx on non-framework builds and gtk3 when running headless) now raises ImportError (instead of RuntimeError and TypeError, respectively).
Third-party backends that integrate with an interactive framework are now encouraged to define the `required_interactive_framework` global value to one of the following values: "qt5", "qt4", "gtk3", "wx", "tk", or "macosx". This information will be used to determine whether it is possible to switch from a backend to another (specifically, whether they use the same interactive framework).

**Axes.hist2d** now uses `pcolormesh` instead of `pcolorfast`.

**Axes.hist2d** now uses `pcolormesh` instead of `pcolorfast`, which will improve the handling of log-axes. Note that the returned `image` now is of type `QuadMesh` instead of `AxesImage`.

**matplotlib.axes.Axes.get_tightbbox** now includes all artists

For Matplotlib 3.0, all artists are now included in the bounding box returned by `matplotlib.axes.Axes.get_tightbbox`.

**matplotlib.axes.Axes.get_tightbbox** adds a new kwarg `bbox_extra_artists` to manually specify the list of artists on the axes to include in the tight bounding box calculation.

Layout tools like `Figure.tight_layout`, `constrained_layout`, and `fig.savefig('fname.png', bbox_inches="tight")` use `matplotlib.axes.Axes.get_tightbbox` to determine the bounds of each axes on a figure and adjust spacing between axes.

In Matplotlib 2.2, `get_tightbbox` started to include legends made on the axes, but still excluded some other artists, like text that may overspill an axes. This has been expanded to include all artists.

This new default may be overridden in either of three ways:

1. Make the artist to be excluded a child of the figure, not the axes. E.g., call `fig.legend()` instead of `ax.legend()` (perhaps using `get_legend_handles_labels` to gather handles and labels from the parent axes).
2. If the artist is a child of the axes, set the artist property `artist.set_in_layout(False)`.
3. Manually specify a list of artists in the new kwarg `bbox_extra_artists`.

**Text.set_text** with string argument `None` sets string to empty

`Text.set_text` when passed a string value of `None` would set the string to "None", so subsequent calls to `Text.get_text` would return the ambiguous "None" string.

This change sets text objects passed `None` to have empty strings, so that `Text.get_text` returns an empty string.

**Axes3D.get_xlim, get_ylim and get_zlim** now return a tuple

They previously returned an array. Returning a tuple is consistent with the behavior for 2D axes.

**font_manager.list_fonts** now follows the platform’s casefolding semantics

i.e., it behaves case-insensitively on Windows only.
bar / barh no longer accepts left / bottom as first named argument

These arguments were renamed in 2.0 to x / y following the change of the default alignment from edge to center.

Different exception types for undocumented options

- Passing style='comma' to ticklabel_format() was never supported. It now raises ValueError like all other unsupported styles, rather than NotImplementedError.
- Passing the undocumented xmin or xmax arguments to set_xlim() would silently override the left and right arguments. set_ylim() and the 3D equivalents (e.g. set_zlim3d()) had a corresponding problem. A TypeError will be raised if they would override the earlier limit arguments. In 3.0 these were kwargs were deprecated, but in 3.1 the deprecation was undone.

Improved call signature for Axes.margins

matplotlib.axes.Axes.margins() and mpl_toolkits.mplot3d.Axes3D.margins() no longer accept arbitrary keywords. TypeError will therefore be raised if unknown kwargs are passed; previously they would be silently ignored.

If too many positional arguments are passed, TypeError will be raised instead of ValueError, for consistency with other call-signature violations.

Axes3D.margins now raises TypeError instead of emitting a deprecation warning if only two positional arguments are passed. To supply only x and y margins, use keyword arguments.

Explicit arguments instead of *args, **kwargs

PEP 3102 describes keyword-only arguments, which allow Matplotlib to provide explicit call signatures - where we previously used *args, **kwargs and kwargs.pop, we can now expose named arguments. In some places, unknown kwargs were previously ignored but now raise TypeError because **kwargs has been removed.

- matplotlib.axes.Axes.stem() no longer accepts unknown keywords, and raises TypeError instead of emitting a deprecation.
- matplotlib.axes.Axes.stem() now raises TypeError when passed unhandled positional arguments. If two or more arguments are passed (ie X, Y, [linefmt], ...) and Y cannot be cast to an array, an error will be raised instead of treating X as Y and Y as linefmt.
- mpl_toolkits.axes_grid1.axes_divider.SubPlotDivider() raises TypeError instead of Exception when passed unknown kwargs.

Cleanup decorators and test classes no longer destroy warnings filter on exit

The decorators and classes in matplotlib.testing.decorators no longer destroy the warnings filter on exit. Instead, they restore the warnings filter that existed before the test started using warnings.catch_warnings.
Non-interactive FigureManager classes are now aliases of FigureManagerBase

The FigureManagerPdf, FigureManagerPS, and FigureManagerSVG classes, which were previously empty subclasses of FigureManagerBase (i.e., not adding or overriding any attribute or method), are now direct aliases for FigureManagerBase.

Change to the output of `image.thumbnail`

When called with `preview=False`, `image.thumbnail` previously returned a figure whose canvas class was set according to the output file extension. It now returns a figure whose canvas class is the base FigureCanvasBase (and relies on FigureCanvasBase.print_figure to handle the canvas switching properly).

As a side effect of this change, `image.thumbnail` now also supports .ps, .eps, and .svgz output.

`FuncAnimation` now draws artists according to their zorder when blitting

`FuncAnimation` now draws artists returned by the user-function according to their zorder when using blitting, instead of using the order in which they are being passed. However, note that only zorder of passed artists will be respected, as they are drawn on top of any existing artists (see #11369).

Contour color autoscaling improvements

Selection of contour levels is now the same for contour and contourf; previously, for contour, levels outside the data range were deleted. (Exception: if no contour levels are found within the data range, the levels attribute is replaced with a list holding only the minimum of the data range.)

When contour is called with levels specified as a target number rather than a list, and the ‘extend’ kwarg is used, the levels are now chosen such that some data typically will fall in the extended range.

When contour is called with a LogNorm or a LogLocator, it will now select colors using the geometric mean rather than the arithmetic mean of the contour levels.

Streamplot last row and column fixed

A bug was fixed where the last row and column of data in streamplot were being dropped.

Changed default `AutoDateLocator` kwarg `interval_multiples` to True

The default value of the tick locator for dates, `dates.AutoDateLocator` kwarg `interval_multiples` was set to False which leads to not-nice looking automatic ticks in many instances. The much nicer `interval_multiples=True` is the new default. See below to get the old behavior back:
Axes.get_position now returns actual position if aspect changed

Axes.get_position used to return the original position unless a draw had been triggered or Axes.apply_aspect had been called, even if the kwarg original was set to False. Now Axes.apply_aspect is called so ax.get_position() will return the new modified position. To get the old behavior use ax.get_position(original=True).

The ticks for colorbar now adjust for the size of the colorbar

Colorbar ticks now adjust for the size of the colorbar if the colorbar is made from a mappable that is not a contour or doesn’t have a BoundaryNorm, or boundaries are not specified. If boundaries, etc are specified, the colorbar maintains the original behavior.

Colorbar for log-scaled hexbin

When using hexbin and plotting with a logarithmic color scale, the colorbar ticks are now correctly log scaled. Previously the tick values were linear scaled log(number of counts).

PGF backend now explicitly makes black text black

Previous behavior with the pgf backend was for text specified as black to actually be the default color of whatever was rendering the pgf file (which was of course usually black). The
new behavior is that black text is black, regardless of the default color. However, this means
that there is no way to fall back on the default color of the renderer.

**Blacklisted rcparams no longer updated by** rcdefaults, rc_file_defaults, rc_file

The rc modifier functions rcdefaults, rc_file_defaults and rc_file now ignore rcParams in
the matplotlib.style.core.STYLE_BLACKLIST set. In particular, this prevents the backend and
interactive rcParams from being incorrectly modified by these functions.

**CallbackRegistry now stores callbacks using stdlib’s WeakMethods**

In particular, this implies that CallbackRegistry.callbacks[signal] is now a mapping of call-
back ids to WeakMethods (i.e., they need to be first called with no arguments to retrieve the
method itself).

**Changes regarding the text.latex.unicode rcParam**

The rcParam now defaults to True and is deprecated (i.e., in future versions of Matplotlib,
unicode input will always be supported).

Moreover, the underlying implementation now uses \usepackage[utf8]{inputenc} instead of
\usepackage{ucs}\usepackage[utf8x]{inputenc}.

**Return type of ArtistInspector.get_aliases changed**

ArtistInspector.get_aliases previously returned the set of aliases as {fullname: {alias1: None, alias2: None, ...}}. The dict-to-None mapping was used to simulate a set in earlier
versions of Python. It has now been replaced by a set, i.e. {fullname: {alias1, alias2, ...}}.

This value is also stored in ArtistInspector.aliases, which has likewise changed.

**Removed pytz as a dependency**

Since dateutil and pytz both provide time zones, and matplotlib already depends on dateutil,
matplotlib will now use dateutil time zones internally and drop the redundant dependency
on pytz. While dateutil time zones are preferred (and currently recommended in the Python
documentation), the explicit use of pytz zones is still supported.

**Deprecations**

**Modules**

The following modules are deprecated:

- matplotlib.compat.subprocess. This was a python 2 workaround, but all the functionality
can now be found in the python 3 standard library subprocess.

- matplotlib.backends.wx_compat. Python 3 is only compatible with wxPython 4, so support
  for wxPython 3 or earlier can be dropped.
Classes, methods, functions, and attributes

The following classes, methods, functions, and attributes are deprecated:

- `RcParams.msg_depr`, `RcParams.msg_depr_ignore`, `RcParams.msg_depr_set`, `RcParams.msg_obsolete`, `RcParams.msg_backend_obsolete`
- `afm.parse_afm`
- `backend_pdf.PdfFile.texFontMap`
- `backend_pgf.get_texcommand`
- `backend_ps.get_bbox`
- `backend_qt5.FigureCanvasQT.keyAutoRepeat` (directly check `event.guiEvent.isAutoRepeat()` in the event handler to decide whether to handle autorepeated key presses).
- `backend_qt5.error_msg_qt`, `backend_qt5.exception_handler`
- `backend_wx.FigureCanvasWx.macros`
- `backends.pylab_setup`
- `cbook.GetRealpathAndStat`, `cbook.Locked`
- `cbook.is_numlike` (use `isinstance(..., numbers.Number)` instead), `cbook.listFiles`, `cbook.unicode_safe`
- `container.Container.set_remove_method`,
- `contour.ContourLabeler.cl`, `.cl_xy`, and `.cl_cvalues`
- `dates DateFormatter.strftime_pre_1900`, `dates DateFormatter.strftime`
- `font_manager.TempCache`
- `_ImageBase.iterpnames`, use the `interpolation_names` property instead. (this affects classes that inherit from `_ImageBase` including `FigureImage`, `BboxImage`, and `AxesImage`)
- `mathtext.unichr_safe` (use `chr` instead)
- `patches.Polygon.xy`
- `table.Table.get_child_artists` (use `get_children` instead)
- `testing.compare.ImageComparisonTest`, `testing.compare.compare_float`
- `testing.decorators.CleanupTest`, `testing.decorators.skip_if_command_unavailable`
- `FigureCanvasQT.keyAutoRepeat` (directly check `event.guiEvent.isAutoRepeat()` in the event handler to decide whether to handle autorepeated key presses)
- `FigureCanvasWx.macros`
- `_ImageBase.iterpnames`, use the `interpolation_names` property instead. (this affects classes that inherit from `_ImageBase` including `FigureImage`, `BboxImage`, and `AxesImage`)
- `patches.Polygon.xy`
- `texmanager.dvipng_hack_alpha`
- `text.Annotation.arrow`
- `Legend.draggable()`, in favor of `Legend.set_draggable()` (Legend.draggable may be reintroduced as a property in future releases)
- `textpath.TextToPath.tex_font_map`
Matplotlib, Release 3.1.1

- `matplotlib.cbook.deprecation.mplDeprecation` will be removed in future versions. It is just an alias for `matplotlib.cbook.deprecation.MatplotlibDeprecationWarning`. Please use the `MatplotlibDeprecationWarning` directly if necessary.

- The `matplotlib.cbook.Bunch` class has been deprecated. Instead, use `types.SimpleNamespace` from the standard library which provides the same functionality.

- `Axes.mouseover_set` is now a frozenset, and deprecated. Directly manipulate the artist’s `.mouseover` attribute to change their mouseover status.

The following keyword arguments are deprecated:

- passing `verts` to `Axes.scatter` (use `marker` instead)
- passing `obj_type` to `cbook.deprecated`

The following call signatures are deprecated:

- passing a `wxEvtHandler` as first argument to `backend_wx.TimerWx`

rcParams

The following rcParams are deprecated:

- `examples.directory` (use `datapath` instead)
- `pgf.debug` (the pgf backend relies on logging)
- `text.latex.unicode` (always True now)

marker styles

- Using `(n, 3)` as marker style to specify a circle marker is deprecated. Use "o" instead.
- Using `([(x0, y0), (x1, y1), ...], 0)` as marker style to specify a custom marker path is deprecated. Use `[(x0, y0), (x1, y1), ...]` instead.

Deprecation of `LocatableAxes` in toolkits

The `LocatableAxes` classes in toolkits have been deprecated. The base `Axes` classes provide the same functionality to all subclasses, thus these mixins are no longer necessary. Related functions have also been deprecated. Specifically:

- `mpl_toolkits.axes_grid1.axes_divider.LocatableAxesBase`: no specific replacement; use any other `Axes`-derived class directly instead.
- `mpl_toolkits.axes_grid1.axes_divider.locatable_axes_factory`: no specific replacement; use any other `Axes`-derived class directly instead.

Removals

Hold machinery

Setting or unsetting hold (deprecated in version 2.0) has now been completely removed. Matplotlib now always behaves as if hold=True. To clear an axes you can manually use cla(), or to clear an entire figure use clf().

Removal of deprecated backends

Deprecated backends have been removed:
• GTKAgg
• GTKCairo
• GTK
• GDK

Deprecated APIs

The following deprecated API elements have been removed:
• The deprecated methods knownfailureif and remove_text have been removed from matplotlib.testing.decorators.
• The entire contents of testing.noseclasses have also been removed.
• matplotlib.checkdep_tex, matplotlib.checkdep_xml lint
• backend_bases.IdleEvent
• cbook.converter, cbook.tostr, cbook.todatetime, cbook.todate, cbook.tofloat, cbook.toint, cbook.unique, cbook.is_string_like, cbook.is_sequence_of_strings, cbook.is_scalar, cbook.soundex, cbook.dict_delall, cbook.get_split_ind, cbook.wrap, cbook.get_recursive_filelist, cbook.pieces, cbook.exception_to_str, cbook.allequal, cbook.alltrue, cbook.onetrue, cbook.allpairs, cbook.finddir, cbook.reverse_dict, cbook.restrict_dict, cbook.issubclass_safe, cbook.recursive_remove, cbook.unmasked_index_ranges, cbook.Null, cbook.RingBuffer, cbook.Sorter, cbook.Xlator,
• font_manager.weight_as_number, font_manager.ttfdict_to_fnames
• pyplot.colors, pyplot.spectral

The following API elements have been removed:
• backend_cairo.HAS_CAIRO_CFFI
• sphinxext.sphinx_version

Proprietary sphinx directives

The matplotlib documentation used the proprietary sphinx directives htmlonly::, and
latexonly::: These have been replaced with the standard sphinx directives only:: html and
only:: latex. This change will not affect any users. Only downstream package main-ainers, who have used the proprietary directives in their docs, will have to switch to the sphinx
directives.

lib/mpl_examples symlink

The symlink from lib/mpl_examples to ../examples has been removed. This is not installed
as an importable package and should not affect end users, however this may require down-
stream packagers to adjust. The content is still available top-level examples directory.

15.1.46 API Changes for 3.0.1

tight_layout.auto_adjust_subplotpars can return None now if the new subplotparams will col-
lapse axes to zero width or height. This prevents tight_layout from being executed. Similarly
tight_layout.get_tight_layout_figure will return None.
To improve import (startup) time, private modules are now imported lazily. These modules are no longer available at these locations:

- `matplotlib.backends.backend_agg._png`
- `matplotlib.contour._contour`
- `matplotlib.image._png`
- `matplotlib.mathtext._png`
- `matplotlib.testing.compare._png`
- `matplotlib.texmanager._png`
- `matplotlib.tri.triangulation._tri`
- `matplotlib.tri.triangulation._qhull`
- `matplotlib.tri.tricontour._tri`
- `matplotlib.tri.trifinder._tri`

### 15.1.47 API Changes for 3.1.0

- **Behavior changes**
- **pgi support dropped**
- **rcParam changes**
- **Exception changes**
- **Removals**
  - `matplotlib.mlab removals`
  - `matplotlib.pyplot removals`
- **mplot3d changes**
- **Testing**
- **Dependency changes**
- **Mathtext changes**
- **Signature deprecations**
- **Changes in parameter names**
- **Class/method/attribute deprecations**
- **Undeprecations**
- **New features**
- **Invalid inputs**
Matplotlib.use

Switching backends via `matplotlib.use` is now allowed by default, regardless of whether `matplotlib.pyplot` has been imported. If the user tries to switch from an already-started interactive backend to a different interactive backend, an `ImportError` will be raised.

mpl_toolkits.mplot3d auto-registration

`mpl_toolkits.mplot3d` is always registered by default now. It is no longer necessary to import mpl_toolkits.mplot3d to create 3d axes with

```python
ax = fig.add_subplot(111, projection="3d")
```

Invalid points in PathCollections

PathCollections created with `scatter` now keep track of invalid points. Previously, points with nonfinite (infinite or nan) coordinates would not be included in the offsets (as returned by `PathCollection.get_offsets`) of a `PathCollection` created by `scatter`, and points with nonfinite values (as specified by the `c` kwarg) would not be included in the array (as returned by `PathCollection.get_array`)

Such points are now included, but masked out by returning a masked array.

If the `plotnonfinite` kwarg to `scatter` is set, then points with nonfinite values are plotted using the bad color of the `collections.PathCollection`'s colormap (as set by `colors.Colormap.set_bad()`).

Alpha blending in imshow of RBGA input

The alpha-channel of RBGA images is now re-sampled independently of RGB channels. While this is a bug fix, it does change the output and may result in some down-stream image comparison tests to fail.

Autoscaling

On log-axes where a single value is plotted at a “full” decade (1, 10, 100, etc.), the autoscaling now expands the axis symmetrically around that point, instead of adding a decade only to the right.

Log-scaled axes

When the default `LogLocator` would generate no ticks for an axis (e.g., an axis with limits from 0.31 to 0.39) or only a single tick, it now instead falls back on the linear `AutoLocator` to pick reasonable tick positions.
Figure.add_subplot with no arguments

Calling `Figure.add_subplot()` with no positional arguments used to do nothing; this now is equivalent to calling `add_subplot(111)` instead.

bxp and rcparams

`bxp` now respects `rcParams["boxplot.boxprops.linewidth"]` even when `patch_artist` is set. Previously, when the `patch_artist` parameter was set, `bxp` would ignore `rcParams["boxplot.boxprops.linewidth"]`. This was an oversight – in particular, `boxplot` did not ignore it.

Major/minor tick collisions

Minor ticks that collide with major ticks are now hidden by default. Previously, certain locator classes (LogLocator, AutoMinorLocator) contained custom logic to avoid emitting tick locations that collided with major ticks when they were used as minor locators. This logic has now moved to the `Axis` class, and is used regardless of the locator class. You can control this behavior via the `remove_overlapping_locs` attribute on `Axis`.

If you were relying on both the major and minor tick labels to appear on the same tick, you may need to update your code. For example, the following snippet

```python
import numpy as np
import matplotlib.dates as mdates
import matplotlib.pyplot as plt

t = np.arange("2018-11-03", "2018-11-06", dtype="datetime64")
x = np.random.rand(len(t))

fig, ax = plt.subplots()
ax.plot(t, x)
ax.xaxis.set(
    major_locator=mdates.DayLocator(),
    major_formatter=mdates.DateFormatter("\n%a"),
    minor_locator=mdates.HourLocator((0, 6, 12, 18)),
    minor_formatter=mdates.DateFormatter("%H:%M"),
)
# disable removing overlapping locations
ax.xaxis.remove_overlapping_locs = False
plt.show()
```
labeled days using major ticks, and hours and minutes using minor ticks and added a newline to the major tick labels to avoid them crashing into the minor tick labels. Setting the `remove_overlapping_locs` property (also accessible via `set_remove_overlapping_locs` / `get_remove_overlapping_locs` and `setp`) disables removing overlapping tick locations.

The major tick labels could also be adjusted include hours and minutes, as the minor ticks are gone, so the `major_formatter` would be:

```python
mdates.DateFormatter("%H:%M\n%a")
```
usetex support

Previously, if `rcParams["text.usetex"]` was True, then constructing a `TextPath` on a non-mathtext string with `usetex=False` would rely on the mathtext parser (but not on usetex support!) to parse the string. The mathtext parser is not invoked anymore, which may cause slight changes in glyph positioning.

get_window_extents

`matplotlib.axes.Axes.get_window_extent` used to return a bounding box that was slightly larger than the axes, presumably to take into account the ticks that may be on a spine. However, it was not scaling the tick sizes according to the dpi of the canvas, and it did not check if the ticks were visible, or on the spine.

Now `matplotlib.axes.Axes.get_window_extent` just returns the axes extent with no padding for ticks.

This affects `matplotlib.axes.Axes.get_tightbbox` in cases where there are outward ticks with no tick labels, and it also removes the (small) pad around axes in that case.

`spines.Spine.get_window_extent` now takes into account ticks that are on the spine.

Sankey

Previously, `Sankey.add` would only accept a single string as the `labels` argument if its length is equal to the number of flows, in which case it would use one character of the string for each flow.

The behavior has been changed to match the documented one: when a single string is passed, it is used to label all the flows.

FontManager scores

`font_manager.FontManager.score_weight` is now more strict with its inputs. Previously, when a weight string was passed to `font_manager.FontManager.score_weight`,

- if the weight was the string representation of an integer, it would be converted to that integer,
- otherwise, if the weight was not a standard weight name, it would be silently replaced by a value of 500 (“normal” weight).

`font_manager.FontManager.score_weight` now raises an exception on such inputs.

Text alignment

Text alignment was previously incorrect, in particular for multiline text objects with large descenders (i.e. subscripts) and rotated text. These have been fixed and made more consistent, but could make old code that has compensated for this no longer have the correct alignment.
Upper case color strings

Support for passing single-letter colors (one of “rgbcmykw”) as UPPERCASE characters is deprecated; these colors will become case-sensitive (lowercase) after the deprecation period has passed.

The goal is to decrease the number of ambiguous cases when using the data keyword to plotting methods; e.g. plot("X", "Y", data={"X": ..., "Y": ...}) will not warn about “Y” possibly being a color anymore after the deprecation period has passed.

Degenerate limits

When bounds passed to set_xlim are degenerate (i.e. the lower and upper value are equal), the method used to “expand” the bounds now matches the expansion behavior of autoscaling when the plot contains a single x-value, and should in particular produce nicer limits for non-linear scales.

plot format string parsing

In certain cases, plot would previously accept format strings specifying more than one linestyle (e.g. "---." which specifies both "--" and "-."); only use one of them would be used. This now raises a ValueError instead.

HTMLWriter

The HTMLWriter constructor is more strict: it no longer normalizes unknown values of default_mode to ‘loop’, but errors out instead.

AFM parsing

In accordance with the AFM spec, the AFM parser no longer truncates the UnderlinePosition and UnderlineThickness fields to integers.

The Notice field (which can only be publicly accessed by the deprecated afm.parse_afm API) is no longer decoded to a str, but instead kept as bytes, to support non-conformant AFM files that use non-ASCII characters in that field.

Artist.set keyword normalisation

Artist.set now normalizes keywords before sorting them. Previously it sorted its keyword arguments in reverse alphabetical order (with a special-case to put color at the end) before applying them.

It now normalizes aliases (and, as above, emits a warning on duplicate properties) before doing the sorting (so c goes to the end too).
Axes.tick_params argument checking

Previously Axes.tick_params silently did nothing when an invalid axis parameter was supplied. This behavior has been changed to raise a ValueError instead.

Axes.hist output

Input that consists of multiple empty lists will now return a list of histogram values for each one of the lists. For example, an input of [],[] will return 2 lists of histogram values. Previously, a single list was returned.

backend_bases.Timer.remove_callback future signature change

Currently, backend_bases.Timer.remove_callback(func, *args, **kwargs) removes a callback previously added by backend_bases.Timer.add_callback(func, *args, **kwargs), but if *args, **kwargs is not passed in (ex, Timer.remove_callback(func)), then the first callback with a matching func is removed, regardless of whether it was added with or without *args, **kwargs.

In a future version, Timer.remove_callback will always use the latter behavior (not consider *args, **kwargs); to specifically consider them, add the callback as a functools.partial object

```python
cb = timer.add_callback(functools.partial(func, *args, **kwargs))
# ...
# later
timer.remove_callback(cb)
```

backend_bases.Timer.add_callback was modified to return func to simplify the above usage (previously it returned None); this also allows using it as a decorator.

The new API is modelled after atexit.register / atexit.unregister.

StemContainer performance increase

StemContainer objects can now store a LineCollection object instead of a list of Line2D objects for stem lines plotted using stem. This gives a very large performance boost to displaying and moving stem plots.

This will become the default behaviour in Matplotlib 3.3. To use it now, the use_line_collection keyword argument to stem can be set to True

```python
ax.stem(..., use_line_collection=True)
```

Individual line segments can be extracted from the LineCollection using get_segments(). See the LineCollection documentation for other methods to retrieve the collection properties.

ColorbarBase inheritance

matplotlib.colorbar.ColorbarBase is no longer a subclass of cm.ScalarMappable. This inheritance lead to a confusing situation where the cm.ScalarMappable passed to matplotlib.colorbar.Colorbar (colorbar) had a set_norm method, as did the colorbar. The colorbar is now purely a follower to the ScalarMappable norm and colormap, and the old inherited methods
set_norm, set_cmap, set_clim are deprecated, as are the getter versions of those calls. To set the norm associated with a colorbar do `colorbar.mappable.set_norm()` etc.

**FreeType and libpng search paths**

The `MPLBASEDIRLIST` environment variables and `basedirlist` entry in `setup.cfg` have no effect anymore. Instead, if building in situations where FreeType or libpng are not in the compiler or linker's default path, set the standard environment variables `CFLAGS/LDFLAGS` on Linux or OSX, or `CL/LINK` on Windows, to indicate the relevant paths.

See details in `Installing`.

**Setting artist properties twice or more in the same call**

Setting the same artist property multiple time via aliases is deprecated. Previously, code such as

```python
plt.plot([0, 1], c="red", color="blue")
```

would emit a warning indicating that `c` and `color` are aliases of one another; and only keep the `color` kwarg. This behavior has been deprecated; in a future version, this will raise a `TypeError`, similar to Python’s behavior when a keyword argument is passed twice

```python
plt.plot([0, 1], c="red", c="blue")
```

This warning is raised by `normalize_kwargs`.

**Path code types**

Path code types like `Path.MOVETO` are now `np.uint8` instead of `int`. `Path.STOP`, `Path.MOVETO`, `Path.LINETO`, `Path.CURVE3`, `Path.CURVE4` and `Path.CLOSEPOLY` are now of the type `Path.code_type` (np. `uint8` by default) instead of plain `int`. This makes their type match the array value type of the `Path.codes` array.

**LaTeX code in matplotlibrc file**

Previously, the rc file keys `pgf.preamble` and `text.latex.preamble` were parsed using commas as separators. This would break valid LaTeX code, such as:

```latex
\usepackage[protrusion=true, expansion=false]{microtype}
```

The parsing has been modified to pass the complete line to the LaTeX system, keeping all commas. Passing a list of strings from within a Python script still works as it used to. Passing a list containing non-strings now fails, instead of coercing the results to strings.

**Axes.spy**

The method `Axes.spy` now raises a `TypeError` for the keyword arguments `interpolation` and `linestyle` instead of silently ignoring them.
Furthermore, `Axes.spy` now allows for an `extent` argument (was silently ignored so far).

A bug with `Axes.spy(..., origin='lower')` is fixed. Previously this flipped the data but not the y-axis resulting in a mismatch between axes labels and actual data indices. Now, `origin='lower'` flips both the data and the y-axis labels.

**Boxplot tick methods**

The `manage_xticks` parameter of `boxplot` and `bxp` has been renamed (with a deprecation period) to `manage_ticks`, to take into account the fact that it manages either x or y ticks depending on the `vert` parameter.

When `manage_ticks=True` (the default), these methods now attempt to take previously drawn boxplots into account when setting the axis limits, ticks, and tick labels.

**MouseEvents**

MouseEvents now include the event name in their `str()`. Previously they contained the prefix "MPL MouseEvent".

**RGBA buffer return type**

`FigureCanvasAgg.buffer_rgba` and `RendererAgg.buffer_rgba` now return a memoryview. The `buffer_rgba` method now allows direct access to the renderer's underlying buffer (as a `(m, n, 4)`-shape memoryview) rather than copying the data to a new bytestring. This is consistent with the behavior on Py2, where a buffer object was returned.

**Axes.fmt_xdata and Axes.fmt_ydata error handling**

Previously, if the user provided an `Axes.fmt_xdata` or `Axes.fmt_ydata` function that raised a `TypeError` (or set them to a non-callable), the exception would be silently ignored and the default formatter be used instead. This is no longer the case; the exception is now propagated out.

**Deprecation of redundant Tick attributes**

The `gridOn`, `tick1On`, `tick2On`, `label1On`, and `label2On` `Tick` attributes have been deprecated. Directly get and set the visibility on the underlying artists, available as the `gridline`, `tick1line`, `tick2line`, `label1`, and `label2` attributes.

The `label` attribute, which was an alias for `label1`, has been deprecated.
Subclasses that relied on setting the above visibility attributes needs to be updated; see e.g. examples/api/skewt.py.

Passing a Line2D’s drawstyle together with the linestyle is deprecated

Instead of `plt.plot(..., linestyle="steps--")`, use `plt.plot(..., linestyle="--", drawstyle="steps")`. `ds` is now an alias for `drawstyle`.

pgi support dropped

Support for pgi in the GTK3 backends has been dropped. pgi is an alternative implementation to PyGObject. PyGObject should be used instead.

rcParam changes

Removed

The following deprecated rcParams have been removed:

- `text.dvipnghack`
- `nbagg.transparent` (use `rcParams["figure.facecolor"]` instead)
- `plugins.directory`
- `axes.hold`
- `backend.qt4` and `backend.qt5` (set the `QT_API` environment variable instead)

Deprecated

The associated validator functions `rcsetup.validate_qt4` and `validate_qt5` are deprecated.

The `verbose.fileo` and `verbose.level` rcParams have been deprecated. These have had no effect since the switch from Matplotlib’s old custom Verbose logging to the stdlib’s `logging` module. In addition the `rcsetup.validate_verbose` function is deprecated.

The `text.latex.unicode` rcParam now defaults to `True` and is deprecated (i.e., in future versions of Matplotlib, unicode input will always be supported). Moreover, the underlying implementation now uses `\usepackage[utf8]{inputenc}` instead of `\usepackage[utf8x]{inputenc}`.

Exception changes

- Previously, subprocess failures in the animation framework would raise either in a `RuntimeError` or a `ValueError` depending on when the error occurred. They now raise a `subprocess.CalledProcessError` with attributes set as documented by the exception class.
In certain cases, Axes methods (and pyplot functions) used to raise a \texttt{RuntimeError} if they were called with a data kwarg and otherwise mismatched arguments. They now raise a \texttt{TypeError} instead.

\texttt{Axes.streamplot} does not support irregularly gridded x and y values. So far, it used to silently plot an incorrect result. This has been changed to raise a \texttt{ValueError} instead.

The \texttt{streamplot.Grid} class, which is internally used by streamplot code, also throws a \texttt{ValueError} when irregularly gridded values are passed in.

\textbf{Removals}

The following deprecated APIs have been removed:

\textbf{Classes and methods}

- \texttt{Verbose} (replaced by python logging library)
- \texttt{artist.Artist.hitlist} (no replacement)
- \texttt{artist.Artist.is_figure_set} (use \texttt{artist.figure is not None} instead)
- \texttt{axis.Axis.unit_data} (use \texttt{axis.Axis.units} instead)
- \texttt{backend_bases.FigureCanvasBase.onRemove} (no replacement) \texttt{backend_bases.FigureManagerBase.show_popup} (this never did anything)
- \texttt{backend_wx.SubplotToolWx} (no replacement)
- \texttt{backend_wx.Toolbar} (use \texttt{backend_wx.NavigationToolbar2Wx} instead)
- \texttt{cbook.align_iterators} (no replacement)
- \texttt{contour.ContourLabeler.get_real_label_width} (no replacement)
- \texttt{legend.Legend.draggable} (use \texttt{legend.Legend.set_draggable()} instead)
- \texttt{texmanager.TexManager.postscriptd}, \texttt{texmanager.TexManager.pscnt}, \texttt{texmanager.TexManager.make_ps}, \texttt{texmanager.TexManager.get_ps_bbox} (no replacements)

\textbf{Arguments}

- The \texttt{fig} kwarg to \texttt{GridSpec.get_subplot_params} and \texttt{GridSpecFromSubplotSpec.get_subplot_params} (use the argument \texttt{figure} instead)
- Passing 'box-forced' to \texttt{Axes.set_adjustable} (use 'box' instead)
- Support for the strings 'on'/true'/off'/false' to mean True / False (directly use True / False instead). The following functions are affected:
  - \texttt{axes.Axes.grid}
  - \texttt{Axes3D.grid}
  - \texttt{Axis.set_tick_params}
  - \texttt{pyplot.box}
- Using \texttt{pyplot.axes} with an \texttt{axes.Axes} type argument (use \texttt{pyplot.sca} instead)
Other

The following miscellaneous API elements have been removed

- **svgfont support (in `rcParams["svg.fonttype"]`)**
- Logging is now done with the standard python `logging` library. `matplotlib.verbose` and the command line switches `--verbose-LEVEL` have been removed.

To control the logging output use:

```python
import logging
logger = logging.getLogger('matplotlib')
logger.setLevel(logging.INFO)
```

- **`__version__numpy__`**
- **`collections.CIRCLE_AREA_FACTOR`**
- **`font_manager.USE_FONTCONFIG`**
- **`font_manager.cachedir`**

**`matplotlib.mlab removals`**

Lots of code inside the `matplotlib.mlab` module which was deprecated in Matplotlib 2.2 has been removed. See below for a list:

- **`mlab.exp_safe`** (use `numpy.exp` instead)
- **`mlab.amap`**
- **`mlab.logspace`** (use `numpy.logspace` instead)
- **`mlab.rms_flat`**
- **`mlab.linorm`** (use `numpy.linalg.norm(a, ord=1)` instead)
- **`mlab.l2norm`** (use `numpy.linalg.norm(a, ord=2)` instead)
- **`mlab.norm_flat`** (use `numpy.linalg.norm(a.flat, ord=2)` instead)
- **`mlab.frange`** (use `numpy.arange` instead)
- **`mlab.identity`** (use `numpy.identity` instead)
- **`mlab.base_repr`**
- **`mlab.binary_repr`**
- **`mlab.ispower2`**
- **`mlab.log2`** (use `numpy.log2` instead)
- **`mlab.isvector`**
- **`mlab.movavg`**
- **`mlab.safe_isinf`** (use `numpy.isinf` instead)
- **`mlab.safe_isnan`** (use `numpy.isnan` instead)
- **`mlab.cohere_pairs`** (use `scipy.signal.coherence` instead)
- **`mlab.entropy`** (use `scipy.stats.entropy` instead)
• mlab.normpdf (use scipy.stats.norm.pdf instead)
• mlab.find (use np.nonzero(np.ravel(condition)) instead)
• mlab.longest_contiguous_ones
• mlab.longest_ones
• mlab.PCA
• mlab.prctile (use numpy.percentile instead)
• mlab.prctile_rank
• mlab.center_matrix
• mlab.rk4 (use scipy.integrate.ode instead)
• mlab.bivariate_normal
• mlab.get_xyz_where
• mlab.get_sparse_matrix
• mlab.dist (use numpy.hypot instead)
• mlab.dist_point_to_segment
• mlab.griddata (use scipy.interpolate.griddata)
• mlab.ess_simple_linear_interpolation (use numpy.interp)
• mlab.slopes
• mlab.stineman_interp
• mlab.segments_intersect
• mlab.fftsurr
• mlab.offset_line
• mlab.quad2cubic
• mlab.vector_lengths
• mlab.distances_along_curve
• mlab.path_length
• mlab.cross_from_above
• mlab.cross_from_below
• mlab.contiguous_regions (use cbook.contiguous_regions instead)
• mlab.is_closed_polygon
• mlab.poly_between
• mlab.poly_below
• mlab.inside_poly
• mlab.csv2rec
• mlab.rec2csv (use numpy.recarray.tofile instead)
• mlab.rec2text (use numpy.recarray.tofile instead)
• mlab.rec_summarize
• mlab.rec_join
• mlab.recs_join
• mlab.rec_groupby
• mlab.rec_keep_fields
• mlab.rec_drop_fields
• mlab.rec_append_fields
• mlab.csvformat_factory
• mlab.get_formatd
• mlab.FormatDatetim(e (use `datetime.datetime.strftime` instead)
• mlab.FormatDate (use `datetime.date.strftime` instead)
• mlab.donothing_callback

**matplotlib.pylab removals**

Lots of code inside the `matplotlib.mlab` module which was deprecated in Matplotlib 2.2 has been removed. This means the following functions are no longer available in the `matplotlib.pylab` module:

• amap
• base_repr
• binary_repr
• bivariate_normal
• center_matrix
• csv2rec (use `numpy.recarray.tofile` instead)
• dist (use `numpy.hypot` instead)
• dist_point_to_segment
• distances_along_curve
• entropy (use `scipy.stats.entropy` instead)
• exp_safe (use `numpy.exp` instead)
• fftsurr
• find (use `np.nonzero(np.ravel(condition))` instead)
• frange (use `numpy.arange` instead)
• get_sparse_matrix
• get_x_yz_where
• griddata (use `scipy.interpolate.griddata` instead)
• identity (use `numpy.identity` instead)
• inside_poly
• is_closed_polygon
• ispower2
• isvector
• l1norm (use numpy.linalg.norm(a, ord=1) instead)
• l2norm (use numpy.linalg.norm(a, ord=2) instead)
• log2 (use numpy.log2 instead)
• longest_contiguous_ones
• longest_ones
• movavg
• norm_flat (use numpy.linalg.norm(a.flat, ord=2) instead)
• normpdf (use scipy.stats.norm.pdf instead)
• path_length
• poly_below
• poly_between
• prctile (use numpy.percentile instead)
• prctile_rank
• rec2csv (use numpy.recarray.tofile instead)
• rec_append_fields
• rec_drop_fields
• rec_join
• rk4 (use scipy.integrate.ode instead)
• rms_flat
• segments_intersect
• slopes
• stineman_interp
• vector_lengths

mplot3d changes

Voxel shading

Axes3D.voxels now shades the resulting voxels; for more details see What’s new. The previous behavior can be achieved by passing

```python
ax.voxels(..., shade=False)
```
Equal aspect axes disabled

Setting the aspect on 3D axes previously returned non-sensical results (e.g. see #1077). Calling `ax.set_aspect('equal')` or `ax.set_aspect(num)` on a 3D axes now raises a `NotImplementedError`.

`Poly3DCollection.set_zsort`

`Poly3DCollection.set_zsort` no longer silently ignores invalid inputs, or `False` (which was always broken). Passing `True` to mean "average" is deprecated.

Testing

The `--no-network` flag to `tests.py` has been removed (no test requires internet access anymore). If it is desired to disable internet access both for old and new versions of Matplotlib, use `tests.py -m 'not network'` (which is now a no-op).

The image comparison test decorators now skip (rather than xfail) the test for uncomparable formats. The affected decorators are `image_comparison` and `check_figures_equal`. The deprecated `ImageComparisonTest` class is likewise changed.

Dependency changes

numpy

Matplotlib 3.1 now requires numpy>=1.11.

ghostscript

Support for ghostscript 8.60 (released in 2007) has been removed. The oldest supported version of ghostscript is now 9.0 (released in 2010).

Mathtext changes

- In constructs such as "$1-2\$", mathtext now interprets the tilde as a space, consistently with TeX (this was previously a parse error).

Deprecations

- The \stackrel mathtext command has been deprecated (it behaved differently from LaTeX's \stackrel. To stack two mathtext expressions, use \genfrac{left-delim}{right-delim}{fraction-bar-thickness}{}{top}{bottom}.
- The mathcircled mathtext command (which is not a real TeX command) is deprecated. Directly use unicode characters (e.g. "\N{CIRCLED LATIN CAPITAL LETTER A}" or "\u24b6") instead.
- Support for setting `rcParams["mathtext.default"]` to circled is deprecated.
Signature deprecations

The following signature related behaviours are deprecated:

• The `withdash` keyword argument to `Axes.text()`. Consider using `Axes.annotate()` instead.
• Passing (n, 1)-shaped error arrays to `Axes.errorbar()`, which was not documented and did not work for n = 2. Pass a 1D array instead.
• The `frameon` kwarg to `savefig` and the `rcParams["savefig.frameon"]` `rcParam`. To emulate `frameon = False`, set `facecolor` to fully transparent ("none", or (0, 0, 0, 0)).
• Passing a non-1D (typically, (n, 1)-shaped) input to `Axes.pie`. Pass a 1D array instead.
• The `TextPath` constructor used to silently drop ignored arguments; this behavior is deprecated.
• The `usetex` parameter of `TextToPath.get_text_path` is deprecated and folded into the `is_math` parameter, which can now take the values `False`, `True`, and "TeX", consistently with other low-level text processing functions.
• Passing ’normal’ to `axes.Axes.axis()` is deprecated, use `ax.axis('auto')` instead.
• Passing the `block` argument of `pyplot.show` positionally is deprecated; it should be passed by keyword.
• When using the nbagg backend, `pyplot.show` used to silently accept and ignore all combinations of positional and keyword arguments. This behavior is deprecated.
• The unused `shape` and `imlim` parameters to `Axes.imshow` are deprecated. To avoid triggering the deprecation warning, the `filternorm`, `filterrad`, `resample`, and `url` arguments should be passed by keyword.
• The `interp_at_native` parameter to `BboxImage`, which has had no effect since Matplotlib 2.0, is deprecated.
• All arguments to the `cbook.deprecated` decorator and `cbook.warn_deprecated` function, except the first one (the version where the deprecation occurred), are now keyword-only. The goal is to avoid accidentally setting the “message” argument when the “name” (or “alternative”) argument was intended, as this has repeatedly occurred in the past.
• The arguments of `matplotlib.testing.compare.calculate_rms` have been renamed from `expectedImage`, `actualImage`, to `expected_image`, `actual_image`.
• Passing positional arguments to `Axes.set_ticklabels` beyond `ticklabels` itself has no effect, and support for them is deprecated.
• Passing `shade=None` to `plot_surface` is deprecated. This was an unintended implementation detail with the same semantics as `shade=False`. Please use the latter code instead.
• `matplotlib.ticker.MaxNLocator` and its `set_params` method will issue a warning on unknown keyword arguments instead of silently ignoring them. Future versions will raise an error.

Changes in parameter names

• The `arg` parameter to `matplotlib.use` has been renamed to `backend`.

This will only affect cases where that parameter has been set as a keyword argument. The common usage pattern as a positional argument `matplotlib.use('Qt5Agg')` is not affected.
• The *normed* parameter to `Axes.hist2d` has been renamed to *density*.
• The *s* parameter to `Annotation` (and indirectly `Axes.annotation`) has been renamed to *text*.
• The *tolerance* parameter to `bezier.find_bezier_t_intersecting_with_closedpath`, `bezier.split_bezier_intersecting_with_closedpath`, `bezier.find_r_to_boundary_of_closedpath`, `bezier.split_path_inout` and `bezier.check_if_parallel` has been renamed to *tolerance*.

In each case, the old parameter name remains supported (it cannot be used simultaneously with the new name), but support for it will be dropped in Matplotlib 3.3.

### Class/method/attribute deprecations

Support for custom backends that do not provide a `GraphicsContextBase.set_hatch_color` method is deprecated. We suggest that custom backends let their `GraphicsContext` class inherit from `GraphicsContextBase`, to at least provide stubs for all required methods.

• `spine.Spine.is_frame_like`
This has not been used in the codebase since its addition in 2009.

• `axis3d.Axis.get_tick_positions`
  This has never been used internally, there is no equivalent method exists on the 2D Axis classes, and despite the similar name, it has a completely different behavior from the 2D Axes' `axis.get_ticks_position` method.

• `backend_pgf.LatexManagerFactory`
• `mpl_toolkits.axisartist.axislines.SimpleChainedObjects`
• `mpl_toolkits.Axes.AxisDict`

### Internal Helper Functions

• `checkdep_dvipng`
• `checkdep_ghostscript`
• `checkdep_pdftops`
• `checkdep_inkscape`
• `ticker.decade_up`
• `ticker.decade_down`
• `cbook.dedent`
• `docstring.Appender`
• `docstring.dedent`
• `docstring.copy_dedent`

Use the standard library’s docstring manipulation tools instead, such as `inspect.cleandoc` and `inspect.getdoc`.

• `matplotlib.scale.get_scale_docs()`
• `matplotlib.pyplot.get_scale_docs()`

These are considered internal and will be removed from the public API in a future version.
• `projections.process_projection_requirements`
• `backend_ps.PsBackendHelper`
• `backend_ps.ps_backend_helper`,
• `cbook.iterable`
• `cbook.get_label`
• `cbook.safesip` Manually check the lengths of the inputs instead, or rely on numpy to do it.
• `cbook.is_hashable` Use `isinstance(..., collections.abc.Hashable)` instead.
• The `backend_bases.RendererBase.strip_math` Use `cbook.strip_math` instead.

Multiple internal functions that were exposed as part of the public API of `mpl_toolkits.mplot3d` are deprecated,

`mpl_toolkits.mplot3d.art3d`
• `mpl_toolkits.mplot3d.art3d.norm_angle()`
• `mpl_toolkits.mplot3d.art3d.norm_text_angle()`
• `mpl_toolkits.mplot3d.art3d.path_to_3d_segment()`
• `mpl_toolkits.mplot3d.art3d.paths_to_3d_segments()`
• `mpl_toolkits.mplot3d.art3d.path_to_3d_segment_with_codes()`
• `mpl_toolkits.mplot3d.art3d.paths_to_3d_segments_with_codes()`
• `mpl_toolkits.mplot3d.art3d.get_patch_verts()`
• `mpl_toolkits.mplot3d.art3d.get_colors()`
• `mpl_toolkits.mplot3d.art3d.zalpha()`

`mpl_toolkits.mplot3d.proj3d`
• `mpl_toolkits.mplot3d.proj3d.line2d()`
• `mpl_toolkits.mplot3d.proj3d.line2d_dist()`
• `mpl_toolkits.mplot3d.proj3d.line2d_seg_dist()`
• `mpl_toolkits.mplot3d.proj3d.mod()`
• `mpl_toolkits.mplot3d.proj3d.proj_transform_vec()`
• `mpl_toolkits.mplot3d.proj3d.proj_transform_vec_clip()`
• `mpl_toolkits.mplot3d.proj3d.vec_pad_ones()`
• `mpl_toolkits.mplot3d.proj3d.proj_trans_clip_points()`

If your project relies on these functions, consider vendoring them.

**Font Handling**

• `backend_pdf.RendererPdf.afm_font_cache`
• `backend_ps.RendererPS.afmfontd`
• `font_manager.OSXInstalledFonts`
• `TextToPath.glyph_to_path` (Instead call `font.get_path()` and manually transform the path.)

**Date related functions**

- `dates.seconds()`
- `dates.minutes()`
- `dates.hours()`
- `dates.weeks()
- `dates.strpdate2num`
- `dates.bytespdate2num`

These are brittle in the presence of locale changes. Use standard datetime parsers such as `time.strptime` or `dateutil.parser.parse`, and additionally call `matplotlib.dates.date2num` if you need to convert to Matplotlib’s internal datetime representation; or use `dates.datestr2num`.

**Axes3D**

- `axes3d.Axes3D.w_xaxis`
- `axes3d.Axes3D.w_yaxis`
- `axes3d.Axes3D.w_zaxis`

**Testing**

- `matplotlib.testing.decorators.switch_backend` decorator

Test functions should use `pytest.mark.backend(...)`, and the mark will be picked up by the `matplotlib.testing.conftest.mpl_test_settings` fixture.

**Quiver**

- `.color` attribute of Quiver objects

Instead, use (as for any Collection) the `get_facecolor` method. Note that setting to the `.color` attribute did not update the quiver artist, whereas calling `set_facecolor` does.

**GUI / backend details**

- `get_py2exe_datafiles`
- `tk_window_focus`
- `backend_gtk3.FileChooserDialog`
- `backend_gtk3.NavigationToolbar2GTK3.get_filechooser`
- `backend_gtk3.SaveFigureGTK3.get_filechooser`
• NavigationToolbar2QT.adj_window attribute. This is unused and always None.

• backend_wx.IDLE_DELAY global variable. This is unused and only relevant to the now removed wx “idling” code (note that as it is a module-level global, no deprecation warning is emitted when accessing it).

• mlab.demean

• backend_gtk3cairo.FigureCanvasGTK3Cairo,

• backend_wx.debug_on_error, backend_wx.fake_stderr, backend_wx.raise_msg_to_str, backend_wx.MenuButtonWx, backend_wx.PrintoutWx,

• matplotlib.backends.qt_editor.formlayout module

This module is a vendored, modified version of the official formlayout module available on PyPI. Install that module separately if you need it.

• GraphicsContextPS.shouldstroke

Transforms / scales

• LogTransformBase
• Log10Transform
• Log2Transform,
• NaturalLogTransformLog
• InvertedLogTransformBase
• InvertedLog10Transform
• InvertedLog2Transform
• InvertedNaturalLogTransform

These classes defined in matplotlib.scales are deprecated. As a replacement, use the general LogTransform and InvertedLogTransform classes, whose constructors take a base argument.

Locators / Formatters

• OldScalarFormatter.pprint_val
• ScalarFormatter.pprint_val
• LogFormatter.pprint_val

These are helper methods that do not have a consistent signature across formatter classes.

Path tools

• path.get_paths_extents
Use get_path_collection_extents instead.

• Path.has_nonfinite attribute
Use not np.isfinite(path.vertices).all() instead.
• `bezier.find_r_to_boundary_of_closedpath` function is deprecated
This has always returned `None` instead of the requested radius.

**Text**

• `text.TextWithDash`
• `Text.is_math_text`
• `TextPath.is_math_text`
• `TextPath.text_get_vertices_codes` (As an alternative, construct a new `TextPath` object.)

**Unused attributes**

• `NavigationToolbar2QT.buttons`
• `Line2D.verticalOffset`
• `Quiver.keytext`
• `Quiver.keyvec`
• `SpanSelector.buttonDown`
These are unused and never updated.

**Sphinx extensions**

• `matplotlib.sphinxext.mathmpl.math_directive`
• `matplotlib.sphinxext.plot_directive.plot_directive`
This is because the `matplotlib.sphinxext.mathmpl` and `matplotlib.sphinxext.plot_directive` interfaces have changed from the (Sphinx-)deprecated function-based interface to a class-based interface; this should not affect end users.
• `mpl_toolkits.axisartist.axis_artist.UnimplementedException`

**Environmental Variables**

• The `MATPLOTLIBDATA` environment variable

**Axis**

• `Axis.iter_ticks`
This only served as a helper to the private `Axis._update_ticks`
Undeprecations

The following API elements have been un-deprecated:

- The `obj_type` kwarg to the `cbook.deprecated` decorator.
- `xmin, xmax` kwargs to `Axes.set_xlim` and `ymin, ymax` kwargs to `Axes.set_ylim`

New features

Text now has a `c` alias for the `color` property

For consistency with `Line2D`, the `Text` class has gained the `c` alias for the `color` property. For example, one can now write

```
ax.text(.5, .5, "foo", c="red")
```

Cn colors now support `n>=10`

It is now possible to go beyond the tenth color in the property cycle using `Cn` syntax, e.g.

```
plt.plot([1, 2], color="C11")
```

now uses the 12th color in the cycle.

Note that previously, a construct such as:

```
plt.plot([1, 2], "C11")
```

would be interpreted as a request to use color `C1` and marker 1 (an "inverted Y"). To obtain such a plot, one should now use

```
plt.plot([1, 2], "1C1")
```

(or so that the first "1" gets correctly interpreted as a marker specification), or, more explicitly:

```
plt.plot([1, 2], marker="1", color="C1")
```

New `Formatter.format_ticks` method

The `Formatter` class gained a new `format_ticks` method, which takes the list of all tick locations as a single argument and returns the list of all formatted values. It is called by the axis tick handling code and, by default, first calls `set_locs` with all locations, then repeatedly calls `__call__` for each location.

Tick-handling code in the codebase that previously performed this sequence (`set_locs` followed by repeated `__call__`) have been updated to use `format_ticks`. `format_ticks` is intended to be overridden by `Formatter` subclasses for which the formatting of a tick value depends on other tick values, such as `ConciseDateFormatter`. 
Added support for RGB(A) images in pcolorfast

pcolorfast now accepts 3D images (RGB or RGBA) arrays if the X and Y specifications allow image or pcolorimage rendering; they remain unsupported by the more general quadmesh rendering

Invalid inputs

Passing invalid locations to legend and table used to fallback on a default location. This behavior is deprecated and will throw an exception in a future version.

offsetbox.AnchoredText is unable to handle the horizontalalignment or verticalalignment kwargs, and used to ignore them with a warning. This behavior is deprecated and will throw an exception in a future version.

Passing steps less than 1 or greater than 10 to MaxNLocator used to result in undefined behavior. It now throws a ValueError.

The signature of the (private) Axis._update_ticks has been changed to not take the renderer as argument anymore (that argument is unused).

15.1.48 API Changes for 3.1.1

- Behavior changes

Behavior changes

Locator.nonsingular return order

Locator.nonsingular (introduced in mpl 3.1) now returns a range \( v_0, v_1 \) with \( v_0 \leq v_1 \). This behavior is consistent with the implementation of nonsingular by the LogLocator and LogitLocator subclasses.

Changes for the latest version are listed below. For new features that were added to Matplotlib, see Whats New.

15.2 API Changes for 3.1.1

- Behavior changes
15.2.1 Behavior changes

Locator.nonsingular return order

Locator.nonsingular (introduced in mpl 3.1) now returns a range \( v_0, v_1 \) with \( v_0 \leq v_1 \). This behavior is consistent with the implementation of nonsingular by the LogLocator and LogitLocator subclasses.

15.3 API Changes for 3.1.0

- Behavior changes
- \texttt{pgi} support dropped
- \texttt{rcParam} changes
- Exception changes
- Removals
  - \texttt{matplotlib.mlab} removals
  - \texttt{matplotlib.pylab} removals
  - mplot3d changes
- Testing
- Dependency changes
- Mathtext changes
- Signature deprecations
- Changes in parameter names
- Class/method/attribute deprecations
- Undeprecations
- New features
- Invalid inputs

15.3.1 Behavior changes

Matplotlib.use

Switching backends via \texttt{matplotlib.use} is now allowed by default, regardless of whether \texttt{matplotlib.pyplot} has been imported. If the user tries to switch from an already-started interactive backend to a different interactive backend, an \texttt{ImportError} will be raised.
**mplot3d auto-registration**

`mpl_toolkits.mplot3d` is always registered by default now. It is no longer necessary to import mplot3d to create 3d axes with

```python
ax = fig.add_subplot(111, projection="3d")
```

**Invalid points in PathCollections**

PathCollections created with `scatter` now keep track of invalid points. Previously, points with nonfinite (infinite or nan) coordinates would not be included in the offsets (as returned by `PathCollection.get_offsets`) of a PathCollection created by `scatter`, and points with nonfinite values (as specified by the `c` kwarg) would not be included in the array (as returned by `PathCollection.get_array`).

Such points are now included, but masked out by returning a masked array.

If the `plotnonfinite` kwarg to `scatter` is set, then points with nonfinite values are plotted using the bad color of the `collections.PathCollection`'s colormap (as set by `colors.Colormap.set_bad()`).

**Alpha blending in imshow of RBGA input**

The alpha-channel of RBGA images is now re-sampled independently of RGB channels. While this is a bug fix, it does change the output and may result in some down-stream image comparison tests to fail.

**Autoscaling**

On log-axes where a single value is plotted at a “full” decade (1, 10, 100, etc.), the autoscaling now expands the axis symmetrically around that point, instead of adding a decade only to the right.

**Log-scaled axes**

When the default `LogLocator` would generate no ticks for an axis (e.g., an axis with limits from 0.31 to 0.39) or only a single tick, it now instead falls back on the `AutoLocator` to pick reasonable tick positions.

**Figure.add_subplot with no arguments**

Calling `Figure.add_subplot()` with no positional arguments used to do nothing; this now is equivalent to calling `add_subplot(111)` instead.

**bxp and rcparams**

`bxp` now respects `rcParams["boxplot.boxprops.linewidth"]` even when `patch_artist` is set. Previously, when the `patch_artist` parameter was set, `bxp` would ignore `rcParams["boxplot.boxprops.linewidth"]`. This was an oversight – in particular, `boxplot` did not ignore it.
Major/minor tick collisions

Minor ticks that collide with major ticks are now hidden by default. Previously, certain locator classes (LogLocator, AutoMinorLocator) contained custom logic to avoid emitting tick locations that collided with major ticks when they were used as minor locators. This logic has now moved to the Axis class, and is used regardless of the locator class. You can control this behavior via the remove_overlapping_locs attribute on Axis.

If you were relying on both the major and minor tick labels to appear on the same tick, you may need to update your code. For example, the following snippet

```python
import numpy as np
import matplotlib.dates as mdates
import matplotlib.pyplot as plt

t = np.arange("2018-11-03", "2018-11-06", dtype="datetime64")
x = np.random.rand(len(t))

fig, ax = plt.subplots()
aplot(t, x)
ax.xaxis.set(
    major_locator=mdates.DayLocator(),
    major_formatter=mdates.DateFormatter("\n%a"),
    minor_locator=mdates.HourLocator((0, 6, 12, 18)),
    minor_formatter=mdates.DateFormatter("%H:%M"),
)

# disable removing overlapping locations
ax.xaxis.remove_overlapping_locs = False
plt.show()
```

labeled days using major ticks, and hours and minutes using minor ticks and added a newline to the major ticks labels to avoid them crashing into the minor tick labels. Setting the remove_overlapping_locs property (also accessible via set_remove_overlapping_locs / get_remove_overlapping_locs and setp) disables removing overlapping tick locations.

The major tick labels could also be adjusted include hours and minutes, as the minor ticks are gone, so the major_formatter would be:

```python
mdates.DateFormatter("%H:%M\n%a")
```

usetex support

Previously, if rcParams["text.usetex"] was True, then constructing a TextPath on a non-mathtext string with usetex=False would rely on the mathtext parser (but not on usetex support!) to parse the string. The mathtext parser is not invoked anymore, which may cause slight changes in glyph positioning.

get_window_extents

matplotlib.axes.Axes.get_window_extent used to return a bounding box that was slightly larger than the axes, presumably to take into account the ticks that may be on a spine. However, it was not scaling the tick sizes according to the dpi of the canvas, and it did not check if the ticks were visible, or on the spine.
Now `matplotlib.axes.Axes.get_window_extent` just returns the axes extent with no padding for ticks.

This affects `matplotlib.axes.Axes.get_tightbbox` in cases where there are outward ticks with no tick labels, and it also removes the (small) pad around axes in that case.

`spines.Spine.get_window_extent` now takes into account ticks that are on the spine.

**Sankey**

Previously, `Sankey.add` would only accept a single string as the `labels` argument if its length is equal to the number of flows, in which case it would use one character of the string for each flow.

The behavior has been changed to match the documented one: when a single string is passed, it is used to label all the flows.

**FontManager scores**

`font_manager.FontManager.score_weight` is now more strict with its inputs. Previously, when a weight string was passed to `font_manager.FontManager.score_weight`,

- if the weight was the string representation of an integer, it would be converted to that integer,
- otherwise, if the weight was not a standard weight name, it would be silently replaced by a value of 500 ("normal" weight).

`font_manager.FontManager.score_weight` now raises an exception on such inputs.

**Text alignment**

Text alignment was previously incorrect, in particular for multiline text objects with large descenders (i.e. subscripts) and rotated text. These have been fixed and made more consistent, but could make old code that has compensated for this no longer have the correct alignment.

**Upper case color strings**

Support for passing single-letter colors (one of "rgbcmykw") as UPPERCASE characters is deprecated; these colors will become case-sensitive (lowercase) after the deprecation period has passed.

The goal is to decrease the number of ambiguous cases when using the `data` keyword to plotting methods; e.g. `plot("X", "Y", data={"X": ..., "Y": ...})` will not warn about "Y" possibly being a color anymore after the deprecation period has passed.

**Degenerate limits**

When bounds passed to `set_xlim` are degenerate (i.e. the lower and upper value are equal), the method used to “expand” the bounds now matches the expansion behavior of autoscaling when the plot contains a single x-value, and should in particular produce nicer limits for non-linear scales.
**plot format string parsing**

In certain cases, `plot` would previously accept format strings specifying more than one linestyle (e.g. "---." which specifies both "--" and "."); only use one of them would be used. This now raises a `ValueError` instead.

**HTMLWriter**

The HTMLWriter constructor is more strict: it no longer normalizes unknown values of `default_mode` to 'loop', but errors out instead.

**AFM parsing**

In accordance with the AFM spec, the AFM parser no longer truncates the `UnderlinePosition` and `UnderlineThickness` fields to integers.

The `Notice` field (which can only be publicly accessed by the deprecated `afm.parse_afm` API) is no longer decoded to a `str`, but instead kept as `bytes`, to support non-conformant AFM files that use non-ASCII characters in that field.

**Artist.set keyword normalisation**

`Artist.set` now normalizes keywords before sorting them. Previously it sorted its keyword arguments in reverse alphabetical order (with a special-case to put `color` at the end) before applying them.

It now normalizes aliases (and, as above, emits a warning on duplicate properties) before doing the sorting (so `c` goes to the end too).

**Axes.tick_params argument checking**

Previously `Axes.tick_params` silently did nothing when an invalid `axis` parameter was supplied. This behavior has been changed to raise a `ValueError` instead.

**Axes.hist output**

Input that consists of multiple empty lists will now return a list of histogram values for each one of the lists. For example, an input of `[[], []]` will return 2 lists of histogram values. Previously, a single list was returned.

**backend_bases.Timer.remove_callback future signature change**

Currently, `backend_bases.Timer.remove_callback(func, *args, **kwargs)` removes a callback previously added by `backend_bases.Timer.add_callback(func, *args, **kwargs)`, but if `*args, **kwargs` is not passed in (ex, `Timer.remove_callback(func)`), then the first callback with a matching `func` is removed, regardless of whether it was added with or without `*args, **kwargs`.

In a future version, `Timer.remove_callback` will always use the latter behavior (not consider `*args, **kwargs`); to specifically consider them, add the callback as a `functools.partial` object.
cb = timer.add_callback(functools.partial(func, *args, **kwargs))
# ...
# later
timer.remove_callback(cb)

backend_bases.Timer.add_callback was modified to return `func` to simplify the above usage (previously it returned None); this also allows using it as a decorator.
The new API is modelled after `atexit.register` / `atexit.unregister`.

**StemContainer performance increase**

StemContainer objects can now store a `LineCollection` object instead of a list of `Line2D` objects for stem lines plotted using `stem`. This gives a very large performance boost to displaying and moving stem plots.

This will become the default behaviour in Matplotlib 3.3. To use it now, the `use_line_collection` keyword argument to `stem` can be set to `True`

```
ax.stem(..., use_line_collection=True)
```

Individual line segments can be extracted from the `LineCollection` using `get_segments()`. See the `LineCollection` documentation for other methods to retrieve the collection properties.

**ColorbarBase inheritance**

`matplotlib.colorbar.ColorbarBase` is no longer a subclass of `cm.ScalarMappable`. This inheritance lead to a confusing situation where the `cm.ScalarMappable` passed to `matplotlib.colorbar.Colorbar` had a `set_norm` method, as did the colorbar. The colorbar is now purely a follower to the ScalarMappable norm and colormap, and the old inherited methods `set_norm`, `set_cmap`, `set_clim` are deprecated, as are the getter versions of those calls. To set the norm associated with a colorbar do `colorbar.mappable.set_norm()` etc.

**FreeType and libpng search paths**

The `MPLBASEDIRLIST` environment variables and `basedirlist` entry in `setup.cfg` have no effect anymore. Instead, if building in situations where FreeType or libpng are not in the compiler or linker's default path, set the standard environment variables `CFLAGS` / `LDFLAGS` on Linux or OSX, or `CL/LINK` on Windows, to indicate the relevant paths.

See details in Installing.

**Setting artist properties twice or more in the same call**

Setting the same artist property multiple time via aliases is deprecated. Previously, code such as

```
plt.plot([0, 1], c="red", color="blue")
```
would emit a warning indicating that `c` and `color` are aliases of one another, and only keep the `color` kwarg. This behavior has been deprecated; in a future version, this will raise a `TypeError`, similar to Python’s behavior when a keyword argument is passed twice.

```python
plt.plot([0, 1], c="red", c="blue")
```

This warning is raised by `normalize_kwargs`.

### Path code types

Path code types like `Path.MOVETO` are now `np.uint8` instead of `int`. `Path.STOP`, `Path.MOVETO`, `Path.LINETO`, `Path.CURVE3`, `Path.CURVE4` and `Path.CLOSEPOLY` are now of the type `Path.code_type` (`np.uint8` by default) instead of plain `int`. This makes their type match the array value type of the `Path.codes` array.

### LaTeX code in matplotlibrc file

Previously, the rc file keys `pgf.preamble` and `text.latex.preamble` were parsed using commas as separators. This would break valid LaTeX code, such as:

```latex
\usepackage[protrusion=true, expansion=false]{microtype}
```

The parsing has been modified to pass the complete line to the LaTeX system, keeping all commas. Passing a list of strings from within a Python script still works as it used to. Passing a list containing non-strings now fails, instead of coercing the results to strings.

### Axes.spy

The method `Axes.spy` now raises a `TypeError` for the keyword arguments `interpolation` and `linestyle` instead of silently ignoring them.

Furthermore, `Axes.spy` spy does now allow for an `extent` argument (was silently ignored so far).

A bug with `Axes.spy(..., origin='lower')` is fixed. Previously this flipped the data but not the y-axis resulting in a mismatch between axes labels and actual data indices. Now, `origin='lower'` flips both the data and the y-axis labels.

### Boxplot tick methods

The `manage_xticks` parameter of `boxplot` and `bxp` has been renamed (with a deprecation period) to `manage_ticks`, to take into account the fact that it manages either x or y ticks depending on the `vert` parameter.

When `manage_ticks=True` (the default), these methods now attempt to take previously drawn boxplots into account when setting the axis limits, ticks, and tick labels.

### MouseEvents

MouseEvents now include the event name in their `str()`. Previously they contained the prefix "MPL MouseEvent".
RGBA buffer return type

FigureCanvasAgg.buffer_rgba and RendererAgg.buffer_rgba now return a memoryview. The buffer_rgba method now allows direct access to the renderer’s underlying buffer (as a \((m, n, 4)\)-shape memoryview) rather than copying the data to a new bytestring. This is consistent with the behavior on Py2, where a buffer object was returned.

matplotlib.font_manager.win32InstalledFonts return type

matplotlib.font_manager.win32InstalledFonts returns an empty list instead of None if no fonts are found.

Axes.fmt_xdata and Axes.fmt_ydata error handling

Previously, if the user provided a Axes.fmt_xdata or Axes.fmt_ydata function that raised a TypeError (or set them to a non-callable), the exception would be silently ignored and the default formatter be used instead. This is no longer the case; the exception is now propagated out.

Deprecation of redundant Tick attributes

The gridOn, tick1On, tick2On, label1On, and label2On Tick attributes have been deprecated. Directly get and set the visibility on the underlying artists, available as the gridline, tick1line, tick2line, label1, and label2 attributes.

The label attribute, which was an alias for label1, has been deprecated.

Subclasses that relied on setting the above visibility attributes needs to be updated; see e.g. examples/api/skewt.py.

Passing a Line2D’s drawstyle together with the linestyle is deprecated

Instead of plt.plot(..., linestyle="steps--"), use plt.plot(..., linestyle="--", drawstyle="steps"). ds is now an alias for drawstyle.

15.3.2 pgi support dropped

Support for pgi in the GTK3 backends has been dropped. pgi is an alternative implementation to PyGObject. PyGObject should be used instead.

15.3.3 rcParam changes

Removed

The following deprecated rcParams have been removed:

- text.dvipnghack
- nbagg.transparent (use rcParams["figure.facecolor"] instead)
• plugins.directory
• axes.hold
• backend.qt4 and backend.qt5 (set the QT_API environment variable instead)

**Deprecated**

The associated validator functions `rcsetup.validate_qt4` and `validate_qt5` are deprecated.

The `verbose.fileo` and `verbose.level` rcParams have been deprecated. These have had no effect since the switch from Matplotlib’s old custom Verbose logging to the stdlib’s `logging` module. In addition the `rcsetup.validate_verbose` function is deprecated.

The `text.latex.unicode` rcParam now defaults to `True` and is deprecated (i.e., in future versions of Matplotlib, unicode input will always be supported). Moreover, the underlying implementation now uses `\usepackage[utf8]{inputenc}` instead of `\usepackage[ucs]\usepackage[utf8x]{inputenc}`.

### 15.3.4 Exception changes

- Previously, subprocess failures in the animation framework would raise either in a `RuntimeError` or a `ValueError` depending on when the error occurred. They now raise a `subprocess.CalledProcessError` with attributes set as documented by the exception class.
- In certain cases, Axes methods (and pyplot functions) used to raise a `RuntimeError` if they were called with a data kwarg and otherwise mismatched arguments. They now raise a `TypeError` instead.
- `Axes.streamplot` does not support irregularly gridded `x` and `y` values. So far, it used to silently plot an incorrect result. This has been changed to raise a `ValueError` instead.
- The `streamplot.Grid` class, which is internally used by streamplot code, also throws a `ValueError` when irregularly gridded values are passed in.

### 15.3.5 Removals

The following deprecated APIs have been removed:

**Classes and methods**

- `Verbose` (replaced by python logging library)
- `artist.Artist.hitlist` (no replacement)
- `artist.Artist.is_figure_set` (use `artist.figure is not None` instead)
- `axis.Axis.unit_data` (use `axis.Axis.units` instead)
- `backend_bases.FigureCanvasBase.onRemove` (no replacement) `backend_bases.FigureManagerBase.show_popup` (this never did anything)
- `backend_wx.SubplotToolWx` (no replacement)
• backend_wx.Toolbar (use backend_wx.NavigationToolbar2Wx instead)
• cbook.align_iterators (no replacement)
• contour.ContourLabeler.get_real_label_width (no replacement)
• legend.Legend.draggable (use legend.Legend.set_draggable() instead)
• texmanager.TexManager.postscriptd, texmanager.TexManager.pscnt, texmanager.TexManager.make_ps, texmanager.TexManager.get_ps_bbox (no replacements)

Arguments

• The fig kwarg to GridSpec.get_subplot_params and GridSpecFromSubplotSpec.get_subplot_params (use the argument figure instead)
• Passing ‘box-forced’ to Axes.set_adjustable (use ‘box’ instead)
• Support for the strings ‘on’/’true’/’off’/’false’ to mean True / False (directly use True / False instead). The following functions are affected:
  - axes.Axes.grid
  - Axes3D.grid
  - Axis.set_tick_params
  - pyplot.box
• Using pyplot.axes with an axes.Axes type argument (use pyplot.sca instead)

Other

The following miscellaneous API elements have been removed
• svgfont support (in rcParams["svg.fonttype"])
• Logging is now done with the standard python logging library. matplotlib.verbose and the command line switches --verbose-LEVEL have been removed.

To control the logging output use:

```python
import logging
logger = logging.getLogger('matplotlib')
logger.set_level(logging.INFO)
```

• __version__.numpy__
• collections.CIRCLE_AREA_FACTOR
• font_manager.USE_FONTCONFIG
• font_manager.cachedir

15.3.6 matplotlib.mlab removals

Lots of code inside the matplotlib.mlab module which was deprecated in Matplotlib 2.2 has been removed. See below for a list:
• mlab.exp_safe (use numpy.exp instead)
• mlab.amap
• mlab.logspace (use numpy.logspace instead)
• mlab.rms_flat
  • mlab.1inorm (use numpy.linalg.norm(a, ord=1) instead)
  • mlab.2norm (use numpy.linalg.norm(a, ord=2) instead)
  • mlab.norm_flat (use numpy.linalg.norm(a.flat, ord=2) instead)
• mlab.frange (use numpy.arange instead)
• mlab.identity (use numpy.identity instead)
• mlab.base_repr
• mlab.binary_repr
• mlab.isspower2
• mlab.log2 (use numpy.log2 instead)
• mlab.isvector
• mlab.movavg
• mlab.safe_isinf (use numpy.isinf instead)
• mlab.safe_isnan (use numpy.isnan instead)
• mlab.cohere_pairs (use scipy.signal.coherence instead)
• mlab.entropy (use scipy.stats.entropy instead)
• mlab.normpdf (use scipy.stats.norm.pdf instead)
• mlab.find (use np.nonzero(np.ravel(condition)) instead)
• mlab.longest_contiguous_ones
• mlab.longest_ones
• mlab.PCA
• mlab.prctile (use numpy.percentile instead)
• mlab.prctile_rank
• mlab.center_matrix
• mlab.rk4 (use scipy.integrate.ode instead)
• mlab.bivariate_normal
• mlab.get_xyz_where
• mlab.get_sparse_matrix
• mlab.dist (use numpy.hypot instead)
• mlab.dist_point_to_segment
• mlab.griddata (use scipy.interpolate.griddata)
• mlab.less_simple_linear_interpolation (use numpy.interp)
• mlab.slopes
• mlab.stineman_interp
• mlab.segments_intersect
• mlab.fftsurr
• mlab.offset_line
• mlab.quad2cubic
• mlab.vector_lengths
• mlab.distances_along_curve
• mlab.path_length
• mlab.cross_from_above
• mlab.cross_from_below
• mlab.contiguous_regions (use cbook.contiguous_regions instead)
• mlab.is_closed_polygon
• mlab.poly_between
• mlab.poly_below
• mlab.inside_poly
• mlab.csv2rec
• mlab.rec2csv (use numpy.recarray.tofile instead)
• mlab.rec2text (use numpy.recarray.tofile instead)
• mlab.rec_summarize
• mlab.rec_join
• mlab.recs_join
• mlab.rec_groupby
• mlab.rec_keep_fields
• mlab.rec_drop_fields
• mlab.rec_append_fields
• mlab.csvformat_factory
• mlab.get_formatd
• mlab.FormatDatetime (use datetime.datetime.strftime instead)
• mlab.FormatDate (use datetime.date.strftime instead)
• mlab.donothing_callback

15.3.7 matplotlib.pylab removals

Lots of code inside the matplotlib.mlab module which was deprecated in Matplotlib 2.2 has been removed. This means the following functions are no longer available in the matplotlib.pylab module:

• amap
• base_repr
• binary_repr
• bivariate_normal
• center_matrix
• csv2rec (use numpy.recarray.tofile instead)
• dist (use numpy.hypot instead)
• dist_point_to_segment
• distances_along_curve
• entropy (use scipy.stats.entropy instead)
• exp_safe (use numpy.exp instead)
• fftsurr
• find (use np.nonzero(np.ravel(condition)) instead)
• frange (use numpy.arange instead)
• get_sparse_matrix
• get_xyz_where
• griddata (use scipy.interpolate.griddata instead)
• identity (use numpy.identity instead)
• inside_poly
• is_closed_polygon
• ispower2
• isvector
• l1norm (use numpy.linalg.norm(a, ord=1) instead)
• l2norm (use numpy.linalg.norm(a, ord=2) instead)
• log2 (use numpy.log2 instead)
• longest_contiguous_ones
• longest_ones
• movavg
• norm_flat (use numpy.linalg.norm(a.flat, ord=2) instead)
• normpdf (use scipy.stats.norm.pdf instead)
• path_length
• poly_below
• poly_between
• prctile (use numpy.percentile instead)
• prctile_rank
• rec2csv (use numpy.recarray.tofile instead)
• rec_append_fields
• rec_drop_fields
• rec_join
• rk4 (use scipy.integrate.ode instead)
• rms_flat
• segments_intersect
• slopes
• stineman_interp
• vector_lengths

15.3.8 mplot3d changes

Voxel shading

Axes3D.voxels now shades the resulting voxels; for more details see What’s new. The previous behavior can be achieved by passing

```python
ax.voxels(..., shade=False)
```

Equal aspect axes disabled

Setting the aspect on 3D axes previously returned non-sensical results (e.g. see #1077). Calling `ax.set_aspect('equal')` or `ax.set_aspect(num)` on a 3D axes now raises a `NotImplementedError`.

Poly3DCollection.set_zsort

`Poly3DCollection.set_zsort` no longer silently ignores invalid inputs, or `False` (which was always broken). Passing `True` to mean "average" is deprecated.

15.3.9 Testing

The --no-network flag to tests.py has been removed (no test requires internet access anymore). If it is desired to disable internet access both for old and new versions of Matplotlib, use `tests.py -m 'not network'` (which is now a no-op).

The image comparison test decorators now skip (rather than xfail) the test for uncomparable formats. The affected decorators are `image_comparison` and `check_figures_equal`. The deprecated `ImageComparisonTest` class is likewise changed.

15.3.10 Dependency changes

numpy

Matplotlib 3.1 now requires numpy>=1.11.
ghostscript

Support for ghostscript 8.60 (released in 2007) has been removed. The oldest supported version of ghostscript is now 9.0 (released in 2010).

15.3.11 Mathtext changes

- In constructs such as "$1-2$", mathtext now interprets the tilde as a space, consistently with TeX (this was previously a parse error).

Deprecations

- The \texttt{\textbackslash stackrel} mathtext command has been deprecated (it behaved differently from LaTeX's \texttt{\textbackslash stackrel}. To stack two mathtext expressions, use \texttt{\textbackslash genfrac\{left-delim\}\{right-delim\}\{fraction-bar-thickness\}\{top\}\{bottom\}}.
- The \texttt{\textbackslash mathcircled} mathtext command (which is not a real TeX command) is deprecated. Directly use unicode characters (e.g. \texttt{\textbackslash u{CIRCLED LATIN CAPITAL LETTER A}} or \texttt{\textbackslash u{24b6}}) instead.
- Support for setting \texttt{rcParams["mathtext.default"]} to circled is deprecated.

15.3.12 Signature deprecations

The following signature related behaviours are deprecated:

- The \texttt{withdash} keyword argument to \texttt{Axes.text()}. Consider using \texttt{Axes.annotate()} instead.
- Passing (n, 1)-shaped error arrays to \texttt{Axes.errorbar()}, which was not documented and did not work for \( n = 2 \). Pass a 1D array instead.
- The \texttt{frameon} kwarg to \texttt{savefig} and the \texttt{rcParams["savefig.frameon"]} rcParam. To emulate \texttt{frameon = False}, set \texttt{facecolor} to fully transparent ("none", or (0, 0, 0, 0)).
- Passing a non-1D (typically, (n, 1)-shaped) input to \texttt{Axes.pie}. Pass a 1D array instead.
- The \texttt{TextPath} constructor used to silently drop ignored arguments; this behavior is deprecated.
- The \texttt{usetex} parameter of \texttt{TextToPath.get_text_path} is deprecated and folded into the \texttt{ismath} parameter, which can now take the values \texttt{False}, \texttt{True}, and "TeX", consistently with other low-level text processing functions.
- Passing 'normal' to \texttt{axes.Axes.axis()} is deprecated, use \texttt{ax.axis('auto')} instead.
- Passing the \texttt{block} argument of \texttt{pyplot.show} positionally is deprecated; it should be passed by keyword.
- When using the nbagg backend, \texttt{pyplot.show} used to silently accept and ignore all combinations of positional and keyword arguments. This behavior is deprecated.
- The unused \texttt{shape} and \texttt{imlim} parameters to \texttt{Axes.imshow} are deprecated. To avoid triggering the deprecation warning, the \texttt{filternorm}, \texttt{filterrad}, \texttt{resample}, and \texttt{url} arguments should be passed by keyword.
- The \texttt{interp at native} parameter to \texttt{BboxImage}, which has had no effect since Matplotlib 2.0, is deprecated.
• All arguments to the cbook.deprecated decorator and cbook.warn_deprecated function, except the first one (the version where the deprecation occurred), are now keyword-only. The goal is to avoid accidentally setting the “message” argument when the “name” (or “alternative”) argument was intended, as this has repeatedly occurred in the past.

• The arguments of matplotlib.testing.compare.calculate_rms have been renamed from expectedImage, actualImage, to expected_image, actual_image.

• Passing positional arguments to Axis.set_ticklabels beyond ticklabels itself has no effect, and support for them is deprecated.

• Passing shade=None to plot_surface is deprecated. This was an unintended implementation detail with the same semantics as shade=False. Please use the latter code instead.

• matplotlib.ticker.MaxNLocator and its set_params method will issue a warning on unknown keyword arguments instead of silently ignoring them. Future versions will raise an error.

15.3.13 Changes in parameter names

• The arg parameter to matplotlib.use has been renamed to backend.

  This will only affect cases where that parameter has been set as a keyword argument. The common usage pattern as a positional argument matplotlib.use('Qt5Agg') is not affected.

• The normed parameter to Axes.hist2d has been renamed to density.

• The s parameter to Annotation (and indirectly Axes.annotation) has been renamed to text.

• The tolerance parameter to bezier.find_bezier_t_intersecting_with_closedpath, bezier.split_bezier_intersecting_with_closedpath, bezier.find_r_to_boundary_of_closedpath, bezier.split_path_inout and bezier.check_if_parallel has been renamed to tolerance.

In each case, the old parameter name remains supported (it cannot be used simultaneously with the new name), but support for it will be dropped in Matplotlib 3.3.

15.3.14 Class/method/attribute deprecations

Support for custom backends that do not provide a GraphicsContextBase.set_hatch_color method is deprecated. We suggest that custom backends let their GraphicsContext class inherit from GraphicsContextBase, to at least provide stubs for all required methods.

• spine.Spine.is_frame_like

This has not been used in the codebase since its addition in 2009.

• axis3d.Axes.get_tick_positions

  This has never been used internally, there is no equivalent method exists on the 2D Axis classes, and despite the similar name, it has a completely different behavior from the 2D Axis.axis.get_ticks_position method.

• backend_pgf.LatezManagerFactory

• mpl_toolkits.axisartist.axislines.SimpleChainedObjects

• mpl_toolkits.Axes.AxisDict
Internal Helper Functions

- `checkdep_dvipng`
- `checkdep_ghostscript`
- `checkdep_pdftops`
- `checkdep_inkscape`
- `ticker.decade_up`
- `ticker.decade_down`
- `cbook.dedent`
- `docstring.Appender`
- `docstring.dedent`
- `docstring.copy_dedent`

Use the standard library’s docstring manipulation tools instead, such as `inspect.cleandoc` and `inspect.getdoc`.

- `matplotlib.scale.get_scale_docs()`
- `matplotlib.pyplot.get_scale_docs()`

These are considered internal and will be removed from the public API in a future version.

- `projections.process_projection_requirements`
- `backend_ps.PsBackendHelper`
- `backend_ps.ps_backend_helper`
- `cbook.iterable`
- `cbook.get_label`
- `cbook.safezip` Manually check the lengths of the inputs instead, or rely on numpy to do it.
- `cbook.is_hashable` Use `isinstance(..., collections.abc.Hashable)` instead.
- The `backend_bases.RendererBase.strip_math` Use `cbook.strip_math` instead.

Multiple internal functions that were exposed as part of the public API of `mpl_toolkits.mplot3d` are deprecated,

`mpl_toolkits.mplot3d.art3d`

- `mpl_toolkits.mplot3d.art3d.norm_angle()`
- `mpl_toolkits.mplot3d.art3d.norm_text_angle()`
- `mpl_toolkits.mplot3d.art3d.path_to_3d_segment()`
- `mpl_toolkits.mplot3d.art3d.paths_to_3d_segments()`
- `mpl_toolkits.mplot3d.art3d.path_to_3d_segment_with_codes()`
- `mpl_toolkits.mplot3d.art3d.paths_to_3d_segments_with_codes()`
- `mpl_toolkits.mplot3d.art3d.get_patch_verts()`
- `mpl_toolkits.mplot3d.art3d.get_colors()`
- `mpl_toolkits.mplot3d.art3d.zalpha()`
mpl_toolkits.mplot3d.proj3d

- `mpl_toolkits.mplot3d.proj3d.line2d()`
- `mpl_toolkits.mplot3d.proj3d.line2d_dist()`
- `mpl_toolkits.mplot3d.proj3d.line2d_seg_dist()`
- `mpl_toolkits.mplot3d.proj3d.mod()`
- `mpl_toolkits.mplot3d.proj3d.proj_transform_vec()`
- `mpl_toolkits.mplot3d.proj3d.proj_transform_vec_clip()`
- `mpl_toolkits.mplot3d.proj3d.vec_pad_ones()`
- `mpl_toolkits.mplot3d.proj3d.proj_trans_clip_points()`

If your project relies on these functions, consider vendoring them.

Font Handling

- `backend_pdf.RendererPdf.afm_font_cache`
- `backend_ps.RendererPS.afmfontd`
- `font_manager.OSXInstalledFonts`
- `TextToPath.glyph_to_path` (Instead call `font.get_path()` and manually transform the path.)

Date related functions

- `dates.seconds()`
- `dates.minutes()`
- `dates.hours()`
- `dates.weeks()`
- `dates.strpdate2num`
- `dates.bytespdate2num`

These are brittle in the presence of locale changes. Use standard datetime parsers such as `time.strptime` or `dateutil.parser.parse`, and additionally call `matplotlib.dates.date2num` if you need to convert to Matplotlib’s internal datetime representation; or use `dates.datestr2num`.

Axes3D

- `axes3d.Axes3D.w_xaxis`
- `axes3d.Axes3D.w_yaxis`
- `axes3d.Axes3D.w_zaxis`

Testing

- `matplotlib.testing.decorators.switch_backend` decorator

Test functions should use `pytest.mark.backend(...)`, and the mark will be picked up by the `matplotlib.testing.conftest.mpl_test_settings` fixture.

Quiver

- `.color` attribute of Quiver objects

Instead, use (as for any `Collection`) the `get_facecolor` method. Note that setting to the `.color` attribute did not update the quiver artist, whereas calling `set_facecolor` does.

GUI / backend details

- `get_py2exe_datafiles`
- `tk_window_focus`
- `backend_gtk3.FileChooserDialog`
- `backend_gtk3.NavigationToolbar2GTK3.get_filechooser`
- `backend_gtk3.SaveFigureGTK3.get_filechooser`
- `NavigationToolbar2QT.adj_window` attribute. This is unused and always `None`.
- `backend_wx.IDLE_DELAY` global variable This is unused and only relevant to the now removed wx “idling” code (note that as it is a module-level global, no deprecation warning is emitted when accessing it).
- `mlab.demean`
- `backend_gtk3cairo.FigureCanvasGTK3Cairo`,
- `backend_wx.debug_on_error, backend_wx.fake_stderr, backend_wx.raise_msg_to_str, backend_wx.MenuButtonWx, backend_wx.PrintoutWx`,
- `matplotlib.backends.qt_editor.formlayout` module

This module is a vendored, modified version of the official `formlayout` module available on PyPI. Install that module separately if you need it.

- `GraphicsContextPS.shouldstroke`

Transforms / scales

- `LogTransformBase`
- `Log10Transform`
- `Log2Transform`
- `NaturalLogTransformLog`
- `InvertedLogTransformBase`
- `InvertedLog10Transform`
- `InvertedLog2Transform`
• InvertedNaturalLogTransform

These classes defined in matplotlib.scales are deprecated. As a replacement, use the general LogTransform and InvertedLogTransform classes, whose constructors take a base argument.

Locators / Formatters

• OldScalarFormatter.pprint_val
• ScalarFormatter.pprint_val
• LogFormatter.pprint_val

These are helper methods that do not have a consistent signature across formatter classes.

Path tools

• path.get_paths_extents

Use get_path_collection_extents instead.

• Path.has_nonfinite attribute

Use not np.isfinite(path.vertices).all() instead.

• bezier.find_r_to_boundary_of_closedpath function is deprecated

This has always returned None instead of the requested radius.

Text

• text.TextWithDash
• Text.is_math_text
• TextPath.is_math_text
• TextPath.text_get_vertices_codes (As an alternative, construct a new TextPath object.)

Unused attributes

• NavigationToolbar2QT.buttons
• Line2D.verticalOffset
• Quiver.keytext
• Quiver.keyvec
• SpanSelector.buttonDown

These are unused and never updated.
Sphinx extensions

- `matplotlib.sphinxext.mathmpl.math_directive`
- `matplotlib.sphinxext.plot_directive.plot_directive`

This is because the `matplotlib.sphinxext.mathmpl` and `matplotlib.sphinxext.plot_directive` interfaces have changed from the (Sphinx-)deprecated function-based interface to a class-based interface; this should not affect end users.

- `mpl_toolkits.axisartist.axis_artist.UnimplementedException`

Environmental Variables

- The `MATPLOTLIBDATA` environment variable

Axis

- `Axis.iter_ticks`

This only served as a helper to the private `Axis._update_ticks`

15.3.15 Undeprecations

The following API elements have been un-deprecated:

- The `obj_type` kwarg to the `cbook.deprecated` decorator.
- `xmin, xmax` kwargs to `Axes.set_xlim` and `ymin, ymax` kwargs to `Axes.set_ylim`

15.3.16 New features

Text now has a `c` alias for the `color` property

For consistency with `Line2D`, the `Text` class has gained the `c` alias for the `color` property. For example, one can now write

```python
ax.text(.5, .5, "foo", c="red")
```

Cn colors now support n>=10

It is now possible to go beyond the tenth color in the property cycle using Cn syntax, e.g.

```python
plt.plot([1, 2], color="C11")
```

now uses the 12th color in the cycle.
Note that previously, a construct such as:

```python
plt.plot([1, 2], "C11")
```
would be interpreted as a request to use color C1 and marker 1 (an “inverted Y”). To obtain such a plot, one should now use

```python
plt.plot([1, 2], "1C1")
```

(so that the first "1" gets correctly interpreted as a marker specification), or, more explicitly:

```python
plt.plot([1, 2], marker="1", color=C1)
```

**New Formatter.format_ticks method**

The *Formatter* class gained a new *format_ticks* method, which takes the list of all tick locations as a single argument and returns the list of all formatted values. It is called by the axis tick handling code and, by default, first calls *set_locs* with all locations, then repeatedly calls *__call__* for each location.

Tick-handling code in the codebase that previously performed this sequence (*set_locs* followed by repeated *__call__*) have been updated to use *format_ticks*.

*format_ticks* is intended to be overridden by *Formatter* subclasses for which the formatting of a tick value depends on other tick values, such as *ConciseDateFormatter*.

**Added support for RGB(A) images in pcolorfast**

pcolorfast now accepts 3D images (RGB or RGBA) arrays if the X and Y specifications allow image or pcolorimage rendering; they remain unsupported by the more general quadmesh rendering

**15.3.17 Invalid inputs**

Passing invalid locations to *legend* and *table* used to fallback on a default location. This behavior is deprecated and will throw an exception in a future version.

*offsetbox.AnchoredText* is unable to handle the *horizontalalignment* or *verticalalignment* kwargs, and used to ignore them with a warning. This behavior is deprecated and will throw an exception in a future version.

Passing steps less than 1 or greater than 10 to *MaxNLocator* used to result in undefined behavior. It now throws a *ValueError*.

The signature of the (private) *Axis._update_ticks* has been changed to not take the renderer as argument anymore (that argument is unused).
See also the *API Changes*. 
Below we describe several common approaches to plotting with Matplotlib.

16.1 The pyplot API

`matplotlib.pyplot` is a collection of command style functions that make Matplotlib work like MATLAB. Each pyplot function makes some change to a figure: e.g., creates a figure, creates a plotting area in a figure, plots some lines in a plotting area, decorates the plot with labels, etc.

`pyplot` is mainly intended for interactive plots and simple cases of programmatic plot generation.

Further reading:
- The `matplotlib.pyplot` function reference
- Pyplot tutorial
- Pyplot examples

16.2 The object-oriented API

At its core, Matplotlib is object-oriented. We recommend directly working with the objects, if you need more control and customization of your plots.

In many cases you will create a `Figure` and one or more `Axes` using `pyplot.subplots` and from then on only work on these objects. However, it’s also possible to create `Figures` explicitly (e.g. when including them in GUI applications).

Further reading:
- `matplotlib.axes.Axes` and `matplotlib.figure.Figure` for an overview of plotting functions.
- Most of the examples use the object-oriented approach (except for the pyplot section)
16.3 The pylab API (disapproved)

**Warning:** Since heavily importing into the global namespace may result in unexpected behavior, the use of pylab is strongly discouraged. Use *matplotlib.pyplot* instead.

*pylab* is a module that includes *matplotlib.pyplot*, *numpy* and some additional functions within a single namespace. Its original purpose was to mimic a MATLAB-like way of working by importing all functions into the global namespace. This is considered bad style nowadays.
Matplotlib consists of the following submodules:

### 17.1 matplotlib

```python
matplotlib.use(backend, warn=False, force=True)
```

Select the backend used for rendering and GUI integration.

**Parameters**

- `backend` [str] The backend to switch to. This can either be one of the standard backend names, which are case-insensitive:
  - interactive backends: GTK3Agg, GTK3Cairo, MacOSX, nbAgg, Qt4Agg, Qt4Cairo, Qt5Agg, Qt5Cairo, TkAgg, TkCairo, WebAgg, WX, WXAgg, WXCairo
  - non-interactive backends: agg, cairo, pdf, pgf, ps, svg, template
  or a string of the form: `module://my.module.name`.

- `warn` [bool, optional, default: False] If True and not `force`, warn that the call will have no effect if this is called after pyplot has been imported and a backend is set up.

- `force` [bool, optional, default: True] If True, attempt to switch the backend. An ImportError is raised if an interactive backend is selected, but another interactive backend has already started.

**See also:**

- `matplotlib.get_backend`

```python
matplotlib.get_backend()
```

Return the name of the current backend.

**See also:**

- `matplotlib.use`

```python
matplotlib.rcParams
```

An instance of `RcParams` for handling default matplotlib values.
matplotlib.rc_context(rc=None, fname=None)
    Return a context manager for managing rc settings.
    This allows one to do:
    
    with mpl.rc_context(fname='screen.rc'):
        plt.plot(x, a)
    with mpl.rc_context(fname='print.rc'):
        plt.plot(x, b)
        plt.plot(x, c)
    
    The 'a' vs 'x' and 'c' vs 'x' plots would have settings from 'screen.rc', while the 'b' vs 'x'
    plot would have settings from 'print.rc'.
    
    A dictionary can also be passed to the context manager:
    
    with mpl.rc_context(rc={'text.usetex': True}, fname='screen.rc'):
        plt.plot(x, a)
    
    The 'rc' dictionary takes precedence over the settings loaded from 'fname'. Passing a
    dictionary only is also valid. For example a common usage is:
    
    with mpl.rc_context(rc={'interactive': False}):
        fig, ax = plt.subplots()
        ax.plot(range(3), range(3))
        fig.savefig('A.png', format='png')
        plt.close(fig)
    
    matplotlib.rc(group, **kwargs)
    Set the current rc params. group is the grouping for the rc, e.g., for lines.linewidth the
group is lines, for axes.facecolor, the group is axes, and so on. Group may also be a list
or tuple of group names, e.g., (xtick, ytick). kwargs is a dictionary attribute name/value
pairs, e.g.,:
    
    rc('lines', linewidth=2, color='r')
    
    sets the current rc params and is equivalent to:
    
    rcParams['lines.linewidth'] = 2
    rcParams['lines.color'] = 'r'
    
    The following aliases are available to save typing for interactive users:
    
    +----------------+------------------+
    | Alias  | Property         |
    +----------------+------------------+
    | 'lw'   | 'linewidth'      |
    | 'ls'   | 'linestyle'      |
    | 'c'    | 'color'          |
    | 'fc'   | 'facecolor'      |
    | 'ec'   | 'edgecolor'      |
    | 'mew'  | 'markeredgewidth'|
    | 'aa'   | 'antialiased'    |
    +----------------+------------------+
    
    Thus you could abbreviate the above rc command as:
Note you can use python's kwargs dictionary facility to store dictionaries of default parameters. e.g., you can customize the font rc as follows:

```python
font = {'family' : 'monospace',
        'weight' : 'bold',
        'size' : 'larger'}
rc('font', **font)  # pass in the font dict as kwargs
```

This enables you to easily switch between several configurations. Use `matplotlib.style.use('default')` or `rcdefaults()` to restore the default rc params after changes.

```python
matplotlib.rc_file(fname, *, use_default_template=True)
```
Update rc params from file.

Style-blacklisted rc params (defined in `matplotlib.style.core.STYLE_BLACKLIST`) are not updated.

**Parameters**

- `fname` [str] Name of file parsed for matplotlib settings.
- `use_default_template` [bool] If True, initialize with default parameters before updating with those in the given file. If False, the current configuration persists and only the parameters specified in the file are updated.

```python
matplotlib.rcdefaults()
```
Restore the rc params from Matplotlib's internal default style.

Style-blacklisted rc params (defined in `matplotlib.style.core.STYLE_BLACKLIST`) are not updated.

**See also:**

- `rc_file_defaults` Restore the rc params from the rc file originally loaded by Matplotlib.
- `matplotlib.style.use` Use a specific style file. Call `style.use('default')` to restore the default style.

```python
matplotlib.rc_file_defaults()
```
Restore the rc params from the original rc file loaded by Matplotlib.

Style-blacklisted rc params (defined in `matplotlib.style.core.STYLE_BLACKLIST`) are not updated.

```python
class matplotlib.RcParams(*args, **kwargs)
```
A dictionary object including validation validating functions are defined and associated with rc parameters in `matplotlib.rcsetup`

```python
copy(self)
```

```python
find_all(self, pattern)
```
Return the subset of this RcParams dictionary whose keys match, using `re.search()`, the given pattern.
**Note:** Changes to the returned dictionary are *not* propagated to the parent `RcParams` dictionary.

```python
msg_backend_obsolete
msg_depr
msg_depr_ignore
msg_depr_set
msgObsolete
validate = {'_internal.classic_mode': <function validate_bool>, 'agg.path.chunksize': <function validate_int>, ...
```

```
matplotlib.rcParams(fail_on_error=False)
Return a `matplotlib.RcParams` instance from the default matplotlib rc file.
```

```
matplotlib.rcParams_from_file(fname, fail_on_error=False, use_default_template=True)
Return `matplotlib.RcParams` from the contents of the given file.
```

**Parameters**

- **fname** [str] Name of file parsed for matplotlib settings.
- **fail_on_error** [bool] If True, raise an error when the parser fails to convert a parameter.
- **use_default_template** [bool] If True, initialize with default parameters before updating with those in the given file. If False, the configuration class only contains the parameters specified in the file. (Useful for updating dicts.)

```
matplotlib.matplotlib_fname()
Get the location of the config file.
```

The file location is determined in the following order:

- $PWD/matplotlibrc
- $MATPLOTLIBRC if it is not a directory
- $MATPLOTLIBRC/matplotlibrc
- $MPLCONFIGDIR/matplotlibrc
- On Linux:
  - $XDG_CONFIG_HOME/matplotlib/matplotlibrc (if $XDG_CONFIG_HOME is defined)
  - or $HOME/.config/matplotlib/matplotlibrc (if $XDG_CONFIG_HOME is not defined)
- On other platforms,
  - $HOME/.matplotlib/matplotlibrc if $HOME is defined
- Lastly, it looks in $MATPLOTLIBDATA/matplotlibrc, which should always exist.

```
matplotlib.interactive(b)
Set interactive mode to boolean b.
```

If b is True, then draw after every plotting command, e.g., after xlabel

```
matplotlib.is_interactive()
Return true if plot mode is interactive
```
matplotlib.set_loglevel(level)
Sets the Matplotlib’s root logger and root logger handler level, creating the handler if it
does not exist yet.

Typically, one should call set_loglevel("info") or set_loglevel("debug") to get additional
debugging information.

Parameters

level [{"notset", "debug", "info", "warning", "error", "critical"}] The log
level of the handler.

Notes

The first time this function is called, an additional handler is attached to Matplotlib’s
root handler; this handler is reused every time and this function simply manipulates the
logger and handler’s level.

17.2 matplotlib.afm

This is a python interface to Adobe Font Metrics Files. Although a number of other python
implementations exist, and may be more complete than this, it was decided not to go with
them because they were either:

1) copyrighted or used a non-BSD compatible license
2) had too many dependencies and a free standing lib was needed
3) Did more than needed and it was easier to write afresh rather than figure out how to get
just what was needed.

It is pretty easy to use, and requires only built-in python libs:

```
>>> from matplotlib import rcParams
>>> import os.path
>>> afm_fname = os.path.join(rcParams['datapath'],
...                         'fonts', 'afm', 'ptmr8a.afm')
>>> from matplotlib.afm import AFM
>>> with open(afm_fname, 'rb') as fh:
...     afm = AFM(fh)
>>> afm.string_width_height('What the heck?')
(6220.0, 694)
>>> afm.get_fontname()
'Times-Roman'
>>> afm.get_kern_dist('A', 'f')
0
>>> afm.get_kern_dist('A', 'y')
-92.0
>>> afm.get_bbox_char('!')
[130, -9, 238, 676]
```

As in the Adobe Font Metrics File Format Specification, all dimensions are given in units of
1/1000 of the scale factor (point size) of the font being used.
class matplotlib.afm.AFM(fh)
   Bases: object
   Parse the AFM file in file object \texttt{fh}.

   \texttt{family\_name}
   The font family name, e.g., 'Times'.

   \texttt{get\_angle}(self)
   Return the fontangle as float.

   \texttt{get\_bbox\_char}(self, c, isord=False)
   get\_capheight(self)
   Return the cap height as float.

   \texttt{get\_familyname}(self)
   Return the font family name, e.g., 'Times'.

   \texttt{get\_fontname}(self)
   Return the font name, e.g., 'Times-Roman'.

   \texttt{get\_fullname}(self)
   Return the font full name, e.g., 'Times-Roman'.

   \texttt{get\_height\_char}(self, c, isord=False)
   Get the bounding box (ink) height of character \texttt{c} (space is 0).

   \texttt{get\_horizontal\_stem\_width}(self)
   Return the standard horizontal stem width as float, or \texttt{None} if not specified in AFM file.

   \texttt{get\_kern\_dist}(self, c1, c2)
   Return the kerning pair distance (possibly 0) for chars \texttt{c1} and \texttt{c2}.

   \texttt{get\_kern\_dist\_from\_name}(self, name1, name2)
   Return the kerning pair distance (possibly 0) for chars \texttt{name1} and \texttt{name2}.

   \texttt{get\_name\_char}(self, c, isord=False)
   Get the name of the character, i.e., '; ' is 'semicolon'.

   \texttt{get\_str\_bbox}(self, s)
   Return the string bounding box.

   \texttt{get\_str\_bbox\_and\_descent}(self, s)
   Return the string bounding box and the maximal descent.

   \texttt{get\_underline\_thickness}(self)
   Return the underline thickness as float.

   \texttt{get\_vertical\_stem\_width}(self)
   Return the standard vertical stem width as float, or \texttt{None} if not specified in AFM file.

   \texttt{get\_weight}(self)
   Return the font weight, e.g., 'Bold' or 'Roman'.

   \texttt{get\_width\_char}(self, c, isord=False)
   Get the width of the character from the character metric WX field.

   \texttt{get\_width\_from\_char\_name}(self, name)
   Get the width of the character from a type1 character name.
get_xheight(self)
    Return the xheight as float.

string_width_height(self, s)
    Return the string width (including kerning) and string height as a (w, h) tuple.

class matplotlib.afm.CharMetrics
    Bases: tuple
    Represents the character metrics of a single character.

    Notes

    The fields do currently only describe a subset of character metrics information defined in the AFM standard.

Create new instance of CharMetrics(width, name, bbox)

bbox
    The bbox of the character (B) as a tuple (llx, lly, urx, ury).

name
    The character name (N).

width
    The character width (WX).

class matplotlib.afm.CompositePart
    Bases: tuple
    Represents the information on a composite element of a composite char.

Create new instance of CompositePart(name, dx, dy)

dx
    x-displacement of the part from the origin.

dy
    y-displacement of the part from the origin.

name
    Name of the part, e.g. ‘acute’.

matplotlib.afm.parse_afm(fh)
    [Deprecated]

    Notes

    Deprecated since version 3.0:

17.3 matplotlib.animation
17.3.1 Animation

The easiest way to make a live animation in matplotlib is to use one of the *Animation* classes.

<table>
<thead>
<tr>
<th>Animation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>FuncAnimation</code></td>
<td>Makes an animation by repeatedly calling a function <em>func</em>.</td>
</tr>
<tr>
<td><code>ArtistAnimation</code></td>
<td>Animation using a fixed set of Artist objects.</td>
</tr>
</tbody>
</table>

```python
matplotlib.animation.Animation
```

class matplotlib.animation.Animation(fig, event_source=None, blit=False)

This class wraps the creation of an animation using matplotlib.
It is only a base class which should be subclassed to provide needed behavior.
This class is not typically used directly.

**Parameters**
- **fig** [matplotlib.figure.Figure] The figure object that is used to get draw, resize, and any other needed events.
- **event_source** [object, optional] A class that can run a callback when desired events are generated, as well as be stopped and started.
  
  Examples include timers (see `TimedAnimation`) and file system notifications.
- **blit** [bool, optional] controls whether blitting is used to optimize drawing. Defaults to False.

**See also:**
- `FuncAnimation`, `ArtistAnimation`

```python
__init__(self, fig[, event_source, blit]) Initialize self. See help(type(self)) for accurate signature.
```

**Methods**
- **__init__(self, fig[, event_source, blit])** Initialize self.
- **new_frame_seq(self)** Return a new sequence of frame information.

Continued on next page
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>new_saved_frame_seq(self)</code></td>
<td>Return a new sequence of saved/cached frame information.</td>
</tr>
<tr>
<td><code>save(self, filename[, writer, fps, dpi, ...])</code></td>
<td>Save the animation as a movie file by drawing every frame.</td>
</tr>
<tr>
<td><code>to_html5_video(self[, embed_limit])</code></td>
<td>Convert the animation to an HTML5 <code>&lt;video&gt;</code> tag.</td>
</tr>
<tr>
<td><code>to_jshtml(self[, fps, embed_frames, ...])</code></td>
<td>Generate HTML representation of the animation</td>
</tr>
</tbody>
</table>

new_frame_seq(self)

Return a new sequence of frame information.

new_saved_frame_seq(self)

Return a new sequence of saved/cached frame information.

save(self, filename, writer=None, fps=None, dpi=None, codec=None, bitrate=None, extra_args=None, metadata=None, extra_anim=None, savefig_kwargs=None, *, progress_callback=None)

Save the animation as a movie file by drawing every frame.

**Parameters**

- **filename** [str] The output filename, e.g., mymovie.mp4.
- **writer** [MovieWriter or str, optional] A MovieWriter instance to use or a key that identifies a class to use, such as ‘ffmpeg’. If None, defaults to rcParams["animation.writer"] = ‘ffmpeg’.
- **fps** [number, optional] Frames per second in the movie. Defaults to None, which will use the animation’s specified interval to set the frames per second.
- **dpi** [number, optional] Controls the dots per inch for the movie frames. This combined with the figure’s size in inches controls the size of the movie. If None, defaults to rcParams["savefig.dpi"].
- **codec** [str, optional] The video codec to be used. Not all codecs are supported by a given MovieWriter. If None, default to rcParams["animation.codec"] = ‘h264’.
- **bitrate** [number, optional] Specifies the number of bits used per second in the compressed movie, in kilobits per second. A higher number means a higher quality movie, but at the cost of increased file size. If None, defaults to rcParams["animation.bitrate"] = -1.
- **extra_args** [list, optional] List of extra string arguments to be passed to the underlying movie utility. If None, defaults to rcParams["animation.extra_args"].
- **metadata** [Dict[str, str], optional] Dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.
- **extra_anim** [list, optional] Additional Animation objects that should be included in the saved movie file. These need to be from the same matplotlib.figure.Figure instance. Also, animation frames will just be simply combined, so there should be a 1:1 correspondence between the frames from the different animations.
**savefig_kwargs** [dict, optional] Is a dictionary containing keyword arguments to be passed on to the `savefig` command which is called repeatedly to save the individual frames.

**progress_callback** [function, optional] A callback function that will be called for every frame to notify the saving progress. It must have the signature

```python
def func(current_frame: int, total_frames: int) -> Any
```

where `current_frame` is the current frame number and `total_frames` is the total number of frames to be saved. `total_frames` is set to None, if the total number of frames can not be determined. Return values may exist but are ignored.

Example code to write the progress to stdout:

```python
progress_callback = lambda i, n: print(f'Saving frame {i} of {n}')
```

**Notes**

`fps`, `codec`, `bitrate`, `extra_args` and `metadata` are used to construct a `MovieWriter` instance and can only be passed if `writer` is a string. If they are passed as non-`None` and `writer` is a `MovieWriter`, a `RuntimeError` will be raised.

**to_html5_video**(self, embed_limit=None)

Convert the animation to an HTML5 `<video>` tag.

This saves the animation as an h264 video, encoded in base64 directly into the HTML5 video tag. This respects the rc parameters for the writer as well as the bitrate. This also makes use of the interval to control the speed, and uses the `repeat` parameter to decide whether to loop.

**Parameters**

- **embed_limit** [float, optional] Limit, in MB, of the returned animation. No animation is created if the limit is exceeded. Defaults to `rcParams['animation.embed_limit'] = 20.0`.

**Returns**

- **video_tag** [str] An HTML5 video tag with the animation embedded as base64 encoded h264 video. If the `embed_limit` is exceeded, this returns the string “Video too large to embed.”

**to_jshtml**(self, fps=None, embed_frames=True, default_mode=None)

Generate HTML representation of the animation

```
matplotlib.animation.FuncAnimation
```

**class matplotlib.animation.FuncAnimation(fig, func, frames=None, init_func=None, fargs=None, save_count=None, *, cache_frame_data=True, **kwargs)**

Makes an animation by repeatedly calling a function `func`.

**Parameters**
**fig** [matplotlib.figure.Figure] The figure object that is used to get draw, resize, and any other needed events.

**func** [callable] The function to call at each frame. The first argument will be the next value in frames. Any additional positional arguments can be supplied via the fargs parameter.

The required signature is:

```python
def func(frame, *fargs) -> iterable_of_artists
```

If blit == True, func must return an iterable of all artists that were modified or created. This information is used by the blitting algorithm to determine which parts of the figure have to be updated. The return value is unused if blit == False and may be omitted in that case.

**frames** [iterable, int, generator function, or None, optional] Source of data to pass func and each frame of the animation

- If an iterable, then simply use the values provided. If the iterable has a length, it will override the save_count kwarg.
- If an integer, then equivalent to passing range(frames)
- If a generator function, then must have the signature:

```python
def gen_function() -> obj
```

- If None, then equivalent to passing itertools.count.

In all of these cases, the values in frames is simply passed through to the user-supplied func and thus can be of any type.

**init_func** [callable, optional] A function used to draw a clear frame. If not given, the results of drawing from the first item in the frames sequence will be used. This function will be called once before the first frame.

The required signature is:

```python
def init_func() -> iterable_of_artists
```

If blit == True, init_func must return an iterable of artists to be re-drawn. This information is used by the blitting algorithm to determine which parts of the figure have to be updated. The return value is unused if blit == False and may be omitted in that case.

**fargs** [tuple or None, optional] Additional arguments to pass to each call to func.

**save_count** [int, optional] The number of values from frames to cache.

**interval** [number, optional] Delay between frames in milliseconds. Defaults to 200.

**repeat_delay** [number, optional] If the animation in repeated, adds a delay in milliseconds before repeating the animation. Defaults to None.

**repeat** [bool, optional] Controls whether the animation should repeat when the sequence of frames is completed. Defaults to True.
**blit** [bool, optional] Controls whether blitting is used to optimize drawing. 
Note: when using blitting any animated artists will be drawn according to their zorder. However, they will be drawn on top of any previous artists, regardless of their zorder. Defaults to *False*.

**cache_frame_data** [bool, optional] Controls whether frame data is cached. 
Defaults to *True*. Disabling cache might be helpful when frames contain large objects.

```python
__init__(self, fig, func, frames=None, init_func=None, fargs=None, save_count=None, *, cache_frame_data=True, **kwargs)
```

Initialize self. See help(type(self)) for accurate signature.

**Methods**

```python
__init__(self, fig, func[, frames, ...]) Initialize self.
new_frame_seq(self) Return a new sequence of frame information.
new_saved_frame_seq(self) Return a new sequence of saved/cached frame information.
save(self, filename[, writer, fps, dpi, ...]) Save the animation as a movie file by drawing every frame.
to_html5_video(self[, embed_limit]) Convert the animation to an HTML5 <video> tag.
to_jshtml(self[, fps, embed_frames, ...]) Generate HTML representation of the animation
```

```python
new_frame_seq(self)
    Return a new sequence of frame information.
new_saved_frame_seq(self)
    Return a new sequence of saved/cached frame information.
```

**matplotlib.animation.ArtistAnimation**

```python
class matplotlib.animation.ArtistAnimation(fig, artists, *args, **kwargs)
```

Animation using a fixed set of Artist objects.

Before creating an instance, all plotting should have taken place and the relevant artists saved.

**Parameters**

```python
fig [matplotlib.figure.Figure] The figure object that is used to get draw, resize, and any other needed events.
artists [list] Each list entry a collection of artists that represent what needs to be enabled on each frame. These will be disabled for other frames.
repeat_delay [number, optional] If the animation in repeated, adds a delay in milliseconds before repeating the animation. Defaults to *None*.
```
**repeat** [bool, optional] Controls whether the animation should repeat when the sequence of frames is completed. Defaults to True.

**blit** [bool, optional] Controls whether blitting is used to optimize drawing. Defaults to False.

```python
__init__(self, fig, artists, *args, **kwargs)
    Initialize self. See help(type(self)) for accurate signature.
```

### Methods

- **new_frame_seq**(self) Return a new sequence of frame information.
- **new_saved_frame_seq**(self) Return a new sequence of saved/cached frame information.
- **save**(self, filename[, writer, fps, dpi, ...]) Save the animation as a movie file by drawing every frame.
- **to_html5_video**(self[, embed_limit]) Convert the animation to an HTML5 `<video>` tag.
- **to_jshtml**(self[, fps, embed_frames, ...]) Generate HTML representation of the animation

In both cases it is critical to keep a reference to the instance object. The animation is advanced by a timer (typically from the host GUI framework) which the `Animation` object holds the only reference to. If you do not hold a reference to the `Animation` object, it (and hence the timers), will be garbage collected which will stop the animation.

To save an animation to disk use `Animation.save` or `Animation.to_html5_video`

See **Helper Classes** below for details about what movie formats are supported.

**FuncAnimation**

The inner workings of `FuncAnimation` is more-or-less:

```python
for d in frames:
    artists = func(d, *fargs)
    fig.canvas.draw_idle()
    fig.canvas.start_event_loop(interval)
```

with details to handle ‘blitting’ (to dramatically improve the live performance), to be non-blocking, not repeatedly start/stop the GUI event loop, handle repeats, multiple animated axes, and easily save the animation to a movie file.

‘Blitting’ is a old technique in computer graphics. The general gist is to take an existing bit map (in our case a mostly rasterized figure) and then ‘blit’ one more artist on top. Thus, by managing a saved ‘clean’ bitmap, we can only re-draw the few artists that are changing at each frame and possibly save significant amounts of time. When we use blitting (by passing `blit=True`), the core loop of `FuncAnimation` gets a bit more complicated:

```python
ax = fig.gca()
```

(continues on next page)
def update_blit(artists):
    fig.canvas.restore_region(bg_cache)
    for a in artists:
        a.axes.draw_artist(a)

        ax.figure.canvas.blit(ax.bbox)

artists = init_func()

for a in artists:
    a.set_animated(True)

fig.canvas.draw()
bg_cache = fig.canvas.copy_from_bbox(ax.bbox)

for f in frames:
    artists = func(f, *fargs)
    update_blit(artists)
    fig.canvas.start_event_loop(interval)

This is of course leaving out many details (such as updating the background when the figure
is resized or fully re-drawn). However, this hopefully minimalist example gives a sense of how
init_func and func are used inside of FuncAnimation and the theory of how ‘blitting’ works.

The expected signature on func and init_func is very simple to keep FuncAnimation out of your
book keeping and plotting logic, but this means that the callable objects you pass in must
know what artists they should be working on. There are several approaches to handling this,
of varying complexity and encapsulation. The simplest approach, which works quite well
in the case of a script, is to define the artist at a global scope and let Python sort things out. For
example

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.animation import FuncAnimation

fig, ax = plt.subplots()
xdata, ydata = [], []
ln, = plt.plot([], [], 'ro')

def init():
    ax.set_xlim(0, 2*np.pi)
    ax.set_ylim(-1, 1)
    return ln,

def update(frame):
    xdata.append(frame)
    ydata.append(np.sin(frame))
    ln.set_data(xdata, ydata)
    return ln,

ani = FuncAnimation(fig, update, frames=np.linspace(0, 2*np.pi, 128),
    init_func=init, blit=True)
plt.show()
```
The second method is to use `functools.partial` to 'bind' artists to function. A third method is to use closures to build up the required artists and functions. A fourth method is to create a class.

**Examples**

**Note:** Click *here* to download the full example code

**Decay**

This example showcases: - using a generator to drive an animation, - changing axes limits during an animation.

```python
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.animation as animation

def data_gen(t=0):
    # (continues on next page)
```
cnt = 0
while cnt < 1000:
    cnt += 1
    t += 0.1
    yield t, np.sin(2*np.pi*t) * np.exp(-t/10.)

def init():
    ax.set_ylim(-1.1, 1.1)
    ax.set_xlim(0, 10)
    del xdata[:]
    del ydata[:]
    line.set_data(xdata, ydata)
    return line,

fig, ax = plt.subplots()
line, = ax.plot([], [], lw=2)
ax.grid()
xdata, ydata = [], []

def run(data):
    # update the data
    t, y = data
    xdata.append(t)
    ydata.append(y)
    xmin, xmax = ax.get_xlim()
    if t >= xmax:
        ax.set_xlim(xmin, 2*xmax)
        ax.figure.canvas.draw()
        line.set_data(xdata, ydata)
    return line,

ani = animation.FuncAnimation(fig, run, data_gen, blit=False, interval=10,
                               repeat=False, init_func=init)
plt.show()

Note: Click here to download the full example code

The Bayes update

This animation displays the posterior estimate updates as it is refitted when new data arrives. The vertical line represents the theoretical value to which the plotted distribution should converge.
import math

import numpy as np
import matplotlib.pyplot as plt
from matplotlib.animation import FuncAnimation

def beta_pdf(x, a, b):
    return (x**(a-1) * (1-x)**(b-1) * math.gamma(a + b) / (math.gamma(a) * math.gamma(b)))

class UpdateDist(object):
    def __init__(self, ax, prob=0.5):
        self.success = 0
        self.prob = prob

Animated histogram

Use a path patch to draw a bunch of rectangles for an animated histogram.

import numpy as np
import matplotlib.pyplot as plt
import matplotlib.patches as patches
import matplotlib.path as path
import matplotlib.animation as animation

# Fixing random state for reproducibility
np.random.seed(19680801)

# histogram our data with numpy
data = np.random.randn(1000)
n, bins = np.histogram(data, 100)

# get the corners of the rectangles for the histogram
left = np.array(bins[:-1])
right = np.array(bins[1:])
bottom = np.zeros(len(left))
top = bottom + n
nrects = len(left)

Here comes the tricky part – we have to set up the vertex and path codes arrays using plt.Path.MOVETO, plt.Path.LINETO and plt.Path.CLOSEPOLY for each rect.

- We need 1 MOVETO per rectangle, which sets the initial point.
- We need 3 LINETO’s, which tell Matplotlib to draw lines from vertex 1 to vertex 2, v2 to v3, and v3 to v4.
- We then need one CLOSEPOLY which tells Matplotlib to draw a line from the v4 to our initial vertex (the MOVETO vertex), in order to close the polygon.

Note: The vertex for CLOSEPOLY is ignored, but we still need a placeholder in the verts array to keep the codes aligned with the vertices.

nverts = nrects * (1 + 3 + 1)
verts = np.zeros((nverts, 2))
codes = np.ones(nverts, int) * path.Path.LINETO
codes[0::5] = path.Path.MOVETO
codes[4::5] = path.Path.CLOSEPOLY
verts[0::5, 0] = left
verts[0::5, 1] = bottom
verts[1::5, 0] = left
verts[1::5, 1] = top
verts[2::5, 0] = right
verts[2::5, 1] = top
verts[3::5, 0] = right
verts[3::5, 1] = bottom

To animate the histogram, we need an animate function, which generates a random set of numbers and updates the locations of the vertices for the histogram (in this case, only the heights of each rectangle). patch will eventually be a Patch object.

patch = None

def animate(i):
    # simulate new data coming in
    data = np.random.randn(1000)
    n, bins = np.histogram(data, 100)
    top = bottom + n
    verts[1::5, 1] = top
    verts[2::5, 1] = top
    return [patch, ]
And now we build the `Path` and `Patch` instances for the histogram using our vertices and codes. We add the patch to the `Axes` instance, and setup the `FuncAnimation` with our animate function.

```python
fig, ax = plt.subplots()
barpath = path.Path(verts, codes)
patch = patches.PathPatch(
    barpath, facecolor='green', edgecolor='yellow', alpha=0.5)
ax.add_patch(patch)

ax.set_xlim(left[0], right[-1])
ax.set_ylim(bottom.min(), top.max())

ani = animation.FuncAnimation(fig, animate, 100, repeat=False, blit=True)
plt.show()
```

# writer = FFMpegWriter(fps=15, metadata=dict(artist='Me'), bitrate=1800)
# ani.save("movie.mp4", writer=writer)

plt.show()
```

### 17.3.2 Writer Classes

The provided writers fall into a few broad categories.

The Pillow writer relies on the Pillow library to write the animation, keeping all data in memory.

**PillowWriter**

```python
matplotlib.animation.PillowWriter

class matplotlib.animation.PillowWriter(*args, **kwargs)

    __init__(self, *args, **kwargs)

        MovieWriter

        Parameters

            fps [int] Framerate for movie.

            codec [string or None, optional] The codec to use. If None (the default)
                the animation.codec rcParam is used.

            bitrate [int or None, optional] The bitrate for the saved movie file, which
                is one way to control the output file size and quality. The default value
```
is `None`, which uses the `animation.bitrate` rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.

**extra_args** [list of strings or `None`, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is `None`, which passes the additional arguments in the `animation.extra_args` rcParam.

**metadata** [Dict[str, str] or `None`] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__init__</code></td>
<td>MovieWriter</td>
</tr>
<tr>
<td><code>bin_path()</code></td>
<td>Return the binary path to the command-line tool used by a specific subclass.</td>
</tr>
<tr>
<td><code>cleanup(self)</code></td>
<td>Clean-up and collect the process used to write the movie file.</td>
</tr>
<tr>
<td><code>finish(self)</code></td>
<td>Finish any processing for writing the movie.</td>
</tr>
<tr>
<td><code>grab_frame(self, \*\*savefig_kwargs)</code></td>
<td>Grab the image information from the figure and save as a movie frame.</td>
</tr>
<tr>
<td><code>isAvailable()</code></td>
<td>Check to see if a MovieWriter subclass is actually available.</td>
</tr>
<tr>
<td><code>saving(self, fig, outfile, dpi, \*args, ...)</code></td>
<td>Context manager to facilitate writing the movie file.</td>
</tr>
<tr>
<td><code>setup(self, fig, outfile[, dpi])</code></td>
<td>Perform setup for writing the movie file.</td>
</tr>
</tbody>
</table>

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>frame_size</code></td>
<td>A tuple (width, height) in pixels of a movie frame.</td>
</tr>
</tbody>
</table>

**Parameters**

- `fig` [matplotlib.figure.Figure] The figure object that contains the information for frames
outfile [string] The filename of the resulting movie file

dpi [int, optional] The DPI (or resolution) for the file. This controls the size in pixels of the resulting movie file. Default is fig.dpi.

The pipe-based writers stream the captured frames over a pipe to an external process. The pipe-based variants tend to be more performant, but may not work on all systems.

<table>
<thead>
<tr>
<th>Writer Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FFMpegWriter</td>
<td>Pipe-based ffmpeg writer.</td>
</tr>
<tr>
<td>ImageMagickWriter</td>
<td>Pipe-based animated gif.</td>
</tr>
<tr>
<td>AVConvWriter</td>
<td>Pipe-based avconv writer.</td>
</tr>
</tbody>
</table>

matplotlib.animation.FFMpegWriter

class matplotlib.animation.FFMpegWriter(fps=5, codec=None, bitrate=None, extra_args=None, metadata=None)

Pipe-based ffmpeg writer.

Frames are streamed directly to ffmpeg via a pipe and written in a single pass.

Parameters

- **fps** [int] Framerate for movie.
- **codec** [string or None, optional] The codec to use. If None (the default) the animation.codec rcParam is used.
- **bitrate** [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is None, which uses the animation.bitrate rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.
- **extra_args** [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is None, which passes the additional arguments in the animation.extra_args rcParam.
- **metadata** [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

__init__(self, fps=5, codec=None, bitrate=None, extra_args=None, metadata=None) MovieWriter

Parameters

- **fps** [int] Framerate for movie.
- **codec** [string or None, optional] The codec to use. If None (the default) the animation.codec rcParam is used.
- **bitrate** [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is None, which uses the animation.bitrate rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.
- **extra_args** [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is None,
which passes the additional arguments in the animation.extra_args rc-Param.

**metadata** [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

**matplotlib.animation.ImageMagickWriter**

class matplotlib.animation.ImageMagickWriter(*fps=5, codec=None, bitrate=None, extra_args=None, metadata=None*)

Pipe-based animated gif.

Frames are streamed directly to ImageMagick via a pipe and written in a single pass.

**Parameters**

- **fps** [int] Frame rate for movie.
- **codec** [string or None, optional] The codec to use. If None (the default) the animation.codec rcParam is used.
- **bitrate** [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is None, which uses the animation.bitrate rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.
**extra_args** [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is `None`, which passes the additional arguments in the `animation.extra_args` rcParam.

**metadata** [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

```python
__init__(self, fps=5, codec=None, bitrate=None, extra_args=None, metadata=None)
```

**MovieWriter**

**Parameters**

**fps** [int] Framerate for movie.

**codec** [string or None, optional] The codec to use. If `None` (the default) the `animation.codec` rcParam is used.

**bitrate** [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is `None`, which uses the `animation.bitrate` rcParam. A value of `-1` implies that the bitrate should be determined automatically by the underlying utility.

**extra_args** [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is `None`, which passes the additional arguments in the `animation.extra_args` rcParam.

**matplotlib.animation.AVConvWriter**

```python
class matplotlib.animation.AVConvWriter(fps=5, codec=None, bitrate=None, extra_args=None, metadata=None)
```

Pipe-based avconv writer.

Frames are streamed directly to avconv via a pipe and written in a single pass.

**Parameters**

- **fps** [int] Framerate for movie.
- **codec** [string or None, optional] The codec to use. If `None` (the default) the `animation.codec` rcParam is used.
- **bitrate** [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is `None`, which uses the `animation.bitrate` rcParam. A value of `-1` implies that the bitrate should be determined automatically by the underlying utility.
- **extra_args** [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is `None`, which passes the additional arguments in the `animation.extra_args` rcParam.
- **metadata** [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

```python
__init__(self, fps=5, codec=None, bitrate=None, extra_args=None, metadata=None)
```

**Parameters**

- **fps** [int] Framerate for movie.
- **codec** [string or None, optional] The codec to use. If `None` (the default) the `animation.codec` rcParam is used.
- **bitrate** [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is `None`, which uses the `animation.bitrate` rcParam. A value of `-1` implies that the bitrate should be determined automatically by the underlying utility.
- **extra_args** [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is `None`, which passes the additional arguments in the `animation.extra_args` rcParam.
- **metadata** [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

supported_formats
```

```
supported_formats = ['png', 'jpeg', 'ppm', 'tiff', 'sgi', 'bmp', 'pbm', 'raw', 'rgba']
```

### matplotlib.animation.ImageMagickFileWriter

```
class matplotlib.animation.ImageMagickFileWriter(*args, **kwargs)
    File-based animated gif writer.
```

Frames are written to temporary files on disk and then stitched together at the end.
MovieWriter

Parameters

fps [int] Framerate for movie.

codec [string or None, optional] The codec to use. If None (the default) the animation.codec rcParam is used.

bitrate [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is None, which uses the animation.bitrate rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.

extra_args [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is None, which passes the additional arguments in the animation.extra_args rcParam.

metadata [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

Methods

__init__(self, *args, **kwargs) MovieWriter

bin_path() Return the binary path to the command-line tool used by a specific subclass.

cleanup(self) Clean-up and collect the process used to write the movie file.

finish(self) Finish any processing for writing the movie.

grab_frame(self, **savefig_kwargs) Grab the image information from the figure and save as a movie frame.

isAvailable() Check to see if a MovieWriter subclass is actually available.

saving(self, fig, outfile, dpi, *args, ...) Context manager to facilitate writing the movie file.

setup(self, fig, outfile[, dpi, ...]) Perform setup for writing the movie file.

Attributes

args_key

delay

exect_key

frame_format Format (png, jpeg, etc.) to use for saving the frames, which can be decided by the individual subclasses.

frame_size A tuple (width, height) in pixels of a movie frame.

output_args

Continued on next page
Table 19 – continued from previous page

**supported_formats**

```python
supported_formats = ['png', 'jpeg', 'ppm', 'tiff', 'sgi', 'bmp', 'pbm', 'raw', 'rgba']
```

**matplotlib.animation.AVConvFileWriter**

class `matplotlib.animation.AVConvFileWriter(*args, **kwargs)`

File-based avconv writer.

```python
__init__(self, *args, **kwargs)  
MovieWriter

Parameters

fps [int] Framerate for movie.

codec [string or None, optional] The codec to use. If None (the default)
the animation.codec rcParam is used.

bitrate [int or None, optional] The bitrate for the saved movie file, which
is one way to control the output file size and quality. The default value
is None, which uses the animation.bitrate rcParam. A value of -1 implies
that the bitrate should be determined automatically by the underlying
utility.

extra_args [list of strings or None, optional] A list of extra string argu-
ments to be passed to the underlying movie utility. The default is None,
which passes the additional arguments in the animation.extra_args rc-
Param.

metadata [Dict[str, str] or None] A dictionary of keys and values for
metadata to include in the output file. Some keys that may be of use
include: title, artist, genre, subject, copyright, srcform, comment.
```

Methods

```python
__init__(self, *args, **kwargs) MovieWriter

bin_path()  
Return the binary path to the command-
line tool used by a specific subclass.

cleanup(self)  
Clean-up and collect the process used to
write the movie file.

finish(self)  
Finish any processing for writing the
movie.

grab_frame(self, **savefig_kwargs)  
Grab the image information from the fig-
ure and save as a movie frame.

isAvailable()  
Check to see if a MovieWriter subclass is
actually available.

saving(self, fig, outfile, dpi, **args, ...)  
Context manager to facilitate writing the
movie file.

setup(self, fig, outfile[, dpi, ...])  
Perform setup for writing the movie file.
```

</table>

Fundamentally, a MovieWriter provides a way to grab sequential frames from the same underlying Figure object. The base class MovieWriter implements 3 methods and a context manager. The only difference between the pipe-based and file-based writers is in the arguments to their respective setup methods.

The setup() method is used to prepare the writer (possibly opening a pipe), successive calls to grab_frame() capture a single frame at a time and finish() finalizes the movie and writes the output file to disk. For example

```python
moviewriter = MovieWriter(...)  
moviewriter.setup(fig=fig, 'my_movie.ext', dpi=100)  
for j in range(n):  
    update_figure(n)  
    moviewriter.grab_frame()  
moviewriter.finish()
```

If using the writer classes directly (not through Animation.save), it is strongly encouraged to use the saving context manager

```python
with moviewriter.saving(fig, 'myfile.mp4', dpi=100):  
    for j in range(n):  
        update_figure(n)  
        moviewriter.grab_frame()
```

to ensure that setup and cleanup are performed as necessary.

Examples

**Note:** Click here to download the full example code

Frame grabbing

Use a MovieWriter directly to grab individual frames and write them to a file. This avoids any event loop integration, and thus works even with the Agg backend. This is not recommended for use in an interactive setting.
import numpy as np
import matplotlib
matplotlib.use("Agg")
import matplotlib.pyplot as plt
from matplotlib.animation import FFMpegWriter

# Fixing random state for reproducibility
np.random.seed(19680801)

metadata = dict(title='Movie Test', artist='Matplotlib',
                comment='Movie support!')
writer = FFMpegWriter(fps=15, metadata=metadata)

fig = plt.figure()
1, = plt.plot([], [], 'k-o')
plt.xlim(-5, 5)
plt.ylim(-5, 5)

x0, y0 = 0, 0

with writer.saving(fig, "writer_test.mp4", 100):
    for i in range(100):
        x0 += 0.1 * np.random.randn()
        y0 += 0.1 * np.random.randn()
        l.set_data(x0, y0)
        writer.grab_frame()

17.3.3 Helper Classes

Animation Base Classes

Animation subclass for time-based animation.

Parameters

- fig [matplotlib.figure Figure] The figure object that is used to get draw, resize, and any other needed events.
**interval** [number, optional] Delay between frames in milliseconds. Defaults to 200.

**repeat_delay** [number, optional] If the animation in repeated, adds a delay in milliseconds before repeating the animation. Defaults to `None`.

**repeat** [bool, optional] Controls whether the animation should repeat when the sequence of frames is completed. Defaults to `True`.

**blit** [bool, optional] Controls whether blitting is used to optimize drawing. Defaults to `False`.

```
__init__(self, fig, interval=200, repeat_delay=None, repeat=True, event_source=None, *args, **kwargs)
```

Initialize self. See help(type(self)) for accurate signature.

### Methods

<table>
<thead>

<td>Generate HTML representation of the animation</td>
</tr>
</tbody>
</table>

### Writer Registry

A module-level registry is provided to map between the name of the writer and the class to allow a string to be passed to `Animation.save` instead of a writer instance.

**MovieWriterRegistry**

Registry of available writer classes by human readable name.

```
matplotlib.animation.MovieWriterRegistry
```

**class matplotlib.animation.MovieWriterRegistry**

Registry of available writer classes by human readable name.

```
__init__(self)
```

Initialize self. See help(type(self)) for accurate signature.

</tr>
</tbody>
</table>

**ensure_not_dirty(self)**

If dirty, reasks the writers if they are available

**is_available(self, name)**

Check if given writer is available by name.

**Parameters**

**name** [str]

**Returns**

**available** [bool]

**list(self)**

Get a list of available MovieWriters.

**register(self, name)**

Decorator for registering a class under a name.

Example use:

```python
@registry.register(name)
class Foo:
    pass
```

**reset_available_writers(self)**

Reset the available state of all registered writers

**set_dirty(self)**

Sets a flag to re-setup the writers.

**Writer Base Classes**

To reduce code duplication base classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>AbstractMovieWriter</td>
<td>Abstract base class for writing movies.</td>
</tr>
<tr>
<td>MovieWriter</td>
<td>Base class for writing movies.</td>
</tr>
<tr>
<td>FileMovieWriter</td>
<td>MovieWriter for writing to individual files and stitching at the end.</td>
</tr>
</tbody>
</table>
matplotlib.animation.AbstractMovieWriter

class matplotlib.animation.AbstractMovieWriter
    Abstract base class for writing movies. Fundamentally, what a MovieWriter does is provide is a way to grab frames by calling grab_frame().

    setup() is called to start the process and finish() is called afterwards.

    This class is set up to provide for writing movie frame data to a pipe. saving() is provided as a context manager to facilitate this process as:

    
    ```python
    with moviewriter.saving(fig, outfile='myfile.mp4', dpi=100):
        # Iterate over frames
        moviewriter.grab_frame(**savefig_kwargs)
    ```

    The use of the context manager ensures that setup() and finish() are performed as necessary.

    An instance of a concrete subclass of this class can be given as the writer argument of Animation.save().

    __init__(self, /, *args, **kwargs)
        Initialize self. See help(type(self)) for accurate signature.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>finish(self)</td>
<td>Finish any processing for writing the movie.</td>
</tr>
<tr>
<td>grab_frame(self, **savefig_kwargs)</td>
<td>Grab the image information from the figure and save as a movie frame.</td>
</tr>
<tr>
<td>saving(self, fig, outfile, dpi, *args, ...)</td>
<td>Context manager to facilitate writing the movie file.</td>
</tr>
<tr>
<td>setup(self, fig, outfile[, dpi])</td>
<td>Perform setup for writing the movie file.</td>
</tr>
</tbody>
</table>

**finish**(self)

Finish any processing for writing the movie.

**grab_frame**(self, **savefig_kwargs)

Grab the image information from the figure and save as a movie frame.

All keyword arguments in savefig_kwargs are passed on to the savefig command that saves the figure.

**saving**(self, fig, outfile, dpi, *args, ...)

Context manager to facilitate writing the movie file.

*args, **kw are any parameters that should be passed to setup.

**setup**(self, fig, outfile, dpi=None)

Perform setup for writing the movie file.

Parameters

- **fig** [matplotlib.figure.Figure instance] The figure object that contains the information for frames
- **outfile** [string] The filename of the resulting movie file
**dpi** [int, optional] The DPI (or resolution) for the file. This controls the size in pixels of the resulting movie file. Default is `fig.dpi`.

```python
matplotlib.animation.MovieWriter

class matplotlib.animation.MovieWriter(fps=5, codec=None, bitrate=None, extra_args=None, metadata=None)
```

Base class for writing movies.

This is a base class for MovieWriter subclasses that write a movie frame data to a pipe. You cannot instantiate this class directly. See examples for how to use its subclasses.

**Attributes**

- `frame_format` [str] The format used in writing frame data, defaults to 'rgba'
- `fig` [Figure] The figure to capture data from. This must be provided by the sub-classes.

**Parameters**

- `fps` [int] Framerate for movie.
- `codec` [string or None, optional] The codec to use. If `None` (the default) the `animation.codec` rcParam is used.
- `bitrate` [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is `None`, which uses the `animation.bitrate` rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.
- `extra_args` [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is `None`, which passes the additional arguments in the `animation.extra_args` rcParam.
- `metadata` [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

```
__init__(self, fps=5, codec=None, bitrate=None, extra_args=None, metadata=None)
```

**Parameters**

- `fps` [int] Framerate for movie.
- `codec` [string or None, optional] The codec to use. If `None` (the default) the `animation.codec` rcParam is used.
- `bitrate` [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is `None`, which uses the `animation.bitrate` rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.
- `extra_args` [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is `None`,
which passes the additional arguments in the animation.

**metadata** [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>frame_size</td>
<td>A tuple (width, height) in pixels of a movie frame.</td>
</tr>
</tbody>
</table>

**classmethod bin_path()**

Return the binary path to the commandline tool used by a specific subclass. This is a class method so that the tool can be looked for before making a particular MovieWriter subclass available.

**cleanup(self)**

Clean-up and collect the process used to write the movie file.

**finish(self)**

Finish any processing for writing the movie.

**frame_size**

A tuple (width, height) in pixels of a movie frame.

**grab_frame(self, **savefig_kwars)**

Grab the image information from the figure and save as a movie frame.

All keyword arguments in savefig_kwars are passed on to the savefig command that saves the figure.

**classmethod isAvailable()**

Check to see if a MovieWriter subclass is actually available.

**setup(self, fig, outfile, dpi=None)**

Perform setup for writing the movie file.
Parameters

**fig** [matplotlib.figure.Figure] The figure object that contains the information for frames

**outfile** [string] The filename of the resulting movie file

**dpi** [int, optional] The DPI (or resolution) for the file. This controls the size in pixels of the resulting movie file. Default is fig.dpi.

Matplotlib.animation.FileMovieWriter

class matplotlib.animation.FileMovieWriter(*args, **kwargs)

MovieWriter for writing to individual files and stitching at the end.

This must be sub-classed to be useful.

__init__(self, *args, **kwargs)

MovieWriter

Parameters

**fps** [int] Framerate for movie.

**codec** [string or None, optional] The codec to use. If None (the default) the animation.codec rcParam is used.

**bitrate** [int or None, optional] The bitrate for the saved movie file, which is one way to control the output file size and quality. The default value is None, which uses the animation.bitrate rcParam. A value of -1 implies that the bitrate should be determined automatically by the underlying utility.

**extra_args** [list of strings or None, optional] A list of extra string arguments to be passed to the underlying movie utility. The default is None, which passes the additional arguments in the animation.extra_args rcParam.

**metadata** [Dict[str, str] or None] A dictionary of keys and values for metadata to include in the output file. Some keys that may be of use include: title, artist, genre, subject, copyright, srcform, comment.

Continued on next page
saving(self, fig, outfile, dpi, \*args, ...)  Context manager to facilitate writing the movie file.

setup(self, fig, outfile[, dpi, ...])  Perform setup for writing the movie file.

**Attributes**

frame_format  Format (png, jpeg, etc.) to use for saving the frames, which can be decided by the individual subclasses.

frame_size  A tuple (width, height) in pixels of a movie frame.

cleanup(self)  Clean-up and collect the process used to write the movie file.

finish(self)  Finish any processing for writing the movie.

frame_format  Format (png, jpeg, etc.) to use for saving the frames, which can be decided by the individual subclasses.

grab_frame(self, **savefig_kwargs)  Grab the image information from the figure and save as a movie frame. All keyword arguments in savefig_kwargs are passed on to the savefig command that saves the figure.

setup(self, fig, outfile, dpi=None, frame_prefix='_tmp', clear_temp=True)  Perform setup for writing the movie file.

**Parameters**

fig  [matplotlib.figure.Figure] The figure to grab the rendered frames from.

outfile  [str] The filename of the resulting movie file.

dpi  [number, optional] The dpi of the output file. This, with the figure size, controls the size in pixels of the resulting movie file. Default is fig.dpi.

frame_prefix  [str, optional] The filename prefix to use for temporary files. Defaults to '_tmp'.

clear_temp  [bool, optional] If the temporary files should be deleted after stitching the final result. Setting this to False can be useful for debugging. Defaults to True.

and mixins

<table>
<thead>

</tbody>
</table>
matplotlib.animation.AVConvBase

class matplotlib.animation.AVConvBase
    Mixin class for avconv output.
    To be useful this must be multiply-inherited from a MovieWriterBase sub-class.
    
    __init__(self, /, *args, **kwargs)
        Initialize self. See help(type(self)) for accurate signature.

    Methods

    isAvailable() Check to see if a MovieWriter subclass is actually available.

    Attributes

    args_key
    exec_key
    output_args

    args_key = 'animation.avconv_args'
    exec_key = 'animation.avconv_path'
    classmethod isAvailable()
        Check to see if a MovieWriter subclass is actually available.

matplotlib.animation.FFMpegBase

class matplotlib.animation.FFMpegBase
    Mixin class for FFMpeg output.
    To be useful this must be multiply-inherited from a MovieWriterBase sub-class.
    
    __init__(self, /, *args, **kwargs)
        Initialize self. See help(type(self)) for accurate signature.

    Methods

    isAvailable()

    Attributes

    args_key
    exec_key
    output_args
Matplotlib, Release 3.1.1

```python
args_key = 'animation.ffmpegs_args'
exec_key = 'animation.ffmpegs_path'
classmethod isAvailable()
output_args
```

**matplotlib.animation.ImageMagickBase**

```python
class matplotlib.animation.ImageMagickBase
    Mixin class for ImageMagick output.
    
    To be useful this must be multiply-inherited from with a MovieWriterBase sub-class.
    __init__(self, *, args, **kwargs)
        Initialize self. See help(type(self)) for accurate signature.
```

**Methods**

- `bin_path()`
- `isAvailable()`

**Attributes**

- `args_key`
- `delay`
- `exec_key`
- `output_args`

```python
args_key = 'animation.convert_args'
classmethod bin_path()
delay
classmethod exec_key = 'animation.convert_path'
classmethod isAvailable()
output_args
```

are provided.

See the source code for how to easily implement new MovieWriter classes.
17.3.4 Inheritance Diagrams
17.4 matplotlib.artist

17.4.1 Artist class

class matplotlib.artist.Artist
    Abstract base class for objects that render into a FigureCanvas.

    Typically, all visible elements in a figure are subclasses of Artist.
Interactive

**Artist.add_callback**  
Add a callback function that will be called whenever one of the Artist's properties changes.

**Artist.remove_callback**  
Remove a callback based on its observer id.

**Artist.pchanged**  
Call all of the registered callbacks.

**Artist.get_cursor_data**  
Return the cursor data for a given event.

**Artist.format_cursor_data**  
Return a string representation of data.

**Artist.mouseover**  
Test whether the artist contains the mouse event.

**Artist.contains**  
Define a custom contains test for the artist.

**Artist.get_contains**  
Return the custom contains function of the artist if set, or None.

**Artist.pick**  
Process a pick event.

**Artist.pickable**  
Return whether the artist is pickable.

**Artist.set_picker**  
Define the picking behavior of the artist.

**Artist.get_picker**  
Return the picking behavior of the artist.

---

**matplotlib.artist.Artist.add_callback**

*Artist.add_callback(self, func)*  
Add a callback function that will be called whenever one of the Artist's properties changes.

**Parameters**

- **func** [callable] The callback function. It must have the signature:

  ```python
  def func(artist: Artist) -> Any
  ```

  where artist is the calling Artist. Return values may exist but are ignored.

**Returns**

- **oid** [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

**See also:**

- remove_callback

---

**matplotlib.artist.Artist.remove_callback**

*Artist.remove_callback(self, oid)*  
Remove a callback based on its observer id.

**See also:**

- add_callback
matplotlib.artist.Artist.pchanged

Artist.pchanged(self)
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:
add_callback
remove_callback

matplotlib.artist.Artist.get_cursor_data

Artist.get_cursor_data(self, event)
Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user of
Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given
event. The default implementation just returns None.
Subclasses can override the method and return arbitrary data. However, when doing so,
they must ensure that format_cursor_data can convert the data to a string representation.
The only current use case is displaying the z-value of an AxesImage in the status bar of a
plot window, while moving the mouse.

Parameters

   event [matplotlib.backend_bases.MouseEvent]

See also:
format_cursor_data

matplotlib.artist.Artist.format_cursor_data

Artist.format_cursor_data(self, data)
Return a string representation of data.

Note: This method is intended to be overridden by artist subclasses. As an end-user of
Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a
comma-separated string enclosed in square brackets.

See also:
get_cursor_data
`matplotlib.artist.Artist.mouseover`

`Artist.mouseover`

`matplotlib.artist.Artist.contains`

`Artist.contains(self, mouseevent)`
Test whether the artist contains the mouse event.

**Parameters**

- `mouseevent` ([`matplotlib.backend_bases.MouseEvent`])

**Returns**

- `contains` [bool] Whether any values are within the radius.
- `details` [dict] An artist-specific dictionary of details of the event context, such as which points are contained in the pick radius. See the individual Artist subclasses for details.

**See also:**

`set_contains`, `get_contains`

`matplotlib.artist.Artist.set_contains`

`Artist.set_contains(self, picker)`
Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

- `picker` [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

  ```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
  ```

  that returns:
  
  - a bool indicating if the event is within the artist
  - a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

`matplotlib.artist.Artist.get_contains`

`Artist.get_contains(self)`
Return the custom contains function of the artist if set, or `None`.

**See also:**

`set_contains`
**Matplotlib, Release 3.1.1**

**matplotlib.artist.Artist.pick**

`Artist.pick(self, mouseevent)`  
Process a pick event.  
Each child artist will fire a pick event if `mouseevent` is over the artist and the artist has picker set.  
**See also:**  
`set_picker, get_picker, pickable`

**matplotlib.artist.Artist.pickable**

`Artist.pickable(self)`  
Return whether the artist is pickable.  
**See also:**  
`set_picker, get_picker, pick`  

**matplotlib.artist.Artist.set_picker**

`Artist.set_picker(self, picker)`  
Define the picking behavior of the artist.  
**Parameters**

- **picker** [None or bool or float or callable] This can be one of the following:
  - `None`: Picking is disabled for this artist (default).
  - A boolean: If `True` then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
  - A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
  - A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

    ```python
    hit, props = picker(artist, mouseevent)
    ```

    to determine the hit test. if the mouse event is over the artist, return `hit=True` and props is a dictionary of properties you want added to the PickEvent attributes.

**matplotlib.artist.Artist.get_picker**

`Artist.get_picker(self)`  
Return the picking behavior of the artist.
The possible values are described in `set_picker`.

**See also:**

`set_picker`, `pickable`, `pick`

**Clipping**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>set_clip_on</code></td>
<td>Set whether the artist uses clipping.</td>
</tr>
<tr>
<td><code>get_clip_on</code></td>
<td>Return whether the artist uses clipping.</td>
</tr>
<tr>
<td><code>set_clip_box</code></td>
<td>Set the artist’s clip Bbox.</td>
</tr>
<tr>
<td><code>get_clip_box</code></td>
<td>Return the clipbox.</td>
</tr>
<tr>
<td><code>set_clip_path</code></td>
<td>Set the artist’s clip path, which may be:</td>
</tr>
<tr>
<td><code>get_clip_path</code></td>
<td>Return the clip path.</td>
</tr>
</tbody>
</table>

```python
matplotlib.artist.Artist.set_clip_on

Artist.set_clip_on(self, b)
Set whether the artist uses clipping.
When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

- `b` [bool]
```
```
```
```python
matplotlib.artist.Artist.get_clip_on

Artist.get_clip_on(self)
Return whether the artist uses clipping.
```
```
```
```python
matplotlib.artist.Artist.set_clip_box

Artist.set_clip_box(self, clipbox)
Set the artist’s clip Bbox.

**Parameters**

- `clipbox` [Bbox]
```
```
```
```python
matplotlib.artist.Artist.get_clip_box

Artist.get_clip_box(self)
Return the clipbox.
```
```
```
```python
matplotlib.artist.Artist.set_clip_path

Artist.set_clip_path(self, path, transform=None)
Set the artist’s clip path, which may be:
```
• a `Patch` (or subclass) instance; or
• a `Path` instance, in which case a `Transform` instance, which will be applied to the path before using it for clipping, must be provided; or
• `None`, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to `None`.

ACCEPTS: `[Path, Transform] | Patch | None`
## Drawing

</tbody>
</table>

### matplotlib.artist.Artist.draw

```python
def draw(self, renderer, *args, **kwargs):
    """Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (Artist.get_visible is False).
    ""
    renderer = [RendererBase subclass.]
```

### matplotlib.artist.Artist.set_animated

```python
def set_animated(self, b):
    """Set the artist's animation state.
    ""
    b [bool]
```
**matplotlib.artist.Artist.get_animated**

```python
Artist.get_animated(self)
    Return the animated state.
```

**matplotlib.artist.Artist.set_alpha**

```python
Artist.set_alpha(self, alpha)
    Set the alpha value used for blending - not supported on all backends.
    
    **Parameters**
    
    alpha [float]
```

**matplotlib.artist.Artist.get_alpha**

```python
Artist.get_alpha(self)
    Return the alpha value used for blending - not supported on all backends
```

**matplotlib.artist.Artist.set_snap**

```python
Artist.set_snap(self, snap)
    Set the snapping behavior.
    
    Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.
    
    Snapping is currently only supported by the Agg and MacOSX backends.
    
    **Parameters**
    
    snap [bool or None]
        Possible values:
        
        • **True**: Snap vertices to the nearest pixel center.
        • **False**: Do not modify vertex positions.
        • **None**: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.
```

**matplotlib.artist.Artist.get_snap**

```python
Artist.get_snap(self)
    Returns the snap setting.
    
    See `set_snap` for details.
```
matplotlib.artist.Artist.set_visible

Artist.set_visible(self, b)
    Set the artist’s visibility.

    Parameters
    b [bool]

matplotlib.artist.Artist.get_visible

Artist.get_visible(self)
    Return the visibility.

matplotlib.artist.Artist.zorder

Artist.zorder = 0

matplotlib.artist.Artist.set_zorder

Artist.set_zorder(self, level)
    Set the zorder for the artist. Artists with lower zorder values are drawn first.

    Parameters
    level [float]

matplotlib.artist.Artist.get_zorder

Artist.get_zorder(self)
    Return the artist’s zorder.

matplotlib.artist.Artist.set_agg_filter

Artist.set_agg_filter(self, filter_func)
    Set the agg filter.

    Parameters
    filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

matplotlib.artist.Artist.set_sketch_params

Artist.set_sketch_params(self, scale=None, length=None, randomness=None)
    Sets the sketch parameters.

    Parameters
scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.

length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

randomness [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

matplotlib.artist.Artist.get_sketch_params

Artist.get_sketch_params(self)
Returns the sketch parameters for the artist.

Returns

sketch_params [tuple or None] A 3-tuple with the following elements:
  - scale: The amplitude of the wiggle perpendicular to the source line.
  - length: The length of the wiggle along the line.
  - randomness: The scale factor by which the length is shrunken or expanded.

Returns None if no sketch parameters were set.

matplotlib.artist.Artist.set_rasterized

Artist.set_rasterized(self, rasterized)
Force rasterized (bitmap) drawing in vector backend output.
Defaults to None, which implies the backend’s default behavior.

Parameters

rasterized [bool or None]

matplotlib.artist.Artist.get_rasterized

Artist.get_rasterized(self)
Return whether the artist is to be rasterized.

matplotlib.artist.Artist.set_path_effects

Artist.set_path_effects(self, path_effects)
Set the path effects.

Parameters

path_effects [AbstractPathEffect]
matplotlib.artist.Artist.get_path_effects

```python
Artist.get_path_effects(self)
```

matplotlib.artist.Artist.get_agg_filter

```python
Artist.get_agg_filter(self)
   Return filter function to be used for agg filter.
```

matplotlib.artist.Artist.get_window_extent

```python
Artist.get_window_extent(self, renderer)
   Get the axes bounding box in display space.

   The bounding box' width and height are nonnegative.

   Subclasses should override for inclusion in the bounding box "tight" calculation. Default
   is to return an empty bounding box at 0, 0.

   Be careful when using this function, the results will not update if the artist window extent
   of the artist changes. The extent can change due to any changes in the transform stack,
   such as changing the axes limits, the figure size, or the canvas used (as is done when
   saving a figure). This can lead to unexpected behavior where interactive figures will look
   fine on the screen, but will save incorrectly.
```

matplotlib.artist.Artist.get_transformed_clip_path_and_affine

```python
Artist.get_transformed_clip_path_and_affine(self)
   Return the clip path with the non-affine part of its transformation applied, and the re-
   maining affine part of its transformation.
```

Figure and Axes

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Artist.remove</td>
<td>Remove the artist from the figure if possible.</td>
</tr>
<tr>
<td>Artist.axes</td>
<td>The Axes instance the artist resides in, or None.</td>
</tr>
<tr>
<td>Artist.set_figure</td>
<td>Set the Figure instance the artist belongs to.</td>
</tr>
<tr>
<td>Artist.get_figure</td>
<td>Return the Figure instance the artist belongs to.</td>
</tr>
</tbody>
</table>

matplotlib.artist.Artist.remove

```python
Artist.remove(self)
   Remove the artist from the figure if possible.

   The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
   draw_idle. Call relim to update the axes limits if desired.

   Note: relim will not see collections even if the collection was added to the axes with
   autolim = True.
```
Note: there is no support for removing the artist’s legend entry.

**matplotlib.artist.Artist.axes**

**Artist.axes**
The *Axes* instance the artist resides in, or *None*.

**matplotlib.artist.Artist.set_figure**

**Artist.set_figure(self, fig)**
Set the *Figure* instance the artist belongs to.

**Parameters**

**fig** [Figure]

**matplotlib.artist.Artist.get_figure**

**Artist.get_figure(self)**
Return the *Figure* instance the artist belongs to.

**Children**

<table>
<thead>
<tr>
<th>Artist.get_children</th>
<th>Return a list of the child <em>Artists</em> of this <em>Artist</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Artist.findobj</td>
<td>Find artist objects.</td>
</tr>
</tbody>
</table>

**matplotlib.artist.Artist.get_children**

**Artist.get_children(self)**
Return a list of the child *Artists* of this *Artist*.

**matplotlib.artist.Artist.findobj**

**Artist.findobj(self, match=None, include_self=True)**
Find artist objects.

Recursively find all *Artist* instances contained in the artist.

**Parameters**

**match** A filter criterion for the matches. This can be

- *None*: Return all objects contained in artist.
- A function with signature `def match(artist: Artist) -> bool`. The result will only contain artists for which the function returns `True`.
- A class instance: e.g., *Line2D*. The result will only contain artists of this class or its subclasses (*isinstance* check).
include_self [bool] Include self in the list to be checked for a match.

Returns

artists [list of Artist]

Transform

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Artist.set_transform</td>
<td>Set the artist transform.</td>
</tr>
<tr>
<td>Artist.get_transform</td>
<td>Return the Transform instance used by this artist.</td>
</tr>
<tr>
<td>Artist.is_transform_set</td>
<td>Return whether the Artist has an explicitly set transform.</td>
</tr>
</tbody>
</table>

matplotlib.artist.Artist.set_transform

Artist.set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]

matplotlib.artist.Artist.get_transform

Artist.get_transform(self)
Return the Transform instance used by this artist.

matplotlib.artist.Artist.is_transform_set

Artist.is_transform_set(self)
Return whether the Artist has an explicitly set transform.

This is True after set_transform has been called.

Units

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Artist.convert_xunits</td>
<td>Convert x using the unit type of the xaxis.</td>
</tr>
<tr>
<td>Artist.convert_yunits</td>
<td>Convert y using the unit type of the yaxis.</td>
</tr>
<tr>
<td>Artist.have_units</td>
<td>Return True if units are set on the x or y axes.</td>
</tr>
</tbody>
</table>

matplotlib.artist.Artist.convert_xunits

Artist.convert_xunits(self, x)
Convert x using the unit type of the xaxis.

If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.
matplotlib.artist.Artist.convert_yunits

```
Artist.convert_yunits(self, y)

Convert y using the unit type of the yaxis.
If the artist is not contained in an Axes or if the yaxis does not have units, y itself is returned.
```

matplotlib.artist.Artist.have_units

```
Artist.have_units(self)

Return True if units are set on the x or y axes.
```

Metadata

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Artist.set_gid</td>
<td>Set the (group) id for the artist.</td>
</tr>
<tr>
<td>Artist.get_gid</td>
<td>Return the group id.</td>

<tr>
<td>Artist.set_url</td>
<td>Set the url for the artist.</td>
</tr>
<tr>
<td>Artist.get_url</td>
<td>Return the url.</td>
</tr>
</tbody>
</table>

matplotlib.artist.Artist.set_gid

```
Artist.set_gid(self, gid)

Set the (group) id for the artist.

Parameters

- **gid** [str]
```

matplotlib.artist.Artist.get_gid

```
Artist.get_gid(self)

Return the group id.
```

matplotlib.artist.Artist.set_label

```
Artist.set_label(self, s)

Set a label that will be displayed in the legend.

Parameters

- **s** [object] s will be converted to a string by calling **str**.
```
Matplotlib, Release 3.1.1

```
matplotlib.artist.Artist.get_label

Artist.get_label(self)
    Return the label used for this artist in the legend.

matplotlib.artist.Artist.set_url

Artist.set_url(self, url)
    Set the url for the artist.

    Parameters
        url [str]

matplotlib.artist.Artist.get_url

Artist.get_url(self)
    Return the url.

Miscellaneous

    Artist.sticky_edges  x and y sticky edge lists for autoscaling.
    Artist.set_in_layout Set if artist is to be included in layout calculations, E.g.
    Artist.get_in_layout Return boolean flag, True if artist is included in layout calculations.
    Artist.stale        Whether the artist is 'stale' and needs to be re-drawn for the output to match the internal state of the artist.

matplotlib.artist.Artist.sticky_edges

Artist.sticky_edges
    x and y sticky edge lists for autoscaling.

    When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added–the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

    This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

Examples

>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```
matplotlib.artist.Artist.set_in_layout

Artist.set_in_layout(self, in_layout)
Set if artist is to be included in layout calculations, E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').

Parameters

in_layout [bool]

matplotlib.artist.Artist.get_in_layout

Artist.get_in_layout(self)
Return boolean flag, True if artist is included in layout calculations.
E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').

matplotlib.artist.Artist.stale

Artist.stale
Whether the artist is 'stale' and needs to be re-drawn for the output to match the internal state of the artist.

17.4.2 Functions

allow_rasterization
Decorator for Artist.draw method.

get
Return the value of object’s property.

getp
Return the value of object’s property.

setp
Set a property on an artist object.

kwdoc
Inspect an Artist class (using ArtistInspector) and return information about its settable properties and their current values.

ArtistInspector
A helper class to inspect an Artist and return information about its settable properties and their current values.

matplotlib.artist.allow_rasterization

matplotlib.artist.allow_rasterization(draw)
Decorator for Artist.draw method. Provides routines that run before and after the draw call. The before and after functions are useful for changing artist-dependent renderer attributes or making other setup function calls, such as starting and flushing a mixed-mode renderer.
Matplotlib, Release 3.1.1

matplotlib.artist.get

```python
matplotlib.artist.get(obj, property=None)
```

Return the value of object’s property. `property` is an optional string for the property you want to return.

Example usage:

```python
getp(obj)  # get all the object properties
getp(obj, 'linestyle')  # get the linestyle property
```

`obj` is a `Artist` instance, e.g., `Line2D` or an instance of a `Axes` or `matplotlib.text.Text`. If the `property` is ‘somename’, this function returns

```python
obj.get_somename()
```

`getp()` can be used to query all the gettable properties with `getp(obj)`. Many properties have aliases for shorter typing, e.g. ‘lw’ is an alias for ‘linewidth’. In the output, aliases and full property names will be listed as:

property or alias = value

e.g.:

```python
linewidth or lw = 2
```

matplotlib.artist.getp

```python
matplotlib.artist.getp(obj, property=None)
```

Return the value of object’s property. `property` is an optional string for the property you want to return.

Example usage:

```python
getp(obj)  # get all the object properties
getp(obj, 'linestyle')  # get the linestyle property
```

`obj` is a `Artist` instance, e.g., `Line2D` or an instance of a `Axes` or `matplotlib.text.Text`. If the `property` is ‘somename’, this function returns

```python
obj.get_somename()
```

`getp()` can be used to query all the gettable properties with `getp(obj)`. Many properties have aliases for shorter typing, e.g. ‘lw’ is an alias for ‘linewidth’. In the output, aliases and full property names will be listed as:

property or alias = value

e.g.:

```python
linewidth or lw = 2
```

matplotlib.artist.setp

```python
matplotlib.artist.setp(obj, *args, **kwargs)
```

Set a property on an artist object.
Matplotlib supports the use of `setp()` ("set property") and `getp()` to set and get object properties, as well as to do introspection on the object. For example, to set the linestyle of a line to be dashed, you can do:

```python
>>> line, = plot([1,2,3])
>>> setp(line, linestyle='--')
```

If you want to know the valid types of arguments, you can provide the name of the property you want to set without a value:

```python
>>> setp(line, 'linestyle')
  linestyle: [ '-' | '--' | '-.' | ':' | 'steps' | 'None' ]
```

If you want to see all the properties that can be set, and their possible values, you can do:

```python
>>> setp(line)
  ... long output listing omitted
```

You may specify another output file to `setp` if `sys.stdout` is not acceptable for some reason using the `file` keyword-only argument:

```python
>>> with fopen('output.log') as f:
...   setp(line, file=f)
```

`setp()` operates on a single instance or an iterable of instances. If you are in query mode introspecting the possible values, only the first instance in the sequence is used. When actually setting values, all the instances will be set. e.g., suppose you have a list of two lines, the following will make both lines thicker and red:

```python
>>> x = arange(0,1.0,0.01)
>>> y1 = sin(2*pi*x)
>>> y2 = sin(4*pi*x)
>>> lines = plot(x, y1, x, y2)
>>> setp(lines, linewidth=2, color='r')
```

`setp()` works with the MATLAB style string/value pairs or with python kwargs. For example, the following are equivalent:

```python
>>> setp(lines, 'linewidth', 2, 'color', 'r')  # MATLAB style
>>> setp(lines, linewidth=2, color='r')       # python style
```

`matplotlib.artist.kwdoc`

`matplotlib.artist.kwdoc(artist)`

Inspect an `Artist` class (using `ArtistInspector`) and return information about its settable properties and their current values.

**Parameters**

- **artist** (`Artist` or an iterable of `Artists`)

**Returns**
**matplotlib.artist.ArtistInspector**

A helper class to inspect an *Artist* and return information about its settable properties and their current values.

Initialize the artist inspector with an *Artist* or an iterable of *Artists*. If an iterable is used, we assume it is a homogeneous sequence (all *Artists* are of the same type) and it is your responsibility to make sure this is so.

```python
__init__(self, o)
```

Initialize the artist inspector with an *Artist* or an iterable of *Artists*. If an iterable is used, we assume it is a homogeneous sequence (all *Artists* are of the same type) and it is your responsibility to make sure this is so.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>init</strong> (self, o)</td>
<td>Initialize the artist inspector with an <em>Artist</em> or an iterable of <em>Artists</em>.</td>
</tr>
<tr>
<td>aliased_name(self, s)</td>
<td>Return 'PROPNAME or alias' if s has an alias, else return 'PROPNAME'.</td>
</tr>
<tr>
<td>aliased_name_rest(self, s, target)</td>
<td>Return 'PROPNAME or alias' if s has an alias, else return 'PROPNAME', formatted for ReST.</td>
</tr>
<tr>
<td>get_aliases(self)</td>
<td>Get a dict mapping property fullnames to sets of aliases for each alias in the <em>ArtistInspector</em>.</td>
</tr>
<tr>
<td>get_setters(self)</td>
<td>Get the attribute strings with setters for object.</td>
</tr>
<tr>
<td>get_valid_values(self, attr)</td>
<td>Get the legal arguments for the setter associated with attr.</td>
</tr>
<tr>
<td>is_alias(self, o)</td>
<td>Return whether method object o is an alias for another method.</td>
</tr>
<tr>
<td>pprint_getters(self)</td>
<td>Return the getters and actual values as list of strings.</td>
</tr>
<tr>
<td>pprint_setters(self[, prop, leadingspace])</td>
<td>If prop is None, return a list of strings of all settable properties and their valid values.</td>
</tr>
<tr>
<td>pprint_setters_rest(self[, prop, leadingspace])</td>
<td>If prop is None, return a list of strings of all settable properties and their valid values.</td>
</tr>
<tr>
<td>properties(self)</td>
<td>Return a dictionary mapping property name -&gt; value.</td>
</tr>
</tbody>
</table>

```python
aliased_name(self, s)
```

Return 'PROPNAME or alias' if s has an alias, else return 'PROPNAME'.

### Example

```python
e.g., for the line markerfacecolor property, which has an alias, return 'markerface-
```
color or mfc' and for the transform property, which does not, return 'transform'.

```python
aliased_name_rest(self, s, target)
    Return 'PROPNAME or alias' if s has an alias, else return 'PROPNAME', formatted for ReST.
    e.g., for the line markerfacecolor property, which has an alias, return 'markerface-
    color or mfc' and for the transform property, which does not, return 'transform'.
```

```python
get_aliases(self)
    Get a dict mapping property fullnames to sets of aliases for each alias in the
    ArtistInspector.
    e.g., for lines:
    ```
    {'markerfacecolor': {'mfc'},
     'linewidth' : {'lw'},
    }
```  

```python
get_setters(self)
    Get the attribute strings with setters for object. e.g., for a line, return
    ['markerfacecolor', 'linewidth', ...].
```

```python
get_valid_values(self, attr)
    Get the legal arguments for the setter associated with attr.
    This is done by querying the docstring of the setter for a line that begins with "AC-
    CEPTS:" or ".. ACCEPTS:”, and then by looking for a numpydoc-style documentation
    for the setter’s first argument.
```

```python
is_alias(self, o)
    Return whether method object o is an alias for another method.
```

```python
pprint_getters(self)
    Return the getters and actual values as list of strings.
```

```python
pprint_setters(self, prop=None, leadingspace=2)
    If prop is None, return a list of strings of all settable properties and their valid values.
    If prop is not None, it is a valid property name and that property will be returned as
    a string of property : valid values.
```

```python
pprint_setters_rest(self, prop=None, leadingspace=4)
    If prop is None, return a list of strings of all settable properties and their valid values.
    Format the output for ReST
    If prop is not None, it is a valid property name and that property will be returned as
    a string of property : valid values.
```

```python
properties(self)
    Return a dictionary mapping property name -> value.
```

17.5.1 The Axes class

class matplotlib.axes.Axes(fig, rect, facecolor=None, frameon=True, sharex=None, sharey=None, label='', xscale=None, yscale=None, **kwargs)

Bases: matplotlib.axes._base._AxesBase

The Axes contains most of the figure elements: Axis, Tick, Line2D, Text, Polygon, etc., and sets the coordinate system.

The Axes instance supports callbacks through a callbacks attribute which is a CallbackRegistry instance. The events you can connect to are 'xlim_changed' and 'ylim_changed' and the callback will be called with func(ax) where ax is the Axes instance.

Attributes

dataLim [BBox] The bounding box enclosing all data displayed in the Axes.

viewLim [BBox] The view limits in data coordinates.

Build an axes in a figure.

Parameters

fig [Figure] The axes is build in the Figure fig.
rect [[left, bottom, width, height]] The axes is build in the rectangle rect. rect is in Figure coordinates.
sharex, sharey [Axes, optional] The x or y axis is shared with the x or y axis in the input Axes.
frameon [bool, optional] True means that the axes frame is visible.

**kwargs Other optional keyword arguments:

**Returns**

17.5.2 Subplots

**SubplotBase**

Base class for subplots, which are Axes instances with additional methods to facilitate generating and manipulating a set of Axes within a figure.

**subplot_class_factory**

This makes a new class that inherits from SubplotBase and the given axes_class (which is assumed to be a subclass of axes.Axes).
**matplotlib.axes.SubplotBase**

```python
class matplotlib.axes.SubplotBase(fig, *args, **kwargs):
    Bases: object

    Base class for subplots, which are Axes instances with additional methods to facilitate generating and manipulating a set of Axes within a figure.

    `fig` is a `matplotlib.figure.Figure` instance.

    `args` is the tuple `(numRows, numCols, plotNum)`, where the array of subplots in the figure has dimensions `numRows, numCols`, and where `plotNum` is the number of the subplot being created. `plotNum` starts at 1 in the upper left corner and increases to the right.

    If `numRows <= numCols <= plotNum < 10`, `args` can be the decimal integer `numRows * 100 + numCols * 10 + plotNum`.

    `change_geometry(self, numrows, numcols, num)`
        change subplot geometry, e.g., from 1,1,1 to 2,2,3

    `get_geometry(self)`
        get the subplot geometry, e.g., 2,2,3

    `get_gridspec(self)`
        get the GridSpec instance associated with the subplot

    `get_subplotspec(self)`
        get the SubplotSpec instance associated with the subplot

    `is_first_col(self)`

    `is_first_row(self)`

    `is_last_col(self)`

    `is_last_row(self)`

    `label_outer(self)`
        Only show "outer" labels and tick labels.

        x-labels are only kept for subplots on the last row; y-labels only for subplots on the first column.

    `set_subplotspec(self, subplotspec)`
        set the SubplotSpec instance associated with the subplot

    `update_params(self)`
        update the subplot position from fig.subplotpars
```

**matplotlib.axes.subplot_class_factory**

```python
axes.subplot_class_factory(axes_class=None)

This makes a new class that inherits from SubplotBase and the given axes_class (which is assumed to be a subclass of axes.Axes). This is perhaps a little bit roundabout to make a new class on the fly like this, but it means that a new Subplot class does not have to be created for every type of Axes.
```
17.5.3 Plotting

Basic

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

<tr>
<td>Axes.vlines</td>
<td>Plot vertical lines.</td>
</tr>
<tr>
<td>Axes.hlines</td>
<td>Plot horizontal lines at each y from xmin to xmax.</td>
</tr>
<tr>
<td>Axes.fill</td>
<td>Plot filled polygons.</td>
</tr>
</tbody>
</table>

matplotlib.axes.Axes.plot

Axes.plot(self, *args, scalex=True, scaley=True, data=None, **kwargs)
Plot y versus x as lines and/or markers.

Call signatures:

```python
plot([x], y, [fmt], *, data=None, **kwargs)
plot([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
```

The coordinates of the points or line nodes are given by x, y.
The optional parameter fmt is a convenient way for defining basic formatting like color, marker and linestyle. It’s a shortcut string notation described in the Notes section below.

```python
>>> plot(x, y)  # plot x and y using default line style and color
>>> plot(x, y, 'bo')  # plot x and y using blue circle markers
>>> plot(y)    # plot y using x as index array 0..N-1
>>> plot(y, 'r+')  # ditto, but with red plusses
```

You can use Line2D properties as keyword arguments for more control on the appearance. Line properties and fmt can be mixed. The following two calls yield identical results:
>>> plot(x, y, 'go--', linewidth=2, markersize=12)
>>> plot(x, y, color='green', marker='o', linestyle='dashed',
      ...     linewidth=2, markersize=12)

When conflicting with fmt, keyword arguments take precedence.

**Plotting labelled data**

There’s a convenient way for plotting objects with labelled data (i.e. data that can be accessed by index `obj['y']`). Instead of giving the data in x and y, you can provide the object in the `data` parameter and just give the labels for x and y:

```python
>>> plot('xlabel', 'ylabel', data=obj)
```

All indexable objects are supported. This could e.g. be a `dict`, a `pandas.DataFrame` or a structured numpy array.

**Plotting multiple sets of data**

There are various ways to plot multiple sets of data.

- The most straight forward way is just to call `plot` multiple times. Example:

  ```python
  >>> plot(x1, y1, 'bo')
  >>> plot(x2, y2, 'go')
  ```

- Alternatively, if your data is already a 2d array, you can pass it directly to `x`, `y`. A separate data set will be drawn for every column.

  Example: an array `a` where the first column represents the x values and the other columns are the y columns:

  ```python
  >>> plot(a[0], a[1:])
  ```

- The third way is to specify multiple sets of `[x], y, [fmt]` groups:

  ```python
  >>> plot(x1, y1, 'g^', x2, y2, 'g-')
  ```

In this case, any additional keyword argument applies to all datasets. Also this syntax cannot be combined with the `data` parameter.

By default, each line is assigned a different style specified by a ‘style cycle’. The `fmt` and line property parameters are only necessary if you want explicit deviations from these defaults. Alternatively, you can also change the style cycle using the ‘axes.prop_cycle’ `rcParam`.

**Parameters**

- `x, y` [array-like or scalar] The horizontal / vertical coordinates of the data points. x values are optional and default to `range(len(y))`.

  Commonly, these parameters are 1D arrays.

  They can also be scalars, or two-dimensional (in that case, the columns represent separate data sets).

  These arguments cannot be passed as keywords.

- `fmt` [str, optional] A format string, e.g. ‘ro’ for red circles. See the Notes section for a full description of the format strings.
Format strings are just an abbreviation for quickly setting basic line properties. All of these and more can also be controlled by keyword arguments.

This argument cannot be passed as keyword.

**data** [indexable object, optional] An object with labelled data. If given, provide the label names to plot in x and y.

**Note:** Technically there’s a slight ambiguity in calls where the second label is a valid `fmt`. `plot('n', 'o', data=obj)` could be `plt(x, y)` or `plt(y, fmt)`. In such cases, the former interpretation is chosen, but a warning is issued. You may suppress the warning by adding an empty format string `plot('n', 'o', '', data=obj)`.

**Returns**

**lines** A list of `Line2D` objects representing the plotted data.

**Other Parameters**

**scalex, scaley** [bool, optional, default: True] These parameters determine if the view limits are adapted to the data limits. The values are passed on to `autoscale_view`.

****kwargs** [Line2D properties, optional] `kwargs` are used to specify properties like a line label (for auto legends), linewidth, antialiasing, marker face color. Example:

```python
>>> plot([[1,2,3], [1,2,3]], ['go-', label='line 1', linewidth=2)
>>> plot([[1,2,3], [1,4,9], 'rs', label='line 2'])
```

If you make multiple lines with one plot command, the `kwargs` apply to all those lines.

Here is a list of available `Line2D` properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>agg_filter</code></td>
<td>a filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array</td>

See also:

scatter  XY scatter plot with markers of varying size and/or color (sometimes also called bubble chart).

Notes

Format Strings

A format string consists of a part for color, marker and line:

```python
fmt = '[marker][line][color]'```

Each of them is optional. If not provided, the value from the style cycle is used. Exception: If line is given, but no marker, the data will be a line without markers.

Other combinations such as [color][marker][line] are also supported, but note that their parsing may be ambiguous.

Markers
<table>
<thead>
<tr>
<th>character</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'.'</td>
<td>point marker</td>
</tr>
<tr>
<td>'o'</td>
<td>circle marker</td>
</tr>
<tr>
<td>'v'</td>
<td>triangle_down marker</td>
</tr>
<tr>
<td>'^'</td>
<td>triangle_up marker</td>
</tr>
<tr>
<td>'&lt;'</td>
<td>triangle_left marker</td>
</tr>
<tr>
<td>'&gt;'</td>
<td>triangle_right marker</td>
</tr>
<tr>
<td>'1'</td>
<td>tri_down marker</td>
</tr>
<tr>
<td>'2'</td>
<td>tri_up marker</td>
</tr>
<tr>
<td>'3'</td>
<td>tri_left marker</td>
</tr>
<tr>
<td>'4'</td>
<td>tri_right marker</td>
</tr>
<tr>
<td>'s'</td>
<td>square marker</td>
</tr>
<tr>
<td>'p'</td>
<td>pentagon marker</td>
</tr>
<tr>
<td>'*'</td>
<td>star marker</td>
</tr>
<tr>
<td>'h'</td>
<td>hexagon1 marker</td>
</tr>
<tr>
<td>'H'</td>
<td>hexagon2 marker</td>
</tr>
<tr>
<td>'+'</td>
<td>plus marker</td>
</tr>
<tr>
<td>'x'</td>
<td>x marker</td>
</tr>
<tr>
<td>'D'</td>
<td>diamond marker</td>
</tr>
<tr>
<td>'d'</td>
<td>thin_diamond marker</td>
</tr>
<tr>
<td>'</td>
<td>'</td>
</tr>
<tr>
<td>'_'</td>
<td>hline marker</td>
</tr>
</tbody>
</table>

## Line Styles

<table>
<thead>
<tr>
<th>character</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-'</td>
<td>solid line style</td>
</tr>
<tr>
<td>'--'</td>
<td>dashed line style</td>
</tr>
<tr>
<td>'-.'</td>
<td>dash-dot line style</td>
</tr>
<tr>
<td>':'</td>
<td>dotted line style</td>
</tr>
</tbody>
</table>

Example format strings:

- `'b'` # blue markers with default shape
- `'or'` # red circles
- `'g'` # green solid line
- `'-'` # dashed line with default color
- `'k:'` # black triangle_up markers connected by a dotted line

## Colors

The supported color abbreviations are the single letter codes
<table>
<thead>
<tr>
<th>character</th>
<th>color</th>
</tr>
</thead>
<tbody>
<tr>
<td>'b'</td>
<td>blue</td>
</tr>
<tr>
<td>'g'</td>
<td>green</td>
</tr>
<tr>
<td>'r'</td>
<td>red</td>
</tr>
<tr>
<td>'c'</td>
<td>cyan</td>
</tr>
<tr>
<td>'m'</td>
<td>magenta</td>
</tr>
<tr>
<td>'y'</td>
<td>yellow</td>
</tr>
<tr>
<td>'k'</td>
<td>black</td>
</tr>
<tr>
<td>'w'</td>
<td>white</td>
</tr>
</tbody>
</table>

and the ‘CN’ colors that index into the default property cycle.

If the color is the only part of the format string, you can additionally use any `matplotlib.colors` spec, e.g. full names (‘green’) or hex strings (‘#008000’).

Examples using `matplotlib.axes.Axes.plot`

- sphx_glr_gallery_lines_bars_and_markers_joinstyle.py
- sphx_glr_gallery_lines_bars_and_markers_simple_plot.py
- sphx_glr_gallery_images_contours_and_fields_triinterp_demo.py

- sphx_glr_gallery_pyplots_fig_axes_labels_simple.py
- sphx_glr_gallery_pyplots_pyplot_formatstr.py
- sphx_glr_gallery_pyplots_pyplot_three.py
- sphx_glr_gallery_color_color_demo.py
- sphx_glr_gallery_color_color_by_yvalue.py
- sphx_glr_gallery_color_color_cycler.py
- sphx_glr_gallery_shapes_and_collections_marker_path.py
- sphx_glr_gallery_user_interfaces_canvasagg.py
- Usage Guide

`matplotlib.axes.Axes.errorbar`

```
Axes.errorbar(self, x, y, yerr=None, xerr=None, fmt='', ecolor=None, elinewidth=None, capsize=None, barsabove=False, lolims=False, uplims=False, xlolims=False, xuplims=False, errorevery=1, capthick=None, *, data=None, **kwargs)
```

Plot y versus x as lines and/or markers with attached errorbars.
x, y define the data locations, xerr, yerr define the errorbar sizes. By default, this draws
the data markers/lines as well the errorbars. Use fmt='none' to draw errorbars without
any data markers.

Parameters

x, y [scalar or array-like] The data positions.

xerr, yerr [scalar or array-like, shape(N,) or shape(2,N), optional] The error
bar sizes:

• scalar: Symmetric +/- values for all data points.
• shape(N,): Symmetric +/- values for each data point.
• shape(2,N): Separate + and values for each bar. First row
  contains the lower errors, the second row contains the upper errors.
• None: No errorbar.

Note that all error arrays should have positive values.

See /gallery/statistics/errorbar_features for an example on the usage of
xerr and yerr.

fmt [plot format string, optional, default: ""] The format for the data points
/data lines. See plot for details.

Use 'none' (case insensitive) to plot errorbars without any data markers.

ecolor [mpl color, optional, default: None] A matplotlib color arg which
gives the color the errorbar lines. If None, use the color of the line connecting
the markers.

elinewidth [scalar, optional, default: None] The linewidth of the errorbar
lines. If None, the linewidth of the current style is used.

capsize [scalar, optional, default: None] The length of the error bar caps in
points. If None, it will take the value from rcParams["errorbar.capsize"].

capthick [scalar, optional, default: None] An alias to the keyword argument
markeredgewidth (a.k.a. mew). This setting is a more sensible name for the
property that controls the thickness of the error bar cap in points.
For backwards compatibility, if mew or markeredgewidth are given, then
they will over-ride capthick. This may change in future releases.

barsabove [bool, optional, default: False] If True, will plot the errorbars
above the plot symbols. Default is below.

lolims, uplims, xlolims, xuplims [bool, optional, default: False] These ar-
guments can be used to indicate that a value gives only upper/lower lim-
its. In that case a caret symbol is used to indicate this. lims-arguments
may be of the same type as xerr and yerr. To use limits with inverted
axes, set_xlim() or set_ylim() must be called before errorbar().

errorevery [positive integer, optional, default: 1] Subsamples the error-
bars. e.g., if errorevery=5, errorbars for every 5-th datapoint will be
plotted. The data plot itself still shows all data points.

Returns

container [ErrorbarContainer] The container contains:

• plotline: Line2D instance of x, y plot markers and/or line.
Matplotlib, Release 3.1.1

- caplines: A tuple of `Line2D` instances of the error bar caps.
- barlinecols: A tuple of `LineCollection` with the horizontal and vertical error ranges.

Other Parameters

**kwa**rgs All other keyword arguments are passed on to the plot command for the markers. For example, this code makes big red squares with thick green edges:

```python
x, y, yerr = rand(3, 10)
errorbar(x, y, yerr, marker='s', mfc='red', mec='green', ms=20, mew=4)
```

where `mfc`, `mec`, `ms` and `mew` are aliases for the longer property names, `markerfacecolor`, `markeredgecolor`, `markersize` and `markeredgewidth`. Valid kwargs for the marker properties are `Lines2D` properties:

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’, ‘xerr’, ‘y’, ‘yerr’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.errorbar

- sphx_glr_gallery_lines_bars_and_markers_errorbar_limits_simple.py

matplotlib.axes.Axes.scatter

Axes.scatter(self, x, y, s=None, c=None, marker=None, cmap=None, norm=None, vmin=None, vmax=None, alpha=None, linewidths=None, verts=None, edgecolors=None, *, plotnonfinite=False, data=None, **kwargs)

A scatter plot of y vs x with varying marker size and/or color.

Parameters

- x, y [array_like, shape (n, )] The data positions.
- s [scalar or array_like, shape (n, ), optional] The marker size in points**2. Default is rcParams['lines.markersize'] ** 2.
- c [color, sequence, or sequence of color, optional] The marker color. Possible values:
  - A single color format string.
  - A sequence of color specifications of length n.
  - A sequence of n numbers to be mapped to colors using cmap and norm.
  - A 2-D array in which the rows are RGB or RGBA.

Note that c should not be a single numeric RGB or RGBA sequence because that is indistinguishable from an array of values to be color-mapped. If you want to specify the same RGB or RGBA value for all
points, use a 2-D array with a single row. Otherwise, value- matching will have precedence in case of a size matching with x and y.

Defaults to None. In that case the marker color is determined by the value of color, facecolor or facecolors. In case those are not specified or None, the marker color is determined by the next color of the Axes’ current "shape and fill" color cycle. This cycle defaults to rcParams["axes.prop_cycle"].

**marker** [MarkerStyle, optional] The marker style. *marker* can be either an instance of the class or the text shorthand for a particular marker. Defaults to None, in which case it takes the value of rcParams["scatter.marker"] = 'o'. See markers for more information about marker styles.

**cmap** [Colormap, optional, default: None] A Colormap instance or registered colormap name. *cmap* is only used if *c* is an array of floats. If None, defaults to rc image.cmap.

**norm** [Normalize, optional, default: None] A Normalize instance is used to scale luminance data to 0, 1. *norm* is only used if *c* is an array of floats. If None, use the default colors.Normalize.

**vmin, vmax** [scalar, optional, default: None] vmin and vmax are used in conjunction with norm to normalize luminance data. If None, the respective min and max of the color array is used. vmin and vmax are ignored if you pass a norm instance.

**alpha** [scalar, optional, default: None] The alpha blending value, between 0 (transparent) and 1 (opaque).

**linewidths** [scalar or array_like, optional, default: None] The linewidth of the marker edges. Note: The default edgecolors is 'face'. You may want to change this as well. If None, defaults to rcParams lines.linewidth.

**edgecolors** [{'face', 'none', None} or color or sequence of color, optional.] The edge color of the marker. Possible values:
- ‘face’: The edge color will always be the same as the face color.
- ‘none’: No patch boundary will be drawn.
- A Matplotlib color or sequence of color.

Defaults to None, in which case it takes the value of rcParams["scatter.edgecolors"] = 'face'.

For non-filled markers, the edgecolors kwarg is ignored and forced to ‘face’ internally.

**plotnonfinite** [boolean, optional, default: False] Set to plot points with non-finite c, in conjunction with set_bad.

**Returns**

- **paths** [PathCollection]

**Other Parameters**

- ****kwargs [Collection properties]

**See also:**

- plot To plot scatter plots when markers are identical in size and color.
Notes

- The `plot` function will be faster for scatterplots where markers don’t vary in size or color.
- Any or all of `x`, `y`, `s`, and `c` may be masked arrays, in which case all masks will be combined and only unmasked points will be plotted.
- Fundamentally, scatter works with 1-D arrays; `x`, `y`, `s`, and `c` may be input as 2-D arrays, but within scatter they will be flattened. The exception is `c`, which will be flattened only if its size matches the size of `x` and `y`.

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

Examples using `matplotlib.axes.Axes.scatter`

- `sphx_glr_gallery_lines_bars_and_markers_scatter_piecharts.py`
- `sphx_glr_gallery_lines_bars_and_markers_scatter_with_legend.py`
- `sphx_glr_gallery_pie_and_polar_charts_polar_scatter.py`
- `sphx_glr_gallery_shapes_and_collections_scatter.py`

`matplotlib.axes.Axes.plot_date`

```python
Axes.plot_date(self, x, y, fmt='o', tz=None, xdate=True, ydate=False, *, data=None, **kwargs)
```

Plot data that contains dates.

Similar to `plot`, this plots `y` vs. `x` as lines or markers. However, the axis labels are formatted as dates depending on `xdate` and `ydate`.

**Parameters**

- `x, y` [array-like] The coordinates of the data points. If `xdate` or `ydate` is `True`, the respective values `x` or `y` are interpreted as Matplotlib dates.
- `fmt` [str, optional] The plot format string. For details, see the corresponding parameter in `plot`.
- `tz` [[ `None` | timezone string | tzinfo instance]] The time zone to use in labeling dates. If `None`, defaults to rcParam `timezone`.
- `xdate` [bool, optional, default: `True`] If `True`, the x-axis will be interpreted as Matplotlib dates.
The **ydate** parameter is a boolean, optional, default: False. If True, the y-axis will be interpreted as Matplotlib dates.

**Returns**

A list of **Line2D** objects representing the plotted data.

**Other Parameters**

****kwargs Keyword arguments control the **Line2D** properties:

<table>
<thead>
<tr>

</table>
See also:

matplotlib.dates Helper functions on dates.
matplotlib.dates.date2num Convert dates to num.
matplotlib.dates.num2date Convert num to dates.
matplotlib.dates.drange Create an equally spaced sequence of dates.

Notes

If you are using custom date tickers and formatters, it may be necessary to set the formatters/locators after the call to `plot_date`. `plot_date` will set the default tick locator to `AutoDateLocator` (if the tick locator is not already set to an `DateLocator` instance) and the default tick formatter to `AutoDateFormatter` (if the tick formatter is not already set to a `DateFormatter` instance).

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: 'x', 'y'.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

matplotlib.axes.Axes.step

```
Axes.step(self, x, y, *args, where='pre', data=None, **kwargs)
```

Make a step plot.

Call signatures:

```
step(x, y, [fmt], *, data=None, where='pre', **kwargs)
step(x, y, [fmt], x2, y2, [fmt2], ..., *, where='pre', **kwargs)
```

This is just a thin wrapper around `plot` which changes some formatting options. Most of the concepts and parameters of plot can be used here as well.

**Parameters**

- **x** [array_like] 1-D sequence of x positions. It is assumed, but not checked, that it is uniformly increasing.
- **y** [array_like] 1-D sequence of y levels.
- **fmt** [str, optional] A format string, e.g. 'g' for a green line. See `plot` for a more detailed description.

  Note: While full format strings are accepted, it is recommended to only specify the color. Line styles are currently ignored (use the keyword argument `linestyle` instead). Markers are accepted and plotted on the given positions, however, this is a rarely needed feature for step plots.
**data** [indexable object, optional] An object with labelled data. If given, provide the label names to plot in x and y.

**where** [{‘pre’, ‘post’, ‘mid’}, optional, default ‘pre’] Define where the steps should be placed:
- ‘pre’: The y value is continued constantly to the left from every x position, i.e. the interval \((x[i-1], x[i])\) has the value \(y[i]\).
- ‘post’: The y value is continued constantly to the right from every x position, i.e. the interval \([x[i], x[i+1))\) has the value \(y[i]\).
- ‘mid’: Steps occur half-way between the x positions.

**Returns**

**lines** A list of *Line2D* objects representing the plotted data.

**Other Parameters**

**kwargs** Additional parameters are the same as those for *plot*.

**Notes**

**Examples using matplotlib.axes.Axes.step**

- sphx_glr_gallery_lines_bars_and_markers_step_demo.py

**matplotlib.axes.Axes.loglog**

Axes.loglog(*self*, *args*, **kwargs)

Make a plot with log scaling on both the x and y axis.

Call signatures:

```
loglog([x], y, [fmt], data=None, **kwargs)
loglog([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
```

This is just a thin wrapper around *plot* which additionally changes both the x-axis and the y-axis to log scaling. All of the concepts and parameters of *plot* can be used here as well.

The additional parameters *base*/*y*, *sub*/*x/y* and *nonpos*/*x/y* control the x/y-axis properties. They are just forwarded to *Axes.set_xscale* and *Axes.set_yscale*.

**Parameters**

- **base*, **basey** [scalar, optional, default 10] Base of the x/y logarithm.
- **sub*, **subsy** [sequence, optional] The location of the minor x/y ticks. If *None*, reasonable locations are automatically chosen depending on the number of decades in the plot. See *Axes.set_xscale*/*Axes.set_yscale* for details.
- **nonpos*, **nonposy** [{‘mask’, ‘clip’}, optional, default ‘mask’] Non-positive values in x or y can be masked as invalid, or clipped to a very small positive number.

**Returns**
**lines** A list of `Line2D` objects representing the plotted data.

**Other Parameters**

**kwargs** All parameters supported by `plot`.

```
matplotlib.axes.Axes.semilogx

Axes.semilogx(self, *args, **kwargs)
Make a plot with log scaling on the x axis.

Call signatures:
semilogx([x], y, [fmt], data=None, **kwargs)
semilogx([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
```

This is just a thin wrapper around `plot` which additionally changes the x-axis to log scaling. All of the concepts and parameters of plot can be used here as well.

The additional parameters `basex`, `subsx` and `nonposx` control the x-axis properties. They are just forwarded to `Axes.set_xscale`.

**Parameters**

- **basex** [scalar, optional, default 10] Base of the x logarithm.
- **subsx** [array_like, optional] The location of the minor xticks. If `None`, reasonable locations are automatically chosen depending on the number of decades in the plot. See `Axes.set_xscale` for details.
- **nonposx** [{'mask', 'clip'}, optional, default 'mask'] Non-positive values in x can be masked as invalid, or clipped to a very small positive number.

**Returns**

- **lines** A list of `Line2D` objects representing the plotted data.

**Other Parameters**

**kwargs** All parameters supported by `plot`.

```
matplotlib.axes.Axes.semilogy

Axes.semilogy(self, *args, **kwargs)
Make a plot with log scaling on the y axis.

Call signatures:
semilogy([x], y, [fmt], data=None, **kwargs)
semilogy([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
```

This is just a thin wrapper around `plot` which additionally changes the y-axis to log scaling. All of the concepts and parameters of plot can be used here as well.

The additional parameters `basey`, `subsy` and `nonposy` control the y-axis properties. They are just forwarded to `Axes.set_yscale`.

**Parameters**

- **basey** [scalar, optional, default 10] Base of the y logarithm.
subsy [array_like, optional] The location of the minor yticks. If None, reasonable locations are automatically chosen depending on the number of decades in the plot. See `Axes.set_yscale` for details.

nonposy [{'mask', 'clip'}, optional, default 'mask'] Non-positive values in y can be masked as invalid, or clipped to a very small positive number.

Returns

lines A list of `Line2D` objects representing the plotted data.

Other Parameters

**kwargs All parameters supported by `plot`.

`matplotlib.axes.Axes.fill_between`

`Axes.fill_between(self, x, y1, y2=0, where=None, interpolate=False, step=None, *, data=None, **kwargs)`

Fill the area between two horizontal curves.

The curves are defined by the points (x, y1) and (x, y2). This creates one or multiple polygons describing the filled area.

You may exclude some horizontal sections from filling using `where`.

By default, the edges connect the given points directly. Use `step` if the filling should be a step function, i.e. constant in between x.

Parameters

x [array (length N)] The x coordinates of the nodes defining the curves.

y1 [array (length N) or scalar] The y coordinates of the nodes defining the first curve.

y2 [array (length N) or scalar, optional, default: 0] The y coordinates of the nodes defining the second curve.

where [array of bool (length N), optional, default: None] Define `where` to exclude some horizontal regions from being filled. The filled regions are defined by the coordinates x[where]. More precisely, fill between x[i] and x[i+1] if where[i] and where[i+1]. Note that this definition implies that an isolated `True` value between two `False` values in `where` will not result in filling. Both sides of the `True` position remain unfilled due to the adjacent `False` values.

interpolate [bool, optional] This option is only relevant if `where` is used and the two curves are crossing each other.

Semantically, `where` is often used for `y1 > y2` or similar. By default, the nodes of the polygon defining the filled region will only be placed at the positions in the x array. Such a polygon cannot describe the above semantics close to the intersection. The x-sections containing the intersection are simply clipped.

Setting `interpolate` to `True` will calculate the actual intersection point and extend the filled region up to this point.
**step** [{‘pre’, ‘post’, ‘mid’}, optional] Define *step* if the filling should be a step function, i.e. constant in between *x*. The value determines where the step will occur:

- ‘pre’: The *y* value is continued constantly to the left from every *x* position, i.e. the interval (*x[i-1], x[i]*) has the value *y[i]*.
- ‘post’: The *y* value is continued constantly to the right from every *x* position, i.e. the interval (*x[i], x[i+1]*) has the value *y[i]*.
- ‘mid’: Steps occur half-way between the *x* positions.

**Returns**

*PolyCollection* A *PolyCollection* containing the plotted polygons.

**Other Parameters**

*****kwargs** All other keyword arguments are passed on to *PolyCollection*. They control the *Polygon* properties:

fill_betweenx Fill between two sets of x-values.

Notes

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘where’, ‘x’, ‘y1’, ‘y2’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.fill_between

- sphx_glr_gallery_lines_bars_and_markers_filled_step.py
- sphx_glr_gallery_pyplots_whats_new_98_4_fill_between.py

matplotlib.axes.Axes.fill_betweenx

Axes.fill_betweenx(self, y, x1, x2=0, where=None, step=None, interpolate=False, *, data=None, **kwargs)

Fill the area between two vertical curves.

The curves are defined by the points (x1, y) and (x2, y). This creates one or multiple polygons describing the filled area.

You may exclude some vertical sections from filling using where.

By default, the edges connect the given points directly. Use step if the filling should be a step function, i.e. constant in between y.

Parameters

- y [array (length N)] The y coordinates of the nodes defining the curves.
- x1 [array (length N) or scalar] The x coordinates of the nodes defining the first curve.
- x2 [array (length N) or scalar, optional, default: 0] The x coordinates of the nodes defining the second curve.
where [array of bool (length N), optional, default: None] Define where to exclude some vertical regions from being filled. The filled regions are defined by the coordinates $y[\text{where}]$. More precisely, fill between $y[i]$ and $y[i+1]$ if $\text{where}[i]$ and $\text{where}[i+1]$. Note that this definition implies that an isolated True value between two False values in where will not result in filling. Both sides of the True position remain unfilled due to the adjacent False values.

interpolate [bool, optional] This option is only relevant if where is used and the two curves are crossing each other.

Semantically, where is often used for $x1 > x2$ or similar. By default, the nodes of the polygon defining the filled region will only be placed at the positions in the y array. Such a polygon cannot describe the above semantics close to the intersection. The y-sections containing the intersection are simply clipped.

Setting interpolate to True will calculate the actual intersection point and extend the filled region up to this point.

step [{'pre', 'post', 'mid'}, optional] Define step if the filling should be a step function, i.e. constant in between $y$. The value determines where the step will occur:

- 'pre': The y value is continued constantly to the left from every x position, i.e. the interval $(x[i-1], x[i])$ has the value $y[i]$.
- 'post': The y value is continued constantly to the right from every x position, i.e. the interval $(x[i], x[i+1])$ has the value $y[i]$.
- 'mid': Steps occur half-way between the x positions.

Returns

PolyCollection A PolyCollection containing the plotted polygons.

Other Parameters

**kwargs All other keyword arguments are passed on to PolyCollection. They control the Polygon properties:

fill_between Fill between two sets of y-values.

Notes

**Note:** In addition to the above described arguments, this function can take a **data** keyword argument. If such a **data** argument is given, the following arguments are replaced by **data**:<arg>:

- All arguments with the following names: ‘where’, ‘x1’, ‘x2’, ‘y’.

Objects passed as **data** must support item access (**data**:<arg>) and membership test (<arg> in **data**).

Examples using matplotlib.axes.Axes.fill_betweenx

- sphx_glr_gallery_lines_bars_and_markers_filled_step.py

matplotlib.axes.Axes.bar

Axes.bar(self, x, height=0.8, bottom=None, *, align='center', data=None, **kwargs)

Make a bar plot.
The bars are positioned at x with the given alignment. Their dimensions are given by width and height. The vertical baseline is bottom (default 0).

Each of x, height, width, and bottom may either be a scalar applying to all bars, or it may be a sequence of length N providing a separate value for each bar.

**Parameters**

- **x** [sequence of scalars] The x coordinates of the bars. See also align for the alignment of the bars to the coordinates.
- **height** [scalar or sequence of scalars] The height(s) of the bars.
- **width** [scalar or array-like, optional] The width(s) of the bars (default: 0.8).
- **bottom** [scalar or array-like, optional] The y coordinate(s) of the bars bases (default: 0).
- **align** [{‘center’, ‘edge’}, optional, default: ‘center’] Alignment of the bars to the x coordinates:
  - ‘center’: Center the base on the x positions.
  - ‘edge’: Align the left edges of the bars with the x positions.
  To align the bars on the right edge pass a negative width and align='edge'.

**Returns**

- **container** [BarContainer] Container with all the bars and optionally errorbars.

**Other Parameters**

- **color** [scalar or array-like, optional] The colors of the bar faces.
- **edgecolor** [scalar or array-like, optional] The colors of the bar edges.
- **linewidth** [scalar or array-like, optional] Width of the bar edge(s). If 0, don’t draw edges.
- **tick_label** [string or array-like, optional] The tick labels of the bars. Default: None (Use default numeric labels.)
- **xerr, yerr** [scalar or array-like of shape(N,) or shape(2,N), optional] If not None, add horizontal / vertical errorbars to the bar tips. The values are +/- sizes relative to the data:
  - scalar: symmetric +/- values for all bars
  - shape(N,): symmetric +/- values for each bar
  - shape(2,N): Separate - and + values for each bar. **First row** contains the lower errors, the second row contains the upper errors.

  - None: No errorbar. (Default)

  See /gallery/statistics/errorbar_features for an example on the usage of xerr and yerr.
- **ecolor** [scalar or array-like, optional, default: ‘black’] The line color of the errorbars.
- **capsize** [scalar, optional] The length of the error bar caps in points. Default: None, which will take the value from rcParams["errorbar.capsize"].
error_kw [dict, optional] Dictionary of kwargs to be passed to the errorbar method. Values of ecolor or capsize defined here take precedence over the independent kwargs.

log [bool, optional, default: False] If True, set the y-axis to be log scale.

orientation [{'vertical', 'horizontal'}, optional] This is for internal use only. Please use barh for horizontal bar plots. Default: ‘vertical’.

See also:

barh Plot a horizontal bar plot.

Notes

The optional arguments color, edgecolor, linewidth, xerr, and yerr can be either scalars or sequences of length equal to the number of bars. This enables you to use bar as the basis for stacked bar charts, or candlestick plots. Detail: xerr and yerr are passed directly to errorbar(), so they can also have shape 2xN for independent specification of lower and upper errors.

Other optional kwargs:

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:
- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.bar

- sphx_glr_gallery_lines_bars_and_markers_barchart.py
- sphx_glr_gallery_statistics_barchart_demo.py
- sphx_glr_gallery_pie_and_polar_charts_bar_of_pie.py
- sphx_glr_gallery_pie_and_polar_charts_nested_pie.py
- sphx_glr_gallery_pie_and_polar_charts_polar_bar.py
- sphx_glr_gallery_shapes_and_collections_hatch_demo.py

matplotlib.axes.Axes.barh

`Axes.barh(self, y, width=0.8, height=0.8, left=None, *, align='center', **kwargs)`

Make a horizontal bar plot.

The bars are positioned at y with the given alignment. Their dimensions are given by width and height. The horizontal baseline is left (default 0).

Each of y, width, height, and left may either be a scalar applying to all bars, or it may be a sequence of length N providing a separate value for each bar.

**Parameters**

- **y** [scalar or array-like] The y coordinates of the bars. See also align for the alignment of the bars to the coordinates.
- **width** [scalar or array-like] The width(s) of the bars.
- **height** [sequence of scalars, optional, default: 0.8] The heights of the bars.
- **left** [sequence of scalars] The x coordinates of the left sides of the bars (default: 0).
- **align** [{‘center’, ‘edge’}, optional, default: ‘center’] Alignment of the base to the y coordinates*:
  - ‘center’: Center the bars on the y positions.
  - ‘edge’: Align the bottom edges of the bars with the y positions.
To align the bars on the top edge pass a negative `height` and `align='edge'`.

**Returns**

- `container [BarContainer]` Container with all the bars and optionally error-bars.

**Other Parameters**

- `color [scalar or array-like, optional]` The colors of the bar faces.
- `edgecolor [scalar or array-like, optional]` The colors of the bar edges.
- `linewidth [scalar or array-like, optional]` Width of the bar edge(s). If 0, don’t draw edges.
- `tick_label [string or array-like, optional]` The tick labels of the bars. Default: None (Use default numeric labels.)
- `xerr, yerr [scalar or array-like of shape(N,) or shape(2,N), optional]` If not `None`, add horizontal / vertical errorbars to the bar tips. The values are +/- sizes relative to the data:
  - scalar: symmetric +/- values for all bars
  - shape(N,): symmetric +/- values for each bar
  - shape(2,N): Separate - and + values for each bar. First row contains the lower errors, the second row contains the upper errors.
  - `None`: No errorbar. (default)

See /gallery/statistics/errorbar_features for an example on the usage of `xerr` and `yerr`.

- `ecolor [scalar or array-like, optional, default: ‘black’]` The line color of the errorbars.
- `capsize [scalar, optional]` The length of the error bar caps in points. Default: None, which will take the value from `rcParams['errorbar.capsize']`.
- `error_kw [dict, optional]` Dictionary of kwargs to be passed to the `errorbar` method. Values of `ecolor` or `capsize` defined here take precedence over the independent kwargs.
- `log [bool, optional, default: False]` If `True`, set the x-axis to be log scale.

**See also:**

- `bar` Plot a vertical bar plot.

**Notes**

The optional arguments `color`, `edgecolor`, `linewidth`, `xerr`, and `yerr` can be either scalars or sequences of length equal to the number of bars. This enables you to use `bar` as the basis for stacked bar charts, or candlestick plots. Detail: `xerr` and `yerr` are passed directly to `errorbar()`, so they can also have shape 2xN for independent specification of lower and upper errors.

### Examples using `matplotlib.axes.Axes.barh`

- sphx_glr_gallery_lines_bars_and_markers_horizontal_barchart_distribution.py

### `matplotlib.axes.Axes.stem`

```python
Axes.stem(self, *args, linefmt=None, markerfmt=None, basefmt=None, bottom=0, label=None, use_line_collection=False, data=None)
```

Create a stem plot.

A stem plot plots vertical lines at each x location from the baseline to y, and places a marker there.

Call signature:

```python
stem([x,] y, linefmt=None, markerfmt=None, basefmt=None)
```
The x-positions are optional. The formats may be provided either as positional or as keyword-arguments.

**Parameters**

- **x** [array-like, optional] The x-positions of the stems. Default: (0, 1, ..., len(y) - 1).
- **y** [array-like] The y-values of the stem heads.
- **linefmt** [str, optional] A string defining the properties of the vertical lines. Usually, this will be a color or a color and a linestyle:

<table>
<thead>
<tr>
<th>Character</th>
<th>Line Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.'</td>
<td>dash-dot line</td>
</tr>
<tr>
<td>':'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Default: 'C0-', i.e. solid line with the first color of the color cycle.

Note: While it is technically possible to specify valid formats other than color or color and linestyle (e.g. 'rx' or '.-'), this is beyond the intention of the method and will most likely not result in a reasonable plot.

- **markerfmt** [str, optional] A string defining the properties of the markers at the stem heads. Default: 'C0o', i.e. filled circles with the first color of the color cycle.
- **basefmt** [str, optional] A format string defining the properties of the baseline.

Default: 'C3-' ('C2-' in classic mode).

- **bottom** [float, optional, default: 0] The y-position of the baseline.
- **label** [str, optional, default: None] The label to use for the stems in legends.

- **use_line_collection** [bool, optional, default: False] If True, store and plot the stem lines as a LineCollection instead of individual lines. This significantly increases performance, and will become the default option in Matplotlib 3.3. If False, defaults to the old behavior of using a list of Line2D objects.

**Returns**

- **container** [StemContainer] The container may be treated like a tuple (mark-erline, stemlines, baseline)

**Notes**

**See also:**

The MATLAB function `stem` which inspired this method.

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:
• All positional and all keyword arguments.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

---

**Examples using `matplotlib.axes.Axes.stem`**

• sphx_glr_gallery_lines_bars_and_markers_stem_plot.py
• sphx_glr_gallery_lines_bars_and_markers_timeline.py

**`matplotlib.axes.Axes.eventplot`**

`Axes.eventplot(self, positions, orientation='horizontal', lineoffsets=1, linelengths=1, linewidths=None, colors=None, linestyles='solid', *, data=None, **kwargs)`

Plot identical parallel lines at the given positions. `positions` should be a 1D or 2D array-like object, with each row corresponding to a row or column of lines.

This type of plot is commonly used in neuroscience for representing neural events, where it is usually called a spike raster, dot raster, or raster plot. However, it is useful in any situation where you wish to show the timing or position of multiple sets of discrete events, such as the arrival times of people to a business on each day of the month or the date of hurricanes each year of the last century.

**Parameters**

- **positions** [1D or 2D array-like object] Each value is an event. If `positions` is a 2D array-like, each row corresponds to a row or a column of lines (depending on the `orientation` parameter).

- **orientation** [{‘horizontal’, ‘vertical’}, optional] Controls the direction of the event collections:
  • ‘horizontal’ : the lines are arranged horizontally in rows, and are vertical.
  • ‘vertical’ : the lines are arranged vertically in columns, and are horizontal.

- **lineoffsets** [scalar or sequence of scalars, optional, default: `1`] The offset of the center of the lines from the origin, in the direction orthogonal to `orientation`.

- **linelengths** [scalar or sequence of scalars, optional, default: `1`] The total height of the lines (i.e. the lines stretches from `lineoffset - linelength/2` to `lineoffset + linelength/2`).

- **linewidths** [scalar, scalar sequence or None, optional, default: `None`] The line width(s) of the event lines, in points. If it is `None`, defaults to its rcParams setting.

- **colors** [color, sequence of colors or None, optional, default: `None`] The color(s) of the event lines. If it is `None`, defaults to its rcParams setting.
**linestyles** [str or tuple or a sequence of such values, optional] Default is 'solid'. Valid strings are ['solid', 'dashed', 'dashdot', 'dotted', '-', '–', '-.', ':']. Dash tuples should be of the form:

```
( offset, onoffseq),
```

where `onoffseq` is an even length tuple of on and off ink in points.

**kwargs [optional] Other keyword arguments are line collection properties. See `LineCollection` for a list of the valid properties.

**Returns**

list [A list of `EventCollection` objects.] Contains the `EventCollection` that were added.

**Notes**

For `linelengths`, `linewidths`, `colors`, and `linestyles`, if only a single value is given, that value is applied to all lines. If an array-like is given, it must have the same length as `positions`, and each value will be applied to the corresponding row of the array.

**Examples**

![Example plots](image-url)
Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

```
matplotlib.axes.Axes.pie
```

Axes.pie(self, x, explode=None, labels=None, colors=None, autopct=None, pctdistance=0.6, shadow=False, labellabeldistance=1.1, startangle=None, radius=None, counterclock=True, wedgeprops=None, textprops=None, center=(0, 0), frame=False, rotatelabels=False, *, data=None)

Plot a pie chart.

Make a pie chart of array x. The fractional area of each wedge is given by \(x/\sum(x)\). If \(\sum(x) < 1\), then the values of x give the fractional area directly and the array will not be normalized. The resulting pie will have an empty wedge of size \(1 - \sum(x)\).

The wedges are plotted counterclockwise, by default starting from the x-axis.

Parameters

- **x** [array-like] The wedge sizes.
- **explode** [array-like, optional, default: None] If not None, is a \(\text{len}(x)\) array which specifies the fraction of the radius with which to offset each wedge.
- **labels** [list, optional, default: None] A sequence of strings providing the labels for each wedge.
- **colors** [array-like, optional, default: None] A sequence of matplotlib color args through which the pie chart will cycle. If None, will use the colors in the currently active cycle.
- **autopct** [None (default), string, or function, optional] If not None, is a string or function used to label the wedges with their numeric value. The label will be placed inside the wedge. If it is a format string, the label will be \(fmt\%pct\). If it is a function, it will be called.
- **pctdistance** [float, optional, default: 0.6] The ratio between the center of each pie slice and the start of the text generated by autopct. Ignored if autopct is None.
- **shadow** [bool, optional, default: False] Draw a shadow beneath the pie.
- **labellabeldistance** [float or None, optional, default: 1.1] The radial distance at which the pie labels are drawn. If set to None, label are not drawn, but are stored for use in legend().
- **startangle** [float, optional, default: None] If not None, rotates the start of the pie chart by angle degrees counterclockwise from the x-axis.
- **radius** [float, optional, default: None] The radius of the pie, if radius is None it will be set to 1.
counterclock [bool, optional, default: True] Specify fractions direction, clockwise or counterclockwise.

wedgeprops [dict, optional, default: None] Dict of arguments passed to the wedge objects making the pie. For example, you can pass in wedgeprops = {'linewidth': 3} to set the width of the wedge border lines equal to 3. For more details, look at the doc/arguments of the wedge object. By default clip_on=False.

textprops [dict, optional, default: None] Dict of arguments to pass to the text objects.

center [list of float, optional, default: (0, 0)] Center position of the chart. Takes value (0, 0) or is a sequence of 2 scalars.

frame [bool, optional, default: False] Plot axes frame with the chart if true.

rotatelabels [bool, optional, default: False] Rotate each label to the angle of the corresponding slice if true.

Returns

patches [list] A sequence of matplotlib.patches.Wedge instances

texts [list] A list of the label matplotlib.text.Text instances.

autotexts [list] A list of Text instances for the numeric labels. This will only be returned if the parameter autopct is not None.

Notes

The pie chart will probably look best if the figure and axes are square, or the Axes aspect is equal. This method sets the aspect ratio of the axis to "equal". The axes aspect ratio can be controlled with Axes.set_aspect.

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

• All arguments with the following names: 'colors', 'explode', 'labels', 'x'.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.pie

• sphx_glr_gallery_pie_and_polar_charts_pie_features.py
• sphx_glr_gallery_pie_and_polar_charts_pie_demo2.py
• sphx_glr_gallery_pie_and_polar_charts_bar_of_pie.py
• sphx_glr_gallery_pie_and_polar_charts_nested_pie.py
• sphx_glr_gallery_pie_and_polar_charts_pie_and_donut_labels.py
Axes.stackplot(axes, x, *args, labels=(), colors=None, baseline='zero', data=None, **kwargs)

Draw a stacked area plot.

**Parameters**

- **x** [1d array of dimension N]
- **y** [2d array (dimension MxN), or sequence of 1d arrays (each dimension 1xN)] The data is assumed to be unstacked. Each of the following calls is legal:

  ```
  stackplot(x, y)  # where y is MxN
  stackplot(x, y1, y2, y3, y4)  # where y1, y2, y3, y4, are all 1xNm
  ```

- **baseline** [{‘zero’, ‘sym’, ‘wiggle’, ‘weighted_wiggle’}] Method used to calculate the baseline:
  - ’zero’: Constant zero baseline, i.e. a simple stacked plot.
  - ’sym’: Symmetric around zero and is sometimes called ‘ThemeRiver’.
  - ’wiggle’: Minimizes the sum of the squared slopes.
  - ’weighted_wiggle’: Does the same but weights to account for size of each layer. It is also called ‘Streamgraph’-layout. More details can be found at [http://leebyron.com/streamgraph/](http://leebyron.com/streamgraph/).

- **labels** [Length N sequence of strings] Labels to assign to each data series.

- **colors** [Length N sequence of colors] A list or tuple of colors. These will be cycled through and used to colour the stacked areas.

- ****kwargs** All other keyword arguments are passed to Axes.fill_between().

**Returns**

- **list** [list of PolyCollection] A list of PolyCollection instances, one for each element in the stacked area plot.

**Notes**

**Note:** In addition to the above described arguments, this function can take a **data** keyword argument. If such a **data** argument is given, the following arguments are replaced by **data[<arg>]:**

- All positional and all keyword arguments.

Objects passed as **data** must support item access (**data[<arg>]**) and membership test (**<arg> in data**).
A rectangle is drawn for each element of \( \textit{xranges} \). All rectangles have the same vertical position and size defined by \( \textit{yrange} \).

This is a convenience function for instantiating a \textit{BrokenBarHCollection}, adding it to the axes and autoscaling the view.

**Parameters**

\textbf{\textit{xranges}} [sequence of tuples \((\textit{xmin}, \textit{xwidth})\)] The x-positions and extends of the rectangles. For each tuple \((\textit{xmin}, \textit{xwidth})\) a rectangle is drawn from \( \textit{xmin} \) to \( \textit{xmin} + \textit{xwidth} \).

\textbf{\textit{yranges}} [(\textit{ymin}, \textit{ymax})] The y-position and extend for all the rectangles.

**Returns**

\textbf{collection} [A \textit{BrokenBarHCollection}]

**Other Parameters**

\textbf{\textit{**kwargs}} [\textit{BrokenBarHCollection} properties] Each \textit{kwarg} can be either a single argument applying to all rectangles, e.g.:

\[
\text{facecolors} = 'black'
\]

or a sequence of arguments over which is cycled, e.g.:

\[
\text{facecolors} = ('black', 'blue')
\]

would create interleaving black and blue rectangles.

**Supported keywords:**

**Notes**

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All positional and all keyword arguments.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

### matplotlib.axes.Axes.vlines

```python
Axes.vlines(self, x, ymin, ymax, colors='k', linestyles='solid', label='', *, data=None, **kwargs)
```

Plot vertical lines.

Plot vertical lines at each `x` from `ymin` to `ymax`.

**Parameters**

- `x` [scalar or 1D array_like] x-indexes where to plot the lines.
- `ymin, ymax` [scalar or 1D array_like] Respective beginning and end of each line. If scalars are provided, all lines will have same length.
- `colors` [array_like of colors, optional, default: ‘k’]
- `linestyles` [{‘solid’, ‘dashed’, ‘dashdot’, ‘dotted’}, optional]
- `label` [string, optional, default: ”]

**Returns**

- `lines` [LineCollection]

**Other Parameters**

- `**kwargs` [LineCollection properties.]
See also:

*hlines* horizontal lines
*axvline* vertical line across the axes

Notes

**Note:** In addition to the above described arguments, this function can take a *data* keyword argument. If such a *data* argument is given, the following arguments are replaced by *data*[<arg>]:

- All arguments with the following names: 'colors', 'x', 'ymax', 'ymin'.

Objects passed as *data* must support item access (*data*[<arg>]) and membership test (*<arg> in data*).

```python
matplotlib.axes.Axes.hlines

Axes.hlines(self, y, xmin, xmax, colors='k', linestyles='solid', label='', *, data=None, **kwargs)
```

Plot horizontal lines at each y from xmin to xmax.

**Parameters**

- **y** [scalar or sequence of scalar] y-indexes where to plot the lines.
- **xmin, xmax** [scalar or 1D array_like] Respective beginning and end of each line. If scalars are provided, all lines will have same length.
- **colors** [array_like of colors, optional, default: 'k']
- **linestyles** [{'solid', 'dashed', 'dashdot', 'dotted'}, optional]
- **label** [string, optional, default: '']

**Returns**

- **lines** [LineCollection]

**Other Parameters**

**kwargs [LineCollection properties.]

See also:

*vlines* vertical lines
*axhline* horizontal line across the axes

Notes

**Note:** In addition to the above described arguments, this function can take a *data* keyword argument. If such a *data* argument is given, the following arguments are replaced by *data*[<arg>]:
• All arguments with the following names: 'colors', 'xmax', 'xmin', 'y'.

Objects passed as data must support item access (data[arg]) and membership test (arg in data).

Examples using matplotlib.axes.Axes.hlines

• sphx_glr_gallery_color_named_colors.py

matplotlib.axes.Axes.fill

Axes.fill(self, *args, data=None, **kwargs)

Plot filled polygons.

Parameters

*args [sequence of x, y, [color]] Each polygon is defined by the lists of x and y positions of its nodes, optionally followed by a color specifier. See matplotlib.colors for supported color specifiers. The standard color cycle is used for polygons without a color specifier.

You can plot multiple polygons by providing multiple x, y, [color] groups.

For example, each of the following is legal:

```
ax.fill(x, y)  # a polygon with default color
ax.fill(x, y, "b")  # a blue polygon
ax.fill(x, y, x2, y2)  # two polygons
ax.fill(x, y, "b", x2, y2, "r")  # a blue and a red polygon
```

data [indexable object, optional] An object with labelled data. If given, provide the label names to plot in x and y, e.g.:

```
ax.fill("time", "signal",
data={"time": [0, 1, 2], "signal": [0, 1, 0]})
```

Returns

a list of Polygon

Other Parameters

**kwargs [Polygon properties]

Notes

Use fill_between() if you would like to fill the region between two curves.

Examples using matplotlib.axes.Axes.fill

• sphx_glr_gallery_lines_bars_and_markers_fill.py
Spans

<table>

</tr>
</tbody>
</table>

**Axes.axhline**

`Axes.axhline(self, y=0, xmin=0, xmax=1, **kwargs)`

Add a horizontal line across the axis.

**Parameters**

- **y** [scalar, optional, default: 0] y position in data coordinates of the horizontal line.
- **xmin** [scalar, optional, default: 0] Should be between 0 and 1, 0 being the far left of the plot, 1 the far right of the plot.
- **xmax** [scalar, optional, default: 1] Should be between 0 and 1, 0 being the far left of the plot, 1 the far right of the plot.

**Returns**

- **line** [Line2D]

**Other Parameters**

- **kwargs** Valid kwargs are Line2D properties, with the exception of ‘transform’:

See also:

- **hlines** Add horizontal lines in data coordinates.
- **axhspan** Add a horizontal span (rectangle) across the axis.

Examples

- draw a thick red hline at ‘y’ = 0 that spans the xrange:
  ```python
  >>> axhline(linewidth=4, color='r')
  ```

- draw a default hline at ‘y’ = 1 that spans the xrange:
  ```python
  >>> axhline(y=1)
  ```

- draw a default hline at ‘y’ = .5 that spans the middle half of the xrange:
  ```python
  >>> axhline(y=.5, xmin=0.25, xmax=0.75)
  ```

Examples using `matplotlib.axes.Axes.axhline`

- sphx_glr_gallery_lines_bars_and_markers_span_regions.py
- sphx_glr_gallery_color_color_cycle_default.py
Axes.axhspan

Axes.axhspan(self, ymin, ymax, xmin=0, xmax=1, **kwargs)

Add a horizontal span (rectangle) across the axis.

Draw a horizontal span (rectangle) from ymin to ymax. With the default values of xmin
= 0 and xmax = 1, this always spans the xrange, regardless of the xlim settings, even if
you change them, e.g., with the set_xlim() command. That is, the horizontal extent is in
axes coords: 0=left, 0.5=middle, 1.0=right but the y location is in data coordinates.

Parameters

ymin [float] Lower limit of the horizontal span in data units.

ymax [float] Upper limit of the horizontal span in data units.

xmin [float, optional, default: 0] Lower limit of the vertical span in axes
(relative 0-1) units.

xmax [float, optional, default: 1] Upper limit of the vertical span in axes
(relative 0-1) units.

Returns

Polygon [Polygon]

Other Parameters

**kwargs [Polygon properties.]

axvspan  Add a vertical span across the axes.

matplotlib.axes.Axes.axvline

Axes.axvline(self, x=0, ymin=0, ymax=1, **kwargs)

Add a vertical line across the axes.

Parameters

- **x** [scalar, optional, default: 0] x position in data coordinates of the vertical line.
- **ymin** [scalar, optional, default: 0] Should be between 0 and 1, 0 being the bottom of the plot, 1 the top of the plot.
- **ymax** [scalar, optional, default: 1] Should be between 0 and 1, 0 being the bottom of the plot, 1 the top of the plot.

Returns

- **line** [Line2D]

Other Parameters

**kwargs  Valid kwargs are Line2D properties, with the exception of 'transform':

See also:

- `vlines` Add vertical lines in data coordinates.
- `axvspan` Add a vertical span (rectangle) across the axis.

Examples

- draw a thick red vline at $x = 0$ that spans the yrange:

```python
>>> axvline(linewidth=4, color='r')
```

- draw a default vline at $x = 1$ that spans the yrange:

```python
>>> axvline(x=1)
```

- draw a default vline at $x = .5$ that spans the middle half of the yrange:

```python
>>> axvline(x=.5, ymin=0.25, ymax=0.75)
```

Examples using `matplotlib.axes.Axes.axvline`

- `sphx_glr_gallery_color_color_cycle_default.py`
matplotlib.axes.Axes.axvspan

`Axes.axvspan(self, xmin, xmax, ymin=0, ymax=1, **kwargs)`  
Add a vertical span (rectangle) across the axes.

Draw a vertical span (rectangle) from `xmin` to `xmax`. With the default values of `ymin = 0` and `ymax = 1`. This always spans the yrange, regardless of the ylim settings, even if you change them, e.g., with the `set_ylim()` command. That is, the vertical extent is in axes coords: `0=bottom, 0.5=middle, 1.0=top` but the x location is in data coordinates.

**Parameters**

- `xmin` [scalar] Number indicating the first X-axis coordinate of the vertical span rectangle in data units.
- `xmax` [scalar] Number indicating the second X-axis coordinate of the vertical span rectangle in data units.
- `ymin` [scalar, optional] Number indicating the first Y-axis coordinate of the vertical span rectangle in relative Y-axis units (0-1). Default to 0.
- `ymax` [scalar, optional] Number indicating the second Y-axis coordinate of the vertical span rectangle in relative Y-axis units (0-1). Default to 1.

**Returns**

- `rectangle` [matplotlib.patches.Polygon] Vertical span (rectangle) from `(xmin, ymin)` to `(xmax, ymax).

**Other Parameters**

- `**kwargs` Optional parameters are properties of the class `matplotlib.patches.Polygon`.

**See also:**

`axhspan` Add a horizontal span across the axes.

**Examples**

Draw a vertical, green, translucent rectangle from `x = 1.25` to `x = 1.55` that spans the yrange of the axes.

```python
>>> axvspan(1.25, 1.55, facecolor='g', alpha=0.5)
```

**Spectral**

Continued on next page
Axes.xcorr

Plot the cross correlation between x and y.

Parameters

- **x** [array-like]
  - **detrend** [callable, optional, default: `mlab.detrend_none`] x is detrended by the `detrend` callable. This must be a function `x = detrend(x)` accepting and returning an `numpy.array`. Default is no normalization.
  - **normed** [bool, optional, default: True] If True, input vectors are normalised to unit length.
  - **usevlines** [bool, optional, default: True] Determines the plot style.
    - If True, vertical lines are plotted from 0 to the acorr value using `Axes.vlines`. Additionally, a horizontal line is plotted at y=0 using `Axes.axhline`.
    - If False, markers are plotted at the acorr values using `Axes.plot`.
  - **maxlags** [int, optional, default: 10] Number of lags to show. If None, will return all `2 * len(x) - 1` lags.

Returns

- **lags** [array (length 2*maxlags+1)] The lag vector.
- **c** [array (length 2*maxlags+1)] The auto correlation vector.
- **line** [LineCollection or Line2D] Artist added to the axes of the correlation:
  - LineCollection if `usevlines` is True.
  - Line2D if `usevlines` is False.
- **b** [Line2D or None] Horizontal line at 0 if `usevlines` is True None `usevlines` is False.

Other Parameters

- **linestyle** [Line2D property, optional] The linestyle for plotting the data points. Only used if `usevlines` is False.
- **marker** [str, optional, default: ‘o’] The marker for plotting the data points. Only used if `usevlines` is False.

Notes

The cross correlation is performed with `numpy.correlate()` with `mode = "full"`.

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by `data[<arg>]`: 

```python
Axes.acorr

Axes.acorr(self, x, *, data=None, **kwargs)

Plot the autocorrelation of x.
```

- **x** [array-like]
- **detrend** [callable, optional, default: `mlab.detrend_none`] x is detrended by the `detrend` callable. This must be a function `x = detrend(x)` accepting and returning an `numpy.array`. Default is no normalization.
- **normed** [bool, optional, default: True] If True, input vectors are normalised to unit length.
- **usevlines** [bool, optional, default: True] Determines the plot style.
  - If True, vertical lines are plotted from 0 to the acorr value using `Axes.vlines`. Additionally, a horizontal line is plotted at y=0 using `Axes.axhline`.
  - If False, markers are plotted at the acorr values using `Axes.plot`.
- **maxlags** [int, optional, default: 10] Number of lags to show. If None, will return all `2 * len(x) - 1` lags.

Returns

- **lags** [array (length 2*maxlags+1)] The lag vector.
- **c** [array (length 2*maxlags+1)] The auto correlation vector.
- **line** [LineCollection or Line2D] Artist added to the axes of the correlation:
  - LineCollection if `usevlines` is True.
  - Line2D if `usevlines` is False.
- **b** [Line2D or None] Horizontal line at 0 if `usevlines` is True None `usevlines` is False.

Other Parameters

- **linestyle** [Line2D property, optional] The linestyle for plotting the data points. Only used if `usevlines` is False.
- **marker** [str, optional, default: ‘o’] The marker for plotting the data points. Only used if `usevlines` is False.
• All arguments with the following names: ‘x’.

Objects passed as **data** must support item access (**data[<arg>]**) and membership test (**<arg> in data**).

Examples using *matplotlib.axes.Axes.acorr*

• sphx_glr_gallery_lines_bars_and_markers_xcorr_acorr_demo.py

*matplotlib.axes.Axes.angle_spectrum*

```python
Axes.angle_spectrum(self, x, Fs=None, Fc=None, window=None, pad_to=None,
                    sides=None, *, data=None, **kwargs)
```

Plot the angle spectrum.

Compute the angle spectrum (wrapped phase spectrum) of *x*. Data is padded to a length of *pad_to* and the windowing function *window* is applied to the signal.

**Parameters**

- **x** [1-D array or sequence] Array or sequence containing the data.
- **Fs** [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.
- **window** [callable or ndarray] A function or a vector of length *NFFT*. To create window vectors see *window_hanning*, *window_none*, *numpy.blackman*, *numpy.hamming*, *numpy.bartlett*, *scipy.signal*, *scipy.signal.get_window*, etc. The default is *window_hanning*. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- **sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- **pad_to** [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the *n* parameter in the call to *fft()*. The default is None, which sets *pad_to* equal to the length of the input signal (i.e. no padding).
- **Fc** [int] The center frequency of *x* (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**Returns**

- **spectrum** [1-D array] The values for the angle spectrum in radians (real valued).
- **freqs** [1-D array] The frequencies corresponding to the elements in *spectrum*. 
line [a Line2D instance] The line created by this function.

Other Parameters

**kwargs Keyword arguments control the Line2D properties:

See also:

magnitude_spectrum() angle_spectrum() plots the magnitudes of the corresponding frequencies.
phase_spectrum() plots the unwrapped version of this function.

specgram() can plot the angle spectrum of segments within the signal in a colormap.

Notes

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[arg]:

- All arguments with the following names: ‘x’.

Objects passed as data must support item access (data[arg]) and membership test (arg in data).

matplotlib.axes.Axes.cohere

Axes.cohere(self, x, y, NFFT=256, Fs=2, Fc=0, detrend=<function detrend_none at 0x7f69881a1378>, window=<function window_hanning at 0x7f6988216bf8>, noverlap=0, pad_to=None, sides='default', scale_by_freq=None, *, data=None, **kwargs)

Plot the coherence between x and y. Coherence is the normalized cross spectral density:

\[ C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}} \]

Parameters

Fs [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

window [callable or ndarray] A function or a vector of length NFFT. To create window vectors see window_hanning, window_none, numpy.blackman, numpy.hamming, numpy.bartlett, scipy.signal, scipy.signal.get_window, etc. The default is window_hanning. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

sides [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

pad_to [int] The number of points to which the data segment is padded when performing the FFT. This can be different from NFFT, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the n parameter in the call to fft(). The default is None, which sets pad_to equal to NFFT.
**NFFT** [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should **NOT** be used to get zero padding, or the scaling of the result will be incorrect. Use `pad_to` for this instead.

**detrend** [{‘none’, ‘mean’, ‘linear’} or callable, default ‘none’] The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the `detrend` parameter is a vector, in Matplotlib is it a function. The `mlab` module defines `detrend_none`, `detrend_mean`, and `detrend_linear`, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls `detrend_none`, ‘mean’ calls `detrend_mean`, ‘linear’ calls `detrend_linear`.

**scale_by_freq** [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

**noverlap** [int] The number of points of overlap between blocks. The default value is 0 (no overlap).

**Fc** [int] The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsamped to baseband.

**Returns**

- **Cxy** [1-D array] The coherence vector.
- **freqs** [1-D array] The frequencies for the elements in Cxy.

**Other Parameters**

****kwargs** Keyword arguments control the `Line2D` properties:

Notes

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]:`

- All arguments with the following names: ‘x’, ‘y’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

References

```python
csd

Axes.csd(self, x, y, NFFT=None, Fs=None, Fc=None, detrend=None, window=None, noverlap=None, pad_to=None, sides=None, scale_by_freq=None, return_line=None, *, data=None, **kwargs)

Plot the cross-spectral density.

The cross spectral density $P_{xy}$ by Welch's average periodogram method. The vectors $x$ and $y$ are divided into $NFFT$ length segments. Each segment is detrended by function
```
detrend and windowed by function window. noverlap gives the length of the overlap between segments. The product of the direct FFTs of \(x\) and \(y\) are averaged over each segment to compute \(P_{xy}\), with a scaling to correct for power loss due to windowing.

If \(\text{len}(x) < NFFT\) or \(\text{len}(y) < NFFT\), they will be zero padded to \(NFFT\).

**Parameters**

- \(x, y\) [1-D arrays or sequences] Arrays or sequences containing the data.
- \(\text{Fs}\) [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, \(\text{freqs}\), in cycles per time unit. The default value is 2.
- \(\text{window}\) [callable or ndarray] A function or a vector of length \(NFFT\). To create window vectors see \(\text{window_hanning}, \text{window_none}, \text{numpy.blackman}, \text{numpy.hamming}, \text{numpy.bartlett}, \text{scipy.signal}, \text{scipy.signal.get_window}\), etc. The default is \(\text{window_hanning}\). If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- \(\text{sides}\) [{'default', 'onesided', 'twosided'}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- \(\text{pad_to}\) [int] The number of points to which the data segment is padded when performing the FFT. This can be different from \(NFFT\), which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the \(n\) parameter in the call to \(\text{fft()}\). The default is None, which sets \(\text{pad_to}\) equal to \(NFFT\).
- \(\text{NFFT}\) [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use \(\text{pad_to}\) for this instead.
- \(\text{detrend}\) [{‘none’, ‘mean’, ‘linear’} or callable, default ‘none’] The function applied to each segment before \(\text{fft()}\)-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the \(\text{detrend}\) parameter is a vector, in Matplotlib it is a function. The \(\text{mlab}\) module defines \(\text{detrend_none}, \text{detrend_mean}, \text{and detrend_linear}\), but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls \(\text{detrend_none}\), ‘mean’ calls \(\text{detrend_mean}\), ‘linear’ calls \(\text{detrend_linear}\).
- \(\text{scale_by_freq}\) [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz\(^{-1}\). This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.
- \(\text{noverlap}\) [int] The number of points of overlap between segments. The default value is 0 (no overlap).
- \(\text{Fc}\) [int] The center frequency of \(x\) (defaults to 0), which offsets the \(x\) extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsamped to baseband.
return_line [bool] Whether to include the line object plotted in the returned values. Default is False.

Returns

Pxy [1-D array] The values for the cross spectrum \( P_{xy} \) before scaling (complex valued).

freqs [1-D array] The frequencies corresponding to the elements in Pxy.

line [a Line2D instance] The line created by this function. Only returned if return_line is True.

Other Parameters

**kwargs Keyword arguments control the Line2D properties:

`psd()` `psd()` is the equivalent to setting y=x.

Notes

For plotting, the power is plotted as $10 \log_{10}(P_{xy})$ for decibels, though $P_{xy}$ itself is returned.

References

Note: In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘x’, ‘y’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

`Axes.magnitude_spectrum()`

Axes.magnitude_spectrum(self, x, Fs=None, Fc=None, window=None, pad_to=None, sides=None, scale=None, *, data=None, **kwargs)

Plot the magnitude spectrum.

Compute the magnitude spectrum of x. Data is padded to a length of `pad_to` and the windowing function `window` is applied to the signal.

Parameters

- `x` [1-D array or sequence] Array or sequence containing the data.
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.
- `window` [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, `scipy.signal.get_window`.
etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

**sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

**pad_to** [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to the length of the input signal (i.e. no padding).

**scale** [{‘default’, ‘linear’, ‘dB’}] The scaling of the values in the `spec`. ‘linear’ is no scaling. ‘dB’ returns the values in dB scale, i.e., the dB amplitude (20 * log10). ‘default’ is ‘linear’.

**Fc** [int] The center frequency of `x` (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**Returns**

-spectrum [1-D array] The values for the magnitude spectrum before scaling (real valued).

-freqs [1-D array] The frequencies corresponding to the elements in `spectrum`.

-line [a `Line2D` instance] The line created by this function.

**Other Parameters**

**See also:**

- `psd()` *psd()* plots the power spectral density.
- `angle_spectrum()` *angle_spectrum()* plots the angles of the corresponding frequencies.
- `phase_spectrum()` *phase_spectrum()* plots the phase (unwrapped angle) of the corresponding frequencies.
- `specgram()` *specgram()* can plot the magnitude spectrum of segments within the signal in a colormap.

**Notes**

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘x’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).
Axes.phase_spectrum(self, x, Fs=None, Fc=None, window=None, pad_to=None, sides=None, *, data=None, **kwargs)

Plot the phase spectrum.

Compute the phase spectrum (unwrapped angle spectrum) of x. Data is padded to a length of pad_to and the windowing function window is applied to the signal.

Parameters

x [1-D array or sequence] Array or sequence containing the data

Fs [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

window [callable or ndarray] A function or a vector of length NFFT. To create window vectors see window_hanning, window_none, numpy.blackman, numpy.hamming, numpy.bartlett, scipy.signal, scipy.signal.get_window, etc. The default is window_hanning. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

sides [{'default', 'onesided', 'twosided'}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

pad_to [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the n parameter in the call to fft(). The default is None, which sets pad_to equal to the length of the input signal (i.e. no padding).

Fc [int] The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

Returns

spectrum [1-D array] The values for the phase spectrum in radians (real valued).

freqs [1-D array] The frequencies corresponding to the elements in spectrum.

line [a Line2D instance] The line created by this function.

Other Parameters

**kwargs Keyword arguments control the Line2D properties:

See also:

:magnitude_spectrum(): magnitude_spectrum() plots the magnitudes of the corresponding frequencies.

:angle_spectrum(): angle_spectrum() plots the wrapped version of this function.

:specgram(): specgram() can plot the phase spectrum of segments within the signal in a colormap.

Notes
**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: 'x'.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (<arg> in data).

```python
matplotlib.axes.Axes.psd

`axes.psd(self, x, NFFT=None, Fs=None, Fc=None, detrend=None, window=None, noverlap=None, pad_to=None, sides=None, scale_by_freq=None, return_line=None, *, data=None, **kwargs)`
```

Plot the power spectral density.

The power spectral density $P_{xx}$ by Welch’s average periodogram method. The vector `x` is divided into `NFFT` length segments. Each segment is detrended by function `detrend` and windowed by function `window`. `noverlap` gives the length of the overlap between segments. The $|\text{fft}(i)|^2$ of each segment $i$ are averaged to compute $P_{xx}$, with a scaling to correct for power loss due to windowing.

If len(x) < `NFFT`, it will be zero padded to `NFFT`.

**Parameters**

- `x` [1-D array or sequence] Array or sequence containing the data
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.
- `window` [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- `sides` [‘default’, ‘onesided’, ‘twosided’] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns onesided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- `noverlap` [int] The number of points to which the data segment is padded when performing the FFT. This can be different from `NFFT`, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `noverlap` equal to `NFFT`
- `NFFT` [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use `pad_to` for this instead.
**detrend** [\{'none’, ‘mean’, ‘linear’\} or callable, default ‘none’] The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the detrend parameter is a vector, in Matplotlib is it a function. The mlab module defines detrend_none, detrend_mean, and detrend_linear, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls detrend_none, ‘mean’ calls detrend_mean, ‘linear’ calls detrend_linear.

**scale_by_freq** [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

**noverlap** [int] The number of points of overlap between segments. The default value is 0 (no overlap).

**Fc** [int] The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**return_line** [bool] Whether to include the line object plotted in the returned values. Default is False.

**Returns**

- **Pxx** [1-D array] The values for the power spectrum $P_{xx}$ before scaling (real valued).
- **freqs** [1-D array] The frequencies corresponding to the elements in Pxx.
- **line** [a Line2D instance] The line created by this function. Only returned if return_line is True.

**Other Parameters**

**kwargs** Keyword arguments control the Line2D properties:

**See also:**

specgram()  specgram() differs in the default overlap; in not returning the mean of the segment periodograms; in returning the times of the segments; and in plotting a colormap instead of a line.

magnitude_spectrum() magnitude_spectrum() plots the magnitude spectrum.

csd()  csd() plots the spectral density between two signals.

**Notes**

For plotting, the power is plotted as $10 \log_{10}(P_{xx})$ for decibels, though $P_{xx}$ itself is returned.

**References**

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’.
Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

**matplotlib.axes.Axes.specgram**

`Axes.specgram(self, x, NFFT=None, Fs=None, Fc=None, detrend=None, window=None, noverlap=None, cmap=None, xextent=None, pad_to=None, sides=None, scale_by_freq=None, mode=None, scale=None, vmin=None, vmax=None, *, data=None, **kwargs)``

Plot a spectrogram.

Compute and plot a spectrogram of data in `x`. Data are split into `NFFT` length segments and the spectrum of each section is computed. The windowing function `window` is applied to each segment, and the amount of overlap of each segment is specified with `noverlap`. The spectrogram is plotted as a colormap (using `imshow`).

**Parameters**

- `x` [1-D array or sequence] Array or sequence containing the data.
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.
- `window` [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- `noverlap` [int] The number of points to which the data segment is padded when performing the FFT. This can be different from `NFFT`, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is `None`, which sets `pad_to` equal to `NFFT`.
- `NFFT` [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should **NOT** be used to get zero padding, or the scaling of the result will be incorrect. Use `pad_to` for this instead.
- `detrend` [{’none’, ’mean’, ’linear’} or callable, default ’none’] The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the `detrend` parameter is a vector, in Matplotlib is it a function. The `mlab` module defines `detrend_none`, `detrend_mean`, and `detrend_linear`, but you can use a custom function as well. You can also use a string to choose one of the functions: ’none’ calls `detrend_none`. ’mean’ calls `detrend_mean`. ’linear’ calls `detrend_linear`. 

---

918 Chapter 17. Modules
scale_by_freq [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

mode [{'default', 'psd', 'magnitude', 'angle', 'phase}] What sort of spectrum to use. Default is ‘psd’, which takes the power spectral density. ‘magnitude’ returns the magnitude spectrum. ‘angle’ returns the phase spectrum without unwrapping. ‘phase’ returns the phase spectrum with unwrapping.

noverlap [int] The number of points of overlap between blocks. The default value is 128.

scale [{'default', 'linear', 'dB'}] The scaling of the values in the spec. ‘linear’ is no scaling. ‘dB’ returns the values in dB scale. When mode is ‘psd’, this is dB power (10 * log10). Otherwise this is dB amplitude (20 * log10). ‘default’ is ‘dB’ if mode is ‘psd’ or ‘magnitude’ and ‘linear’ otherwise. This must be ‘linear’ if mode is ‘angle’ or ‘phase’.

Fc [int] The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampling to baseband.

cmap A matplotlib.colors.Colormap instance; if None, use default determined by rc

xextent [None or (xmin, xmax)] The image extent along the x-axis. The default sets xmin to the left border of the first bin (spectrum column) and xmax to the right border of the last bin. Note that for noverlap>0 the width of the bins is smaller than those of the segments.

**kwargs Additional kwargs are passed on to imshow which makes the specgram image.

Returns

spectrum [2-D array] Columns are the periodograms of successive segments.

freqs [1-D array] The frequencies corresponding to the rows in spectrum.

t [1-D array] The times corresponding to midpoints of segments (i.e., the columns in spectrum).

im [instance of class AxesImage] The image created by imshow containing the spectrogram

See also:

psd() psd() differs in the default overlap; in returning the mean of the segment periodograms; in not returning times; and in generating a line plot instead of colormap.

magnitude_spectrum() A single spectrum, similar to having a single segment when mode is ‘magnitude’. Plots a line instead of a colormap.

angle_spectrum() A single spectrum, similar to having a single segment when mode is ‘angle’. Plots a line instead of a colormap.

phase_spectrum() A single spectrum, similar to having a single segment when mode is ‘phase’. Plots a line instead of a colormap.
Notes

The parameters `detrend` and `scale_by_freq` do only apply when `mode` is set to ‘psd’.

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘x’.

Objects passed as `data` must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using `matplotlib.axes.Axes.specgram`

- sphx_glr_gallery_images_contours_and_fields_specgram_demo.py

`matplotlib.axes.Axes.xcorr`

```
Axes.xcorr(self, x, y, normed=True, detrend=<function detrend_none at 0x7f69881a1378>, usevlines=True, maxlags=10, *, data=None, **kwargs)
```

Plot the cross correlation between `x` and `y`.

The correlation with lag k is defined as \( \sum_n x[n+k] \cdot y^*[n] \), where \( y^* \) is the complex conjugate of `y`.

**Parameters**

- `x` [array-like of length n]
- `y` [array-like of length n]
- `detrend` [callable, optional, default: `mlab.detrend_none`] `x` and `y` are detrended by the `detrend` callable. This must be a function \( x = \text{detrend}(x) \) accepting and returning an `numpy.array`. Default is no normalization.
- `normed` [bool, optional, default: True] If True, input vectors are normalised to unit length.
- `usevlines` [bool, optional, default: True] Determines the plot style.
  - If True, vertical lines are plotted from 0 to the xcorr value using `Axes.vlines`. Additionally, a horizontal line is plotted at \( y=0 \) using `Axes.axhline`.
  - If False, markers are plotted at the xcorr values using `Axes.plot`.
- `maxlags` [int, optional, default: 10] Number of lags to show. If None, will return all \( 2 \cdot \text{len}(x) - 1 \) lags.

**Returns**

- `lags` [array (length 2*maxlags+1)] The lag vector.
- `c` [array (length 2*maxlags+1)] The auto correlation vector.
- `line` [LineCollection or Line2D] Artist added to the axes of the correlation:
• **LineCollection** if `usevlines` is True.
• **Line2D** if `usevlines` is False.

**b** [**Line2D** or None] Horizontal line at 0 if `usevlines` is True None `usevlines` is False.

**Other Parameters**

**linestyle** [**Line2D** property, optional] The linestyle for plotting the data points. Only used if `usevlines` is False.

**marker** [str, optional, default: ’o’] The marker for plotting the data points. Only used if `usevlines` is False.

**Notes**

The cross correlation is performed with `numpy.correlate()` with `mode = "full"`.

**Note:** In addition to the above described arguments, this function can take a **data** keyword argument. If such a **data** argument is given, the following arguments are replaced by **data[<arg>]**:

• All arguments with the following names: ’x’, ‘y’.

Objects passed as **data** must support item access (data[<arg>]) and membership test (<arg> in data).

**Examples using matplotlib.axes.Axes.xcorr**

• sphx_glr_gallery_lines_bars_and_markers_xcorr_acorr_demo.py

**matplotlib.axes.Axes.boxplot**

`Axes.boxplot(self, x, notch=None, sym=None, vert=None, whis=None, positions=None, widths=None, patch_artist=None, bootstrap=None, usermedians=None, conf_intervale=None, meanline=None, showmeans=None, showcaps=None, showbox=None, showfliers=None, boxprops=None, labels=None, flierprops=None, medianprops=None, meanprops=None, capprops=None, whiskerprops=None, manage_ticks=True, autorange=False, zorder=None, *, data=None)`

Make a box and whisker plot.

Make a box and whisker plot for each column of `x` or each vector in sequence `x`. The box extends from the lower to upper quartile values of the data, with a line at the median.
The whiskers extend from the box to show the range of the data. Flier points are those past the end of the whiskers.

**Parameters**

- **x** [Array or a sequence of vectors.] The input data.

- **notch** [bool, optional (False)] If True, will produce a notched box plot. Otherwise, a rectangular boxplot is produced. The notches represent the confidence interval (CI) around the median. See the entry for the bootstrap parameter for information regarding how the locations of the notches are computed.

**Note:** In cases where the values of the CI are less than the lower quartile or greater than the upper quartile, the notches will extend beyond the box, giving it a distinctive “flipped” appearance. This is expected behavior and consistent with other statistical visualization packages.

- **sym** [str, optional] The default symbol for flier points. Enter an empty string (") if you don’t want to show fliers. If None, then the fliers default to ‘b+’ if you want more control use the flierprops kwarg.

- **vert** [bool, optional (True)] If True (default), makes the boxes vertical. If False, everything is drawn horizontally.

- **whis** [float, sequence, or string (default = 1.5)] As a float, determines the reach of the whiskers to the beyond the first and third quartiles. In other words, where IQR is the interquartile range (Q3–Q1), the upper whisker will extend to last datum less than Q3 + whis*IQR. Similarly, the lower whisker will extend to the first datum greater than Q1 - whis*IQR. Beyond the whiskers, data are considered outliers and are plotted as individual points. Set this to an unreasonably high value to force the whiskers to show the min and max values. Alternatively, set this to an ascending sequence of percentile (e.g., [5, 95]) to set the whiskers at specific percentiles of the data. Finally, whis can be the string 'range' to force the whiskers to the min and max of the data.

- **bootstrap** [int, optional] Specifies whether to bootstrap the confidence intervals around the median for notched boxplots. If bootstrap is None, no bootstrapping is performed, and notches are calculated using a Gaussian-based asymptotic approximation (see McGill, R., Tukey, J.W., and Larsen, W.A., 1978, and Kendall and Stuart, 1967). Otherwise, bootstrap specifies the number of times to bootstrap the median to determine its 95% confidence intervals. Values between 1000 and 10000 are recommended.

- **usermedians** [array-like, optional] An array or sequence whose first dimension (or length) is compatible with x. This overrides the medians computed by matplotlib for each element of usermedians that is not None. When an element of usermedians is None, the median will be computed by matplotlib as normal.

- **conf_intervals** [array-like, optional] Array or sequence whose first dimension (or length) is compatible with x and whose second dimension is 2. When the an element of conf_intervals is not None, the notch locations computed by matplotlib are overridden (provided notch is True).
an element of `conf_intervals` is `None`, the notches are computed by the
method specified by the other kwargs (e.g., `bootstrap`).

**positions** [array-like, optional] Sets the positions of the boxes. The ticks
and limits are automatically set to match the positions. Defaults to
`range(1, N+1)` where N is the number of boxes to be drawn.

**widths** [scalar or array-like] Sets the width of each box either with a scalar
or a sequence. The default is 0.5, or `0.15*(distance between extreme
positions)`, if that is smaller.

**patch_artist** [bool, optional (False)] If `False` produces boxes with the
Line2D artist. Otherwise, boxes and drawn with Patch artists.

**labels** [sequence, optional] Labels for each dataset. Length must be com-
patible with dimensions of `x`.

**manage_ticks** [bool, optional (True)] If True, the tick locations and labels
will be adjusted to match the boxplot positions.

**autorange** [bool, optional (False)] When `True` and the data are distributed
such that the 25th and 75th percentiles are equal, `whis` is set to 'range'
such that the whisker ends are at the minimum and maximum of the data.

**meanline** [bool, optional (False)] If `True` (and `showmeans` is `True`), will try to
render the mean as a line spanning the full width of the box according
to `meanprops` (see below). Not recommended if `shownotches` is also `True`. Otherwise, means will be shown as points.

**zorder** [scalar, optional (None)] Sets the zorder of the boxplot.

**Returns**

**result** [dict] A dictionary mapping each component of the boxplot to a list of
the `matplotlib.lines.Line2D` instances created. That dictionary has the
following keys (assuming vertical boxplots):

- **boxes**: the main body of the boxplot showing the quartiles and the me-
dian’s confidence intervals if enabled.
- **medians**: horizontal lines at the median of each box.
- **whiskers**: the vertical lines extending to the most extreme, non-outlier
data points.
- **caps**: the horizontal lines at the ends of the whiskers.
- **fliers**: points representing data that extend beyond the whiskers
  (fliers).
- **means**: points or lines representing the means.

**Other Parameters**

**showcaps** [bool, optional (True)] Show the caps on the ends of whiskers.

**showbox** [bool, optional (True)] Show the central box.

**showfliers** [bool, optional (True)] Show the outliers beyond the caps.

**showmeans** [bool, optional (False)] Show the arithmetic means.

**capprops** [dict, optional (None)] Specifies the style of the caps.

**boxprops** [dict, optional (None)] Specifies the style of the box.
whiskerprops [dict, optional (None)] Specifies the style of the whiskers.
flerprops [dict, optional (None)] Specifies the style of the fliers.
medianprops [dict, optional (None)] Specifies the style of the median.
meanprops [dict, optional (None)] Specifies the style of the mean.

Notes

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.boxplot

- sphx_glr_gallery_pyplots_boxplot_demo_pyplot.py

matplotlib.axes.Axes.violinplot

Axes.violinplot(self, dataset, positions=None, vert=True, widths=0.5,
showmeans=False, showextrema=True, showmedians=False,
points=100, bw_method=None, *, data=None)

Make a violin plot.

Make a violin plot for each column of dataset or each vector in sequence dataset. Each filled area extends to represent the entire data range, with optional lines at the mean, the median, the minimum, and the maximum.

Parameters

dataset [Array or a sequence of vectors.] The input data.
positions [array-like, default = [1, 2, ..., n]] Sets the positions of the violins. The ticks and limits are automatically set to match the positions.
vert [bool, default = True.] If true, creates a vertical violin plot. Otherwise, creates a horizontal violin plot.
widths [array-like, default = 0.5] Either a scalar or a vector that sets the maximal width of each violin. The default is 0.5, which uses about half of the available horizontal space.
showmeans [bool, default = False] If True, will toggle rendering of the means.
showextrema [bool, default = True] If True, will toggle rendering of the extrema.
showmedians [bool, default = False] If True, will toggle rendering of the medians.
**points** [scalar, default = 100] Defines the number of points to evaluate each of the gaussian kernel density estimations at.

**bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If a scalar, this will be used directly as kde.factor. If a callable, it should take a GaussianKDE instance as its only parameter and return a scalar. If None (default), ‘scott’ is used.

**Returns**

**result** [dict] A dictionary mapping each component of the violinplot to a list of the corresponding collection instances created. The dictionary has the following keys:

- **bodies**: A list of the `matplotlib.collections.PolyCollection` instances containing the filled area of each violin.
- **cmeans**: A `matplotlib.collections.LineCollection` instance created to identify the mean values of each of the violin’s distribution.
- **cmins**: A `matplotlib.collections.LineCollection` instance created to identify the bottom of each violin’s distribution.
- **cmaxes**: A `matplotlib.collections.LineCollection` instance created to identify the top of each violin’s distribution.
- **cbars**: A `matplotlib.collections.LineCollection` instance created to identify the centers of each violin’s distribution.
- **cmedians**: A `matplotlib.collections.LineCollection` instance created to identify the median values of each of the violin’s distribution.

**Notes**

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘dataset’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

```
matplotlib.axes.Axes.violin
```

```
Axes.violin(self, vpstats, positions=None, vert=True, widths=0.5, showmeans=False, showextrema=True, showmedians=False)
```

Drawing function for violin plots.

Draw a violin plot for each column of `vpstats`. Each filled area extends to represent the entire data range, with optional lines at the mean, the median, the minimum, and the maximum.

**Parameters**
vpstats [list of dicts] A list of dictionaries containing stats for each violin plot. Required keys are:

• coords: A list of scalars containing the coordinates that the violin’s kernel density estimate were evaluated at.
• vals: A list of scalars containing the values of the kernel density estimate at each of the coordinates given in coords.
• mean: The mean value for this violin’s dataset.
• median: The median value for this violin’s dataset.
• min: The minimum value for this violin’s dataset.
• max: The maximum value for this violin’s dataset.

positions [array-like, default = [1, 2, ..., n]] Sets the positions of the violins. The ticks and limits are automatically set to match the positions.

vert [bool, default = True.] If true, plots the violins vertically. Otherwise, plots the violins horizontally.

widths [array-like, default = 0.5] Either a scalar or a vector that sets the maximal width of each violin. The default is 0.5, which uses about half of the available horizontal space.

showmeans [bool, default = False] If true, will toggle rendering of the means.

showextrema [bool, default = True] If true, will toggle rendering of the extrema.

showmedians [bool, default = False] If true, will toggle rendering of the medians.

Returns

result [dict] A dictionary mapping each component of the violinplot to a list of the corresponding collection instances created. The dictionary has the following keys:

• bodies: A list of the matplotlib.collections.PolyCollection instances containing the filled area of each violin.
• cmeans: A matplotlib.collections.LineCollection instance created to identify the mean values of each of the violin’s distribution.
• cmins: A matplotlib.collections.LineCollection instance created to identify the bottom of each violin’s distribution.
• cmaxes: A matplotlib.collections.LineCollection instance created to identify the top of each violin’s distribution.
• cbars: A matplotlib.collections.LineCollection instance created to identify the centers of each violin’s distribution.
• cmedians: A matplotlib.collections.LineCollection instance created to identify the median values of each of the violin’s distribution.
Axes.bxp

Drawing function for box and whisker plots.

Make a box and whisker plot for each column of x or each vector in sequence x. The box extends from the lower to upper quartile values of the data, with a line at the median. The whiskers extend from the box to show the range of the data. Flier points are those past the end of the whiskers.

Parameters

bxpstats [list of dicts] A list of dictionaries containing stats for each box-plot. Required keys are:
- **med**: The median (scalar float).
- **q1**: The first quartile (25th percentile) (scalar float).
- **q3**: The third quartile (75th percentile) (scalar float).
- **whislo**: Lower bound of the lower whisker (scalar float).
- **whishi**: Upper bound of the upper whisker (scalar float).

Optional keys are:
- **mean**: The mean (scalar float). Needed if showmeans=True.
- **fliers**: Data beyond the whiskers (sequence of floats). Needed if showfliers=True.
- **ci**: Lower and upper confidence intervals about the median. Needed if shownotches=True.
- **label**: Name of the dataset (string). If available, this will be used a tick label for the boxplot

positions [array-like, default = [1, 2, ..., n]] Sets the positions of the boxes. The ticks and limits are automatically set to match the positions.

widths [array-like, default = None] Either a scalar or a vector and sets the width of each box. The default is 0.15*(distance between extreme positions), clipped to no less than 0.15 and no more than 0.5.

vert [bool, default = True] If True (default), makes the boxes vertical. If False, makes horizontal boxes.

patch_artist [bool, default = False] If False produces boxes with the Line2D artist. If True produces boxes with the Patch artist.

shownotches [bool, default = False] If False (default), produces a rectangular box plot. If True, will produce a notched box plot

showmeans [bool, default = False] If True, will toggle on the rendering of the means

showcaps [bool, default = True] If True, will toggle on the rendering of the caps
showbox [bool, default = True] If True, will toggle on the rendering of the box
showfliers [bool, default = True] If True, will toggle on the rendering of the fliers
boxprops [dict or None (default)] If provided, will set the plotting style of the boxes
whiskerprops [dict or None (default)] If provided, will set the plotting style of the whiskers
capprops [dict or None (default)] If provided, will set the plotting style of the caps
flierprops [dict or None (default)] If provided will set the plotting style of the fliers
medianprops [dict or None (default)] If provided, will set the plotting style of the medians
meanprops [dict or None (default)] If provided, will set the plotting style of the means
meanline [bool, default = False] If True (and showmeans is True), will try to render the mean as a line spanning the full width of the box according to meanprops. Not recommended if shownotches is also True. Otherwise, means will be shown as points.
manageticks [bool, default = True] If True, the tick locations and labels will be adjusted to match the boxplot positions.
zorder [scalar, default = None] The zorder of the resulting boxplot.

Returns

dict] A dictionary mapping each component of the boxplot to a list of the matplotlib.lines.Line2D instances created. That dictionary has the following keys (assuming vertical boxplots):

- boxes: the main body of the boxplot showing the quartiles and the median’s confidence intervals if enabled.
- medians: horizontal lines at the median of each box.
- whiskers: the vertical lines extending to the most extreme, non-outlier data points.
- caps: the horizontal lines at the ends of the whiskers.
- fliers: points representing data that extend beyond the whiskers (fliers).
- means: points or lines representing the means.

Examples

Binned

Axes.hexbin

Make a hexagonal binning plot.
### Table 74 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axes.hist</code></td>
<td>Plot a histogram.</td>
</tr>
<tr>
<td><code>Axes.hist2d</code></td>
<td>Make a 2D histogram plot.</td>
</tr>
</tbody>
</table>

#### matplotlib.axes.Axes.hexbin

```python
Axes.hexbin(self, x, y, C=None, gridsize=100, bins=None, xscale='linear', yscale='linear', extent=None, cmap=None, norm=None, vmin=None, vmax=None, alpha=None, linewidths=None, edgecolors='face', reduce_C_function=<function mean at 0x7f6977bac268>, mincnt=None, marginals=False, *, data=None, **kwargs)
```

Make a hexagonal binning plot.

Make a hexagonal binning plot of `x` versus `y`, where `x, y` are 1-D sequences of the same length, `N`. If `C` is `None` (the default), this is a histogram of the number of occurrences of the observations at `(x[i],y[i])`.

If `C` is specified, it specifies values at the coordinate `(x[i], y[i])`. These values are accumulated for each hexagonal bin and then reduced according to `reduce_C_function`, which defaults to `numpy.mean`. (If `C` is specified, it must also be a 1-D sequence of the same length as `x` and `y`.)

#### Parameters

- `x, y` [array or masked array]
- `C` [array or masked array, optional, default is `None`]
- `gridsize` [int or (int, int), optional, default is 100] The number of hexagons in the x-direction, default is 100. The corresponding number of hexagons in the y-direction is chosen such that the hexagons are approximately regular. Alternatively, `gridsize` can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.
- `bins` ['log' or int or sequence, optional, default is `None`] If `None`, no binning is applied; the color of each hexagon directly corresponds to its count value.
  - If 'log', use a logarithmic scale for the color map. Internally, $\log_{10}(i + 1)$ is used to determine the hexagon color.
  - If an integer, divide the counts in the specified number of bins, and color the hexagons accordingly.
  - If a sequence of values, the values of the lower bound of the bins to be used.
- `xscale` [{‘linear’, ‘log’}, optional, default is ‘linear’] Use a linear or log10 scale on the horizontal axis.
- `yscale` [{‘linear’, ‘log’}, optional, default is ‘linear’] Use a linear or log10 scale on the vertical axis.
- `mincnt` [int > 0, optional, default is `None`] If not `None`, only display cells with more than `mincnt` number of points in the cell.
- `marginals` [bool, optional, default is `False`] If `marginals` is `True`, plot the marginal density as colormapped rectangles along the bottom of the x-axis and left of the y-axis.
Default

showmeans=True
meanline=True

Tufte Style
(showbox=False,
showcaps=False)

notch=True
showfliers=False
I never said they'd be pretty

Custom boxprops

Custom medianprops and flierprops

Custom mean as point

Custom mean as line
**extent** [scalar, optional, default is None] The limits of the bins. The default assigns the limits based on `gridsize`, `x`, `yscale`, and `yscale`.

If `yscale` or `yscale` is set to 'log', the limits are expected to be the exponent for a power of 10. E.g. for x-limits of 1 and 50 in 'linear' scale and y-limits of 10 and 1000 in 'log' scale, enter (1, 50, 1, 3).

Order of scalars is (left, right, bottom, top).

**Returns**

**polycollection** A `PolyCollection` instance; use `PolyCollection.get_array` on this to get the counts in each hexagon.

If `marginals` is True, horizontal bar and vertical bar (both PolyCollections) will be attached to the return collection as attributes `hbar` and `vbar`.

**Other Parameters**

**cmap** [object, optional, default is None] a `matplotlib.colors.Colormap` instance. If None, defaults to rc `image.cmap`.

**norm** [object, optional, default is None] `matplotlib.colors.Normalize` instance is used to scale luminance data to 0,1.

**vmin, vmax** [scalar, optional, default is None] `vmin` and `vmax` are used in conjunction with `norm` to normalize luminance data. If None, the min and max of the color array `C` are used. Note if you pass a norm instance your settings for `vmin` and `vmax` will be ignored.

**alpha** [scalar between 0 and 1, optional, default is None] the alpha value for the patches

**linewidths** [scalar, optional, default is None] If None, defaults to 1.0.

**edgecolors** [‘face’, ‘none’, None] or color, optional] If ‘face’ (the default), draws the edges in the same color as the fill color.

If ‘none’, no edge is drawn; this can sometimes lead to unsightly unpainted pixels between the hexagons.

If None, draws outlines in the default color.

If a matplotlib color arg, draws outlines in the specified color.

**Notes**

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[arg]:

- All arguments with the following names: 'x', 'y'.

Objects passed as data must support item access (data[arg]) and membership test (arg in data).

**matplotlib.axes.Axes.hist**

Axes.hist(self, x, bins=None, range=None, density=None, weights=None, cumulative=False, bottom=None, histtype='bar', align='mid', orientation='vertical', rwidth=None, log=False, color=None, label=None, stacked=False, normed=None, *, data=None, **kwargs)

Plot a histogram.
Compute and draw the histogram of \( x \). The return value is a tuple \((n, \text{bins}, \text{patches})\) or \(([n_0, n_1, \ldots], \text{bins}, [\text{patches}_0, \text{patches}_1, \ldots])\) if the input contains multiple data. See the documentation of the \texttt{weights} parameter to draw a histogram of already-binned data.

Multiple data can be provided via \( x \) as a list of datasets of potentially different length ([\( x_0, x_1, \ldots \)]), or as a 2-D ndarray in which each column is a dataset. Note that the ndarray form is transposed relative to the list form.

Masked arrays are not supported at present.

**Parameters**

\( x \) [(\( n, \) array or sequence of (\( n, \) arrays)] Input values, this takes either a single array or a sequence of arrays which are not required to be of the same length.

\textbf{bins} [int or sequence or str, optional] If an integer is given, \( \text{bins} + 1 \) bin edges are calculated and returned, consistent with \texttt{numpy.histogram}.

If \( \text{bins} \) is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, \( \text{bins} \) is returned unmodified.

All but the last (righthand-most) bin is half-open. In other words, if \( \text{bins} \) is:

\[
[1, 2, 3, 4]
\]

then the first bin is \( [1, 2) \) (including 1, but excluding 2) and the second \( [2, 3) \). The last bin, however, is \( [3, 4) \), which \textit{includes} 4.

Unequally spaced bins are supported if \( \text{bins} \) is a sequence.

With Numpy 1.11 or newer, you can alternatively provide a string describing a binning strategy, such as ‘auto’, ‘sturges’, ‘fd’, ‘doane’, ‘scott’, ‘rice’ or ‘sqrt’, see \texttt{numpy.histogram}.

The default is taken from \texttt{rcParams["hist.bins"]}.

\textbf{range} [tuple or None, optional] The lower and upper range of the bins. Lower and upper outliers are ignored. If not provided, \( \text{range} \) is \((x.\text{min}(), x.\text{max}())\). Range has no effect if \( \text{bins} \) is a sequence.

If \( \text{bins} \) is a sequence or \( \text{range} \) is specified, autoscaling is based on the specified bin range instead of the range of \( x \).

Default is None

\textbf{density} [bool, optional] If \texttt{True}, the first element of the return tuple will be the counts normalized to form a probability density, i.e., the area (or integral) under the histogram will sum to 1. This is achieved by dividing the count by the number of observations times the bin width and not dividing by the total number of observations. If \texttt{stacked} is also \texttt{True}, the sum of the histograms is normalized to 1.

Default is None for both \texttt{normed} and \texttt{density}. If either is set, then that value will be used. If neither are set, then the args will be treated as \texttt{False}.

If both \texttt{density} and \texttt{normed} are set an error is raised.

\textbf{weights} [(\( n, \) array_like or None, optional] An array of weights, of the same shape as \( x \). Each value in \( x \) only contributes its associated weight towards the bin count (instead of 1). If \texttt{normed} or \texttt{density} is \texttt{True}, the
weights are normalized, so that the integral of the density over the range remains 1.
Default is None.
This parameter can be used to draw a histogram of data that has already been binned, e.g. using np.histogram (by treating each bin as a single point with a weight equal to its count)

```python
counts, bins = np.histogram(data)
plt.hist(bins[:-1], bins, weights=counts)
```
(or you may alternatively use bar()).

cumulative [bool, optional] If True, then a histogram is computed where each bin gives the counts in that bin plus all bins for smaller values. The last bin gives the total number of datapoints. If normed or density is also True then the histogram is normalized such that the last bin equals 1. If cumulative evaluates to less than 0 (e.g., -1), the direction of accumulation is reversed. In this case, if normed and/or density is also True, then the histogram is normalized such that the first bin equals 1.
Default is False

default {array_like, scalar, or None] Location of the bottom baseline of each bin. If a scalar, the base line for each bin is shifted by the same amount. If an array, each bin is shifted independently and the length of bottom must match the number of bins. If None, defaults to 0.
Default is None

• ‘bar’ is a traditional bar-type histogram. If multiple data are given the bars are arranged side by side.
• ‘barstacked’ is a bar-type histogram where multiple data are stacked on top of each other.
• ‘step’ generates a lineplot that is by default unfilled.
• ‘stepfilled’ generates a lineplot that is by default filled.
Default is ‘bar’

align [{‘left’, ‘mid’, ‘right’}, optional] Controls how the histogram is plotted.
• ‘left’: bars are centered on the left bin edges.
• ‘mid’: bars are centered between the bin edges.
• ‘right’: bars are centered on the right bin edges.
Default is ‘mid’

orientation [{‘horizontal’, ‘vertical’}, optional] If ‘horizontal’, barh will be used for bar-type histograms and the bottom kwarg will be the left edges.

rwidth [scalar or None, optional] The relative width of the bars as a fraction of the bin width. If None, automatically compute the width.
Ignored if histtype is ‘step’ or ‘stepfilled’.
Default is None

**log** [bool, optional] If True, the histogram axis will be set to a log scale. If log is True and x is a 1D array, empty bins will be filtered out and only the non-empty (n, bins, patches) will be returned.

Default is False

**color** [color or array like of colors or None, optional] Color spec or sequence of color specs, one per dataset. Default (None) uses the standard line color sequence.

Default is None

**label** [str or None, optional] String, or sequence of strings to match multiple datasets. Bar charts yield multiple patches per dataset, but only the first gets the label, so that the legend command will work as expected.

default is None

**stacked** [bool, optional] If True, multiple data are stacked on top of each other. If False, multiple data are arranged side by side if histtype is 'bar' or on top of each other if histtype is 'step'.

Default is False

**normed** [bool, optional] Deprecated; use the density keyword argument instead.

Returns

**n** [array or list of arrays] The values of the histogram bins. See density and weights for a description of the possible semantics. If input x is an array, then this is an array of length nbins. If input is a sequence of arrays [data1, data2,...], then this is a list of arrays with the values of the histograms for each of the arrays in the same order. The dtype of the array n (or of its element arrays) will always be float even if no weighting or normalization is used.

**bins** [array] The edges of the bins. Length nbins + 1 (nbins left edges and right edge of last bin). Always a single array even when multiple data sets are passed in.

**patches** [list or list of lists] Silent list of individual patches used to create the histogram or list of such list if multiple input datasets.

Other Parameters

****kwargs [Patch properties]

See also:

**hist2d** 2D histograms

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

936 Chapter 17. Modules
• All arguments with the following names: ‘weights’, ‘x’.
Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.hist

• sphx_glr_gallery_statistics_histogram_features.py
• sphx_glr_gallery_pyplots_fig_axes_labels_simple.py
• sphx_glr_gallery_misc_histogram_path.py

matplotlib.axes.Axes.hist2d

Axes.hist2d(self, x, y, bins=10, range=None, density=False, weights=None, cmin=None, cmax=None, *, data=None, **kwargs)
Make a 2D histogram plot.

Parameters

x, y [array_like, shape (n, )] Input values

bins [None or int or [int, int] or array_like or [array, array]] The bin specification:
• If int, the number of bins for the two dimensions (nx=ny=bins).
• If [int, int], the number of bins in each dimension (nx, ny = bins).
• If array_like, the bin edges for the two dimensions (x_edges=y_edges=bins).
• If [array, array], the bin edges in each dimension (x_edges, y_edges = bins).
The default value is 10.

range [array_like shape(2, 2), optional, default: None] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the bins parameters): [[xmin, xmax], [ymin, ymax]]. All values outside of this range will be considered outliers and not tallied in the histogram.

density [bool, optional, default: False] Normalize histogram. normed is a deprecated synonym for this parameter.

weights [array_like, shape (n, ), optional, default: None] An array of values w_i weighing each sample (x_i, y_i).

cmin [scalar, optional, default: None] All bins that has count less than cmin will not be displayed and these count values in the return value count histogram will also be set to nan upon return.

cmax [scalar, optional, default: None] All bins that has count more than cmax will not be displayed (set to none before passing to imshow) and these count values in the return value count histogram will also be set to nan upon return.
Returns

- **h** [2D array] The bi-dimensional histogram of samples x and y. Values in x are histogrammed along the first dimension and values in y are histogrammed along the second dimension.

- **xedges** [1D array] The bin edges along the x axis.

- **yedges** [1D array] The bin edges along the y axis.

- **image** [QuadMesh]

Other Parameters

- **cmap** [Colormap or str, optional] A `colors.Colormap` instance. If not set, use rc settings.

- **norm** [Normalize, optional] A `colors.Normalize` instance is used to scale luminance data to [0, 1]. If not set, defaults to `colors.Normalize()`.

- **vmin/vmax** [None or scalar, optional] Arguments passed to the `Normalize` instance.

- **alpha** [0 <= scalar <= 1 or None, optional] The alpha blending value.

See also:

**hist** 1D histogram plotting

Notes

- Currently `hist2d` calculates its own axis limits, and any limits previously set are ignored.

- Rendering the histogram with a logarithmic color scale is accomplished by passing a `colors.LogNorm` instance to the `norm` keyword argument. Likewise, power-law normalization (similar in effect to gamma correction) can be accomplished with `colors.PowerNorm`.

Note: In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘weights’, ‘x’, ‘y’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

Examples using `matplotlib.axes.Axes.hist2d`

- `sphx_glr_gallery_scales_power_norm.py`

Contours
Aaxes.clabel

Label a contour plot.

Aaxes.contour

Plot contours.

Aaxes.contourf

Plot contours.

**matplotlib.axes.Axes.clabel**

Aaxes.clabel(self, CS, *args, **kwargs)

Label a contour plot.

Call signature:

```python
clabel(cs, [levels,] **kwargs)
```

Adds labels to line contours in `cs`, where `cs` is a `ContourSet` object returned by `contour()`.

**Parameters**

- `cs` [`ContourSet`] The `ContourSet` to label.
- `levels` [array-like, optional] A list of level values, that should be labeled. The list must be a subset of `cs.levels`. If not given, all levels are labeled.
- `fontsize` [string or float, optional] Size in points or relative size e.g., ‘smaller’, ‘x-large’. See `Text.set_size` for accepted string values.
- `colors` [color-spec, optional] The label colors:
  - If `None`, the color of each label matches the color of the corresponding contour.
  - If one string color, e.g., `colors = 'r'` or `colors = 'red'`, all labels will be plotted in this color.
  - If a tuple of matplotlib color args (string, float, rgb, etc), different labels will be plotted in different colors in the order specified.
- `inline` [bool, optional] If True, the underlying contour is removed where the label is placed. Default is True.
- `inline_spacing` [float, optional] Space in pixels to leave on each side of label when placing inline. Defaults to 5.
  
  This spacing will be exact for labels at locations where the contour is straight, less so for labels on curved contours.
- `fmt` [string or dict, optional] A format string for the label. Default is ‘%1.3f’
  
  Alternatively, this can be a dictionary matching contour levels with arbitrary strings to use for each contour level (i.e., `fmt[level]=string`), or it can be any callable, such as a `Formatter` instance, that returns a string when called with a numeric contour level.
- `manual` [bool or iterable, optional] If True, contour labels will be placed manually using mouse clicks. Click the first button near a contour to add a label, click the second button (or potentially both mouse buttons at once) to finish adding labels. The third button can be used to remove the last label added, but only if labels are not inline. Alternatively, the keyboard can be used to select label locations (enter to end label placement, delete or backspace act like the third mouse button, and any other key will select a label location).
can also be an iterable object of x,y tuples. Contour labels will be created as if mouse is clicked at each x,y positions.

**rightside_up** [bool, optional] If True, label rotations will always be plus or minus 90 degrees from level. Default is True.

**use_clabeltext** [bool, optional] If True, `ClabelText` class (instead of `Text`) is used to create labels. `ClabelText` recalculates rotation angles of texts during the drawing time, therefore this can be used if aspect of the axes changes. Default is False.

**Returns**

*labels* A list of `Text` instances for the labels.

**Examples using matplotlib.axes.Axes.clabel**

- sphx_glr_gallery_images_contours_and_fields_contour_demo.py
- sphx_glr_gallery_images_contours_and_fields_contour_label_demo.py
- sphx_glr_gallery_images_contours_and_fields_contourf_demo.py

**matplotlib.axes.Axes.contour**

```python
Axes.contour(self, *args, data=None, **kwargs)
```

Plot contours.

Call signature:

```python
contour([X, Y,] Z, [levels], **kwargs)
```

`contour` and `contourf` draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

**Parameters**

**X, Y** [array-like, optional] The coordinates of the values in Z.

X and Y must both be 2-D with the same shape as Z (e.g. created via `numpy.meshgrid`), or they must both be 1-D such that `len(X) == M` is the number of columns in Z and `len(Y) == N` is the number of rows in Z.

If not given, they are assumed to be integer indices, i.e. `X = range(M), Y = range(N).

**Z** [array-like(N, M)] The height values over which the contour is drawn.

**levels** [int or array-like, optional] Determines the number and positions of the contour lines / regions.

If an int n, use n data intervals; i.e. draw `n+1` contour lines. The level heights are automatically chosen.

If array-like, draw contour lines at the specified levels. The values must be in increasing order.

**Returns**

**c** [QuadContourSet]
Other Parameters

**corner_mask** [bool, optional] Enable/disable corner masking, which only has an effect if Z is a masked array. If `False`, any quad touching a masked point is masked out. If `True`, only the triangular corners of quads nearest those points are always masked out, other triangular corners comprising three unmasked points are contoured as usual.

Defaults to `rcParams["contour.corner_mask"]`, which defaults to `True`.

**colors** [color string or sequence of colors, optional] The colors of the levels, i.e. the lines for `contour` and the areas for `contourf`.

The sequence is cycled for the levels in ascending order. If the sequence is shorter than the number of levels, it’s repeated.

As a shortcut, single color strings may be used in place of one-element lists, i.e. `"red"` instead of `['red']` to color all levels with the same color. This shortcut does only work for color strings, not for other ways of specifying colors.

By default (value `None`), the colormap specified by `cmap` will be used.

**alpha** [float, optional] The alpha blending value, between 0 (transparent) and 1 (opaque).

**cmap** [str or `Colormap`, optional] A `Colormap` instance or registered colormap name. The colormap maps the level values to colors. Defaults to `rcParams["image.cmap"]`.

If given, `colors` take precedence over `cmap`.

**norm** [`Normalize`, optional] If a colormap is used, the `Normalize` instance scales the level values to the canonical colormap range [0, 1] for mapping to colors. If not given, the default linear scaling is used.

**vmin, vmax** [float, optional] If not `None`, either or both of these values will be supplied to the `Normalize` instance, overriding the default color scaling based on `levels`.

**origin** [{`None`, ‘upper’, ‘lower’, ‘image’}, optional] Determines the orientation and exact position of Z by specifying the position of Z[0, 0]. This is only relevant, if X, Y are not given.

- `None`: Z[0, 0] is at X=0, Y=0 in the lower left corner.
- ‘lower’: Z[0, 0] is at X=0.5, Y=0.5 in the lower left corner.
- ‘upper’: Z[0, 0] is at X=N+0.5, Y=0.5 in the upper left corner.
- ‘image’: Use the value from `rcParams["image.origin"]`.

**extent** [(x0, x1, y0, y1), optional] If `origin` is not `None`, then `extent` is interpreted as in `imshow`. It gives the outer pixel boundaries. In this case, the position of Z[0,0] is the center of the pixel, not a corner. If `origin` is `None`, then (x0, y0) is the position of Z[0,0], and (x1, y1) is the position of Z[-1,-1].

This argument is ignored if X and Y are specified in the call to contour.

**locator** [ticker.Locator subclass, optional] The locator is used to determine the contour levels if they are not given explicitly via `levels`. Defaults to `MaskLocator`.
**extend** [{‘neither’, ‘both’, ‘min’, ‘max’}, optional, default: ‘neither’] Determines the contour-coloring of values that are outside the *levels* range.

If ‘neither’, values outside the *levels* range are not colored. If ‘min’, ‘max’ or ‘both’, color the values below, above or below and above the *levels* range.

Values below \(\text{min}(\text{levels})\) and above \(\text{max}(\text{levels})\) are mapped to the under/over values of the *Colormap*. Note, that most colormaps do not have dedicated colors for these by default, so that the over and under values are the edge values of the colormap. You may want to set these values explicitly using *Colormap.set_under* and *Colormap.set_over*.

**Note:** An existing *QuadContourSet* does not get notified if properties of its colormap are changed. Therefore, an explicit call *QuadContourSet.changed()* is needed after modifying the colormap. The explicit call can be left out, if a colorbar is assigned to the *QuadContourSet* because it internally calls *QuadContourSet.changed()*.

Example:

```python
x = np.arange(1, 10)
y = x.reshape(-1, 1)
h = x * y

cs = plt.contourf(h, levels=[10, 30, 50],
                 colors=['#808080', '#A0A0A0', '#C0C0C0'], extend='both')
cs.cmap.set_over('red')
cs.cmap.set_under('blue')
cs.changed()
```

**xunits, yunits** [registered units, optional] Override axis units by specifying an instance of a *matplotlib.units.ConversionInterface*.

**antialiased** [bool, optional] Enable antialiasing, overriding the defaults. For filled contours, the default is *True*. For line contours, it is taken from *rcParams*["lines.antialiased"].

**Nchunk** [int >= 0, optional] If 0, no subdivision of the domain. Specify a positive integer to divide the domain into subdomains of *nchunk* by *nchunk* quads. Chunking reduces the maximum length of polygons generated by the contouring algorithm which reduces the rendering workload passed on to the backend and also requires slightly less RAM. It can however introduce rendering artifacts at chunk boundaries depending on the backend, the *antialiased* flag and value of *alpha*.

**lineweight** [float or sequence of float, optional] Only applies to *contour*. The line width of the contour lines.

If a number, all levels will be plotted with this linewidth.

If a sequence, the levels in ascending order will be plotted with the linewidths in the order specified.

Defaults to *rcParams*["lines.linewidth"].

If *linestyles* is *None*, the default is ‘solid’ unless the lines are monochrome. In that case, negative contours will take their linestyle from *rcParams["contour.negative_linestyle"]* setting.

*linestyles* can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

**hatches** [List[str], optional] Only applies to *contourf*.

A list of cross hatch patterns to use on the filled areas. If None, no hatching will be added to the contour. Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

**Notes**

1. *contourf* differs from the MATLAB version in that it does not draw the polygon edges. To draw edges, add line contours with calls to *contour*.

2. *contourf* fills intervals that are closed at the top; that is, for boundaries *z1* and *z2*, the filled region is:

   \[ z1 < Z \leq z2 \]

   except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

**Examples using matplotlib.axes.Axes.contour**

- sphx_glr_gallery_images_contours_and_fields_contour_corner_mask.py
- sphx_glr_gallery_images_contours_and_fields_contour_demo.py
- sphx_glr_gallery_images_contours_and_fields_contour_image.py
- sphx_glr_gallery_images_contours_and_fields_contour_label_demo.py
- sphx_glr_gallery_images_contours_and_fields_contourf_demo.py
- sphx_glr_gallery_images_contours_and_fields_contourf_hatching.py
- sphx_glr_gallery_images_contours_and_fields_image_transparency_blend.py
- sphx_glr_gallery_images_contours_and_fields_irregulardatagrid.py

**matplotlib.axes.Axes.contourf**

*Axes.contourf*(self, *args, data=None, **kwargs)

Plot contours.

Call signature:

\[
\text{contour}([X, Y,] Z, [levels], **kwargs)
\]
contour and contourf draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

Parameters

**X, Y** [array-like, optional] The coordinates of the values in Z.

X and Y must both be 2-D with the same shape as Z (e.g. created via numpy.meshgrid), or they must both be 1-D such that len(X) == M is the number of columns in Z and len(Y) == N is the number of rows in Z.

If not given, they are assumed to be integer indices, i.e. X = range(M), Y = range(N).

**Z** [array-like(N, M)] The height values over which the contour is drawn.

**levels** [int or array-like, optional] Determines the number and positions of the contour lines / regions.

If an int n, use n data intervals; i.e. draw n+1 contour lines. The level heights are automatically chosen.

If array-like, draw contour lines at the specified levels. The values must be in increasing order.

Returns

**c** [QuadContourSet]

Other Parameters

**corner_mask** [bool, optional] Enable/disable corner masking, which only has an effect if Z is a masked array. If False, any quad touching a masked point is masked out. If True, only the triangular corners of quads nearest those points are always masked out, other triangular corners comprising three unmasked points are contoured as usual.

Defaults to rcParams["contour.corner_mask"], which defaults to True.

**colors** [color string or sequence of colors, optional] The colors of the levels, i.e. the lines for contour and the areas for contourf.

The sequence is cycled for the levels in ascending order. If the sequence is shorter than the number of levels, it’s repeated.

As a shortcut, single color strings may be used in place of one-element lists, i.e. 'red' instead of ['red'] to color all levels with the same color. This shortcut does only work for color strings, not for other ways of specifying colors.

By default (value None), the colormap specified by cmap will be used.

**alpha** [float, optional] The alpha blending value, between 0 (transparent) and 1 (opaque).

**cmap** [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps the level values to colors. Defaults to rcParams["image.cmap"].

If given, colors take precedence over cmap.

**norm** [Normalize, optional] If a colormap is used, the Normalize instance scales the level values to the canonical colormap range [0, 1] for mapping to colors. If not given, the default linear scaling is used.
**vmin, vmax** [float, optional] If not *None*, either or both of these values will be supplied to the *Normalize* instance, overriding the default color scaling based on *levels*.

**origin** [{*None*, ‘upper’, ‘lower’, ‘image’}, optional] Determines the orientation and exact position of $Z$ by specifying the position of $Z[0, 0]$. This is only relevant, if $X$, $Y$ are not given.

- *None*: $Z[0, 0]$ is at $X=0, Y=0$ in the lower left corner.
- ‘lower’: $Z[0, 0]$ is at $X=0.5, Y=0.5$ in the lower left corner.
- ‘upper’: $Z[0, 0]$ is at $X=N+0.5, Y=0.5$ in the upper left corner.
- ‘image’: Use the value from rcParams["image.origin"].

**extent** [(x0, x1, y0, y1), optional] If *origin* is not *None*, then *extent* is interpreted as in *imshow*: it gives the outer pixel boundaries. In this case, the position of $Z[0,0]$ is the center of the pixel, not a corner. If *origin* is *None*, then $(x0, y0)$ is the position of $Z[0,0]$, and $(xI, yI)$ is the position of $Z[-1,-1]$.

This argument is ignored if $X$ and $Y$ are specified in the call to contour.

**locator** [ticker.Locator subclass, optional] The locator is used to determine the contour levels if they are not given explicitly via *levels*. Defaults to *MaxNLocator*.

**extend** [{‘neither’, ‘both’, ‘min’, ‘max’}, optional, default: ‘neither’] Determines the *contourf*-coloring of values that are outside the *levels* range.

If ‘neither’, values outside the *levels* range are not colored. If ‘min’, ‘max’ or ‘both’, color the values below, above or below and above the *levels* range.

Values below $\text{min(levels)}$ and above $\text{max(levels)}$ are mapped to the under/over values of the *Colormap*. Note, that most colormaps do not have dedicated colors for these by default, so that the over and under values are the edge values of the colormap. You may want to set these values explicitly using *Colormap.set_under* and *Colormap.set_over*.

**Note:** An existing *QuadContourSet* does not get notified if properties of its colormap are changed. Therefore, an explicit call *QuadContourSet.changed()* is needed after modifying the colormap. The explicit call can be left out, if a colorbar is assigned to the *QuadContourSet* because it internally calls *QuadContourSet.changed()*.

**Example:**

```python
x = np.arange(1, 10)
y = x.reshape(-1, 1)
h = x * y

cs = plt.contourf(h, levels=[10, 30, 50],
                 colors=['#808080', '#A0A0A0', '#C0C0C0'], extend='both')

cs.cmap.set_over('red')

cs.cmap.set_under('blue')

cs.changed()
```
**xunits, yunits** [registered units, optional] Override axis units by specifying an instance of a `matplotlib.units.ConversionInterface`.

**antialiased** [bool, optional] Enable antialiasing, overriding the defaults. For filled contours, the default is `True`. For line contours, it is taken from `rcParams["lines.antialiased"]`.

**Nchunk** [int >= 0, optional] If 0, no subdivision of the domain. Specify a positive integer to divide the domain into subdomains of `nchunk` by `nchunk` quads. Chunking reduces the maximum length of polygons generated by the contouring algorithm which reduces the rendering workload passed on to the backend and also requires slightly less RAM. It can however introduce rendering artifacts at chunk boundaries depending on the backend, the `antialiased` flag and value of `alpha`.

**linewidths** [float or sequence of float, optional] Only applies to `contour`.

The line width of the contour lines.

- If a number, all levels will be plotted with this linewidth.
- If a sequence, the levels in ascending order will be plotted with the linewidths in the order specified.

Defaults to `rcParams["lines.linewidth"]`.

**linestyles** [{None, 'solid', 'dashed', 'dashdot', 'dotted'}, optional] Only applies to `contour`.

If `linestyles` is `None`, the default is 'solid' unless the lines are monochrome. In that case, negative contours will take their linestyle from `rcParams["contour.negative_linestyle"]` setting.

`linestyles` can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

**hatches** [List[str], optional] Only applies to `contourf`.

A list of cross hatch patterns to use on the filled areas. If None, no hatching will be added to the contour. Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

### Notes

1. `contourf` differs from the MATLAB version in that it does not draw the polygon edges. To draw edges, add line contours with calls to `contour`.

2. `contourf` fills intervals that are closed at the top; that is, for boundaries `z1` and `z2`, the filled region is:

   \[ z_1 < Z \leq z_2 \]

   except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

matplotlib.axes.Axes.imshow

Axes.imshow(self, X, cmap=None, norm=None, aspect=None, interpolation=None, alpha=None, vmin=None, vmax=None, origin=None, extent=None, shape=<deprecated parameter>, filternorm=1, filterrad=4.0, imlim=<deprecated parameter>, resample=None, url=None, *, data=None, **kwargs)

Display an image, i.e. data on a 2D regular raster.

Parameters

X [array-like or PIL image] The image data. Supported array shapes are:

• (M, N): an image with scalar data. The data is visualized using a colormap.
• (M, N, 3): an image with RGB values (0-1 float or 0-255 int).
• (M, N, 4): an image with RGBA values (0-1 float or 0-255 int), i.e. including transparency.

The first two dimensions (M, N) define the rows and columns of the image.

Out-of-range RGB(A) values are clipped.

cmap [str or Colormap, optional] The Colormap instance or registered colormap name used to map scalar data to colors. This parameter is ignored for RGB(A) data. Defaults to rcParams["image.cmap"].

norm [Normalize, optional] The Normalize instance used to scale scalar data to the [0, 1] range before mapping to colors using cmap. By default, a
linear scaling mapping the lowest value to 0 and the highest to 1 is used. This parameter is ignored for RGBA data.

**aspect** [{‘equal’, ‘auto’} or float, optional] Controls the aspect ratio of the axes. The aspect is of particular relevance for images since it may distort the image, i.e. pixel will not be square.

This parameter is a shortcut for explicitly calling `Axes.set_aspect`. See there for further details.

- ‘equal’: Ensures an aspect ratio of 1. Pixels will be square (unless pixel sizes are explicitly made non-square in data coordinates using `extent`).
- ‘auto’: The axes is kept fixed and the aspect is adjusted so that the data fit in the axes. In general, this will result in non-square pixels.

If not given, use `rcParams["image.aspect"]` (default: ‘equal’).

**interpolation** [str, optional] The interpolation method used. If `None` `rcParams["image.interpolation"]` is used, which defaults to ‘nearest’.

If `interpolation` is ‘none’, then no interpolation is performed on the Agg, ps, pdf and svg backends. Other backends will fall back to ‘nearest’. Note that most SVG renders perform interpolation at rendering and that the default interpolation method they implement may differ.

See `/gallery/images_contours_and_fields/interpolation_methods` for an overview of the supported interpolation methods.

Some interpolation methods require an additional radius parameter, which can be set by `filterrad`. Additionally, the antigrain image resize filter is controlled by the parameter `filternorm`.

**alpha** [scalar, optional] The alpha blending value, between 0 (transparent) and 1 (opaque). This parameter is ignored for RGBA input data.

**vmin, vmax** [scalar, optional] When using scalar data and no explicit `norm`, `vmin` and `vmax` define the data range that the colormap covers. By default, the colormap covers the complete value range of the supplied data. `vmin, vmax` are ignored if the `norm` parameter is used.

**origin** [{‘upper’, ‘lower’}, optional] Place the [0,0] index of the array in the upper left or lower left corner of the axes. The convention ‘upper’ is typically used for matrices and images. If not given, `rcParams["image.origin"]` is used, defaulting to ‘upper’.

Note that the vertical axes points upward for ‘lower’ but downward for ‘upper’.

See the `origin and extent in imshow` tutorial for examples and a more detailed description.

**extent** [scalars (left, right, bottom, top), optional] The bounding box in data coordinates that the image will fill. The image is stretched individually along x and y to fill the box.

The default extent is determined by the following conditions. Pixels have unit size in data coordinates. Their centers are on integer coordinates,
and their center coordinates range from 0 to columns-1 horizontally and from 0 to rows-1 vertically.

Note that the direction of the vertical axis and thus the default values for top and bottom depend on `origin`:

- For `origin == 'upper'` the default is `(-0.5, numcols-0.5, numrows-0.5, -0.5)`.
- For `origin == 'lower'` the default is `(-0.5, numcols-0.5, -0.5, numrows-0.5)`.

See the `origin and extent in imshow` tutorial for examples and a more detailed description.

**filtnorm** [bool, optional, default: True] A parameter for the antigrain image resize filter (see the antigrain documentation). If `filtnorm` is set, the filter normalizes integer values and corrects the rounding errors. It doesn’t do anything with the source floating point values, it corrects only integers according to the rule of 1.0 which means that any sum of pixel weights must be equal to 1.0. So, the filter function must produce a graph of the proper shape.

**filterrad** [float > 0, optional, default: 4.0] The filter radius for filters that have a radius parameter, i.e. when interpolation is one of: ‘sinc’, ‘lanczos’ or ‘blackman’.

**resample** [bool, optional] When `True`, use a full resampling method. When `False`, only resample when the output image is larger than the input image.

**url** [str, optional] Set the url of the created `AxesImage`. See `Artist.set_url`.

**Returns**

- **image** [`AxesImage`]

**Other Parameters**

- ****kwargs** [Artist properties] These parameters are passed on to the constructor of the `AxesImage` artist.

**See also:**

- **matshow** Plot a matrix or an array as an image.

**Notes**

Unless `extent` is used, pixel centers will be located at integer coordinates. In other words: the origin will coincide with the center of pixel (0, 0).

There are two common representations for RGB images with an alpha channel:

- Straight (unassociated) alpha: R, G, and B channels represent the color of the pixel, disregarding its opacity.
- Premultiplied (associated) alpha: R, G, and B channels represent the color of the pixel, adjusted for its opacity by multiplication.

`imshow` expects RGB images adopting the straight (unassociated) alpha representation.
Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[key]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[key]) and membership test (key in data).

- sphx_glr_gallery_color.custom.cmap.py

matplotlib.axes.Axes.matshow

Axes.matshow(self, Z, **kwargs)
Plot the values of a 2D matrix or array as color-coded image.

The matrix will be shown the way it would be printed, with the first row at the top. Row and column numbering is zero-based.

Parameters

- Z [array-like(M, N)] The matrix to be displayed.

Returns
image [AxesImage]

Other Parameters

**kwargs [imshow arguments]

See also:

imshow More general function to plot data on a 2D regular raster.

Notes

This is just a convenience function wrapping imshow to set useful defaults for a displaying a matrix. In particular:

- Set origin='upper'.
- Set interpolation='nearest'.
- Set aspect='equal'.
- Ticks are placed to the left and above.
- Ticks are formatted to show integer indices.

Examples using matplotlib.axes.Axes.matshow

- sphx_glr_gallery_images_contours_and_fields_matshow.py

matplotlib.axes.Axes.pcolor

Axes.pcolor(self, *args, alpha=None, norm=None, cmap=None, vmin=None, vmax=None, data=None, **kwargs)

Create a pseudocolor plot with a non-regular rectangular grid.

Call signature:

```
pcolor([X, Y,] C, **kwargs)
```

X and Y can be used to specify the corners of the quadrilaterals.

Hint: pcolor() can be very slow for large arrays. In most cases you should use the similar but much faster pcolormesh instead. See there for a discussion of the differences.

Parameters

- **C** [array_like] A scalar 2-D array. The values will be color-mapped.
- **X, Y** [array_like, optional] The coordinates of the quadrilateral corners. The quadrilateral for C[i,j] has corners at:
Note that the column index corresponds to the x-coordinate, and the row index corresponds to y. For details, see the Notes section below.

The dimensions of X and Y should be one greater than those of C. Alternatively, X, Y and C may have equal dimensions, in which case the last row and column of C will be ignored.

If X and/or Y are 1-D arrays or column vectors they will be expanded as needed into the appropriate 2-D arrays, making a rectangular grid.

**cmap** [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps the C values to colors. Defaults to rcParams["image.cmap"].

**norm** [Normalize, optional] The Normalize instance scales the data values to the canonical colormap range [0, 1] for mapping to colors. By default, the data range is mapped to the colorbar range using linear scaling.

**vmin, vmax** [scalar, optional, default: None] The colorbar range. If None, suitable min/max values are automatically chosen by the Normalize instance (defaults to the respective min/max values of C in case of the default linear scaling).

**edgecolors** [{‘none’, None, ‘face’, color, color sequence}, optional] The color of the edges. Defaults to ‘none’. Possible values:

- ‘none’ or ‘": No edge.
- None: rcParams["patch.edgecolor"] will be used. Note that currently rcParams["patch.force_edgecolor"] has to be True for this to work.
- ‘face’: Use the adjacent face color.
- An mpl color or sequence of colors will set the edge color.

The singular form edgecolor works as an alias.

**alpha** [scalar, optional, default: None] The alpha blending value of the face color, between 0 (transparent) and 1 (opaque). Note: The edgecolor is currently not affected by this.

**snap** [bool, optional, default: False] Whether to snap the mesh to pixel boundaries.

**Returns**

**collection** [matplotlib.collections.Collection]

**Other Parameters**

**antialiaseds** [bool, optional, default: False] The default antialiaseds is False if the default edgecolors=“none” is used. This eliminates artificial lines at patch boundaries, and works regardless of the value of alpha. If edgecolors is not “none”, then the default antialiaseds is taken from rcParams["patch.antialiased"], which defaults to True. Stroking the edges may be preferred if alpha is 1, but will cause artifacts otherwise.
**kwargs Additionally, the following arguments are allowed. They are passed along to the `PolyCollection` constructor:

</tbody>
</table>

**See also:**

- `pcolormesh` for an explanation of the differences between pcolor and pcolormesh.
- `imshow` If X and Y are each equidistant, `imshow` can be a faster alternative.

**Notes**

**Masked arrays**
X, Y and C may be masked arrays. If either c[i, j], or one of the vertices surrounding 
c[i, j] (X or Y at [i, j], [i+1, j], [i, j+1], [i+1, j+1]) is masked, nothing is plotted.

**Grid orientation**

The grid orientation follows the standard matrix convention: An array C with shape 
(nrows, ncolumns) is plotted with the column number as X and the row number as Y.

**Handling of pcolor() end-cases**

pcolor() displays all columns of C if X and Y are not specified, or if X and Y have one 
more column than C. If X and Y have the same number of columns as C then the last 
column of C is dropped. Similarly for the rows.

Note: This behavior is different from MATLAB’s pcolor(), which always discards the last 
row and column of C.

---

**Note:** In addition to the above described arguments, this function can take a data key-
word argument. If such a data argument is given, the following arguments are replaced 
by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test 
(<arg> in data).

---

**Examples using matplotlib.axes.Axes.pcolor**

- sphx_glr_gallery_images_contours_and_fields_pcolor_demo.py
- sphx_glr_gallery_subplots_axes_and_figures_axesMargins.py

**matplotlib.axes.Axes.pcolorfast**

Axes.pcolorfast(self, *args, alpha=None, norm=None, cmap=None, vmin=None, 
vmax=None, data=None, **kwargs)

Create a pseudocolor plot with a non-regular rectangular grid.

Call signature:

```python
tax.pcolorfast([X, Y], C, /, **kwargs)
```

This method is similar to ~Axes.pcolor’ and pcolormesh. It’s designed to provide the 
fastest pcolor-type plotting with the Agg backend. To achieve this, it uses different al-
gorithms internally depending on the complexity of the input grid (regular rectangular, 
non-regular rectangular or arbitrary quadrilateral).

**Warning:** This method is experimental. Compared to pcolor or pcolormesh it has 
some limitations:

- It supports only flat shading (no outlines)
- It lacks support for log scaling of the axes.
- It does not have a have a pyplot wrapper.
Parameters

- **C** [array-like(M, N)] A 2D array or masked array. The values will be color-mapped. This argument can only be passed positionally.

  C can in some cases be 3D with the last dimension as rgb(a). This is available when C qualifies for image or pcolorimage type, will throw a TypeError if C is 3D and quadmesh.

- **X, Y** [tuple or array-like, default: (0, N), (0, M)] X and Y are used to specify the coordinates of the quadrilaterals. There are different ways to do this:
  
  - Use tuples \(X=(\text{xmin}, \text{xmax})\) and \(Y=(\text{ymin}, \text{ymax})\) to define a uniform rectangular grid.
    
    The tuples define the outer edges of the grid. All individual quadrilaterals will be of the same size. This is the fastest version.
  
  - Use 1D arrays \(X, Y\) to specify a non-uniform rectangular grid.
    
    In this case \(X\) and \(Y\) have to be monotonic 1D arrays of length \(N+1\) and \(M+1\), specifying the \(x\) and \(y\) boundaries of the cells.
    
    The speed is intermediate. Note: The grid is checked, and if found to be uniform the fast version is used.
  
  - Use 2D arrays \(X, Y\) if you need an arbitrary quadrilateral grid (i.e. if the quadrilaterals are not rectangular).
    
    In this case \(X\) and \(Y\) are 2D arrays with shape \((M, N)\), specifying the \(x\) and \(y\) coordinates of the corners of the colored quadrilaterals. See pcolormesh for details.
    
    This is the most general, but the slowest to render. It may produce faster and more compact output using ps, pdf, and svg backends, however.

These arguments can only be passed positionally.

- **cmap** [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps the \(C\) values to colors. Defaults to rcParams["image.cmap"].

- **norm** [Normalize, optional] The Normalize instance scales the data values to the canonical colormap range \([0, 1]\) for mapping to colors. By default, the data range is mapped to the colorbar range using linear scaling.

- **vmin, vmax** [scalar, optional, default: None] The colorbar range. If None, suitable min/max values are automatically chosen by the Normalize instance (defaults to the respective min/max values of \(C\) in case of the default linear scaling).

- **alpha** [scalar, optional, default: None] The alpha blending value, between 0 (transparent) and 1 (opaque).

- **snap** [bool, optional, default: False] Whether to snap the mesh to pixel boundaries.

Returns

- **image** [AxesImage or PcolorImage or QuadMesh] The return type depends on the type of grid:
  
  - **AxesImage** for a regular rectangular grid.
• **PcolorImage** for a non-regular rectangular grid.
• **QuadMesh** for a non-rectangular grid.

**Notes**

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All positional and all keyword arguments.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

**Examples using** `matplotlib.axes.Axes.pcolorfast`

- `sphx_glr_gallery_images_contours_and_fields_pcolor_demo.py`

`matplotlib.axes.Axes.pcolormesh`

```python
def pcolormesh(self, *args, alpha=None, norm=None, cmap=None, vmin=None, vmax=None, shading='flat', antialiased=False, data=None, **kwargs)
```

Call signature:

```python
color([X, Y,] C, **kwargs)
```

`X` and `Y` can be used to specify the corners of the quadrilaterals.

**Note:** `pcolormesh()` is similar to `pcolor()`. It’s much faster and preferred in most cases. For a detailed discussion on the differences see *Differences between pcolor() and pcolormesh()*.

**Parameters**

- **C** [array_like] A scalar 2-D array. The values will be color-mapped.
- **X, Y** [array_like, optional] The coordinates of the quadrilateral corners. The quadrilateral for `C[i,j]` has corners at:

```
(X[i+1, j], Y[i+1, j])  (X[i+1, j+1], Y[i+1, j+1])
+-----------+                    +-----------+
|           |                   |           |
| C[i,j]    |                   | C[i,j]    |
+-----------+                   +-----------+
(X[i, j], Y[i, j])  (X[i, j+1], Y[i, j+1]),
```
Note that the column index corresponds to the x-coordinate, and the row index corresponds to y. For details, see the *Notes* section below.

The dimensions of X and Y should be one greater than those of C. Alternatively, X, Y and C may have equal dimensions, in which case the last row and column of C will be ignored.

If X and/or Y are 1-D arrays or column vectors they will be expanded as needed into the appropriate 2-D arrays, making a rectangular grid.

cmap [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps the C values to colors. Defaults to `rcParams["image.cmap"]`.

norm [Normalize, optional] The Normalize instance scales the data values to the canonical colormap range [0, 1] for mapping to colors. By default, the data range is mapped to the colorbar range using linear scaling.

vmin, vmax [scalar, optional, default: None] The colorbar range. If None, suitable min/max values are automatically chosen by the Normalize instance (defaults to the respective min/max values of C in case of the default linear scaling).

dgecolors [{‘none’, None, ‘face’, color, color sequence}, optional] The color of the edges. Defaults to ‘none’. Possible values:

- ‘none’ or ‘’ : No edge.
- None: `rcParams["patch.edgecolor"]` will be used. Note that currently `rcParams["patch.force_edgecolor"]` has to be True for this to work.
- ‘face’: Use the adjacent face color.
- An mpl color or sequence of colors will set the edge color.

The singular form `edgecolor` works as an alias.

alpha [scalar, optional, default: None] The alpha blending value, between 0 (transparent) and 1 (opaque).

shading [{‘flat’, ‘gouraud’}, optional] The fill style. Possible values:

- ‘flat’: A solid color is used for each quad. The color of the quad (i, j), (i+1, j), (i, j+1), (i+1, j+1) is given by C[i,j].
- ‘gouraud’: Each quad will be Gouraud shaded: The color of the corners (i’, j’) are given by C[i’,j’]. The color values of the area in between is interpolated from the corner values. When Gouraud shading is used, `edgecolors` is ignored.

snap [bool, optional, default: False] Whether to snap the mesh to pixel boundaries.

Returns

mesh [matplotlib.collections.QuadMesh]

Other Parameters

**kwarsg** Additionally, the following arguments are allowed. They are passed along to the QuadMesh constructor:
<table>

**See also:**

*pcolor* An alternative implementation with slightly different features. For a detailed discussion on the differences see *Differences between pcolor() and pcolormesh()*.

*imshow* If X and Y are each equidistant, *imshow* can be a faster alternative.

**Notes**

**Masked arrays**

*C* may be a masked array. If *C[i, j]* is masked, the corresponding quadrilateral will be
transparent. Masking of $X$ and $Y$ is not supported. Use $pcolor$ if you need this functionality.

**Grid orientation**

The grid orientation follows the standard matrix convention: An array $C$ with shape (nrows, ncolumns) is plotted with the column number as $X$ and the row number as $Y$.

**Differences between $pcolor()$ and $pcolormesh()$**

Both methods are used to create a pseudocolor plot of a 2-D array using quadrilaterals. The main difference lies in the created object and internal data handling: While $pcolor$ returns a $PolyCollection$, $pcolormesh$ returns a $QuadMesh$. The latter is more specialized for the given purpose and thus is faster. It should almost always be preferred.

There is also a slight difference in the handling of masked arrays. Both $pcolor$ and $pcolormesh$ support masked arrays for $C$. However, only $pcolor$ supports masked arrays for $X$ and $Y$. The reason lies in the internal handling of the masked values. $pcolor$ leaves out the respective polygons from the $PolyCollection$. $pcolormesh$ sets the facecolor of the masked elements to transparent. You can see the difference when using edgecolors. While all edges are drawn irrespective of masking in a $QuadMesh$, the edge between two adjacent masked quadrilaterals in $pcolor$ is not drawn as the corresponding polygons do not exist in the $PolyCollection$.

Another difference is the support of Gouraud shading in $pcolormesh$, which is not available with $pcolor$.

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[[arg]]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[[arg]]) and membership test (<arg> in data).

**Examples using matplotlib.axes.Axes.pcolormesh**

- sphx_glr_gallery_images_contours_and_fields_pcolor_demo.py
- sphx_glr_gallery_images_contours_and_fields_pcolormesh_levels.py
- sphx_glr_gallery_images_contours_and_fields_quadmesh_demo.py
- Creating Colormaps in Matplotlib

**matplotlib.axes.Axes.spy**

Axes.spy(self, Z, precision=0, marker=None, markersize=None, aspect='equal', origin='upper', **kwargs)

Plot the sparsity pattern of a 2D array.

This visualizes the non-zero values of the array.

Two plotting styles are available: image and marker. Both are available for full arrays, but only the marker style works for scipy.sparse.spmatrix instances.
Image style

If `marker` and `markersize` are None, `imshow` is used. Any extra remaining kwargs are passed to this method.

Marker style

If `Z` is a `scipy.sparse.spmatrix` or `marker` or `markersize` are None, a `Line2D` object will be returned with the value of `marker` determining the marker type, and any remaining kwargs passed to `plot`.

Parameters

- **Z** [array-like (M, N)] The array to be plotted.
- **precision** [float or ‘present’, optional, default: 0] If `precision` is 0, any non-zero value will be plotted. Otherwise, values of $|Z| > precision$ will be plotted.
  
  For `scipy.sparse.spmatrix` instances, you can also pass ‘present’. In this case any value present in the array will be plotted, even if it is identically zero.
- **origin** [{‘upper’, ‘lower’}, optional] Place the [0,0] index of the array in the upper left or lower left corner of the axes. The convention ‘upper’ is typically used for matrices and images. If not given, `rcParams["image.origin"]` is used, defaulting to ‘upper’.
- **aspect** [{‘equal’, ‘auto’, None} or float, optional] Controls the aspect ratio of the axes. The aspect is of particular relevance for images since it may distort the image, i.e. pixel will not be square.
  
  This parameter is a shortcut for explicitly calling `Axes.set_aspect`. See there for further details.

  - ‘equal’: Ensures an aspect ratio of 1. Pixels will be square.
  - ‘auto’: The axes is kept fixed and the aspect is adjusted so that the data fit in the axes. In general, this will result in non-square pixels.
  - `None`: Use `rcParams["image.aspect"]` (default: ‘equal’).
  
  Default: ‘equal’

Returns

- **ret** [`AxesImage` or `Line2D`] The return type depends on the plotting style (see above).

Other Parameters

- ****kwargs The supported additional parameters depend on the plotting style.
  
  For the image style, you can pass the following additional parameters of `imshow`:

  - `cmap`
  - `alpha`
  - `url`
  - any `Artist` properties (passed on to the `AxesImage`)
For the marker style, you can pass any `Line2D` property except for `linestyle`:

</tbody>
</table>

#### `matplotlib.axes.Axes.tripcolor`

```python
taxes.tripcolor(ax, *args, alpha=1.0, norm=None, cmap=None, vmin=None, vmax=None, shading='flat', facecolors=None, **kwargs)
```

Create a pseudocolor plot of an unstructured triangular grid.

The triangulation can be specified in one of two ways; either:

- `tripcolor(triangulation, ...)`
- `tripcolor(x, y, ...)
  tripcolor(x, y, triangles, ...)
  tripcolor(x, y, triangles=triangles, ...)
  tripcolor(x, y, mask=mask, ...)
  tripcolor(x, y, triangles, mask=mask, ...)`

where `triangulation` is a `matplotlib.tri.Triangulation` object, or in which case a Triangulation object will be created. See `Triangulation` for a explanation of these possibilities.

The next argument must be `C`, the array of color values, either one per point in the triangulation if color values are defined at points, or one per triangle in the triangulation if color values are defined at triangles. If there are the same number of points and triangles in the triangulation it is assumed that color values are defined at points; to force the use of color values at triangles use the kwarg `facecolors=C` instead of just `C`.

`shading` may be ‘flat’ (the default) or ‘gouraud’. If `shading` is ‘flat’ and `C` values are defined at points, the color values used for each triangle are from the mean `C` of the triangle’s three points. If `shading` is ‘gouraud’ then color values must be defined at points.

The remaining kwargs are the same as for `pcolor()`.

#### Examples using `matplotlib.axes.Axes.tripcolor`

- `sphx_glr_gallery_images_contours_and_fields_tripcolor_demo.py`

#### `matplotlib.axes.Axes.triplot`

```python
taxes.triplot(ax, *args, **kwargs)
```

Draw a unstructured triangular grid as lines and/or markers.
The triangulation to plot can be specified in one of two ways; either:

```
triplot(triangulation, ...)
```

where triangulation is a `matplotlib.tri.Triangulation` object, or

```
triplot(x, y, ...)
triplot(x, y, triangles, ...)
triplot(x, y, triangles=triangles, ...)
triplot(x, y, mask=mask, ...)
triplot(x, y, triangles, mask=mask, ...)
```

in which case a `Triangulation` object will be created. See `Triangulation` for an explanation of these possibilities.

The remaining args and kwargs are the same as for `plot()`.

Return a list of 2 `Line2D` containing respectively:

- the lines plotted for triangles edges
- the markers plotted for triangles nodes

**Examples using `matplotlib.axes.Axes.triplot`**

- sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_delaunay.py
- sphx_glr_gallery_images_contours_and_fields_trigradient_demo.py
- sphx_glr_gallery_images_contours_and_fields_triinterp_demo.py
- sphx_glr_gallery_images_contours_and_fields_triplot_demo.py

**matplotlib.axes.Axes.tricontour**

```
Axes.tricontour(ax, *args, **kwargs)
```

Draw contours on an unstructured triangular grid.

`tricontour` and `tricontourf` draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

The triangulation can be specified in one of two ways; either

```
tricontour(triangulation, ...)
```

where `triangulation` is a `matplotlib.tri.Triangulation` object, or

```
tricontour(x, y, ...)
tricontour(x, y, triangles, ...)
tricontour(x, y, triangles=triangles, ...)
tricontour(x, y, mask=mask, ...)
tricontour(x, y, triangles, mask=mask, ...)
```

in which case a `Triangulation` object will be created. See that class’ docstring for an explanation of these cases.

The remaining arguments may be:
tricontour(..., Z)

where Z is the array of values to contour, one per point in the triangulation. The level values are chosen automatically.

tricontour(..., Z, N)

countour up to $N+1$ automatically chosen contour levels ($N$ intervals).

tricontour(..., Z, V)

draw contour lines at the values specified in sequence $V$, which must be in increasing order.

tricontourf(..., Z, V)

fill the $(\text{len}(V)-1)$ regions between the values in $V$, which must be in increasing order.

tricontour(Z, **kwargs)

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details.

tricontour(...) returns a TriContourSet object.

Optional keyword arguments:

- **colors**: [None | string | (mpl_colors)] If None, the colormap specified by cmap will be used.
  - If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.
  - If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be plotted in different colors in the order specified.
- **alpha**: float The alpha blending value
- **cmap**: [None | Colormap] A cm Colormap instance or None. If cmap is None and colors is None, a default Colormap is used.
- **norm**: [None | Normalize] A matplotlib.colors.Normalize instance for scaling data values to colors. If norm is None and colors is None, the default linear scaling is used.
- **levels**: [level0, level1, ..., leveln] A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass levels=[0]
- **origin**: [None | ‘upper’ | ‘lower’ | ‘image’] If None, the first value of Z will correspond to the lower left corner, location (0,0). If ‘image’, the rc value for image.origin will be used.
  - This keyword is not active if X and Y are specified in the call to contour.
- **extent**: [None | (x0,x1,y0,y1)]
  - If origin is not None, then extent is interpreted as in matplotlib.pyplot.imshow(): it gives the outer pixel boundaries. In this case, the position of Z[0,0] is the center of the pixel, not a corner. If origin is None, then (x0, y0) is the position of Z[0,0], and (x1, y1) is the position of Z[-1,-1].
  - This keyword is not active if X and Y are specified in the call to contour.
**locator:** [ *None* | `ticker.Locator` subclass ] If `locator` is None, the default `MaxNLocator` is used. The locator is used to determine the contour levels if they are not given explicitly via the `V` argument.

**extend:** [ ‘neither’ | ‘both’ | ‘min’ | ‘max’ ] Unless this is ‘neither’, contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via `matplotlib.colors.Colormap.set_under()` and `matplotlib.colors.Colormap.set_over()` methods.

**xunits, yunits:** [ *None* | registered units ] Override axis units by specifying an instance of a `matplotlib.units.ConversionInterface`.

**tricontour-only keyword arguments:**

**linewidths:** [ *None* | `number` | `tuple of numbers` ] If `linewidths` is `None`, defaults to `rc:lines.linewidth`. If a number, all levels will be plotted with this linewidth. If a tuple, different levels will be plotted with different linewidths in the order specified.

**linestyles:** [ *None* | ‘solid’ | ‘dashed’ | ‘dashdot’ | ‘dotted’ ] If `linestyles` is `None`, the ‘solid’ is used. `linestyles` can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

If `contour` is using a monochrome colormap and the contour level is less than 0, then the linestyle specified in `rcParams["contour.negative_linestyle"]` will be used.

**tricontourf-only keyword arguments:**

**antialiased:** bool enable antialiasing

Note: `tricontourf` fills intervals that are closed at the top; that is, for boundaries `z1` and `z2`, the filled region is:

```
z1 < Z <= z2
```

except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

**Examples using `matplotlib.axes.Axes.tricontour`**

- `sphx_glr_gallery_images_contours_and_fields_irregulardatagrid.py`
- `sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_delaunay.py`
- `sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_user.py`
- `sphx_glr_gallery_images_contours_and_fields_trigradient_demo.py`
matplotlib.axes.Axes.tricontourf

Axes.tricontourf(ax, *args, **kwargs)

Draw contours on an unstructured triangular grid.

draw contours and tricontourf draw contour lines and filled contours, respectively. Except
as noted, function signatures and return values are the same for both versions.

The triangulation can be specified in one of two ways; either

```python
tricontour(triangulation, ...)
```

where triangulation is a matplotlib.tri.Triangulation object, or

```python
tricontour(x, y, ...) tricontour(x, y, triangles, ...) tricontour(x, y, triangles=triangles, ...) tricontour(x, y, mask=mask, ...) tricontour(x, y, triangles, mask=mask, ...)
```

in which case a Triangulation object will be created. See that class’ docstring for an
explanation of these cases.

The remaining arguments may be:

```python
tricontour(..., Z)
```

where Z is the array of values to contour, one per point in the triangulation. The level
values are chosen automatically.

```python
tricontour(..., Z, N)
```

contour up to \(N+1\) automatically chosen contour levels \((N\text{ intervals})\).

```python
tricontour(..., Z, V)
```

draw contour lines at the values specified in sequence \(V\), which must be in increasing
order.

```python
tricontourf(..., Z, V)
```

fill the \((\text{len}(V)-1)\) regions between the values in \(V\), which must be in increasing order.

```python
tricontour(Z, **kwargs)
```

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details.

tricontour(...) returns a TriContourSet object.

Optional keyword arguments:

colors: \([\text{None}|\text{string}|\text{mpl_colors}]\) If \text{None}, the colormap specified by cmap
will be used.

If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.

If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be
plotted in different colors in the order specified.

alpha: float The alpha blending value
**cmap:** [ None | Colormap ] A `Colormap` instance or `None`. If `cmap` is `None` and `colors` is `None`, a default `Colormap` is used.

**norm:** [ None | Normalize ] A `matplotlib.colors.Normalize` instance for scaling data values to colors. If `norm` is `None` and `colors` is `None`, the default linear scaling is used.

**levels** [level0, level1, ..., levelN] A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass `levels=[0]`

**origin:** [ None | ‘upper’ | ‘lower’ | ‘image’ ] If `None`, the first value of `Z` will correspond to the lower left corner, location (0,0). If ‘image’, the rc value for `image.origin` will be used. This keyword is not active if `X` and `Y` are specified in the call to contour.

**extent:** [ None | (x0,x1,y0,y1) ]

If `origin` is not `None`, then `extent` is interpreted as in `matplotlib.pyplot.imshow()`: it gives the outer pixel boundaries. In this case, the position of Z[0,0] is the center of the pixel, not a corner. If `origin` is `None`, then (x0, y0) is the position of Z[0,0], and (x1, y1) is the position of Z[-1,-1]. This keyword is not active if `X` and `Y` are specified in the call to contour.

**locator:** [ None | ticker.Locator subclass ] If `locator` is `None`, the default `MaxNLocator` is used. The locator is used to determine the contour levels if they are not given explicitly via the `V` argument.

**extend:** [ ‘neither’ | ‘both’ | ‘min’ | ‘max’ ] Unless this is ‘neither’, contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via `matplotlib.colors.Colormap.set_under()` and `matplotlib.colors.Colormap.set_over()` methods.

**xunits, yunits:** [ None | registered units ] Override axis units by specifying an instance of a `matplotlib.units.ConversionInterface`.

**tricontour-only keyword arguments:**

**linewidths:** [ None | number | tuple of numbers ] If `linewidths` is `None`, defaults to `rc:lines.linewidth`. If a number, all levels will be plotted with this linewidth.

If a tuple, different levels will be plotted with different linewidths in the order specified.

**linestyles:** [ None | ‘solid’ | ‘dashed’ | ‘dashdot’ | ‘dotted’ ] If `linestyles` is `None`, the ‘solid’ is used.

`linestyles` can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

If contour is using a monochrome colormap and the contour level is less than 0, then the linestyle specified in `rcParams[“contour.negative_linestyle”]` will be used.

**tricontourf-only keyword arguments:**
antialiased: bool enable antialiasing

Note: tricontour fills intervals that are closed at the top; that is, for boundaries \( z1 \) and \( z2 \), the filled region is:

\[
z1 < Z \leq z2
\]

except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

matplotlib.axes.Axes.annotate

\newcommand{Axes.annotate}{\textbf{Axes.annotate}}(\textbf{self}, \textbf{s}, \textbf{xy}, *\textbf{args}, **\textbf{kwargs})

Annotate the point \( xy \) with text \text. In the simplest form, the text is placed at \( xy \).

Optionally, the text can be displayed in another position \text. An arrow pointing from the text to the annotated point \( xy \) can then be added by defining \textprops.}

Parameters

text [str] The text of the annotation. \( s \) is a deprecated synonym for this parameter.

xy [(float, float)] The point \((x,y)\) to annotate.

xytext [(float, float), optional] The position \((x,y)\) to place the text at. If None, defaults to \( xy \).
**xycoords** [str, *Artist*, *Transform*, callable or tuple, optional] The coordinate system that \( xy \) is given in. The following types of values are supported:

- One of the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'figure points'</td>
<td>Points from the lower left of the figure</td>
</tr>
<tr>
<td>'figure pixels'</td>
<td>Pixels from the lower left of the figure</td>
</tr>
<tr>
<td>'figure fraction'</td>
<td>Fraction of figure from lower left</td>
</tr>
<tr>
<td>'axes points'</td>
<td>Points from lower left corner of axes</td>
</tr>
<tr>
<td>'axes pixels'</td>
<td>Pixels from lower left corner of axes</td>
</tr>
<tr>
<td>'axes fraction'</td>
<td>Fraction of axes from lower left</td>
</tr>
<tr>
<td>'data'</td>
<td>Use the coordinate system of the object being annotated (default)</td>
</tr>
<tr>
<td>'polar'</td>
<td>((\theta, r)) if not native 'data' coordinates</td>
</tr>
</tbody>
</table>

- An *Artist*: \( xy \) is interpreted as a fraction of the artists \( Bbox \). E.g. \((0, 0)\) would be the lower left corner of the bounding box and \((0.5, 1)\) would be the center top of the bounding box.

- A *Transform* to transform \( xy \) to screen coordinates.

- A function with one of the following signatures:

  ```python
def transform(renderer) -> Bbox
def transform(renderer) -> Transform
```

  where *renderer* is a *RendererBase* subclass.

  The result of the function is interpreted like the *Artist* and *Transform* cases above.

- A tuple \((xcoords, ycoords)\) specifying separate coordinate systems for \( x \) and \( y \). *xcoords* and *ycoords* must each be of one of the above described types.

  See *Advanced Annotation* for more details.

  Defaults to ‘data’.

**textcoords** [str, *Artist*, *Transform*, callable or tuple, optional] The coordinate system that \( xytext \) is given in.

All \( xycoords \) values are valid as well as the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'offset points'</td>
<td>Offset (in points) from the ( xy ) value</td>
</tr>
<tr>
<td>'offset pixels'</td>
<td>Offset (in pixels) from the ( xy ) value</td>
</tr>
</tbody>
</table>

Defaults to the value of \( xycoords \), i.e. use the same coordinate system for annotation point and text position.

**arrowprops** [dict, optional] The properties used to draw a *FancyArrowPatch* arrow between the positions \( xy \) and \( xytext \).
If `arrowprops` does not contain the key ‘arrowstyle’ the allowed keys are:

<table>
<thead>
<tr>

<tr>
<td>?</td>
<td>any key for matplotlib.patches.PathPatch</td>
</tr>
</tbody>
</table>

Defaults to None, i.e. no arrow is drawn.

**annotation_clip** [bool or None, optional] Whether to draw the annotation when the annotation point `xy` is outside the axes area.

- If `True`, the annotation will only be drawn when `xy` is within the axes.
- If `False`, the annotation will always be drawn.
- If `None`, the annotation will only be drawn when `xy` is within the axes and `xycoords` is ‘data’.

Defaults to `None`.

**kwargs** Additional kwargs are passed to `Text`.  

Returns

    annotation [Annotation]

See also:

    Advanced Annotation

Examples using matplotlib.axes.Axes.annotate

- sphx_glr_gallery_lines_bars_and_markers_barchart.py
- sphx_glr_gallery_lines_bars_and_markers_timeline.py

- sphx_glr_gallery_userdemo_connectionstyle_demo.py

matplotlib.axes.Axes.text

    Axes.text(self, x, y, s, fontdict=None, withdash=<deprecated parameter>, **kwargs)

Add text to the axes.

    Add the text s to the axes at location x, y in data coordinates.

Parameters

    x, y [scalars] The position to place the text. By default, this is in data coordinates. The coordinate system can be changed using the transform parameter.

    s [str] The text.

    fontdict [dictionary, optional, default: None] A dictionary to override the default text properties. If fontdict is None, the defaults are determined by your rc parameters.

Returns

    text [Text] The created Text instance.

Other Parameters

    **kwargs [Text properties.] Other miscellaneous text parameters.
Examples

Individual keyword arguments can be used to override any given parameter:

```python
>>> text(x, y, s, fontsize=12)
```

The default transform specifies that text is in data coords, alternatively, you can specify text in axis coords (0,0 is lower-left and 1,1 is upper-right). The example below places text in the center of the axes:

```python
>>> text(0.5, 0.5, 'matplotlib', horizontalalignment='center',
       ... verticalalignment='center', transform=ax.transAxes)
```

You can put a rectangular box around the text instance (e.g., to set a background color) by using the keyword `bbox`. `bbox` is a dictionary of `Rectangle` properties. For example:

```python
>>> text(x, y, s, bbox=dict(facecolor='red', alpha=0.5))
```

Examples using `matplotlib.axes.Axes.text`

- sphx_glr_gallery_lines_bars_and_markers_horizontal_barchart_distribution.py
- sphx_glr_gallery_text_labels_and_annotations_demo_text_rotation_mode.py
- sphx_glr_gallery_pyplots_pyplot_mathtext.py
- sphx_glr_gallery_pyplots_text_commands.py
- sphx_glr_gallery_pyplots_text_layout.py
- sphx_glr_gallery_pyplots_whats_new_98_4_fancy.py
- sphx_glr_gallery_color_named_colors.py

`matplotlib.axes.Axes.table`

```python
Axes.table(ax, cellText=None, cellColours=None, cellLoc='right', colWidths=None, rowLabels=None, rowColours=None, rowLoc='left', colLabels=None, colColours=None, colLoc='center', loc='bottom', bbox=None, edges='closed', **kwargs)
```

Add a table to an `Axes`.

At least one of `cellText` or `cellColours` must be specified. These parameters must be 2D lists, in which the outer lists define the rows and the inner list define the column values per row. Each row must have the same number of elements.

The table can optionally have row and column headers, which are configured using `rowLabels`, `rowColours`, `rowLoc` and `colLabels`, `colColours`, `colLoc` respectively.

For finer grained control over tables, use the `Table` class and add it to the axes with `Axes.add_table`.

**Parameters**

- `cellText` [2D list of str, optional] The texts to place into the table cells.

  *Note:* Line breaks in the strings are currently not accounted for and will result in the text exceeding the cell boundaries.
cellColours [2D list of matplotlib color specs, optional] The background colors of the cells.

cellLoc [{‘left’, ‘center’, ‘right’}, default: ‘right’] The alignment of the text within the cells.

colWidths [list of float, optional] The column widths in units of the axes. If not given, all columns will have a width of \(1 / ncols\).

rowLabels [list of str, optional] The text of the row header cells.

rowColours [list of matplotlib color specs, optional] The colors of the row header cells.

colLabels [list of str, optional] The text of the column header cells.

colColours [list of matplotlib color specs, optional] The colors of the column header cells.

loc [str, optional] The position of the cell with respect to `ax`. This must be one of the `codes`.

bbox [Bbox, optional] A bounding box to draw the table into. If this is not `None`, this overrides `loc`.

edges [substring of ‘BRTL’ or {‘open’, ‘closed’, ‘horizontal’, ‘vertical’}] The cell edges to be drawn with a line. See also `visible_edges`.

Returns

table [Table] The created table.

Other Parameters

**kwargs `Table` properties.

`matplotlib.axes.Axes.arrow`

`Axes.arrow(self, x, y, dx, dy, **kwargs)`

Add an arrow to the axes.

This draws an arrow from (x, y) to (x+dx, y+dy).

**Parameters**

- **x, y** [float] The x and y coordinates of the arrow base.
- **dx, dy** [float] The length of the arrow along x and y direction.

**Returns**

- **arrow** [FancyArrow] The created FancyArrow object.

**Other Parameters**

- ****kwarg** Optional kwargs (inherited from FancyArrow patch) control the arrow construction and properties:

**Constructor arguments**

- **width**: float (default: 0.001) width of full arrow tail
- **length_includes_head**: bool (default: False) True if head is to be counted in calculating the length.
- **head_width**: float or None (default: 3*width) total width of the full arrow head
head_length: float or None (default: 1.5 * head_width) length of arrow head

shape: ['full', 'left', 'right'] (default: 'full') draw the left-half, right-half, or full arrow

overhang: float (default: 0) fraction that the arrow is swept back (0 overhang means triangular shape). Can be negative or greater than one.

head_starts_at_zero: bool (default: False) if True, the head starts being drawn at coordinate 0 instead of ending at coordinate 0.

Other valid kwargs (inherited from class:`Patch`) are:

<table>

</tr>
</tbody>
</table>

Notes

The resulting arrow is affected by the axes aspect ratio and limits. This may produce an arrow whose head is not square with its stem. To create an arrow whose head is square with its stem, use `annotate()` for example:
ax.annotate("", xy=(0.5, 0.5), xytext=(0, 0),
...      arrowprops=dict(arrowstyle="->"))

matplotlib.axes.Axes.inset_axes

`Axes.inset_axes(self, bounds, *, transform=None, zorder=5, **kwargs)`
Add a child inset axes to this existing axes.

**Parameters**

- `bounds` `[[x0, y0, width, height]]` Lower-left corner of inset axes, and its width and height.
- `transform` `[Transform]` Defaults to `ax.transAxes`, i.e. the units of `rect` are in axes-relative coordinates.
- `zorder` `[number]` Defaults to 5 (same as `Axes.legend`). Adjust higher or lower to change whether it is above or below data plotted on the parent axes.
- `**kwargs` Other `kwargs` are passed on to the `axes.Axes` child axes.

**Returns**

- `Axes` The created `axes.Axes` instance.

**Warning:** This method is experimental as of 3.0, and the API may change.

**Examples**

This example makes two inset axes, the first is in axes-relative coordinates, and the second in data-coordinates:

```python
fig, ax = plt.subplots()
ax.plot(range(10))
axin1 = ax.inset_axes([0.8, 0.1, 0.15, 0.15])
axin2 = ax.inset_axes([5, 7, 2.3, 2.3], transform=ax.transData)
```

**Examples using matplotlib.axes.Axes.inset_axes**

- sphx_glr_gallery_subplots_axes_and_figures_zoom_inset_axes.py

**matplotlib.axes.Axes.indicate_inset**

`Axes.indicate_inset(self, bounds, inset_ax=None, *, transform=None, facecolor='none', edgecolor='0.5', alpha=0.5, zorder=4.99, **kwargs)`
Add an inset indicator to the axes. This is a rectangle on the plot at the position indicated by `bounds` that optionally has lines that connect the rectangle to an inset axes (`Axes.inset_axes`).

976 Chapter 17. Modules
Parameters

- **bounds** ([x0, y0, width, height]) Lower-left corner of rectangle to be marked, and its width and height.

- **inset_ax** ([Axes]) An optional inset axes to draw connecting lines to. Two lines are drawn connecting the indicator box to the inset axes on corners chosen so as to not overlap with the indicator box.

- **transform** ([Transform]) Transform for the rectangle co-ordinates. Defaults to `ax.transAxes`, i.e. the units of `rect` are in axes-relative coordinates.

- **facecolor** ([Matplotlib color]) Facecolor of the rectangle (default ‘none’).

- **edgecolor** ([Matplotlib color]) Color of the rectangle and color of the connecting lines. Default is ‘0.5’.

- **alpha** ([number]) Transparency of the rectangle and connector lines. Default is 0.5.

- **zorder** ([number]) Drawing order of the rectangle and connector lines. Default is 4.99 (just below the default level of inset axes).

- ****kw**args** Other `kwargs` are passed on to the rectangle patch.

Returns

- **rectangle_patch** ([Patches.Rectangle]) Rectangle artist.

- **connector_lines** ([4-tuple of Patches.ConnectionPatch]) One for each of four connector lines. Two are set with visibility to `False`, but the user can set the visibility to `True` if the automatic choice is not deemed correct.

**Warning:** This method is experimental as of 3.0, and the API may change.

```python
matplotlib.axes.Axes.indicate_inset_zoom
```

```python
Axes.indicate_inset_zoom(self, inset_ax, **kwargs)
```

Add an inset indicator rectangle to the axes based on the axis limits for an `inset_ax` and draw connectors between `inset_ax` and the rectangle.

Parameters

- **inset_ax** ([Axes]) Inset axes to draw connecting lines to. Two lines are drawn connecting the indicator box to the inset axes on corners chosen so as to not overlap with the indicator box.

- ****kw**args** Other `kwargs` are passed on to `Axes.inset_rectangle`

Returns

- **rectangle_patch** ([Patches.Rectangle]) Rectangle artist.

- **connector_lines** ([4-tuple of Patches.ConnectionPatch]) One for each of four connector lines. Two are set with visibility to `False`, but the user can set the visibility to `True` if the automatic choice is not deemed correct.
**Warning:** This method is experimental as of 3.0, and the API may change.

Examples using `matplotlib.axes.Axes.indicate_inset_zoom`

- sphx_glr_gallery_subplots_axes_and_figures_zoom_inset_axes.py

`matplotlib.axes.Axes.secondary_xaxis`

`Axes.secondary_xaxis(self, location, *, functions=None, **kwargs)`

Add a second x-axis to this axes.

For example if we want to have a second scale for the data plotted on the xaxis.

**Parameters**

- **location** [string or scalar] The position to put the secondary axis. Strings can be ‘top’ or ‘bottom’, for x-oriented axises or ‘left’ or ‘right’ for y-oriented axises or a scalar can be a float indicating the relative position on the axes to put the new axes (0 being the bottom (left), and 1.0 being the top (right)).

- **functions** [2-tuple of func, or Transform with an inverse] If a 2-tuple of functions, the user specifies the transform function and its inverse. i.e. `functions=(lambda x: 2 / x, lambda x: 2 / x)` would be an reciprocal transform with a factor of 2.

  The user can also directly supply a subclass of `transforms.Transform` so long as it has an inverse.

  See /gallery/subplots_axes_and_figures/secondary_axis for examples of making these conversions.

**Returns**

- **ax** [axes._secondary_axes.SecondaryAxis]

**Other Parameters**

- ****kwargs [Axes properties.] Other miscellaneous axes parameters.

**Warning:** This method is experimental as of 3.1, and the API may change.

Examples

The main axis shows frequency, and the secondary axis shows period.

Examples using `matplotlib.axes.Axes.secondary_xaxis`

- sphx_glr_gallery_subplots_axes_and_figures_secondary_axis.py
matplotlib.axes.Axes.secondary_yaxis

`axes.secondary_yaxis(self, location, *, functions=None, **kwargs)`

Add a second y-axis to this axes.

For example if we want to have a second scale for the data plotted on the yaxis.

%(_secax_docstring)s

**Examples**

Add a secondary axes that converts from radians to degrees

**Examples using** `matplotlib.axes.Axes.secondary_yaxis`

- sphx_glr_gallery_subplots_axes_and_figures_secondary_axis.py

**Fields**

| `Axes.barbs` | Plot a 2D field of barbs. |
| `Axes.quiver` | Plot a 2D field of arrows. |

Continued on next page
Table 84 – continued from previous page

<td>Draw streamlines of a vector flow.</td>
</tr>
</tbody>
</table>

**matplotlib.axes.Axes.barbs**

```python
Axes.barbs(self, *args, data=None, **kw)
```

Plot a 2D field of barbs.

Call signature:

```python
barbs([X, Y], U, V, [C], **kw)
```

Where `X, Y` define the barb locations, `U, V` define the barb directions, and `C` optionally sets the color.

All arguments may be 1D or 2D. `U, V, C` may be masked arrays, but masked `X, Y` are not supported at present.

Barbs are traditionally used in meteorology as a way to plot the speed and direction of wind observations, but can technically be used to plot any two dimensional vector quantity. As opposed to arrows, which give vector magnitude by the length of the arrow, the barbs give more quantitative information about the vector magnitude by putting slanted lines or a triangle for various increments in magnitude, as shown schematically below:

```
/ \  
/  \ 
/   \ 
\   \
---
```

The largest increment is given by a triangle (or “flag”). After those come full lines (barbs). The smallest increment is a half line. There is only, of course, ever at most 1 half line. If the magnitude is small and only needs a single half-line and no full lines or triangles, the half-line is offset from the end of the barb so that it can be easily distinguished from barbs with a single full line. The magnitude for the barb shown above would nominally be 65, using the standard increments of 50, 10, and 5.

**Parameters**

- `X, Y` [1D or 2D array-like, optional] The x and y coordinates of the barb locations. See `pivot` for how the barbs are drawn to the x, y positions.
  - If not given, they will be generated as a uniform integer meshgrid based on the dimensions of `U` and `V`.
  - If `X` and `Y` are 1D but `U, V` are 2D, `X, Y` are expanded to 2D using `X, Y = np.meshgrid(X, Y)`. In this case `len(X)` and `len(Y)` must match the column and row dimensions of `U` and `V`.
- `U, V` [1D or 2D array-like] The x and y components of the barb shaft.
- `C` [1D or 2D array-like, optional] Numeric data that defines the barb colors by colormapping via `norm` and `cmap`. 

This does not support explicit colors. If you want to set colors directly, use `barbcolor` instead.

**length** [float, default: 7] Length of the barb in points; the other parts of the barb are scaled against this.

**pivot** [{‘tip’, ‘middle’} or float, default: ‘tip’] The part of the arrow that is anchored to the X, Y grid. The barb rotates about this point. This can also be a number, which shifts the start of the barb that many points away from grid point.

**barbcolor** [color or color sequence] Specifies the color of all parts of the barb except for the flags. This parameter is analogous to the `edgecolor` parameter for polygons, which can be used instead. However this parameter will override facecolor.

**flagcolor** [color or color sequence] Specifies the color of any flags on the barb. This parameter is analogous to the `facecolor` parameter for polygons, which can be used instead. However, this parameter will override facecolor. If this is not set (and `C` has not either) then `flagcolor` will be set to match `barbcolor` so that the barb has a uniform color. If `C` has been set, `flagcolor` has no effect.

**sizes** [dict, optional] A dictionary of coefficients specifying the ratio of a given feature to the length of the barb. Only those values one wishes to override need to be included. These features include:

- ‘spacing’ - space between features (flags, full/half barbs)
• ‘height’ - height (distance from shaft to top) of a flag or full barb
• ‘width’ - width of a flag, twice the width of a full barb
• ‘emptybarb’ - radius of the circle used for low magnitudes

fill_empty [bool, default: False] Whether the empty barbs (circles) that are drawn should be filled with the flag color. If they are not filled, the center is transparent.

rounding [bool, default: True] Whether the vector magnitude should be rounded when allocating barb components. If True, the magnitude is rounded to the nearest multiple of the half-barb increment. If False, the magnitude is simply truncated to the next lowest multiple.

barb_increments [dict, optional] A dictionary of increments specifying values to associate with different parts of the barb. Only those values one wishes to override need to be included.
• ‘half’ - half barbs (Default is 5)
• ‘full’ - full barbs (Default is 10)
• ‘flag’ - flags (default is 50)

flip_barb [bool or array-like of bool, default: False] Whether the lines and flags should point opposite to normal. Normal behavior is for the barbs and lines to point right (comes from wind barbs having these features point towards low pressure in the Northern Hemisphere).

A single value is applied to all barbs. Individual barbs can be flipped by passing a bool array of the same size as U and V.

Returns
barbs [Barbs]

Other Parameters

**kwargs The barbs can further be customized using PolyCollection keyword arguments:

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.barbs

- sphx_glr_gallery_images_contours_and_fields_barb_demo.py

matplotlib.axes.Axes.quiver

Axes.quiver(self, *args, data=None, **kw)
Plot a 2D field of arrows.
Call signature:

```python
quiver([X, Y], U, V, [C], **kw)
```
Where $X$, $Y$ define the arrow locations, $U$, $V$ define the arrow directions, and $C$ optionally sets the color.

**Arrow size**

The default settings auto-scales the length of the arrows to a reasonable size. To change this behavior see the `scale` and `scale_units` parameters.

**Arrow shape**

The defaults give a slightly swept-back arrow; to make the head a triangle, make `headaxislength` the same as `headlength`. To make the arrow more pointed, reduce `headwidth` or increase `headlength` and `headaxislength`. To make the head smaller relative to the shaft, scale down all the head parameters. You will probably do best to leave minshaft alone.

**Arrow outline**

`linewidths` and `edgecolors` can be used to customize the arrow outlines.

**Parameters**

- **X, Y** [1D or 2D array-like, optional] The x and y coordinates of the arrow locations.
  
  If not given, they will be generated as a uniform integer meshgrid based on the dimensions of $U$ and $V$.
  
  If $X$ and $Y$ are 1D but $U$, $V$ are 2D, $X$, $Y$ are expanded to 2D using $x, y = np.mgrid(x, y)$. In this case $len(x)$ and $len(y)$ must match the column and row dimensions of $U$ and $V$.

- **U, V** [1D or 2D array-like] The x and y direction components of the arrow vectors.

- **C** [1D or 2D array-like, optional] Numeric data that defines the arrow colors by colormapping via `norm` and `cmap`.
  
  This does not support explicit colors. If you want to set colors directly, use `color` instead.

- **units** [{‘width’, ‘height’, ‘dots’, ‘inches’, ‘x’, ‘y’ ‘xy’}, default: ‘width’] The arrow dimensions (except for `length`) are measured in multiples of this unit.
  
  The following values are supported:
  
  - ‘width’, ‘height’: The width or height of the axis.
  - ‘dots’, ‘inches’: Pixels or inches based on the figure dpi.
  - ‘x’, ‘y’, ‘xy’: $X$, $Y$ or $\sqrt{X^2 + Y^2}$ in data units.

  The arrows scale differently depending on the units. For ‘x’ or ‘y’, the arrows get larger as one zooms in; for other units, the arrow size is independent of the zoom state. For ‘width or ‘height’, the arrow size increases with the width and height of the axes, respectively, when the window is resized; for ‘dots’ or ‘inches’, resizing does not change the arrows.

- **angles** [{‘uv’, ‘xy’} or array-like, optional, default: ‘uv’] Method for determining the angle of the arrows.
• ‘uv’: The arrow axis aspect ratio is 1 so that if $U = V$ the orientation of the arrow on the plot is 45 degrees counter-clockwise from the horizontal axis (positive to the right).

Use this if the arrows symbolize a quantity that is not based on X, Y data coordinates.

• ‘xy’: Arrows point from (x,y) to (x+u, y+v). Use this for plotting a gradient field, for example.

• Alternatively, arbitrary angles may be specified explicitly as an array of values in degrees, counter-clockwise from the horizontal axis.

In this case $U$, $V$ is only used to determine the length of the arrows.

Note: inverting a data axis will correspondingly invert the arrows only with angles='xy'.

**scale** [float, optional] Number of data units per arrow length unit, e.g., m/s per plot width; a smaller scale parameter makes the arrow longer. Default is None.

If None, a simple autoscaling algorithm is used, based on the average vector length and the number of vectors. The arrow length unit is given by the scale_units parameter.

**scale_units** [{‘width’, ‘height’, ‘dots’, ‘inches’, ‘x’, ‘y’, ‘xy’}, optional] If the scale kwarg is None, the arrow length unit. Default is None.

e.g. scale_units is ‘inches’, scale is 2.0, and $(u,v) = (1,0)$, then the vector will be 0.5 inches long.

If scale units is ‘width’ or ‘height’, then the vector will be half the width/height of the axes.

If scale_units is ‘x’ then the vector will be 0.5 x-axis units. To plot vectors in the x-y plane, with u and v having the same units as x and y, use angles='xy', scale_units='xy', scale=1.

**width** [float, optional] Shaft width in arrow units; default depends on choice of units, above, and number of vectors; a typical starting value is about 0.005 times the width of the plot.

**headwidth** [float, optional, default: 3] Head width as multiple of shaft width.

**headlength** [float, optional, default: 5] Head length as multiple of shaft width.

**headaxislength** [float, optional, default: 4.5] Head length at shaft intersection.

**minshaft** [float, optional, default: 1] Length below which arrow scales, in units of head length. Do not set this to less than 1, or small arrows will look terrible!

**minlength** [float, optional, default: 1] Minimum length as a multiple of shaft width; if an arrow length is less than this, plot a dot (hexagon) of this diameter instead.

**pivot** [{‘tail’, ‘mid’, ‘middle’, ‘tip’}, optional, default: ‘tail’] The part of the arrow that is anchored to the X, Y grid. The arrow rotates about this point.
'mid' is a synonym for 'middle'.

**color** [color or color sequence, optional] Explicit color(s) for the arrows. If
*C* has been set, *color* has no effect.

This is a synonym for the *PolyCollection* *facecolor* parameter.

**Other Parameters**

**kwargs [PolyCollection properties, optional]** All other keyword arguments are passed on to *PolyCollection*:

**See also:**

**quiverkey** Add a key to a quiver plot.
Examples using `matplotlib.axes.Axes.quiver`

- `sphx_glr_gallery_images_contours_and_fields_quiver_demo.py`
- `sphx_glr_gallery_images_contours_and_fields_quiver_simple_demo.py`
- `sphx_glr_gallery_images_contours_and_fields_trigradient_demo.py`

`matplotlib.axes.Axes.quiverkey`

`Axes.quiverkey(self, Q, X, Y, U, label, **kw)`

Add a key to a quiver plot.

Call signature:

```python
quiverkey(Q, X, Y, U, label, **kw)
```

Arguments:

- `Q`: The Quiver instance returned by a call to `quiver`.
- `X, Y`: The location of the key; additional explanation follows.
- `U`: The length of the key
- `label`: A string with the length and units of the key

Keyword arguments:

- `angle = 0` The angle of the key arrow. Measured in degrees anti-clockwise from the x-axis.
- `coordinates = [‘axes’ | ‘figure’ | ‘data’ | ‘inches’]` Coordinate system and units for `X, Y`: ‘axes’ and ‘figure’ are normalized coordinate systems with 0,0 in the lower left and 1,1 in the upper right; ‘data’ are the axes data coordinates (used for the locations of the vectors in the quiver plot itself); ‘inches’ is position in the figure in inches, with 0,0 at the lower left corner.
- `color`: overrides face and edge colors from `Q`.
- `labelpos = [‘N’ | ‘S’ | ‘E’ | ‘W’]` Position the label above, below, to the right, to the left of the arrow, respectively.
- `labelsep`: Distance in inches between the arrow and the label. Default is 0.1
- `labelcolor`: defaults to default Text color.
- `fontproperties`: A dictionary with keyword arguments accepted by the `FontProperties` initializer: `family, style, variant, size, weight`

Any additional keyword arguments are used to override vector properties taken from `Q`.

The positioning of the key depends on `X, Y, coordinates`, and `labelpos`. If `labelpos` is ‘N’ or ‘S’, `X, Y` give the position of the middle of the key arrow. If `labelpos` is ‘E’, `X, Y` positions the head, and if `labelpos` is ‘W’, `X, Y` positions the tail; in either of these two cases, `X, Y` is somewhere in the middle of the arrow+label key object.
Matplotlib, Release 3.1.1

Examples using `matplotlib.axes.Axes.quiverkey`

- `sphx_glr_gallery_images_contours_and_fields_quiver_demo.py`
- `sphx_glr_gallery_images_contours_and_fields_quiver_simple_demo.py`

`matplotlib.axes.Axes.streamplot`

`Axes.streamplot(ax, x, y, u, v, density=1, linewidth=None, color=None, cmap=None, norm=None, arrowsize=1, arrowstyle='-', minlength=0.1, transform=None, zorder=None, start_points=None, maxlength=4.0, integration_direction='both', *, data=None)`

Draw streamlines of a vector flow.

**Parameters**

- `x, y` [1D arrays] An evenly spaced grid.
- `u, v` [2D arrays] x and y-velocities. The number of rows and columns must match the length of `y` and `x`, respectively.
- `density` [float or (float, float)] Controls the closeness of streamlines. When `density = 1`, the domain is divided into a 30x30 grid. `density` linearly scales this grid. Each cell in the grid can have, at most, one traversing streamline. For different densities in each direction, use a tuple `(density_x, density_y)`.
- `linewidth` [float or 2D array] The width of the stream lines. With a 2D array the line width can be varied across the grid. The array must have the same shape as `u` and `v`.
- `color` [matplotlib color code, or 2D array] The streamline color. If given an array, its values are converted to colors using `cmap` and `norm`. The array must have the same shape as `u` and `v`.
- `cmap` [Colormap] Colormap used to plot streamlines and arrows. This is only used if `color` is an array.
- `norm` [Normalize] Normalize object used to scale luminance data to 0, 1. If `None`, stretch (min, max) to (0, 1). This is only used if `color` is an array.
- `arrowsize` [float] Scaling factor for the arrow size.
- `start_points` [Nx2 array] Coordinates of starting points for the streamlines in data coordinates (the same coordinates as the `x` and `y` arrays).
- `zorder` [int] The zorder of the stream lines and arrows. Artists with lower zorder values are drawn first.
- `maxlength` [float] Maximum length of streamline in axes coordinates.
- `integration_direction` [‘forward’, ‘backward’, ‘both’] Integrate the streamline in forward, backward or both directions. default is ‘both’.

**Returns**

- `stream_container` [StreamplotSet] Container object with attributes
• lines: LineCollection of streamlines

• arrows: PatchCollection containing FancyArrowPatch objects representing the arrows half-way along stream lines.

This container will probably change in the future to allow changes to the colormap, alpha, etc. for both lines and arrows, but these changes should be backward compatible.

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: 'start_points', 'u', 'v', 'x', 'y'.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.axes.Axes.streamplot

matplotlib.axes.Axes.cla

Axes.cla(self)

Clear the current axes.

Examples using matplotlib.axes.Axes.cla

• sphx_glr_gallery_misc_custom_projection.py

matplotlib.axes.Axes.clear

Axes.clear(self)

Clear the axes.

17.5.5 Appearance

17.5. matplotlib.axes
Axes.axis

Convenience method to get or set some axis properties.

Axes.set_axis_off

Turn the x- and y-axis off.

Axes.set_axis_on

Turn the x- and y-axis on.

Axes.set_frame_on

Set whether the axes rectangle patch is drawn.

Axes.get_frame_on

Get whether the axes rectangle patch is drawn.

Axes.set_axisbelow

Set whether axis ticks and gridlines are above or below most artists.

Axes.get_axisbelow

Get whether axis ticks and gridlines are above or below most artists.

Axes.grid

Configure the grid lines.

Axes.get_facecolor

Get the facecolor of the Axes.

Axes.get_fc

Get the facecolor of the Axes.

Axes.set_facecolor

Set the facecolor of the Axes.

Axes.set_fc

Set the facecolor of the Axes.

matplotlib.axes.Axes.axis

Axes.axis(self, *args, **kwargs)

Convenience method to get or set some axis properties.

Call signatures:

xmin, xmax, ymin, ymax = axis()
xmin, xmax, ymin, ymax = axis([xmin, xmax, ymin, ymax])
xmin, xmax, ymin, ymax = axis(option)
xmin, xmax, ymin, ymax = axis(**kwargs)

Parameters

xmin, xmax, ymin, ymax [float, optional] The axis limits to be set. Either none or all of the limits must be given. This can also be achieved using

ax.set(xlim=(xmin, xmax), ylim=(ymin, ymax))

option [bool or str] If a bool, turns axis lines and labels on or off. If a string, possible values are:
### axis

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'on'</td>
<td>Turn on axis lines and labels. Same as True.</td>
</tr>
<tr>
<td>'off'</td>
<td>Turn off axis lines and labels. Same as False.</td>
</tr>
<tr>
<td>'equal'</td>
<td>Set equal scaling (i.e., make circles circular) by changing axis limits.</td>
</tr>
<tr>
<td>'scaled'</td>
<td>Set equal scaling (i.e., make circles circular) by changing dimensions of the plot box.</td>
</tr>
<tr>
<td>'tight'</td>
<td>Set limits just large enough to show all data.</td>
</tr>
<tr>
<td>'auto'</td>
<td>Automatic scaling (fill plot box with data).</td>
</tr>
<tr>
<td>'normal'</td>
<td>Same as 'auto'; deprecated.</td>
</tr>
<tr>
<td>'image'</td>
<td>'scaled' with axis limits equal to data limits.</td>
</tr>
<tr>
<td>'square'</td>
<td>Square plot; similar to 'scaled', but initially forcing ( \text{xmax-xmin} = \text{ymax-ymin} ).</td>
</tr>
</tbody>
</table>

**emit** [bool, optional, default True] Whether observers are notified of the axis limit change. This option is passed on to `set_xlim` and `set_ylim`.

**Returns**

**See also:**

- `matplotlib.axes.Axes.set_xlim`
- `matplotlib.axes.Axes.set_ylim`

**Examples using `matplotlib.axes.Axes.axis`**

- sphx_glr_gallery_lines_bars_and_markers_fill.py

**Examples using `matplotlib.axes.Axes.set_axis_off`**

- `Axes.set_axis_off(self)`
  - Turn the x- and y-axis off.
  - This affects the axis lines, ticks, ticklabels, grid and axis labels.

- sphx_glr_gallery_images_contours_and_fields_image_transparency_blend.py
- sphx_glr_gallery_pie_and_polar_charts_nested_pie.py
- sphx_glr_gallery_color_colormap_reference.py
Axes.set_axis_on

Axes.set_axis_on(self)
    Turn the x- and y-axis on.
    This affects the axis lines, ticks, ticklabels, grid and axis labels.

Axes.set_frame_on

Axes.set_frame_on(self, b)
    Set whether the axes rectangle patch is drawn.

    Parameters
    b [bool]

Axes.get_frame_on

Axes.get_frame_on(self)
    Get whether the axes rectangle patch is drawn.

Axes.set_axisbelow

Axes.set_axisbelow(self, b)
    Set whether axis ticks and gridlines are above or below most artists.
    This controls the zorder of the ticks and gridlines. For more information on the zorder
    see /gallery/misc/zorder_demo.

    Parameters
    b [bool or 'line'] Possible values:
    • True (zorder = 0.5): Ticks and gridlines are below all Artists.
    • 'line' (zorder = 1.5): Ticks and gridlines are above patches (e.g. rectangles, with default zorder = 1) but still below lines and markers (with their default zorder = 2).
    • False (zorder = 2.5): Ticks and gridlines are above patches and lines / markers.

    See also:
    get_axisbelow

Axes.get_axisbelow

Axes.get_axisbelow(self)
    Get whether axis ticks and gridlines are above or below most artists.

    Returns
    axisbelow [bool or 'line']

    See also:
set_axisbelow

matplotlib.axes.Axes.grid

Axes.grid(self, b=None, which='major', axis='both', **kwargs)

Configure the grid lines.

**Parameters**

- **b** [bool or None, optional] Whether to show the grid lines. If any `kwargs` are supplied, it is assumed you want the grid on and `b` will be set to True.
  
  If `b` is `None` and there are no `kwargs`, this toggles the visibility of the lines.

- **which** [{‘major’, ‘minor’, ‘both’}, optional] The grid lines to apply the changes on.

- **axis** [{‘both’, ‘x’, ‘y’}, optional] The axis to apply the changes on.

- **kwargs** [Line2D properties] Define the line properties of the grid, e.g.:

  ```python
  grid(color='r', linestyle='-', linewidth=2)
  ```

  Valid `kwargs` are

### Notes

The axis is drawn as a unit, so the effective zorder for drawing the grid is determined by the zorder of each axis, not by the zorder of the *Line2D* objects comprising the grid. Therefore, to set grid zorder, use *set_axisbelow* or, for more control, call the *set_zorder* method of each axis.

**matplotlib.axes.Axes.get_facecolor**

*Axes.*

**get_facecolor(self)**

Get the facecolor of the Axes.

**matplotlib.axes.Axes.get_fc**

*Axes.*

**get_fc(self)**

Get the facecolor of the Axes.

**matplotlib.axes.Axes.set_facecolor**

*Axes.*

**set_facecolor(self, color)**

Set the facecolor of the Axes.

**Parameters**

- **color** [color]

**Examples using** *matplotlib.axes.Axes.set_facecolor*

- sphx_glr_gallery_color_color_demo.py
- sphx_glr_gallery_color_color_cycle_default.py
Axes.set_fc(self, color)
Set the facecolor of the Axes.

Parameters

color [color]

17.5.6 Property cycle

Axes.set_prop_cycle
Set the property cycle of the Axes.

Axes.set_prop_cycle(self, *args, **kwargs)
Set the property cycle of the Axes.

The property cycle controls the style properties such as color, marker and linestyle of future plot commands. The style properties of data already added to the Axes are not modified.

Call signatures:

set_prop_cycle(cycler)
set_prop_cycle(label=values[, label2=values2[, ...]])
set_prop_cycle(label, values)

Form 1 sets given Cycler object.

Form 2 creates a Cycler which cycles over one or more properties simultaneously and set it as the property cycle of the axes. If multiple properties are given, their value lists must have the same length. This is just a shortcut for explicitly creating a cycler and passing it to the function, i.e. it’s short for set_prop_cycle(cycler(label=values label2=values2, ...)).

Form 3 creates a Cycler for a single property and set it as the property cycle of the axes. This form exists for compatibility with the original cycler.cycler interface. Its use is discouraged in favor of the kwarg form, i.e. set_prop_cycle(label=values).

Parameters

cycler [Cycler] Set the given Cycler. None resets to the cycle defined by the current style.

label [str] The property key. Must be a valid Artist property. For example, 'color' or 'linestyle'. Aliases are allowed, such as 'c' for 'color' and 'lw' for 'linewidth'.

values [iterable] Finite-length iterable of the property values. These values are validated and will raise a ValueError if invalid.

See also:

matplotlib.rcsetup.cycler Convenience function for creating validated cyclers for properties.
cycler.cycler The original function for creating unvalidated cyclers.
Examples

Setting the property cycle for a single property:

```python
>>> ax.set_prop_cycle(color=['red', 'green', 'blue'])
```

Setting the property cycle for simultaneously cycling over multiple properties (e.g. red circle, green plus, blue cross):

```python
>>> ax.set_prop_cycle(color=['red', 'green', 'blue'],
                    marker=['o', '+', 'x'])
```

Examples using `matplotlib.axes.Axes.set_prop_cycle`

- `sphx_glr_gallery_color_color_cycler.py`
- *Styling with cycler*

17.5.7 Axis / limits

```python
Axes.get_xaxis
```

Return the XAxis instance.

```python
Axes.get_yaxis
```

Return the YAxis instance.

**matplotlib.axes.Axes.get_xaxis**

```python
Axes.get_xaxis(self)
```

Return the XAxis instance.

**matplotlib.axes.Axes.get_yaxis**

```python
Axes.get_yaxis(self)
```

Return the YAxis instance.

**Axis Limits and direction**

```python
Axes.invert_xaxis
```

Invert the x-axis.

```python
Axes.xaxis_inverted
```

Return whether the x-axis is inverted.

```python
Axes.invert_yaxis
```

Invert the y-axis.

```python
Axes.yaxis_inverted
```

Return whether the y-axis is inverted.

```python
Axes.set_xlim
```

Set the x-axis view limits.

```python
Axes.get_xlim
```

Return the x-axis view limits.

```python
Axes.set_ylim
```

Set the y-axis view limits.

```python
Axes.get_ylim
```

Return the y-axis view limits.

```python
Axes.update_datalim
```

Extend the dataLim BBox to include the given points.

`matplotlib.axes.Axes.invert_xaxis`

`Axes.invert_xaxis(self)`

Invert the x-axis.

See also:

`xaxis_inverted`  
`get_xlim, set_xlim`  
`get_xbound, set_xbound`

`matplotlib.axes.Axes.xaxis_inverted`

`Axes.xaxis_inverted(self)`

Return whether the x-axis is inverted.

The axis is inverted if the left value is larger than the right value.

See also:

`invert_xaxis`  
`get_xlim, set_xlim`  
`get_xbound, set_xbound`

`matplotlib.axes.Axes.invert_yaxis`

`Axes.invert_yaxis(self)`

Invert the y-axis.

See also:

`yaxis_inverted`  
`get_ylim, set_ylim`  
`get_ybound, set_ybound`
Axes.yaxis_inverted(self)
    Return whether the y-axis is inverted.
    The axis is inverted if the bottom value is larger than the top value.

See also:

invert_yaxis
get_ylim, set_ylim
get_ybound, set_ybound

Axes.set_xlim(left=None, right=None, emit=True, auto=False, *, xmin=None, xmax=None)
Set the x-axis view limits.

Parameters

left [scalar, optional] The left xlim in data coordinates. Passing None leaves
    the limit unchanged.
    The left and right xlims may be passed as the tuple (left, right) as the
    first positional argument (or as the left keyword argument).

right [scalar, optional] The right xlim in data coordinates. Passing None leaves
    the limit unchanged.

emit [bool, optional] Whether to notify observers of limit change (default: True).

auto [bool or None, optional] Whether to turn on autoscaling of the x-axis.
    True turns on, False turns off (default action), None leaves unchanged.

xmin, xmax [scalar, optional] They are equivalent to left and right respectively, and it is an error to pass both xmin and left or xmax and right.

Returns

left, right [(float, float)] The new x-axis limits in data coordinates.

See also:

get_xlim
set_xbound, get_xbound
invert_xaxis, xaxis_inverted

Notes

The left value may be greater than the right value, in which case the x-axis values will
decrease from left to right.
Examples

```python
>>> set_xlim(left, right)
>>> set_xlim((left, right))
>>> left, right = set_xlim(left, right)
```

One limit may be left unchanged.

```python
>>> set_xlim(right=right_lim)
```

Limits may be passed in reverse order to flip the direction of the x-axis. For example, suppose x represents the number of years before present. The x-axis limits might be set like the following so 5000 years ago is on the left of the plot and the present is on the right.

```python
>>> set_xlim(5000, 0)
```
**bottom** [scalar, optional] The bottom ylim in data coordinates. Passing
None leaves the limit unchanged.

The bottom and top ylims may be passed as the tuple *(bottom, top)* as
the first positional argument (or as the *bottom* keyword argument).

**top** [scalar, optional] The top ylim in data coordinates. Passing *None* leaves
the limit unchanged.

**emit** [bool, optional] Whether to notify observers of limit change (default:
*True*).

**auto** [bool or *None*, optional] Whether to turn on autoscaling of the y-axis.
*True* turns on, *False* turns off (default action), *None* leaves unchanged.

**ymin, ymax** [scalar, optional] They are equivalent to bottom and top re-
spectively, and it is an error to pass both *ymin* and *bottom* or *ymax* and
*top*.

**Returns**

*bottom, top* [(float, float)] The new y-axis limits in data coordinates.

**See also:**

*get_ylim*

*set_ybound, get_ybound*

*invert_yaxis, yaxis_inverted*

**Notes**

The *bottom* value may be greater than the *top* value, in which case the y-axis values will
decrease from *bottom* to *top*.

**Examples**

```python
>>> set_ylim(bottom, top)
>>> set_ylim((bottom, top))
>>> bottom, top = set_ylim(bottom, top)
```

One limit may be left unchanged.

```python
>>> set_ylim(top=top_lim)
```

Limits may be passed in reverse order to flip the direction of the y-axis. For example,
suppose *y* represents depth of the ocean in m. The y-axis limits might be set like the
following so 5000 m depth is at the bottom of the plot and the surface, 0 m, is at the top.

```python
>>> set_ylim(5000, 0)
```

**Examples using** matplotlib.axes.Axes.set_ylim

- sphx_glr_gallery_pyplots_align_ylabels.py
matplotlib.axes.Axes.get_ylim

Axes.get_ylim(self)
Return the y-axis view limits.

Returns

bottom, top [(float, float)] The current y-axis limits in data coordinates.

See also:

set_ylim
set_ybound, get_ybound
invert_yaxis, yaxis_inverted

Notes

The y-axis may be inverted, in which case the bottom value will be greater than the top value.

matplotlib.axes.Axes.update_datalim

Axes.update_datalim(self, xys, updatex=True, updatey=True)
Extend the dataLim BBox to include the given points.

If no data is set currently, the BBox will ignore its limits and set the bound to be the bounds of the xydata (xys). Otherwise, it will compute the bounds of the union of its current data and the data in xys.

Parameters

xys [2D array-like] The points to include in the data limits BBox. This can be either a list of (x, y) tuples or a Nx2 array.

updatex, updatey [bool, optional, default True] Whether to update the x/y limits.

matplotlib.axes.Axes.update_datalim_bounds

Axes.update_datalim_bounds(self, bounds)
Extend the datalim BBox to include the given Bbox.

Parameters

bounds [Bbox]
Axes.

\texttt{Axes.set_xbound}(\texttt{self}, \texttt{lower=None, upper=None})

Set the lower and upper numerical bounds of the x-axis.

This method will honor axes inversion regardless of parameter order. It will not change the autoscaling setting \((\texttt{Axes._ autoscaleXon})\).

\textbf{Parameters}

\textbf{lower, upper} [float or None] The lower and upper bounds. If \texttt{None}, the respective axis bound is not modified.

\textbf{See also:}

get\_xbound
get\_xlim, set\_xlim
invert\_xaxis, xaxis\_inverted

\texttt{Axes.get_xbound}(\texttt{self})

Return the lower and upper x-axis bounds, in increasing order.

\textbf{See also:}

set\_xbound
get\_xlim, set\_xlim
invert\_xaxis, xaxis\_inverted

\texttt{Axes.set_ybound}(\texttt{self}, \texttt{lower=None, upper=None})

Set the lower and upper numerical bounds of the y-axis.

This method will honor axes inversion regardless of parameter order. It will not change the autoscaling setting \((\texttt{Axes._ autoscaleYon})\).

\textbf{Parameters}

\textbf{lower, upper} [float or None] The lower and upper bounds. If \texttt{None}, the respective axis bound is not modified.

\textbf{See also:}

get\_ybound
get\_ylim, set\_ylim
invert\_yaxis, yaxis\_inverted
Axes.get_ybound(self)
    Return the lower and upper y-axis bounds, in increasing order.

See also:

    set_ybound
    get_ylim, set_ylim
    invert_yaxis, yaxis_inverted

Axis Labels, title, and legend

<table>
<thead>
<tr>
<th>Axes.set_xlabel</th>
<th>Set the label for the x-axis.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axes.get_xlabel</td>
<td>Get the xlabel text string.</td>
</tr>
<tr>
<td>Axes.set_ylabel</td>
<td>Set the label for the y-axis.</td>
</tr>
<tr>
<td>Axes.get_ylabel</td>
<td>Get the ylabel text string.</td>
</tr>
<tr>
<td>Axes.set_title</td>
<td>Set a title for the axes.</td>
</tr>
<tr>
<td>Axes.get_title</td>
<td>Get an axes title.</td>
</tr>
<tr>

<td>Return the Legend instance, or None if no legend is defined.</td>
</tr>
<tr>
<td>Axes.get_legend_handles_labels</td>
<td>Return handles and labels for legend</td>
</tr>
</tbody>
</table>

Axes.set_xlabel(self, xlabel, fontdict=None, labelpad=None, **kwargs)
    Set the label for the x-axis.

Parameters

    xlabel [str] The label text.

    labelpad [scalar, optional, default: None] Spacing in points from the axes bounding box including ticks and tick labels.

Other Parameters

    **kwargs [Text properties] Text properties control the appearance of the label.

See also:

    text for information on how override and the optional args work

Examples using matplotlib.axes.Axes.set_xlabel

- sphx_glr_gallery_statistics_histogram_features.py
- sphx_glr_gallery_pyplots_fig_axes_labels_simple.py
- sphx_glr_gallery_pyplots_text_commands.py
- sphx_glr_gallery_color_color_demo.py
Axes.get_xlabel(self)
Get the xlabel text string.

Axes.set_ylabel(self, ylabel, fontdict=None, labelpad=None, **kwargs)
Set the label for the y-axis.

Parameters
- ylabel [str] The label text.
- labelpad [scalar, optional, default: None] Spacing in points from the axes bounding box including ticks and tick labels.

Other Parameters
- **kwargs [Text properties] Text properties control the appearance of the label.

See also:
- text for information on how override and the optional args work

Examples using matplotlib.axes.Axes.set_ylabel

- sphx_glr_gallery_statistics_histogram_features.py
- sphx_glr_gallery_pyplots_align_ylabels.py
- sphx_glr_gallery_pyplots_fig_axes_labels_simple.py
- sphx_glr_gallery_pyplots_text_commands.py
- sphx_glr_gallery_color_color_demo.py

Axes.get_ylabel(self)
Get the ylabel text string.

Axes.set_title(self, label, fontdict=None, loc='center', pad=None, **kwargs)
Set a title for the axes.

Set one of the three available axes titles. The available titles are positioned above the axes in the center, flush with the left edge, and flush with the right edge.

Parameters
- label [str] Text to use for the title
**fontdict** [dict] A dictionary controlling the appearance of the title text, the
default fontdict is:

```python
{'fontsize': rcParams['axes.titlesize'],
'fontweight': rcParams['axes.titleweight'],
'verticalalignment': 'baseline',
'horizontalalignment': loc}
```

**loc** [{'center', 'left', 'right'}, str, optional] Which title to set, defaults to
'center'

**pad** [float] The offset of the title from the top of the axes, in points. Default
is None to use rcParams['axes.titlepad'].

**Returns**

**text** [Text] The matplotlib text instance representing the title

**Other Parameters**

****kwargs [Text properties] Other keyword arguments are text properties,
see Text for a list of valid text properties.

**Examples using matplotlib.axes.Axes.set_title**

- sphx_glr_gallery_statistics_histogram_features.py
- sphx_glr_gallery_text_labels_and_annotations_font_file.py
- sphx_glr_gallery_pyplots_align_ylabels.py
- sphx_glr_gallery_pyplots_fig_axes_labels_simple.py
- sphx_glr_gallery_pyplots_text_commands.py
- sphx_glr_gallery_color_color_demo.py
- sphx_glr_gallery_shapes_and_collections_donut.py

**matplotlib.axes.Axes.get_title**

Axes.get_title(self, loc='center')

Get an axes title.

Get one of the three available axes titles. The available titles are positioned above the
axes in the center, flush with the left edge, and flush with the right edge.

**Parameters**

**loc** [{'center', 'left', 'right'}, str, optional] Which title to get, defaults to
'center'.

**Returns**

**title** [str] The title text string.
Matplotlib, Release 3.1.1

**matplotlib.axes.Axes.legend**

**Axes.legend(self, *args, **kwargs)**

Place a legend on the axes.

Call signatures:

```python
legend()
legend(labels)
legend(handles, labels)
```

The call signatures correspond to three different ways how to use this method.

1. **Automatic detection of elements to be shown in the legend**

   The elements to be added to the legend are automatically determined, when you do not pass in any extra arguments.

   In this case, the labels are taken from the artist. You can specify them either at artist creation or by calling the `set_label()` method on the artist:

   ```python
   line, = ax.plot([1, 2, 3], label='Inline label')
   ax.legend()
   ```

   or:

   ```python
   line, = ax.plot([1, 2, 3])
   line.set_label('Label via method')
   ax.legend()
   ```

   Specific lines can be excluded from the automatic legend element selection by defining a label starting with an underscore. This is default for all artists, so calling `Axes.legend` without any arguments and without setting the labels manually will result in no legend being drawn.

2. **Labeling existing plot elements**

   To make a legend for lines which already exist on the axes (via plot for instance), simply call this function with an iterable of strings, one for each legend item. For example:

   ```python
   ax.plot([1, 2, 3])
   ax.legend(['A simple line'])
   ```

   Note: This way of using is discouraged, because the relation between plot elements and labels is only implicit by their order and can easily be mixed up.

3. **Explicitly defining the elements in the legend**

   For full control of which artists have a legend entry, it is possible to pass an iterable of legend artists followed by an iterable of legend labels respectively:

   ```python
   legend((line1, line2, line3), ('label1', 'label2', 'label3'))
   ```

**Parameters**

- **handles** [sequence of Artist, optional] A list of Artists (lines, patches) to be added to the legend. Use this together with `labels`, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.
The length of handles and labels should be the same in this case. If they are not, they are truncated to the smaller length.

**labels** [sequence of strings, optional] A list of labels to show next to the artists. Use this together with *handles*, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.

**Returns**

`matplotlib.legend.Legend` instance

**Other Parameters**

**loc** [str or pair of floats, default: `rcParams["legend.loc"]` (‘best’ for axes, ‘upper right’ for figures)] The location of the legend.

The strings 'upper left', 'upper right', 'lower left', 'lower right' place the legend at the corresponding corner of the axes/figure.

The strings 'upper center', 'lower center', 'center left', 'center right' place the legend at the center of the corresponding edge of the axes/figure.

The string 'center' places the legend at the center of the axes/figure.

The string 'best' places the legend at the location, among the nine locations defined so far, with the minimum overlap with other drawn artists. This option can be quite slow for plots with large amounts of data; your plotting speed may benefit from providing a specific location.

The location can also be a 2-tuple giving the coordinates of the lower-left corner of the legend in axes coordinates (in which case *bbox_to_anchor* will be ignored).

For back-compatibility, 'center right' (but no other location) can also be spelled 'right', and each "string" locations can also be given as a numeric value:

<table>
<thead>
<tr>
<th>Location String</th>
<th>Location Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>'best'</td>
<td>0</td>
</tr>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>

**bbox_to_anchor** [BboxBase, 2-tuple, or 4-tuple of floats] Box that is used to position the legend in conjunction with *loc*. Defaults to `axes.bbox` (if called as a method to `Axes.legend`) or `figure.bbox` (if `Figure.legend`). This argument allows arbitrary placement of the legend.

Bbox coordinates are interpreted in the coordinate system given by `bbox_transform`, with the default transform Axes or Figure coordinates,
depending on which legend is called.

If a 4-tuple or BboxBase is given, then it specifies the bbox \((x, y, width, height)\) that the legend is placed in. To put the legend in the best location in the bottom right quadrant of the axes (or figure):

\[
\text{loc='best', bbox_to_anchor=(0.5, 0.5, 0.5, 0.5)}
\]

A 2-tuple \((x, y)\) places the corner of the legend specified by \textit{loc} at \(x, y\). For example, to put the legend’s upper right-hand corner in the center of the axes (or figure) the following keywords can be used:

\[
\text{loc='upper right', bbox_to_anchor=(0.5, 0.5)}
\]

\textbf{ncol} [integer] The number of columns that the legend has. Default is 1.

\textbf{prop} [None or matplotlib.font_manager.FontProperties or dict] The font properties of the legend. If None (default), the current \textit{matplotlib.rcParams} will be used.

\textbf{fontsize} [int or float or {'xx-small', 'x-small', 'small', 'medium', 'large', 'x-large', 'xx-large'}] Controls the font size of the legend. If the value is numeric the size will be the absolute font size in points. String values are relative to the current default font size. This argument is only used if \textit{prop} is not specified.

\textbf{numpoints} [None or int] The number of marker points in the legend when creating a legend entry for a Line2D (line). Default is None, which will take the value from \textit{rcParams['legend.numpoints']}.

\textbf{scatterpoints} [None or int] The number of marker points in the legend when creating a legend entry for a PathCollection (scatter plot). Default is None, which will take the value from \textit{rcParams['legend.scatterpoints']}.

\textbf{scatteryoffsets} [iterable of floats] The vertical offset (relative to the font size) for the markers created for a scatter plot legend entry. 0.0 is at the base the legend text, and 1.0 is at the top. To draw all markers at the same height, set to [0.5]. Default is [0.375, 0.5, 0.3125].

\textbf{markerscale} [None or int or float] The relative size of legend markers compared with the originally drawn ones. Default is None, which will take the value from \textit{rcParams['legend.markerscale']}.

\textbf{markerfirst} [bool] If True, legend marker is placed to the left of the legend label. If False, legend marker is placed to the right of the legend label. Default is True.

\textbf{frameon} [None or bool] Control whether the legend should be drawn on a patch (frame). Default is None, which will take the value from \textit{rcParams['legend.frameon']}.

\textbf{fancybox} [None or bool] Control whether round edges should be enabled around the FancyBoxPatch which makes up the legend’s background. Default is None, which will take the value from \textit{rcParams['legend.fancybox']}.

\textbf{shadow} [None or bool] Control whether to draw a shadow behind the legend. Default is None, which will take the value from \textit{rcParams['legend.shadow']}.
framealpha [None or float] Control the alpha transparency of the legend’s background. Default is None, which will take the value from rcParams["legend.framealpha"]. If shadow is activated and framealpha is None, the default value is ignored.

facecolor [None or “inherit” or a color spec] Control the legend’s background color. Default is None, which will take the value from rcParams["legend.facecolor"]. If “inherit”, it will take rcParams["axes.facecolor"].

decorcolor [None or “inherit” or a color spec] Control the legend’s background patch edge color. Default is None, which will take the value from rcParams["legend.edgecolor"]. If “inherit”, it will take rcParams["axes.edgecolor"].

mode [{“expand”, None}] If mode is set to "expand" the legend will be horizontally expanded to fill the axes area (or bbox_to_anchor if defines the legend’s size).

bbox_transform [None or matplotlib.transforms.Transform] The transform for the bounding box (bbox_to_anchor). For a value of None (default) the Axes’ transAxes transform will be used.

title [str or None] The legend’s title. Default is no title (None).

title_fontsize: str or None The fontsize of the legend’s title. Default is the default fontsize.

borderpad [float or None] The fractional whitespace inside the legend border. Measured in font-size units. Default is None, which will take the value from rcParams["legend.borderpad"].

labelspacing [float or None] The vertical space between the legend entries. Measured in font-size units. Default is None, which will take the value from rcParams["legend.labelspacing"].

handlelength [float or None] The length of the legend handles. Measured in font-size units. Default is None, which will take the value from rcParams["legend.handlelength"].

handletextpad [float or None] The pad between the legend handle and text. Measured in font-size units. Default is None, which will take the value from rcParams["legend.handletextpad"].

borderaxespad [float or None] The pad between the axes and legend border. Measured in font-size units. Default is None, which will take the value from rcParams["legend.borderaxespad"].

columnspacing [float or None] The spacing between columns. Measured in font-size units. Default is None, which will take the value from rcParams["legend.columnspacing"].

handler_map [dict or None] The custom dictionary mapping instances or types to a legend handler. This handler_map updates the default handler map found at matplotlib.legend.Legend.get_legend_handler_map().
Notes

Not all kinds of artist are supported by the legend command. See *Legend guide* for details.

Examples

Examples using `matplotlib.axes.Axes.legend`

- `sphx_glr_gallery_lines_bars_and_markers_horizontal_barchart_distribution.py`
- `sphx_glr_gallery_lines_bars_and_markers_scatter_with_legend.py`
- `sphx_glr_gallery_images_contours_and_fields_contourf_hatching.py`
- `sphx_glr_gallery_images_contours_and_fields_contourf_log.py`
- `sphx_glr_gallery_pie_and_polarCharts_pie_and_donut_labels.py`
- `sphx_glr_gallery_pie_and_polarCharts_polar_legend.py`
- `sphx_glr_gallery_text_labels_and_annotations_legend.py`
- `sphx_glr_gallery_pyplots_whats_new_98_4_legend.py`
**Axes.get_legend**

`Axes.get_legend(self)`

Return the Legend instance, or None if no legend is defined.

**Axes.get_legend_handles_labels**

`Axes.get_legend_handles_labels(self, legend_handler_map=None)`

Return handles and labels for legend

`ax.legend()` is equivalent to

```python
h, l = ax.get_legend_handles_labels()
ax.legend(h, l)
```

**Axis scales**

<table>
<thead>
<tr>
<th>Axes.set_xscale</th>
<th>Set the x-axis scale.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axes.get_xscale</td>
<td>Return the x-axis scale as string.</td>
</tr>
<tr>
<td>Axes.set_yscale</td>
<td>Set the y-axis scale.</td>
</tr>
<tr>
<td>Axes.get_yscale</td>
<td>Return the y-axis scale as string.</td>
</tr>
</tbody>
</table>

**Axes.set_xscale**

`Axes.set_xscale(self, value, **kwargs)`

Set the x-axis scale.

**Parameters**

- **value** [{“linear”, “log”, “symlog”, “logit”, ...}] The axis scale type to apply.
- **kwargs** Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:
  - `matplotlib.scale.LinearScale`
  - `matplotlib.scale.LogScale`
  - `matplotlib.scale.SymmetricalLogScale`
  - `matplotlib.scale.LogitScale`

**Notes**

By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using `matplotlib.scale.register_scale`. These scales can then also be used here.

**Examples using** `matplotlib.axes.Axes.set_xscale`

- `sphx_glr_gallery_scales_scales.py`
Axes.get_xscale(self)
    Return the x-axis scale as string.

    See also:

    set_xscale

Axes.set_yscale(self, value, **kwargs)
    Set the y-axis scale.

    Parameters

    value [{"linear", "log", "symlog", "logit", ...}] The axis scale type to apply.
    **kwargs Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:
    • matplotlib.scale.LinearScale
    • matplotlib.scale.LogScale
    • matplotlib.scale.SymmetricalLogScale
    • matplotlib.scale.LogitScale

    Notes

    By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using matplotlib.scale.register_scale. These scales can then also be used here.

Examples using matplotlib.axes.Axes.set_yscale
    • sphx_glr_gallery_scales_scales.py

Axes.get_yscale(self)
    Return the y-axis scale as string.

    See also:

    set_yscale

Autoscaling and margins
### Axes.use_sticky_edges
When autoscaling, whether to obey all Artist.sticky_edges.

Default is True.

Setting this to False ensures that the specified margins will be applied, even if the plot includes an image, for example, which would otherwise force a view limit to coincide with its data limit.

The changing this property does not change the plot until autoscale or autoscale_view is called.

### Axes.margins
Set or retrieve autoscaling margins.

The padding added to each limit of the axes is the margin times the data interval. All input parameters must be floats within the range [0, 1]. Passing both positional and keyword arguments is invalid and will raise a TypeError. If no arguments (positional or otherwise) are provided, the current margins will remain in place and simply be returned.

Specifying any margin changes only the autoscaling; for example, if xmargin is not None, then xmargin times the X data interval will be added to each end of that interval before it is used in autoscaling.

#### Parameters
**margins** [float, optional] If a single positional argument is provided, it specifies both margins of the x-axis and y-axis limits. If two positional arguments are provided, they will be interpreted as *xmargin, ymargin*. If setting the margin on a single axis is desired, use the keyword arguments described below.

**x, y** [float, optional] Specific margin values for the x-axis and y-axis, respectively. These cannot be used with positional arguments, but can be used individually to alter on e.g., only the y-axis.

**tight** [bool or None, default is True] The tight parameter is passed to autoscale_view(), which is executed after a margin is changed; the default here is True, on the assumption that when margins are specified, no additional padding to match tick marks is usually desired. Set tight to None will preserve the previous setting.

**Returns**

*xmargin, ymargin* [float]

**Notes**

If a previously used Axes method such as pcolor() has set use_sticky_edges to True, only the limits not set by the “sticky artists” will be modified. To force all of the margins to be set, set use_sticky_edges to False before calling margins().

**Examples using matplotlib.axes.Axes.margins**

- sphx_glr_gallery_subplots_axes_and_figures_axesMargins.py

**matplotlib.axes.Axes.set_xmargin**

Axes.set_xmargin(self, m)

Set padding of X data limits prior to autoscaling.

*m* times the data interval will be added to each end of that interval before it is used in autoscaling. For example, if your data is in the range [0, 2], a factor of *m* = 0.1 will result in a range [-0.2, 2.2].

Negative values -0.5 < *m* < 0 will result in clipping of the data range. I.e. for a data range [0, 2], a factor of *m* = -0.1 will result in a range [0.2, 1.8].

**Parameters**

*m* [float greater than -0.5]

**matplotlib.axes.Axes.set_ymargin**

Axes.set_ymargin(self, m)

Set padding of Y data limits prior to autoscaling.

*m* times the data interval will be added to each end of that interval before it is used in autoscaling. For example, if your data is in the range [0, 2], a factor of *m* = 0.1 will result in a range [-0.2, 2.2].
Negative values \(-0.5 < m < 0\) will result in clipping of the data range. I.e. for a data range \([0, 2]\), a factor of \(m = -0.1\) will result in a range \([0.2, 1.8]\).

**Parameters**

\[m\] [float greater than -0.5]

```python
matplotlib.axes.Axes.relim

Axes.relim(self, visible_only=False)
Recompute the data limits based on current artists.

At present, Collection instances are not supported.

**Parameters**

\[visible_only\] [bool] Whether to exclude invisible artists. Defaults to False.
```

```python
matplotlib.axes.Axes.autoscale

Axes.autoscale(self, enable=True, axis='both', tight=None)
Autoscale the axis view to the data (toggle).

Convenience method for simple axis view autoscaling. It turns autoscaling on or off, and then, if autoscaling for either axis is on, it performs the autoscaling on the specified axis or axes.

**Parameters**

\[enable\] [bool or None, optional] True (default) turns autoscaling on, False turns it off. None leaves the autoscaling state unchanged.

\[axis\] [{‘both’, ‘x’, ‘y’}, optional] which axis to operate on; default is ‘both’

\[tight\] [bool or None, optional] If True, set view limits to data limits; if False, let the locator and margins expand the view limits; if None, use tight scaling if the only artist is an image, otherwise treat tight as False. The tight setting is retained for future autoscaling until it is explicitly changed.
```

```python
matplotlib.axes.Axes.autoscale_view

Axes.autoscale_view(self, tight=None, scalex=True, scaley=True)
Autoscale the view limits using the data limits.

You can selectively autoscale only a single axis, e.g., the xaxis by setting scaley to False. The autoscaling preserves any axis direction reversal that has already been done.

If \(tight\) is False, the axis major locator will be used to expand the view limits if rc-Params[‘axes.autolimit_mode’] is ‘round_numbers’. Note that any margins that are in effect will be applied first, regardless of whether \(tight\) is True or False. Specifying \(tight\) as True or False saves the setting as a private attribute of the Axes; specifying it as None (the default) applies the previously saved value.

The data limits are not updated automatically when artist data are changed after the artist has been added to an Axes instance. In that case, use matplotlib.axes.Axes.relim() prior to calling autoscale_view.
```
**Examples using** `matplotlib.axes.Axes.autoscale_view`

- `sphx_glr_gallery_shapes_and_collections_collections.py`
- `sphx_glr_gallery_shapes_and_collections_compound_path.py`
- `sphx_glr_gallery_shapes_and_collections_ellipse_collection.py`

```python
matplotlib.axes.Axes.set_autoscale_on
```

`Axes.set_autoscale_on(self, b)`

Set whether autoscaling is applied on plot commands

**Parameters**

- **b** ([bool])

```python
matplotlib.axes.Axes.get_autoscale_on
```

`Axes.get_autoscale_on(self)`

Get whether autoscaling is applied for both axes on plot commands

```python
matplotlib.axes.Axes.set_autoscalex_on
```

`Axes.set_autoscalex_on(self, b)`

Set whether autoscaling for the x-axis is applied on plot commands

**Parameters**

- **b** ([bool])

```python
matplotlib.axes.Axes.get_autoscalex_on
```

`Axes.get_autoscalex_on(self)`

Get whether autoscaling for the x-axis is applied on plot commands

```python
matplotlib.axes.Axes.set_autoscaley_on
```

`Axes.set_autoscaley_on(self, b)`

Set whether autoscaling for the y-axis is applied on plot commands

**Parameters**

- **b** ([bool])

```python
matplotlib.axes.Axes.get_autoscaley_on
```

`Axes.get_autoscaley_on(self)`

Get whether autoscaling for the y-axis is applied on plot commands
Aspect ratio

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axes.apply_aspect</td>
<td>Adjust the Axes for a specified data aspect ratio.</td>
</tr>
<tr>
<td>Axes.set_aspect</td>
<td>Set the aspect of the axis scaling, i.e.</td>
</tr>
<tr>
<td>Axes.get_adjustable</td>
<td>Define which parameter the Axes will change to achieve a given aspect.</td>
</tr>
<tr>
<td>Axes.get_adjustable</td>
<td></td>
</tr>
</tbody>
</table>

**Axes.apply_aspect**

**Axes.apply_aspect**(self, position=None)

Adjust the Axes for a specified data aspect ratio.

Depending on `get_adjustable` this will modify either the Axes box (position) or the view limits. In the former case, `get_anchor` will affect the position.

**See also:**

- `Axes.set_aspect` for a description of aspect ratio handling.
- `Axes.set_adjustable` defining the parameter to adjust in order to meet the required aspect.
- `Axes.set_anchor` defining the position in case of extra space.

**Notes**

This is called automatically when each Axes is drawn. You may need to call it yourself if you need to update the Axes position and/or view limits before the Figure is drawn.

**Axes.set_aspect**

**Axes.set_aspect**(self, aspect, adjustable=None, anchor=None, share=False)

Set the aspect of the axis scaling, i.e. the ratio of y-unit to x-unit.

**Parameters**

- **aspect** [‘auto’, ‘equal’] or num] Possible values:

<table>
<thead>
<tr>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘auto’</td>
<td>automatic; fill the position rectangle with data</td>
</tr>
<tr>
<td>‘equal’</td>
<td>same scaling from data to plot units for x and y</td>
</tr>
<tr>
<td>num</td>
<td>a circle will be stretched such that the height is num times the width. aspect=1 is the same as aspect=’equal’.</td>
</tr>
</tbody>
</table>

- **adjustable** [None or {‘box’, ‘datalim’}, optional] If not None, this defines which parameter will be adjusted to meet the required aspect. See `set_adjustable` for further details.
**anchor** [None or str or 2-tuple of float, optional] If not None, this defines where the Axes will be drawn if there is extra space due to aspect constraints. The most common way to specify the anchor are abbreviations of cardinal directions:

<table>
<thead>
<tr>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘C’</td>
<td>centered</td>
</tr>
<tr>
<td>‘SW’</td>
<td>lower left corner</td>
</tr>
<tr>
<td>‘S’</td>
<td>middle of bottom edge</td>
</tr>
<tr>
<td>‘SE’</td>
<td>lower right corner</td>
</tr>
<tr>
<td>etc.</td>
<td></td>
</tr>
</tbody>
</table>

See *set_anchor* for further details.

**share** [bool, optional] If True, apply the settings to all shared Axes. Default is False.

See also:

* `matplotlib.axes.Axes.set_adjustable` defining the parameter to adjust in order to meet the required aspect.
* `matplotlib.axes.Axes.set_anchor` defining the position in case of extra space.

Examples using `matplotlib.axes.Axes.set_aspect`

- sphx_glr_gallery_shapes_and_collections_donut.py

`matplotlib.axes.Axes.get_aspect`

`Axes.get_aspect(self)`

`matplotlib.axes.Axes.set_adjustable`

`Axes.set_adjustable(self, adjustable, share=False)`

Define which parameter the Axes will change to achieve a given aspect.

**Parameters**

- **adjustable** [{‘box’, ‘datalim’}] If ‘box’, change the physical dimensions of the Axes. If ‘datalim’, change the x or y data limits.

- **share** [bool, optional] If True, apply the settings to all shared Axes. Default is False.

See also:

Notes

Shared Axes (of which twinned Axes are a special case) impose restrictions on how aspect ratios can be imposed. For twinned Axes, use ‘datalim’. For Axes that share both x and y, use ‘box’. Otherwise, either ‘datalim’ or ‘box’ may be used. These limitations are partly a requirement to avoid over-specification, and partly a result of the particular implementation we are currently using, in which the adjustments for aspect ratios are done sequentially and independently on each Axes as it is drawn.

matplotlib.axes.Axes.get_adjustable

Axes.get_adjustable(self)

Ticks and tick labels

</tr>
</tbody>
</table>
matplotlib.axes.Axes.set_xticks

```python
Axes.set_xticks(self, ticks, minor=False)
```
Set the x ticks with list of ticks

**Parameters**

- `ticks` [list] List of x-axis tick locations.
- `minor` [bool, optional] If False sets major ticks, if True sets minor ticks. Default is False.

matplotlib.axes.Axes.get_xticks

```python
Axes.get_xticks(self, minor=False)
```
Return the x ticks as a list of locations

matplotlib.axes.Axes.set_xticklabels

```python
Axes.set_xticklabels(self, labels, fontdict=None, minor=False, **kwargs)
```
Set the x-tick labels with list of string labels.

**Parameters**

- `labels` [List[str]] List of string labels.
- `fontdict` [dict, optional] A dictionary controlling the appearance of the tick-labels. The default `fontdict` is:

```python
{
    'fontsize': rcParams['axes.titlesize'],
    'fontweight': rcParams['axes.titleweight'],
    'verticalalignment': 'baseline',
    'horizontalalignment': 'loc'
}
```
- `minor` [bool, optional] Whether to set the minor ticklabels rather than the major ones.

**Returns**

A list of `Text` instances.

**Other Parameters**

- `**kwargs` [Text properties.]

matplotlib.axes.Axes.get_xticklabels

```python
Axes.get_xticklabels(self, minor=False, which=None)
```
Get the x tick labels as a list of `Text` instances.

**Parameters**

- `minor` [bool, optional] If True return the minor ticklabels, else return the major ticklabels.
which [None, ('minor', 'major', 'both')] Overrides minor.

Selects which ticklabels to return

Returns
ret [list] List of Text instances.

matplotlib.axes.Axes.get_xmajorticklabels

Axes.get_xmajorticklabels(self)
Get the major x tick labels.

Returns
labels [list] List of Text instances

matplotlib.axes.Axes.get_xminorticklabels

Axes.get_xminorticklabels(self)
Get the minor x tick labels.

Returns
labels [list] List of Text instances

matplotlib.axes.Axes.get_xgridlines

Axes.get_xgridlines(self)
Get the x grid lines as a list of Line2D instances.

matplotlib.axes.Axes.get_xticklines

Axes.get_xticklines(self)
Get the x tick lines as a list of Line2D instances.

matplotlib.axes.Axes.xaxis_date

Axes.xaxis_date(self, tz=None)
Sets up x-axis ticks and labels that treat the x data as dates.

Parameters

tz [string or tzinfo instance, optional] Timezone. Defaults to rcParams["timezone"].

matplotlib.axes.Axes.set_yticks

Axes.set_yticks(self, ticks, minor=False)
Set the y ticks with list of ticks

Parameters
ticks [list] List of y-axis tick locations

minor [bool, optional] If False sets major ticks, if True sets minor ticks. Default is False.

```
matplotlib.axes.Axes.get_yticks

Axes.get_yticks(self, minor=False)
    Return the y ticks as a list of locations
```

```
matplotlib.axes.Axes.set_yticklabels

Axes.set_yticklabels(self, labels, fontdict=None, minor=False, **kwargs)
    Set the y-tick labels with list of strings labels.

Parameters

    labels [List[str]] list of string labels

    fontdict [dict, optional] A dictionary controlling the appearance of the ticklabels. The default fontdict is:

        ```
        {'fontsize': rcParams['axes.titlesize'],
         'fontweight': rcParams['axes.titleweight'],
         'verticalalignment': 'baseline',
         'horizontalalignment': 'loc'}
        ```

    minor [bool, optional] Whether to set the minor ticklabels rather than the major ones.

Returns

    A list of Text instances.

Other Parameters

    **kwargs [Text properties.]
```

```
matplotlib.axes.Axes.get_yticklabels

Axes.get_yticklabels(self, minor=False, which=None)
    Get the y tick labels as a list of Text instances.

Parameters

    minor [bool] If True return the minor ticklabels, else return the major ticklabels

    which [None, ('minor', 'major', 'both')] Overrides minor.

    Selects which ticklabels to return

Returns

    ret [list] List of Text instances.
```
Matplotlib, Release 3.1.1

matplotlib.axes.Axes.get_ymajorticklabels

Axes.get_ymajorticklabels(self)
    Get the major y tick labels.

    Returns
    labels [list] List of Text instances

matplotlib.axes.Axes.get_yminorticklabels

Axes.get_yminorticklabels(self)
    Get the minor y tick labels.

    Returns
    labels [list] List of Text instances

matplotlib.axes.Axes.get_ygridlines

Axes.get_ygridlines(self)
    Get the y grid lines as a list of Line2D instances.

matplotlib.axes.Axes.get_yticklines

Axes.get_yticklines(self)
    Get the y tick lines as a list of Line2D instances.

matplotlib.axes.Axes.yaxis_date

Axes.yaxis_date(self, tz=None)
    Sets up y-axis ticks and labels that treat the y data as dates.

    Parameters
    tz [string or tzinfo instance, optional] Timezone. Defaults to
    rcParams["timezone"].

matplotlib.axes.Axes.minorticks_off

Axes.minorticks_off(self)
    Remove minor ticks from the axes.

matplotlib.axes.Axes.minorticks_on

Axes.minorticks_on(self)
    Display minor ticks on the axes.

    Displaying minor ticks may reduce performance; you may turn them off using
    minorticks_off() if drawing speed is a problem.
**matplotlib.axes.Axes.ticklabel_format**

_axes_.ticklabel_format(self, *, axis='both', style='', scilimits=None, useOffset=None, useLocale=None, useMathText=None)

Change the `ScalarFormatter` used by default for linear axes.

Optional keyword arguments:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>axis</td>
<td>[ 'x'</td>
</tr>
<tr>
<td>style</td>
<td>[ 'sci' (or 'scientific')</td>
</tr>
<tr>
<td>scilimits</td>
<td>(m, n), pair of integers; if style is 'sci', scientific notation will be used for numbers outside the range $10^m$ to $10^n$. Use (0,0) to include all numbers. Use (m,m) where m &lt;&gt; 0 to fix the order of magnitude to $10^m$.</td>
</tr>
<tr>
<td>use-Offset</td>
<td>[ bool</td>
</tr>
<tr>
<td>use-Locale</td>
<td>If True, format the number according to the current locale. This affects things such as the character used for the decimal separator. If False, use C-style (English) formatting. The default setting is controlled by the axes.formatter.use_locale rcparam.</td>
</tr>
<tr>
<td>use-Math-Text</td>
<td>If True, render the offset and scientific notation in mathtext</td>
</tr>
</tbody>
</table>

Only the major ticks are affected. If the method is called when the `ScalarFormatter` is not the `Formatter` being used, an `AttributeError` will be raised.

**matplotlib.axes.Axes.tick_params**

_axes_.tick_params(self, axis='both', **kwargs)

Change the appearance of ticks, tick labels, and gridlines.

**Parameters**

- **axis** [{‘x’, ‘y’, ‘both’}, optional] Which axis to apply the parameters to.

**Other Parameters**

- **axis** [{‘x’, ‘y’, ‘both’}] Axis on which to operate; default is ‘both’.
- **reset** [bool] If True, set all parameters to defaults before processing other keyword arguments. Default is False.
- **which** [{‘major’, ‘minor’, ‘both’}] Default is ‘major’; apply arguments to which ticks.
- **direction** [{‘in’, ‘out’, ‘inout’}] Puts ticks inside the axes, outside the axes, or both.
- **length** [float] Tick length in points.
- **width** [float] Tick width in points.
- **color** [color] Tick color; accepts any mpl color spec.
pad [float] Distance in points between tick and label.

labels [float or str] Tick label font size in points or as a string (e.g., 'large').

labelcolor [color] Tick label color; mpl color spec.

colors [color] Changes the tick color and the label color to the same value: mpl color spec.

zorder [float] Tick and label zorder.

tickbottom, ticktop, tickleft, tickright [bool] Whether to draw the respective ticks.

labelbottom, labeltop, labelleft, labelright [bool] Whether to draw the respective tick labels.

labelrotation [float] Tick label rotation

grid_color [color] Changes the gridline color to the given mpl color spec.

grid_alpha [float] Transparency of gridlines: 0 (transparent) to 1 (opaque).

grid_linewidth [float] Width of gridlines in points.

grid_linestyle [string] Any valid Line2D line style spec.

Examples

Usage

```
ax.tick_params(direction='out', length=6, width=2, colors='r',
grid_color='r', grid_alpha=0.5)
```

This will make all major ticks be red, pointing out of the box, and with dimensions 6 points by 2 points. Tick labels will also be red. Gridlines will be red and translucent.

Examples using matplotlib.axes.Axes.tick_params

- sphx_glr_gallery_subplots_axes_and_figures_two_scales.py
- sphx_glr_gallery_color_color_demo.py

matplotlib.axes.Axes.locator_params

```
Axes.locator_params(self, axis='both', tight=None, **kwargs)
```

Control behavior of major tick locators.

Because the locator is involved in autoscaling, autoscale_view is called automatically after the parameters are changed.

Parameters

- axis [{‘both’, ‘x’, ‘y’}, optional] The axis on which to operate.

- tight [bool or None, optional] Parameter passed to autoscale_view. Default is None, for no change.

Other Parameters
**kwargs Remaining keyword arguments are passed to directly to the set_params() method of the locator. Supported keywords depend on the type of the locator. See for example set_params for the ticker.MaxNLocator used by default for linear axes.

**Examples**

When plotting small subplots, one might want to reduce the maximum number of ticks and use tight bounds, for example:

```python
ax.locator_params(tight=True, nbins=4)
```

### 17.5.8 Units

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axes.convert_xunits</code></td>
<td>Convert x using the unit type of the xaxis.</td>
</tr>
<tr>
<td><code>Axes.convert_yunits</code></td>
<td>Convert y using the unit type of the yaxis.</td>
</tr>
<tr>
<td><code>Axes.have_units</code></td>
<td>Return <code>True</code> if units are set on the x or y axes.</td>
</tr>
</tbody>
</table>

#### matplotlib.axes.Axes.convert_xunits

```python
def Axes.convert_xunits(self, x):
    # Convert x using the unit type of the xaxis.
    # If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.
```

#### matplotlib.axes.Axes.convert_yunits

```python
def Axes.convert_yunits(self, y):
    # Convert y using the unit type of the yaxis.
    # If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.
```

#### matplotlib.axes.Axes.have_units

```python
def Axes.have_units(self):
    # Return `True` if units are set on the x or y axes.
```

### 17.5.9 Adding Artists

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axes.add_artist</code></td>
<td>Add an Artist to the axes, and return the artist.</td>
</tr>
<tr>
<td><code>Axes.add_child_axes</code></td>
<td>Add an AxesBase to the axes' children; return the child axes.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>Axes.add_collection</code></td>
<td>Add a Collection to the axes' collections; return the collection.</td>
</tr>
<tr>
<td><code>Axes.add_container</code></td>
<td>Add a Container to the axes' containers; return the container.</td>
</tr>
<tr>
<td><code>Axes.add_image</code></td>
<td>Add an AxesImage to the axes' images; return the image.</td>
</tr>
<tr>
<td><code>Axes.add_line</code></td>
<td>Add a Line2D to the axes' lines; return the line.</td>
</tr>
<tr>
<td><code>Axes.add_patch</code></td>
<td>Add a Patch to the axes' patches; return the patch.</td>
</tr>
<tr>
<td><code>Axes.add_table</code></td>
<td>Add a Table to the axes' tables; return the table.</td>
</tr>
</tbody>
</table>

**matplotlib.axes.Axes.add_artist**

`Axes.add_artist(self, a)`

Add an Artist to the axes, and return the artist.

Use `add_artist` only for artists for which there is no dedicated "add" method; and if necessary, use a method such as `update_datalim` to manually update the dataLim if the artist is to be included in autoscaling.

If no `transform` has been specified when creating the artist (e.g. `artist.get_transform()` == `None`) then the transform is set to `ax.transData`.

**Examples using matplotlib.axes.Axes.add_artist**

- sphx_glr_gallery_shapes_and_collections_ellipse_demo.py

**matplotlib.axes.Axes.add_child_axes**

`Axes.add_child_axes(self, ax)`

Add an AxesBase to the axes' children; return the child axes.

This is the lowlevel version. See `axes.Axes.inset_axes`.

**Examples using matplotlib.axes.Axes.add_child_axes**

- sphx_glr_gallery_lines_bars_and_markers_span_regions.py
- sphx_glr_gallery_shapes_and_collections_artist_reference.py
- sphx_glr_gallery_shapes_and_collections_collections.py
- sphx_glr_gallery_shapes_and_collections_ellipse_collection.py

17.5. matplotlib.axes
• sphx_glr_gallery_shapes_and_collections_line_collection.py
• sphx_glr_gallery_shapes_and_collections_patch_collection.py

```
matplotlib.axes.Axes.add_container

Axes.add_container(self, container)
    Add a Container to the axes' containers; return the container.
```

```
matplotlib.axes.Axes.add_image

Axes.add_image(self, image)
    Add an AxesImage to the axes' images; return the image.
```

```
matplotlib.axes.Axes.add_line

Axes.add_line(self, line)
    Add a Line2D to the axes' lines; return the line.
```

**Examples using** matplotlib.axes.Axes.add_line

• sphx_glr_gallery_text_labels_and_annotations_line_with_text.py
• sphx_glr_gallery_shapes_and_collections_artist_reference.py

```
matplotlib.axes.Axes.add_patch

Axes.add_patch(self, p)
    Add a Patch to the axes' patches; return the patch.
```

**Examples using** matplotlib.axes.Axes.add_patch

• sphx_glr_gallery_shapes_and_collections_compound_path.py
• sphx_glr_gallery_shapes_and_collections_dolphin.py
• sphx_glr_gallery_shapes_and_collections_donut.py
• sphx_glr_gallery_shapes_and_collections_hatch_demo.py
• sphx_glr_gallery_shapes_and_collections_path_patch.py
• sphx_glr_gallery_shapes_and_collections_quadBezier.py
• sphx_glr_gallery_misc_histogram_path.py

```
matplotlib.axes.Axes.add_table

Axes.add_table(self, tab)
    Add a Table to the axes' tables; return the table.
```
### 17.5.10 Twinning

| **Axes.twinx** | Create a twin Axes sharing the xaxis |
| **Axes.twiny** | Create a twin Axes sharing the yaxis |
| **Axes.get_shared_x_axes** | Return a reference to the shared axes Grouper object for x axes. |
| **Axes.get_shared_y_axes** | Return a reference to the shared axes Grouper object for y axes. |

**matplotlib.axes.Axes.twinx**

**Axes.twinx**(self)
Create a twin Axes sharing the xaxis

Create a new Axes instance with an invisible x-axis and an independent y-axis positioned opposite to the original one (i.e. at right). The x-axis autoscale setting will be inherited from the original Axes. To ensure that the tick marks of both y-axes align, see `LinearLocator`

**Returns**

- **ax_twin** [Axes] The newly created Axes instance

**Notes**

For those who are ‘picking’ artists while using twinx, pick events are only called for the artists in the top-most axes.

**Examples using matplotlib.axes.Axes.twinx**

- sphx_glr_gallery_subplots_axes_and_figures_two_scales.py
- sphx_glr_gallery_statistics_barchart_demo.py

**matplotlib.axes.Axes.twiny**

**Axes.twiny**(self)
Create a twin Axes sharing the yaxis

Create a new Axes instance with an invisible y-axis and an independent x-axis positioned opposite to the original one (i.e. at top). The y-axis autoscale setting will be inherited from the original Axes. To ensure that the tick marks of both x-axes align, see `LinearLocator`

**Returns**

- **ax_twin** [Axes] The newly created Axes instance

**Notes**

For those who are ‘picking’ artists while using twiny, pick events are only called for the artists in the top-most axes.
Examples using `matplotlib.axes.Axes.twiny`

- `sphx_glr_gallery_subplots_axes_and_figures_two_scales.py`

`matplotlib.axes.Axes.get_shared_x_axes`

`Axes.get_shared_x_axes(self)`
  Return a reference to the shared axes Grouper object for x axes.

`matplotlib.axes.Axes.get_shared_y_axes`

`Axes.get_shared_y_axes(self)`
  Return a reference to the shared axes Grouper object for y axes.

### 17.5.11 Axes Position

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axes.get_anchor</code></td>
<td>Get the anchor location.</td>
</tr>
<tr>
<td><code>Axes.set_anchor</code></td>
<td>Define the anchor location.</td>
</tr>
<tr>
<td><code>Axes.get_axes_locator</code></td>
<td>Return the axes locator.</td>
</tr>
<tr>
<td><code>Axes.set_axes_locator</code></td>
<td>Set the axes locator.</td>
</tr>
<tr>
<td><code>Axes.reset_position</code></td>
<td>Reset the active position to the original position.</td>
</tr>
<tr>
<td><code>Axes.get_position</code></td>
<td>Get a copy of the axes rectangle as a <code>Bbox</code>.</td>
</tr>
<tr>
<td><code>Axes.set_position</code></td>
<td>Set the axes position.</td>
</tr>
</tbody>
</table>

`matplotlib.axes.Axes.get_anchor`

`Axes.get_anchor(self)`
  Get the anchor location.

**See also:**

`matplotlib.axes.Axes.set_anchor`

`Axes.set_anchor(self, anchor, share=False)`
  Define the anchor location.

  The actual drawing area (active position) of the Axes may be smaller than the Bbox (original position) when a fixed aspect is required. The anchor defines where the drawing area will be located within the available space.

  **Parameters**

  - `anchor` [2-tuple of floats or {'C', 'SW', 'S', 'SE', ...}] The anchor position may be either:
• a sequence \((cx, cy)\). \(cx\) and \(cy\) may range from 0 to 1, where 0 is left or bottom and 1 is right or top.

• a string using cardinal directions as abbreviation:
  - ‘C’ for centered
  - ‘S’ (south) for bottom-center
  - ‘SW’ (south west) for bottom-left
  - etc.

Here is an overview of the possible positions:

<table>
<thead>
<tr>
<th>NW</th>
<th>N</th>
<th>NE</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>C</td>
<td>E</td>
</tr>
<tr>
<td>SW</td>
<td>S</td>
<td>SE</td>
</tr>
</tbody>
</table>

**share** [bool, optional] If True, apply the settings to all shared Axes. Default is False.

**See also:**

```python
matplotlib.axes.Axes.get_axes_locator

Axes.get_axes_locator(self)
Return the axes_locator.
```

```python
matplotlib.axes.Axes.set_axes_locator

Axes.set_axes_locator(self, locator)
Set the axes locator.

**Parameters**

`locator` [Callable[[Axes, Renderer], Bbox]]
```

```python
matplotlib.axes.Axes.reset_position

Axes.reset_position(self)
Reset the active position to the original position.

This resets the a possible position change due to aspect constraints. For an explanation of the positions see `set_position`.
```

```python
matplotlib.axes.Axes.get_position

Axes.get_position(self, original=False)
Get a copy of the axes rectangle as a Bbox.

**Parameters**

```
original [bool] If True, return the original position. Otherwise return the active position. For an explanation of the positions see set_position.

Returns

pos [Bbox]

Examples using matplotlib.axes.Axes.get_position

• sphx_glr_gallery_images_contours_and_fields_contour_demo.py

matplotlib.axes.Axes.set_position

Axes.set_position(self, pos, which='both')

Set the axes position.

Axes have two position attributes. The ‘original’ position is the position allocated for the Axes. The ‘active’ position is the position the Axes is actually drawn at. These positions are usually the same unless a fixed aspect is set to the Axes. See set_aspect for details.

Parameters

pos [[left, bottom, width, height] or Bbox] The new position of the in Figure coordinates.

which [{‘both’, ‘active’, ‘original’}, optional] Determines which position variables to change.

Examples using matplotlib.axes.Axes.set_position

• sphx_glr_gallery_images_contours_and_fields_contour_demo.py

17.5.12 Async/Event based

Axes.stale

Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

Axes.pchanged

Call all of the registered callbacks.

Axes.add_callback

Add a callback function that will be called whenever one of the Artist's properties changes.

Axes.remove_callback

Remove a callback based on its observer id.

matplotlib.axes.Axes.stale

Axes.stale

Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
Axes.pchanged

`Axes.pchanged(self)`
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:

`add_callback`
`remove_callback`

Axes.add_callback

`Axes.add_callback(self, func)`
Add a callback function that will be called whenever one of the Artist’s properties changes.

Parameters

`func` [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where `artist` is the calling `Artist`. Return values may exist but are ignored.

Returns

`oid` [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

See also:

`remove_callback`

Axes.remove_callback

`Axes.remove_callback(self, oid)`
Remove a callback based on its observer id.

See also:

`add_callback`

17.5.13 Interactive

<tr>
<td>Axes.get_cursor_data</td>
<td>Return the cursor data for a given event.</td>
</tr>
</tbody>
</table>

Matplotlib.axes.Axes.can_pan

Axes.can_pan(self)
Return True if this axes supports any pan/zoom button functionality.

Matplotlib.axes.Axes.can_zoom

Axes.can_zoom(self)
Return True if this axes supports the zoom box button functionality.

Matplotlib.axes.Axes.get_navigate

Axes.get_navigate(self)
Get whether the axes responds to navigation commands
```

```matlab
Axes.set_navigate

Axes.set_navigate(self, b)

Set whether the axes responds to navigation toolbar commands

**Parameters**

- `b` [bool]

```matlab
Axes.get_navigate_mode

Axes.get_navigate_mode(self)

Get the navigation toolbar button status: 'PAN', 'ZOOM', or None

```matlab
Axes.set_navigate_mode

Axes.set_navigate_mode(self, b)

Set the navigation toolbar button status;

**Warning:** this is not a user-API function.

```matlab
Axes.start_pan

Axes.start_pan(self, x, y, button)

Called when a pan operation has started.

- `x, y` are the mouse coordinates in display coords. `button` is the mouse button number:
  - 1: LEFT
  - 2: MIDDLE
  - 3: RIGHT

**Note:** Intended to be overridden by new projection types.

```matlab
Axes.drag_pan

Axes.drag_pan(self, button, key, x, y)

Called when the mouse moves during a pan operation.

- `button` is the mouse button number:
  - 1: LEFT
  - 2: MIDDLE
  - 3: RIGHT
key is a “shift” key
x, y are the mouse coordinates in display coords.

**Note:** Intended to be overridden by new projection types.

```python
matplotlib.axes.Axes.end_pan

Axes.end_pan(self)
Called when a pan operation completes (when the mouse button is up.)

**Note:** Intended to be overridden by new projection types.
```

```python
matplotlib.axes.Axes.format_coord

Axes.format_coord(self, x, y)
Return a format string formatting the x, y coordinates.

**Examples using** `matplotlib.axes.Axes.format_coord`

- sphx_glr_gallery_images_contours_and_fields_image_zcoord.py
```

```python
matplotlib.axes.Axes.format_cursor_data

Axes.format_cursor_data(self, data)
Return a string representation of data.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

`get_cursor_data`

```python
matplotlib.axes.Axes.format_xdata

Axes.format_xdata(self, x)
Return x formatted as an x-value.

This function will use the fmt_xdata attribute if it is not None, else will fall back on the xaxis major formatter.
matplotlib.axes.Axes.format_ydata

Axes.format_ydata(self, y)
    Return y formatted as an y-value.
    This function will use the fmt_ydata attribute if it is not None, else will fall back on the yaxis major formatter.

matplotlib.axes.Axes.mouseover

Axes.mouseover

matplotlib.axes.Axes.in_axes

Axes.in_axes(self, mouseevent)
    Return True if the given mouseevent (in display coords) is in the Axes

matplotlib.axes.Axes.pick

Axes.pick(self, mouseevent)
    Process a pick event.
    Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.
    See also:

    set_picker, get_picker, pickable

matplotlib.axes.Axes.pickable

Axes.pickable(self)
    Return whether the artist is pickable.
    See also:

    set_picker, get_picker, pick

matplotlib.axes.Axes.get_picker

Axes.get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.
    See also:

    set_picker, pickable, pick
Axes.set_picker

Axes.set_picker(self, picker)

Define the picking behavior of the artist.

Parameters

- **picker** [None or bool or float or callable] This can be one of the following:
  - None: Picking is disabled for this artist (default).
  - A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
  - A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
  - A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. If the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes.

Axes.set_contains

Axes.set_contains(self, picker)

Define a custom contains test for the artist.

The provided callable replaces the default contains method of the artist.

Parameters

- **picker** [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:
  - a bool indicating if the event is within the artist
  - a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

Axes.get_contains

Axes.get_contains(self)

Return the custom contains function of the artist if set, or None.

See also:
**set_contains**

```python
matplotlib.axes.Axes.contains
```

*Axes.contains*(self, mouseevent)
Test whether the artist contains the mouse event.

**Parameters**

- `mouseevent` [matplotlib.backend_bases.MouseEvent]

**Returns**

- `contains` [bool] Whether any values are within the radius.
- `details` [dict] An artist-specific dictionary of details of the event context, such as which points are contained in the pick radius. See the individual Artist subclasses for details.

**See also:**

`set_contains, get_contains`

---

**set_contains_point**

```python
matplotlib.axes.Axes.contains_point
```

*Axes.contains_point*(self, point)
Return whether `point` (pair of pixel coordinates) is inside the axes patch.

**get_cursor_data**

```python
matplotlib.axes.Axes.get_cursor_data
```

*Axes.get_cursor_data*(self, event)
Return the cursor data for a given event.

---

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns `None`.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation.

The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

- `event` [matplotlib.backend_bases.MouseEvent]

**See also:**

`format_cursor_data`
17.5.14 Children

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axes.get_children</td>
<td>Return a list of the child Artists of this Artist.</td>
</tr>
<tr>
<td>Axes.get_images</td>
<td>Return a list of Axes images contained by the Axes.</td>
</tr>
<tr>
<td>Axes.get_lines</td>
<td>Return a list of lines contained by the Axes.</td>
</tr>
<tr>
<td>Axes.findobj</td>
<td>Find artist objects.</td>
</tr>
</tbody>
</table>

```python
class Axes:
    def get_children(self):
        """Return a list of the child Artists of this Artist."
        
    def get_images(self):
        """Return a list of Axes images contained by the Axes."
        
    def get_lines(self):
        """Return a list of lines contained by the Axes."
        
    def findobj(self, match=None, include_self=True):
        """Find artist objects.
        Recursively find all Artist instances contained in the artist.
       "

Parameters

match A filter criterion for the matches. This can be

- None: Return all objects contained in artist.
- A function with signature `def match(artist: Artist) -> bool`. The result will only contain artists for which the function returns `True`.
- A class instance: e.g., `Line2D`. The result will only contain artists of this class or its subclasses (`isinstance` check).

include_self [bool] Include self in the list to be checked for a match.

Returns

artists [list of Artist]  

17.5.15 Drawing
### Axes.draw
Draw everything (plot lines, axes, labels)

### Axes.draw_artist
This method can only be used after an initial draw which caches the renderer.

### Axes.redraw_in_frame
This method can only be used after an initial draw which caches the renderer.

### Axes.get_renderer_cache

### Axes.get_rasterization_zorder
Return the zorder value below which artists will be rasterized.

### Axes.set_rasterization_zorder

#### Parameters

### Axes.get_window_extent
Return the axes bounding box in display space; `args` and `kwargs` are empty.

### Axes.get_tightbbox
Return the tight bounding box of the axes, including axis and their decorators (xlabel, title, etc).

---

**matplotlib.axes.Axes.draw**

```python
Axes.draw(self, renderer=None, inframe=False)
```

Draw everything (plot lines, axes, labels)

**matplotlib.axes.Axes.draw_artist**

```python
Axes.draw_artist(self, a)
```

This method can only be used after an initial draw which caches the renderer. It is used to efficiently update Axes data (axis ticks, labels, etc are not updated)

**matplotlib.axes.Axes.redraw_in_frame**

```python
Axes.redraw_in_frame(self)
```

This method can only be used after an initial draw which caches the renderer. It is used to efficiently update Axes data (axis ticks, labels, etc are not updated)

**matplotlib.axes.Axes.get_renderer_cache**

```python
Axes.get_renderer_cache(self)
```

**matplotlib.axes.Axes.get_rasterization_zorder**

```python
Axes.get_rasterization_zorder(self)
```

Return the zorder value below which artists will be rasterized.

**matplotlib.axes.Axes.set_rasterization_zorder**

```python
Axes.set_rasterization_zorder(self, z)
```

**Parameters**

z [float or None] zorder below which artists are rasterized. None means that artists do not get rasterized based on zorder.

matplotlib.axes.Axes.get_window_extent

Axes.get_window_extent(self, *args, **kwargs)
Return the axes bounding box in display space; args and kwargs are empty.
This bounding box does not include the spines, ticks, ticklables, or other labels. For a bounding box including these elements use get_tightbbox.

See also:

- matplotlib.axes.Axes.get_tightbbox
- matplotlib.axis.Axis.get_tightbbox
- matplotlib.spines.get_window_extent

matplotlib.axes.Axes.get_tightbbox

Axes.get_tightbbox(self, renderer, call_axes_locator=True, bbox_extra_artists=None)
Return the tight bounding box of the axes, including axis and their decorators (xlabel, title, etc).
Artists that have artist.set_in_layout(False) are not included in the bbox.

Parameters

- renderer [RendererBase instance] renderer that will be used to draw the figures (i.e. fig.canvas.get_renderer())
- bbox_extra_artists [list of Artist or None] List of artists to include in the tight bounding box. If None (default), then all artist children of the axes are included in the tight bounding box.
- call_axes_locator [boolean (default True)] If call_axes_locator is False, it does not call the _axes_locator attribute, which is necessary to get the correct bounding box. call_axes_locator=False can be used if the caller is only interested in the relative size of the tightbbox compared to the axes bbox.

Returns

- bbox [BboxBase] bounding box in figure pixel coordinates.

See also:

- matplotlib.axis.Axes.get_window_extent
- matplotlib.axis.Axis.get_tightbbox
- matplotlib.spines.get_window_extent

</tbody>
</table>

**matplotlib.axes.Axes.set_agg_filter**

Set the agg filter.

**Parameters**

- `filter_func` [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

**matplotlib.axes.Axes.set_alpha**

Set the alpha value used for blending - not supported on all backends.

**Parameters**

- `alpha` [float]
matplotlib.axes.Axes.set_animated

```python
Axes.set_animated(self, b)
```
Set the artist's animation state.

**Parameters**

- `b` [bool]

matplotlib.axes.Axes.set_clip_box

```python
Axes.set_clip_box(self, clipbox)
```
Set the artist's clip Bbox.

**Parameters**

- `clipbox` [Bbox]

matplotlib.axes.Axes.set_clip_on

```python
Axes.set_clip_on(self, b)
```
Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

- `b` [bool]

matplotlib.axes.Axes.set_clip_path

```python
Axes.set_clip_path(self, path, transform=None)
```
Set the artist's clip path, which may be:

- a `Patch` (or subclass) instance; or
- a `Path` instance, in which case a `Transform` instance, which will be applied to the path before using it for clipping, must be provided; or
- `None`, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to `None`.

**ACCEPTS:** [(Path, Transform) | Patch | None]

matplotlib.axes.Axes.set_gid

```python
Axes.set_gid(self, gid)
```
Set the (group) id for the artist.

**Parameters**

- `gid` [str]
Axes.set_label(self, s)

Set a label that will be displayed in the legend.

Parameters

- s [object] s will be converted to a string by calling str.

Axes.set_path_effects(self, path_effects)

Set the path effects.

Parameters

- path_effects [AbstractPathEffect]

Axes.set_rasterized(self, rasterized)

Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

Parameters

- rasterized [bool or None]

Axes.set_sketch_params(self, scale=None, length=None, randomness=None)

Sets the sketch parameters.

Parameters

- scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.
- length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
- randomness [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

Axes.set_snap(self, snap)

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move
the line to the nearest integer pixel value, so that the resulting image will really contain
a 1px wide black line.
Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

**snap** [bool or None] Possible values:
- True: Snap vertices to the nearest pixel center.
- False: Do not modify vertex positions.
- None: (auto) If the path contains only rectilinear line segments, round
to the nearest pixel center.

`matplotlib.axes.Axes.set_transform`

`Axes.set_transform(self, t)`
Set the artist transform.

**Parameters**

**t** [Transform]

`matplotlib.axes.Axes.set_url`

`Axes.set_url(self, url)`
Set the url for the artist.

**Parameters**

**url** [str]

`matplotlib.axes.Axes.set_visible`

`Axes.set_visible(self, b)`
Set the artist’s visibility.

**Parameters**

**b** [bool]

`matplotlib.axes.Axes.set_zorder`

`Axes.set_zorder(self, level)`
Set the zorder for the artist. Artists with lower zorder values are drawn first.

**Parameters**

**level** [float]

`matplotlib.axes.Axes.get_agg_filter`

`Axes.get_agg_filter(self)`
Return filter function to be used for agg filter.
matplotlib.axes.Axes.get_alpha

Axes.get_alpha(self)
    Return the alpha value used for blending - not supported on all backends

matplotlib.axes.Axes.get_animated

Axes.get_animated(self)
    Return the animated state.

matplotlib.axes.Axes.get_clip_box

Axes.get_clip_box(self)
    Return the clipbox.

matplotlib.axes.Axes.get_clip_on

Axes.get_clip_on(self)
    Return whether the artist uses clipping.

matplotlib.axes.Axes.get_clip_path

Axes.get_clip_path(self)
    Return the clip path.

matplotlib.axes.Axes.get_gid

Axes.get_gid(self)
    Return the group id.

matplotlib.axes.Axes.get_label

Axes.get_label(self)
    Return the label used for this artist in the legend.

matplotlib.axes.Axes.get_path_effects

Axes.get_path_effects(self)

matplotlib.axes.Axes.get_rasterized

Axes.get_rasterized(self)
    Return whether the artist is to be rasterized.
matplotlib.axes.Axes.get_sketch_params

Axes.get_sketch_params(self)
    Returns the sketch parameters for the artist.

**Returns**

**sketch_params** [tuple or None] A 3-tuple with the following elements:
- *scale*: The amplitude of the wiggle perpendicular to the source line.
- *length*: The length of the wiggle along the line.
- *randomness*: The scale factor by which the length is shrunken or expanded.

Returns *None* if no sketch parameters were set.

matplotlib.axes.Axes.get_snap

Axes.get_snap(self)
    Returns the snap setting.

    See *set_snap* for details.

matplotlib.axes.Axes.get_transform

Axes.get_transform(self)
    Return the *Transform* instance used by this artist.

matplotlib.axes.Axes.get_url

Axes.get_url(self)
    Return the url.

matplotlib.axes.Axes.get_visible

Axes.get_visible(self)
    Return the visibility.

matplotlib.axes.Axes.get_zorder

Axes.get_zorder(self)
    Return the artist’s zorder.

matplotlib.axes.Axes.axes

Axes.axes
    The *Axes* instance the artist resides in, or *None*.
matplotlib.axes.Axes.set_figure

Axes.set_figure(self, fig)
Set the Figure for this Axes.

Parameters

fig [Figure]

matplotlib.axes.Axes.get_figure

Axes.get_figure(self)
Return the Figure instance the artist belongs to.

17.5.18 Artist Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axes.remove</td>
<td>Remove the artist from the figure if possible.</td>
</tr>
<tr>
<td>Axes.is_transform_set</td>
<td>Return whether the Artist has an explicitly set transform.</td>
</tr>
</tbody>
</table>

matplotlib.axes.Axes.remove

Axes.remove(self)
Remove the artist from the figure if possible.

The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.draw_idle. Call relim to update the axes limits if desired.

Note: relim will not see collections even if the collection was added to the axes with autolim = True.

Note: there is no support for removing the artist’s legend entry.

matplotlib.axes.Axes.is_transform_set

Axes.is_transform_set(self)
Return whether the Artist has an explicitly set transform.

This is True after set_transform has been called.

17.5.19 Projection

Methods used by Axis that must be overridden for non-rectilinear Axes.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axes.name</td>
<td></td>
</tr>
<tr>
<td>Axes.get_xaxis_transform</td>
<td>Get the transformation used for drawing x-axis labels, ticks and gridlines.</td>
</tr>
<tr>
<td>Axes.get_yaxis_transform</td>
<td>Get the transformation used for drawing y-axis labels, ticks and gridlines.</td>
</tr>
<tr>
<td>Axes.get_data_ratio</td>
<td>Return the aspect ratio of the raw data.</td>
</tr>
</tbody>
</table>

Continued on next page
Axes.get_data_ratio_log

Return the aspect ratio of the raw data in log scale.

Axes.get_xaxis_text1_transform

Returns

Axes.get_xaxis_text2_transform

Returns

Axes.get_yaxis_text1_transform

Returns

Axes.get_yaxis_text2_transform

Returns

matplotlib.axes.Axes.name

Axes.name = 'rectilinear'

matplotlib.axes.Axes.get_xaxis_transform

Axes.get_xaxis_transform(self, which='grid')

Get the transformation used for drawing x-axis labels, ticks and gridlines. The x-direction is in data coordinates and the y-direction is in axis coordinates.

Note: This transformation is primarily used by the Axes class, and is meant to be over-ridden by new kinds of projections that may need to place axis elements in different locations.

Examples using matplotlib.axes.Axes.get_xaxis_transform

- Transformations Tutorial

17.5. matplotlib.axes

1051
Examples using `matplotlib.axes.Axes.get_yaxis_transform`

- *Transformations Tutorial*

`matplotlib.axes.Axes.get_data_ratio`

```python
Axes.get_data_ratio(self)
    Return the aspect ratio of the raw data.
```

**Notes**

This method is intended to be overridden by new projection types.

`matplotlib.axes.Axes.get_data_ratio_log`

```python
Axes.get_data_ratio_log(self)
    Return the aspect ratio of the raw data in log scale.
```

**Notes**

Will be used when both axis are in log scale.

`matplotlib.axes.Axes.get_xaxis_text1_transform`

```python
Axes.get_xaxis_text1_transform(self, pad_points)
    Returns
        transform [Transform] The transform used for drawing x-axis labels, which
        will add `pad_points` of padding (in points) between the axes and the la-
        bel. The x-direction is in data coordinates and the y-direction is in axis
        coordinates
        valign [ {’center’, ‘top’, ‘bottom’, ’baseline’, ’center_baseline’}] The text
        vertical alignment.
        halign [ {’center’, ’left’, ’right’}] The text horizontal alignment.
```

**Notes**

This transformation is primarily used by the `Axis` class, and is meant to be overridden by
new kinds of projections that may need to place axis elements in different locations.
Axes.get_xaxis_text2_transform

```
Axes.get_xaxis_text2_transform(self, pad_points)
```

**Returns**

- **transform** [Transform] The transform used for drawing secondary x-axis labels, which will add `pad_points` of padding (in points) between the axes and the label. The x-direction is in data coordinates and the y-direction is in axis coordinates.
- **valign** `{'center', 'top', 'bottom', 'baseline', 'center_baseline'}` The text vertical alignment.
- **halign** `{'center', 'left', 'right'}` The text horizontal alignment.

**Notes**

This transformation is primarily used by the `Axes` class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

Axes.get_yaxis_text1_transform

```
Axes.get_yaxis_text1_transform(self, pad_points)
```

**Returns**

- **transform** [Transform] The transform used for drawing y-axis labels, which will add `pad_points` of padding (in points) between the axes and the label. The x-direction is in axis coordinates and the y-direction is in data coordinates.
- **valign** `{'center', 'top', 'bottom', 'baseline', 'center_baseline'}` The text vertical alignment.
- **halign** `{'center', 'left', 'right'}` The text horizontal alignment.

**Notes**

This transformation is primarily used by the `Axes` class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

Axes.get_yaxis_text2_transform

```
Axes.get_yaxis_text2_transform(self, pad_points)
```

**Returns**

- **transform** [Transform] The transform used for drawing secondary y-axis labels, which will add `pad_points` of padding (in points) between the axes and the label. The x-direction is in axis coordinates and the y-direction is in data coordinates.
- **valign** `{'center', 'top', 'bottom', 'baseline', 'center_baseline'}` The text vertical alignment.
**halign** [\{'center', 'left', 'right'\}] The text horizontal alignment.

**Notes**

This transformation is primarily used by the *Axis* class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

### 17.5.20 Other

**Axes.zorder**

`Axes.zorder = 0`

**Axes.get_default_bbox_extra_artists**

`Axes.get_default_bbox_extra_artists()`  
Return a default list of artists that are used for the bounding box calculation.  
Artists are excluded either by not being visible or artist.set_in_layout(False).

**Axes.get_transformed_clip_path_and_affine**

`Axes.get_transformed_clip_path_and_affine()`  
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

**Axes.has_data**

`Axes.has_data()`  
Return *True* if any artists have been added to axes.  
This should not be used to determine whether the *dataLim* need to be updated, and may not actually be useful for anything.
17.5.21 Inheritance

Classes for the ticks and x and y axis.
17.6.1 Inheritance

17.6.2 Axis objects

class matplotlib.axis.Axis(axes, pickradius=15)
    Base class for XAxis and YAxis.

    Attributes
    isDefault_label [bool]
        axes [matplotlib.axes.Axes] The Axes instance the artist resides in, or None.
    major [matplotlib.axis.Ticker] Determines the major tick positions and their label format.
    minor [matplotlib.axis.Ticker] Determines the minor tick positions and their label format.
    callbacks [matplotlib.cbook.CallbackRegistry]
    label [Text] The axis label.
    labelpad [float] The distance between the axis label and the tick labels. Defaults to rcParams["axes.labelpad"] = 4.
    offsetText [Text] A Text object containing the data offset of the ticks (if any).
    pickradius [float] The acceptance radius for containment tests. See also Axis.contains.
    majorTicks [list of Tick] The major ticks.
    minorTicks [list of Tick] The minor ticks.

    Parameters
    pickradius [float] The acceptance radius for containment tests. See also Axis.contains.
class matplotlib.axis.XAxis(axes, pickradius=15)

Parameters

pickradius [float] The acceptance radius for containment tests. See also Axis.contains.

class matplotlib.axis.YAxis(axes, pickradius=15)

Parameters

pickradius [float] The acceptance radius for containment tests. See also Axis.contains.

class matplotlib.axis.Ticker
A container for the objects defining tick position and format.

Attributes

locator [matplotlib.ticker.Locator subclass] Determines the positions of the ticks.
formatter [matplotlib.ticker.Formatter subclass] Determines the format of the tick labels.

Axis.cla clear the current axis
Axis.get_scale

matplotlib.axis.Axis.cla

Axis.cla(self)
clear the current axis

matplotlib.axis.Axis.get_scale

Axis.get_scale(self)

Formatters and Locators

Axis.get_major_formatter Get the formatter of the major ticker
Axis.get_major_locator Get the locator of the major ticker
Axis.get_minor_formatter Get the formatter of the minor ticker
Axis.get_minor_locator Get the locator of the minor ticker
Axis.set_major_formatter Set the formatter of the major ticker
Axis.set_major_locator Set the locator of the major ticker
Axis.set_minor_formatter Set the formatter of the minor ticker
Axis.set_minor_locator Set the locator of the minor ticker
Axis.remove_overlapping_locs If minor ticker locations that overlap with major ticker locations should be trimmed.
Axis.get_remove_overlapping_locs

Continued on next page

17.6. matplotlib.axis 1057
Table 112 – continued from previous page

Axis.set_remove_overlapping_locs

matplotlib.axis.Axis.get_major_formatter

Axis.get_major_formatter(self)
    Get the formatter of the major ticker

matplotlib.axis.Axis.get_major_locator

Axis.get_major_locator(self)
    Get the locator of the major ticker

matplotlib.axis.Axis.get_minor_formatter

Axis.get_minor_formatter(self)
    Get the formatter of the minor ticker

matplotlib.axis.Axis.get_minor_locator

Axis.get_minor_locator(self)
    Get the locator of the minor ticker

matplotlib.axis.Axis.set_major_formatter

Axis.set_major_formatter(self, formatter)
    Set the formatter of the major ticker.

    Parameters

    formatter [Formatter]

Examples using matplotlib.axis.Axis.set_major_formatter

• sphx_glr_gallery_lines_bars_and_markers_timeline.py
• sphx_glr_gallery_pyplots_dollar_ticks.py

matplotlib.axis.Axis.set_major_locator

Axis.set_major_locator(self, locator)
    Set the locator of the major ticker.

    Parameters

    locator [Locator]
Examples using matplotlib.axis.Axis.set_major_locator

- sphx_glr_gallery_lines_bars_and_markers_filled_step.py
- sphx_glr_gallery_lines_bars_and_markers_timeline.py
- sphx_glr_gallery_scales_scales.py

matplotlib.axis.Axis.set_minor_formatter

Axis.set_minor_formatter(self, formatter)

Set the formatter of the minor ticker.

Parameters

- **formatter** [Formatter]

Examples using matplotlib.axis.Axis.set_minor_formatter

- sphx_glr_gallery_pyplots_pyplot_scales.py

matplotlib.axis.Axis.set_minor_locator

Axis.set_minor_locator(self, locator)

Set the locator of the minor ticker.

Parameters

- **locator** [Locator]

matplotlib.axis.Axis.remove_overlapping_locs

Axis.remove_overlapping_locs

If minor ticker locations that overlap with major ticker locations should be trimmed.

matplotlib.axis.Axis.get_remove_overlapping_locs

Axis.get_remove_overlapping_locs(self)

matplotlib.axis.Axis.set_remove_overlapping_locs

Axis.set_remove_overlapping_locs(self, val) 

Continued on next page
Axis Label

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axis.set_label_coords</code></td>
<td>Set the coordinates of the label.</td>

<tr>
<td><code>Axis.get_label_position</code></td>
<td>Return the label position (top or bottom)</td>
</tr>
<tr>
<td><code>Axis.get_label_text</code></td>
<td>Get the text of the label</td>
</tr>
</tbody>
</table>

**matplotlib.axis.Axis.set_label_coords**

`Axis.set_label_coords(self, x, y, transform=None)`

Set the coordinates of the label.

By default, the x coordinate of the y label is determined by the tick label bounding boxes, but this can lead to poor alignment of multiple ylabels if there are multiple axes. Ditto for the y coordinate of the x label.

You can also specify the coordinate system of the label with the transform. If None, the default coordinate system will be the axes coordinate system (0,0) is (left,bottom), (0.5, 0.5) is middle, etc

**Examples using matplotlib.axis.Axis.set_label_coords**

- sphx_glr_gallery_pyplots_align_ylabels.py

**matplotlib.axis.Axis.set_label_position**

`Axis.set_label_position(self, position)`

Set the label position (top or bottom)

**Parameters**

- `position` [str] {'top', 'bottom'}

**matplotlib.axis.Axis.set_label_text**

`Axis.set_label_text(self, label, fontdict=None, **kwargs)`

Set the text value of the axis label.

**Parameters**

- `label` [str] Text string.
- `fontdict` [dict] Text properties.
- `**kwargs` Merged into fontdict.
Matplotlib, Release 3.1.1

**matplot.lib.axis.Axis.get_label_position**

```
Axis.get_label_position(self)
    Return the label position (top or bottom)
```

**matplot.lib.axis.Axis.get_label_text**

```
Axis.get_label_text(self)
    Get the text of the label
```

**Ticks, tick labels and Offset text**

```

`matplotlib.axis.Axis.get_majorticklocs`

```
Axis.get_majorticklocs(self)
    Get the array of major tick locations in data coordinates.
```

`matplotlib.axis.Axis.get_minor_ticks`

```
Axis.get_minor_ticks(self, numticks=None)
    Get the minor tick instances; grow as necessary.
```

`matplotlib.axis.Axis.get_minorticklabels`

```
Axis.get_minorticklabels(self)
    Return a list of Text instances for the minor ticklabels.
```

`matplotlib.axis.Axis.get_minorticklines`

```
Axis.get_minorticklines(self)
    Return the minor tick lines as a list of Line2D instances
```

`matplotlib.axis.Axis.get_minorticklocs`

```
Axis.get_minorticklocs(self)
    Get the array of minor tick locations in data coordinates.
```

`matplotlib.axis.Axis.get_offset_text`

```
Axis.get_offset_text(self)
    Return the axis offsetText as a Text instance
```
Matplotlib, Release 3.1.1

matplotlib.axis.Axis.get_tick_padding

Axis.get_tick_padding(self)

matplotlib.axis.Axis.get_ticklabels

Axis.get_ticklabels(self, minor=False, which=None)
Get the tick labels as a list of Text instances.

Parameters

 minor [bool] If True return the minor ticklabels, else return the major ticklabels

 which [None, ('minor', 'major', 'both')] Overrides minor.
Selects which ticklabels to return

Returns

ret [list] List of Text instances.

Examples using matplotlib.axis.Axis.get_ticklabels

• sphx_glr_gallery_pyplots_fig_axes_customize_simple.py

matplotlib.axis.Axis.get_ticklines

Axis.get_ticklines(self, minor=False)
Return the tick lines as a list of Line2D instances

Examples using matplotlib.axis.Axis.get_ticklines

• sphx_glr_gallery_pyplots_fig_axes_customize_simple.py

matplotlib.axis.Axis.get_ticklocs

Axis.get_ticklocs(self, minor=False)
Get the array of tick locations in data coordinates.

matplotlib.axis.Axis.get_gridlines

Axis.get_gridlines(self)
Return the grid lines as a list of Line2D instances.
matplotlib.axis.Axis.grid

`Axis.grid(self, b=None, which='major', **kwargs)`
Configure the grid lines.

**Parameters**

- **b** [bool or None] Whether to show the grid lines. If any `kwargs` are supplied, it is assumed you want the grid on and `b` will be set to True.
  
  If `b` is `None` and there are no `kwargs`, this toggles the visibility of the lines.

- **which** [{‘major’, ‘minor’, ‘both’}] The grid lines to apply the changes on.

- **kwargs** [Line2D properties] Define the line properties of the grid, e.g.:
  ```
  grid(color='r', linestyle='-', linewidth=2)
  ```

matplotlib.axis.Axis.set_tick_params

`Axis.set_tick_params(self, which='major', reset=False, **kw)`
Set appearance parameters for ticks, ticklabels, and gridlines.

For documentation of keyword arguments, see `matplotlib.axes.Axes.tick_params()`.

matplotlib.axis.Axis.axis_date

`Axis.axis_date(self, tz=None)`
Sets up axis ticks and labels treating data along this axis as dates.

**Parameters**

- **tz** [tzinfo or str or None] The timezone used to create date labels.

Data and view intervals

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axis.get_data_interval</code></td>
<td>Return the Interval instance for this axis data limits.</td>
</tr>
<tr>
<td><code>Axis.get_view_interval</code></td>
<td>Return the Interval instance for this axis view limits.</td>
</tr>
<tr>
<td><code>Axis.set_data_interval</code></td>
<td>Set the axis data limits.</td>
</tr>
<tr>
<td><code>Axis.set_view_interval</code></td>
<td>Set the axis view view limits.</td>
</tr>
</tbody>
</table>

matplotlib.axis.Axis.get_data_interval

`Axis.get_data_interval(self)`

Return the Interval instance for this axis data limits.
matplotlib.axis.Axis.get_view_interval

Axis.get_view_interval(self)
    Return the Interval instance for this axis view limits.

matplotlib.axis.Axis.set_data_interval

Axis.set_data_interval(self, vmin, vmax, ignore=False)
Set the axis data limits. This method is for internal use.

    If ignore is False (the default), this method will never reduce the preexisting data limits, only expand them if vmin or vmax are not within them. Moreover, the order of vmin and vmax does not matter; the orientation of the axis will not change.

    If ignore is True, the data limits will be set exactly to (vmin, vmax) in that order.

matplotlib.axis.Axis.set_view_interval

Axis.set_view_interval(self, vmin, vmax, ignore=False)
Set the axis view limits. This method is for internal use; Matplotlib users should typically use e.g. set_xlim and set_ylim.

    If ignore is False (the default), this method will never reduce the preexisting view limits, only expand them if vmin or vmax are not within them. Moreover, the order of vmin and vmax does not matter; the orientation of the axis will not change.

    If ignore is True, the view limits will be set exactly to (vmin, vmax) in that order.

Rendering helpers

Axis.get_minpos
Axis.get_tick_space
    Return the estimated number of ticks that can fit on the axis.

Axis.get_ticklabel_extents
    Get the extents of the tick labels on either side of the axes.

Axis.get_tightbbox
    Return a bounding box that encloses the axis.

matplotlib.axis.Axis.get_minpos

Axis.get_minpos(self)

matplotlib.axis.Axis.get_tick_space

Axis.get_tick_space(self)
    Return the estimated number of ticks that can fit on the axis.
`Axis.get_ticklabel_extents`  
`Axis.get_ticklabel_extents(self, renderer)`  
Get the extents of the tick labels on either side of the axes.

`Axis.get_tightbbox`  
`Axis.get_tightbbox(self, renderer)`  
Return a bounding box that encloses the axis. It only accounts tick labels, axis label, and `offsetText`.

**Interactive**

`Axis.get_pickradius`  
`Axis.set_pickradius`  
Return the depth of the axis used by the picker

`Axis.get_pickradius`  
`Axis.get_pickradius(self)`  
Return the depth of the axis used by the picker

`Axis.set_pickradius`  
`Axis.set_pickradius(self, pickradius)`  
Set the depth of the axis used by the picker.

**Parameters**

`pickradius` [float]

**Units**

`Axis.convert_units`  
`Axis.set_units`  
`Axis.get_units`  
`Axis.update_units`  
Set the units for axis.

**Introspect**

`Axis.convert_units`  
`Axis.set_units`  
`Axis.get_units`  
`Axis.update_units`  
`Axis.update_units(introspect data for units converter and update the axis.converter instance if necessary.)`
matplotlib.axis.Axis.set_units

Axis.set_units(self, u)
    Set the units for axis.

Parameters
    u [units tag]

matplotlib.axis.Axis.get_units

Axis.get_units(self)
    Return the units for axis.

matplotlib.axis.Axis.update_units

Axis.update_units(self, data)
    Introspect data for units converter and update the axis.converter instance if necessary. Return True if data is registered for unit conversion.

Incremental navigation

Axis.pan
    Pan by numsteps (can be positive or negative).

Axis.zoom
    Zoom in/out on axis; if direction is >0 zoom in, else zoom out.

matplotlib.axis.Axis.pan

Axis.pan(self, numsteps)
    Pan by numsteps (can be positive or negative).

matplotlib.axis.Axis.zoom

Axis.zoom(self, direction)
    Zoom in/out on axis; if direction is >0 zoom in, else zoom out.

YAxis Specific

YAxis.axis_name
YAxis.get_text_widths
YAxis.get_ticks_position
    Return the ticks position ("left", "right", "default", or "unknown").
YAxis.set_offset_position

Parameters

Continued on next page
Matplotlib, Release 3.1.1

Table 120 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>YAxis.set_ticks_position</code></td>
<td>Set the ticks position (left, right, both, default or none) ‘both’ sets the ticks to appear on both positions, but does not change the tick labels.</td>
</tr>
<tr>
<td><code>YAxis.tick_left</code></td>
<td>Move ticks and ticklabels (if present) to the left of the axes.</td>
</tr>
<tr>
<td><code>YAxis.tick_right</code></td>
<td>Move ticks and ticklabels (if present) to the right of the axes.</td>
</tr>
</tbody>
</table>

```
matplotlib.axis.YAxis.axis_name

YAxis.axis_name = 'y'
```

```
matplotlib.axis.YAxis.get_text_widths

YAxis.get_text_widths(self, renderer)
```

```
matplotlib.axis.YAxis.get_ticks_position

YAxis.get_ticks_position(self)
    Return the ticks position ("left", "right", "default", or "unknown”).
```

```
matplotlib.axis.YAxis.set_offset_position

YAxis.set_offset_position(self, position)
    Parameters
    position [{‘left’, ‘right’}]
```

```
matplotlib.axis.YAxis.set_ticks_position

YAxis.set_ticks_position(self, position)
    Set the ticks position (left, right, both, default or none) ‘both’ sets the ticks to appear on both positions, but does not change the tick labels. ‘default’ resets the tick positions to the default: ticks on both positions, labels at left. ‘none’ can be used if you don’t want any ticks. ‘none’ and ‘both’ affect only the ticks, not the labels.
    Parameters
    position [{‘left’, ‘right’, ‘both’, ‘default’, ‘none’}]
```

Examples using `matplotlib.axis.YAxis.set_ticks_position`

- sphx_glr_gallery_pyplots_whats_new_99_spines.py
```python
matplotlib.axis.YAxis.tick_left

YAxis.tick_left(self)
    Move ticks and ticklabels (if present) to the left of the axes.

matplotlib.axis.YAxis.tick_right

YAxis.tick_right(self)
    Move ticks and ticklabels (if present) to the right of the axes.

**XAxis Specific**

<table>
<thead>
<tr>
<th>XAxis.axis_name</th>
<th>Returns the amount of space one should reserve for text above and below the axes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>XAxis.get_text_heights</td>
<td>Return the ticks position (&quot;top&quot;, &quot;bottom&quot;, &quot;default&quot;, or &quot;unknown&quot;).</td>
</tr>
<tr>
<td>XAxis.set_ticks_position</td>
<td>Set the ticks position (top, bottom, both, default or none) both sets the ticks to appear on both positions, but does not change the tick labels.</td>
</tr>
<tr>
<td>XAxis.tick_bottom</td>
<td>Move ticks and ticklabels (if present) to the bottom of the axes.</td>
</tr>
<tr>
<td>XAxis.tick_top</td>
<td>Move ticks and ticklabels (if present) to the top of the axes.</td>
</tr>
</tbody>
</table>

matplotlib.axis.XAxis.axis_name

XAxis.axis_name = 'x'

matplotlib.axis.XAxis.get_text_heights

XAxis.get_text_heights(self, renderer)
    Returns the amount of space one should reserve for text above and below the axes. Returns a tuple (above, below)

matplotlib.axis.XAxis.get_ticks_position

XAxis.get_ticks_position(self)
    Return the ticks position ("top", "bottom", "default", or "unknown").

matplotlib.axis.XAxis.set_ticks_position

XAxis.set_ticks_position(self, position)
    Set the ticks position (top, bottom, both, default or none) both sets the ticks to appear on both positions, but does not change the tick labels. 'default' resets the tick positions
```
to the default: ticks on both positions, labels at bottom. ‘none’ can be used if you don’t want any ticks. ‘none’ and ‘both’ affect only the ticks, not the labels.

**Parameters**

position [{‘top’, ‘bottom’, ‘both’, ‘default’, ‘none’}]

**Examples using** matplotlib.axis.XAxis.set_ticks_position

- sphx_glr_gallery_pyplots_whats_new_99_spines.py

```python
matplotlib.axis.XAxis.tick_bottom
```

`XAxis.tick_bottom(self)`

Move ticks and ticklabels (if present) to the bottom of the axes.

```python
matplotlib.axis.XAxis.tick_top
```

`XAxis.tick_top(self)`

Move ticks and ticklabels (if present) to the top of the axes.

**Other**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axis.OFFSETTEXTPAD</code></td>
<td></td>
</tr>
<tr>
<td><code>Axis.limit_range_for_scale</code></td>
<td>Re-initialize the major and minor Tick lists.</td>
</tr>
<tr>
<td><code>Axis.reset_ticks</code></td>
<td>Set the default limits for the axis data and view interval if they have not been not mutated yet.</td>
</tr>
<tr>
<td><code>Axis.set_default_intervals</code></td>
<td></td>
</tr>
<tr>
<td><code>Axis.get_smart_bounds</code></td>
<td>Return whether the axis has smart bounds.</td>
</tr>
<tr>
<td><code>Axis.set_smart_bounds</code></td>
<td>Set the axis to have smart bounds.</td>
</tr>
</tbody>
</table>

```python
matplotlib.axis.Axis.OFFSETTEXTPAD
```

`Axis.OFFSETTEXTPAD = 3`

```python
matplotlib.axis.Axis.limit_range_for_scale
```

`Axis.limit_range_for_scale(self, vmin, vmax)`

```python
matplotlib.axis.Axis.reset_ticks
```

`Axis.reset_ticks(self)`

Re-initialize the major and minor Tick lists.

Each list starts with a single fresh Tick.
**matplotlib.axis.Axis.set_default_intervals**

```python
Axis.set_default_intervals(self)
```

Set the default limits for the axis data and view interval if they have not been not mutated yet.

**matplotlib.axis.Axis.get_smart_bounds**

```python
Axis.get_smart_bounds(self)
```

Return whether the axis has smart bounds.

**matplotlib.axis.Axis.set_smart_bounds**

```python
Axis.set_smart_bounds(self, value)
```

Set the axis to have smart bounds.

**Discouraged**

These methods implicitly use `FixedLocator` and `FixedFormatter`. They can be convenient, but if not used together may de-couple your tick labels from your data.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Axis.set_ticklabels</code></td>
<td>Set the text values of the tick labels.</td>
</tr>
<tr>
<td><code>Axis.set_ticks</code></td>
<td>Set the locations of the tick marks from sequence ticks</td>
</tr>
</tbody>
</table>

**matplotlib.axis.Axis.set_ticklabels**

```python
Axis.set_ticklabels(self, ticklabels, *args, minor=False, **kwargs)
```

Set the text values of the tick labels.

**Parameters**

- `ticklabels` [sequence of str or of Texts] List of texts for tick labels; must include values for non-visible labels.
- `minor` [bool] If True, set minor ticks instead of major ticks.
- `**kwargs` Text properties.

**Returns**

- `labels` [list of Texts] For each tick, includes `tick.label1` if it is visible, then `tick.label2` if it is visible, in that order.

**matplotlib.axis.Axis.set_ticks**

```python
Axis.set_ticks(self, ticks, minor=False)
```

Set the locations of the tick marks from sequence ticks

**Parameters**
ticks [sequence of floats]
minor [bool]

Examples using matplotlib.axis.Axis.set_ticks

• sphx_glr_gallery_pyplots_whats_new_99_spines.py

17.6.3 Tick objects

class matplotlib.axis.Tick(axes, loc, label, size=None, width=None, color=None, tickdir=None, pad=None, labelsize=None, labelcolor=None, zorder=None, gridOn=None, tick1On=True, tick2On=True, label1On=True, label2On=False, major=True, labelrotation=0, grid_color=None, grid_linestyle=None, grid_linewidth=None, grid_alpha=None, **kw)

Abstract base class for the axis ticks, grid lines and labels.

Ticks mark a position on an Axis. They contain two lines as markers and two labels; one each for the bottom and top positions (in case of an XAxis) or for the left and right positions (in case of a YAxis).

Attributes

tick1line [Line2D] The left/bottom tick marker.
tick2line [Line2D] The right/top tick marker.
gridline [Line2D] The grid line associated with the label position.
label1 [Text] The left/bottom tick label.
label2 [Text] The right/top tick label.

bbox is the Bound2D bounding box in display coords of the Axes loc is the tick location in data coords size is the tick size in points

class matplotlib.axis.XTick(axes, loc, label, size=None, width=None, color=None, tickdir=None, pad=None, labelsize=None, labelcolor=None, zorder=None, gridOn=None, tick1On=True, tick2On=True, label1On=True, label2On=False, major=True, labelrotation=0, grid_color=None, grid_linestyle=None, grid_linewidth=None, grid_alpha=None, **kw)

Contains all the Artists needed to make an x tick - the tick line, the label text and the grid line

bbox is the Bound2D bounding box in display coords of the Axes loc is the tick location in data coords size is the tick size in points

class matplotlib.axis.YTick(axes, loc, label, size=None, width=None, color=None, tickdir=None, pad=None, labelsize=None, labelcolor=None, zorder=None, gridOn=None, tick1On=True, tick2On=True, label1On=True, label2On=False, major=True, labelrotation=0, grid_color=None, grid_linestyle=None, grid_linewidth=None, grid_alpha=None, **kw)
Contains all the Artists needed to make a Y tick - the tick line, the label text and the grid line
bbox is the Bound2D bounding box in display coords of the Axes loc is the tick location in data coords size is the tick size in points

```python
matplotlib.axis.Tick.apply_tickdir

Tick.apply_tickdir(self, tickdir)
    Calculate self._pad and self._tickmarkers.

matplotlib.axis.Tick.get_loc

Tick.get_loc(self)
    Return the tick location (data coords) as a scalar

matplotlib.axis.Tick.get_pad

Tick.get_pad(self)
    Get the value of the tick label pad in points

matplotlib.axis.Tick.get_pad_pixels

Tick.get_pad_pixels(self)

matplotlib.axis.Tick.get_tick_padding

Tick.get_tick_padding(self)
    Get the length of the tick outside of the axes.
```
Matplotlib, Release 3.1.1

matplotlib.axis.Tick.get_tickdir

Tick.get_tickdir(self)

matplotlib.axis.Tick.get_view_interval

Tick.get_view_interval(self)
return the view Interval instance for the axis this tick is ticking

matplotlib.axis.Tick.set_label1

Tick.set_label1(self, s)
Set the label1 text.

Parameters
s [str]

matplotlib.axis.Tick.set_label2

Tick.set_label2(self, s)
Set the label2 text.

Parameters
s [str]

matplotlib.axis.Tick.set_pad

Tick.set_pad(self, val)
Set the tick label pad in points

Parameters
val [float]

matplotlib.axis.Tick.update_position

Tick.update_position(self, loc)
Set the location of tick in data coords with scalar loc

17.6.4 Common and inherited methods

XTick

<table>

```python
matplotlib.axis.XTick.get_tickdir

XTick.get_tickdir(self)
```

```python
matplotlib.axis.XTick.get_view_interval

XTick.get_view_interval(self)
    Return the view Interval instance for the axis this tick is ticking
```
Matplotlib, Release 3.1.1

**Matplotlib.axis.XTick.set_label1**

```python
XTick.set_label1(self, s)
Set the label1 text.

**Parameters**

- `s` [str]
```

**Matplotlib.axis.XTick.set_label2**

```python
XTick.set_label2(self, s)
Set the label2 text.

**Parameters**

- `s` [str]
```

**Matplotlib.axis.XTick.set_pad**

```python
XTick.set_pad(self, val)
Set the tick label pad in points

**Parameters**

- `val` [float]
```

**Matplotlib.axis.XTick.update_position**

```python
XTick.update_position(self, loc)
Set the location of tick in data coords with scalar `loc`.
```

YTick

</tbody>
</table>
```

matplotlib.axis.YTick.apply_tickdir

YTick.apply_tickdir(self, tickdir)
    Calculate self._pad and self._tickmarkers.

matplotlib.axis.YTick.get_loc

YTick.get_loc(self)
    Return the tick location (data coords) as a scalar

matplotlib.axis.YTick.get_pad

YTick.get_pad(self)
    Get the value of the tick label pad in points

matplotlib.axis.YTick.get_pad_pixels

YTick.get_pad_pixels(self)

matplotlib.axis.YTick.get_tick_padding

YTick.get_tick_padding(self)
    Get the length of the tick outside of the axes.

matplotlib.axis.YTick.get_tickdir

YTick.get_tickdir(self)

matplotlib.axis.YTick.get_view_interval

YTick.get_view_interval(self)
    Return the Interval instance for this axis view limits.

matplotlib.axis.YTick.set_label1

YTick.set_label1(self, s)
    Set the label1 text.

    Parameters
    s [str]
```
Matplotlib, Release 3.1.1

.. _yaxis:

YAxis

YAxis.OFFSETTEXTPAD

YAxis.axis_date

Sets up axis ticks and labels treating data along this axis as dates.

YAxis.cla

clear the current axis

YAxis.convert_units

YAxis.get_data_interval

Return the grid lines as a list of Line2D instances

YAxis.get_label_position

Return the label position (top or bottom)

YAxis.get_label_text

Get the text of the label

YAxis.get_major_formatter

Get the formatter of the major ticker

YAxis.get_major_locator

Get the locator of the major ticker

YAxis.get_major_ticks

Get the tick instances; grow as necessary.

YAxis.get_major_ticklabels

Return a list of Text instances for the major ticklabels.

YAxis.get_major_ticklines

Return the major tick lines as a list of Line2D instances

YAxis.get_major_ticklocs

Get the array of major tick locations in data coordinates.

YAxis.get_minor_formatter

Get the formatter of the minor ticker

YAxis.get_minor_locator

Get the locator of the minor ticker

YAxis.get_minor_ticks

Get the minor tick instances; grow as necessary.

YAxis.get_minor_ticklabels

Return a list of Text instances for the minor ticklabels.

.. _ytick:

YTick

YTick.set_label2

Set the label2 text.

**Parameters**

- `s` [str]

YTick.set_pad

Set the tick label pad in points

**Parameters**

- `val` [float]

YTick.update_position

Set the location of tick in data coords with scalar `loc`.

matplotlib.axis.YAxis.get_minor_ticks

YAxis.get_minor_ticks(self, numticks=None)
    Get the minor tick instances; grow as necessary.

matplotlib.axis.YAxis.get_minorticklabels

YAxis.get_minorticklabels(self)
    Return a list of Text instances for the minor ticklabels.

matplotlib.axis.YAxis.get_minorticklines

YAxis.get_minorticklines(self)
    Return the minor tick lines as a list of Line2D instances

matplotlib.axis.YAxis.get_minorticklocs

YAxis.get_minorticklocs(self)
    Get the array of minor tick locations in data coordinates.

matplotlib.axis.YAxis.get_minpos

YAxis.get_minpos(self)

matplotlib.axis.YAxis.get_offset_text

YAxis.get_offset_text(self)
    Return the axis offsetText as a Text instance

matplotlib.axis.YAxis.get_pickradius

YAxis.get_pickradius(self)
    Return the depth of the axis used by the picker

matplotlib.axis.YAxis.get_scale

YAxis.get_scale(self)

matplotlib.axis.YAxis.get_smart_bounds

YAxis.get_smart_bounds(self)
    Return whether the axis has smart bounds.
matplotlib.axis.YAxis.get_tick_padding

YAxis.get_tick_padding(self)

matplotlib.axis.YAxis.get_tick_space

YAxis.get_tick_space(self)
    Return the estimated number of ticks that can fit on the axis.

matplotlib.axis.YAxis.get_ticklabel_extents

YAxis.get_ticklabel_extents(self, renderer)
    Get the extents of the tick labels on either side of the axes.

matplotlib.axis.YAxis.get_ticklabels

YAxis.get_ticklabels(self, minor=False, which=None)
    Get the tick labels as a list of Text instances.

    Parameters

    minor [bool] If True return the minor ticklabels, else return the major tick-lables

    which [None, ('minor', 'major', 'both')] Overrides minor.
        Selects which ticklabels to return

    Returns

    ret [list] List of Text instances.

matplotlib.axis.YAxis.get_ticklines

YAxis.get_ticklines(self, minor=False)
    Return the tick lines as a list of Line2D instances

matplotlib.axis.YAxis.get_ticklocs

YAxis.get_ticklocs(self, minor=False)
    Get the array of tick locations in data coordinates.

matplotlib.axis.YAxis.get_tightbbox

YAxis.get_tightbbox(self, renderer)
    Return a bounding box that encloses the axis. It only accounts tick labels, axis label, and offsetText.
matplotlib.axis.YAxis.get_units

YAxis.get_units(self)
    Return the units for axis.

matplotlib.axis.YAxis.get_view_interval

YAxis.get_view_interval(self)

matplotlib.axis.YAxis.grid

YAxis.grid(self, b=None, which='major', **kwargs)
    Configure the grid lines.

    **Parameters**
    
    - **b** [bool or None] Whether to show the grid lines. If any **kwargs** are supplied, it is assumed you want the grid on and b will be set to True. If b is None and there are no **kwargs**, this toggles the visibility of the lines.
    - **which** [{‘major’, ‘minor’, ‘both’}] The grid lines to apply the changes on.
    - ****kwargs** [Line2D properties] Define the line properties of the grid, e.g.: grid(color='r', linestyle='-', linewidth=2)

matplotlib.axis.YAxis.limit_range_for_scale

YAxis.limit_range_for_scale(self, vmin, vmax)

matplotlib.axis.YAxis.pan

YAxis.pan(self, numsteps)
    Pan by numsteps (can be positive or negative).

matplotlib.axis.YAxis.reset_ticks

YAxis.reset_ticks(self)
    Re-initialize the major and minor Tick lists.
    Each list starts with a single fresh Tick.

matplotlib.axis.YAxis.set_data_interval

YAxis.set_data_interval(self, vmin, vmax, ignore=False)
**matplotlib.axis.YAxis.set_default_intervals**

YAxis.set_default_intervals(self)

Set the default limits for the axis data and view interval if they have not been not mutated yet.

**matplotlib.axis.YAxis.set_label_coords**

YAxis.set_label_coords(self, x, y, transform=None)

Set the coordinates of the label.

By default, the x coordinate of the y label is determined by the tick label bounding boxes, but this can lead to poor alignment of multiple ylabels if there are multiple axes. Ditto for the y coordinate of the x label.

You can also specify the coordinate system of the label with the transform. If None, the default coordinate system will be the axes coordinate system (0,0) is (left,bottom), (0.5, 0.5) is middle, etc.

**matplotlib.axis.YAxis.set_label_position**

YAxis.set_label_position(self, position)

Set the label position (left or right)

**Parameters**

position [‘left’, ‘right’]

**matplotlib.axis.YAxis.set_label_text**

YAxis.set_label_text(self, label, fontdict=None, **kwargs)

Set the text value of the axis label.

**Parameters**

label [str] Text string.
fontdict [dict] Text properties.
**kwargs Merged into fontdict.

**matplotlib.axis.YAxis.set_major_formatter**

YAxis.set_major_formatter(self, formatter)

Set the formatter of the major ticker.

**Parameters**

formatter [Formatter]
**matplotlib.axis.YAxis.set_major_locator**

YAxis.set_major_locator(self, locator)

Set the locator of the major ticker.

**Parameters**

- **locator** [Locator]

**matplotlib.axis.YAxis.set_minor_formatter**

YAxis.set_minor_formatter(self, formatter)

Set the formatter of the minor ticker.

**Parameters**

- **formatter** [Formatter]

**matplotlib.axis.YAxis.set_minor_locator**

YAxis.set_minor_locator(self, locator)

Set the locator of the minor ticker.

**Parameters**

- **locator** [Locator]

**matplotlib.axis.YAxis.set_pickradius**

YAxis.set_pickradius(self, pickradius)

Set the depth of the axis used by the picker.

**Parameters**

- **pickradius** [float]

**matplotlib.axis.YAxis.set_smart_bounds**

YAxis.set_smart_bounds(self, value)

Set the axis to have smart bounds.

**matplotlib.axis.YAxis.set_tick_params**

YAxis.set_tick_params(self, which='major', reset=False, **kw)

Set appearance parameters for ticks, ticklabels, and gridlines.

For documentation of keyword arguments, see `matplotlib.axes.Axes.tick_params()`.
YAxis.set_ticklabels

Set the text values of the tick labels.

**Parameters**

- **ticklabels** [sequence of str or of Texts] List of texts for tick labels; must include values for non-visible labels.
- **minor** [bool] If True, set minor ticks instead of major ticks.
- **kwargs** Text properties.

**Returns**

- **labels** [list of Texts] For each tick, includes `tick.label1` if it is visible, then `tick.label2` if it is visible, in that order.

YAxis.set_ticks

Set the locations of the tick marks from sequence ticks

**Parameters**

- **ticks** [sequence of floats]
- **minor** [bool]

YAxis.set_units

Set the units for axis.

**Parameters**

- **u** [units tag]

YAxis.set_view_interval

Set the view interval on axis.

**Parameters**

- **vmin**
- **vmax**
- **ignore** [bool]

YAxis.update_units

Introspect `data` for units converter and update the axis.converter instance if necessary. Return `True` if `data` is registered for unit conversion.

YAxis.zoom

Zoom in/out on axis; if `direction` is >0 zoom in, else zoom out.
XAxis

XAxis.OFFSETTEXTPAD

XAxis.axis_date
Sets up axis ticks and labels treating data along this axis as dates.

XAxis.cla
Clear the current axis

XAxis.convert_units

XAxis.get_data_interval

XAxis.get_gridlines
Return the grid lines as a list of Line2D instances

XAxis.get_label_position
Return the label position (top or bottom)

XAxis.get_label_text
Get the text of the label

XAxis.get_major_formatter
Get the formatter of the major ticker

XAxis.get_major_locator
Get the locator of the major ticker

XAxis.get_major_ticks
Get the tick instances; grow as necessary.

XAxis.get_major_ticklabels
Return a list of Text instances for the major ticklabels.

XAxis.get_major_ticklines
Return the major tick lines as a list of Line2D instances

XAxis.get_major_ticklocs
Get the array of major tick locations in data coordinates.

XAxis.get_minor_formatter
Get the formatter of the minor ticker

XAxis.get_minor_locator
Get the locator of the minor ticker

XAxis.get_minor_ticks
Get the minor tick instances; grow as necessary.

XAxis.get_minor_ticklabels
Return a list of Text instances for the minor ticklabels.

XAxis.get_minor_ticklines
Return the minor tick lines as a list of Line2D instances

XAxis.get_minor_ticklocs
Get the array of minor tick locations in data coordinates.

XAxis.get_minpos

XAxis.get_offset_text
Return the axis offsetText as a Text instance

XAxis.get_pickradius
Return the depth of the axis used by the picker

XAxis.get_scale
Return whether the axis has smart bounds.

XAxis.get_smart_bounds

XAxis.get_tick_padding
Return the estimated number of ticks that can fit on the axis.

XAxis.get_ticklabel_extents
Get the extents of the tick labels on either side of the axes.

XAxis.get_ticklabels
Get the tick labels as a list of Text instances.

XAxis.get_ticklines
Return the tick lines as a list of Line2D instances

XAxis.get_ticklocs
Get the array of tick locations in data coordinates.

XAxis.get_tightbbox
Return a bounding box that encloses the axis.

XAxis.get_units
Return the units for axis.

XAxis.get_view_interval

**matplotlib.axis.XAxis.OFFSETTEXTPAD**

`XAxis.OFFSETTEXTPAD = 3`

**matplotlib.axis.XAxis.axis_date**

`XAxis.axis_date(self, tz=None)`

Sets up axis ticks and labels treating data along this axis as dates.

**Parameters**

- `tz` [tzinfo or str or None] The timezone used to create date labels.

**matplotlib.axis.XAxis.cla**

`XAxis.cla(self)`

Clear the current axis.
`matplotlib.axis.XAxis.convert_units`

`XAxis.convert_units(self, x)`

`matplotlib.axis.XAxis.get_data_interval`

`XAxis.get_data_interval(self)`

`matplotlib.axis.XAxis.get_gridlines`

`XAxis.get_gridlines(self)`  
Return the grid lines as a list of `Line2D` instance

`matplotlib.axis.XAxis.get_label_position`

`XAxis.get_label_position(self)`  
Return the label position (top or bottom)

`matplotlib.axis.XAxis.get_label_text`

`XAxis.get_label_text(self)`  
Get the text of the label

`matplotlib.axis.XAxis.get_major_formatter`

`XAxis.get_major_formatter(self)`  
Get the formatter of the major ticker

`matplotlib.axis.XAxis.get_major_locator`

`XAxis.get_major_locator(self)`  
Get the locator of the major ticker

`matplotlib.axis.XAxis.get_major_ticks`

`XAxis.get_major_ticks(self, numticks=None)`  
Get the tick instances; grow as necessary.

`matplotlib.axis.XAxis.get_majorticklabels`

`XAxis.get_majorticklabels(self)`  
Return a list of `Text` instances for the major ticklabels.
matplotlib.axis.XAxis.get_majorticklines

XAxis.get_majorticklines(self)
    Return the major tick lines as a list of Line2D instances

matplotlib.axis.XAxis.get_majorticklocs

XAxis.get_majorticklocs(self)
    Get the array of major tick locations in data coordinates.

matplotlib.axis.XAxis.get_minor_formatter

XAxis.get_minor_formatter(self)
    Get the formatter of the minor ticker

matplotlib.axis.XAxis.get_minor_locator

XAxis.get_minor_locator(self)
    Get the locator of the minor ticker

matplotlib.axis.XAxis.get_minor_ticks

XAxis.get_minor_ticks(self, numticks=None)
    Get the minor tick instances; grow as necessary.

matplotlib.axis.XAxis.get_minorticklabels

XAxis.get_minorticklabels(self)
    Return a list of Text instances for the minor ticklabels.

matplotlib.axis.XAxis.get_minorticklines

XAxis.get_minorticklines(self)
    Return the minor tick lines as a list of Line2D instances

matplotlib.axis.XAxis.get_minorticklocs

XAxis.get_minorticklocs(self)
    Get the array of minor tick locations in data coordinates.

matplotlib.axis.XAxis.get_minpos

XAxis.get_minpos(self)
matplotlib.axis.XAxis.get_offset_text

XAxis.get_offset_text(self)
    Return the axis offsetText as a Text instance

matplotlib.axis.XAxis.get_pickradius

XAxis.get_pickradius(self)
    Return the depth of the axis used by the picker

matplotlib.axis.XAxis.get_scale

XAxis.get_scale(self)

matplotlib.axis.XAxis.get_smart_bounds

XAxis.get_smart_bounds(self)
    Return whether the axis has smart bounds.

matplotlib.axis.XAxis.get_tick_padding

XAxis.get_tick_padding(self)

matplotlib.axis.XAxis.get_tick_space

XAxis.get_tick_space(self)
    Return the estimated number of ticks that can fit on the axis.

matplotlib.axis.XAxis.get_ticklabel_extents

XAxis.get_ticklabel_extents(self, renderer)
    Get the extents of the tick labels on either side of the axes.

matplotlib.axis.XAxis.get_ticklabels

XAxis.get_ticklabels(self, minor=False, which=None)
    Get the tick labels as a list of Text instances.

    **Parameters**

    minor [bool] If True return the minor ticklabels, else return the major ticklabels

    which [None, ('minor', 'major', 'both')] Overrides minor.
    Selects which ticklabels to return

    **Returns**
ret [list] List of Text instances.

matplotlib.axis.XAxis.get_ticklines

XAxis.get_ticklines(self, minor=False)
Return the tick lines as a list of Line2D instances

matplotlib.axis.XAxis.get_ticklocs

XAxis.get_ticklocs(self, minor=False)
Get the array of tick locations in data coordinates.

matplotlib.axis.XAxis.get_tightbbox

XAxis.get_tightbbox(self, renderer)
Return a bounding box that encloses the axis. It only accounts tick labels, axis label, and offsetText.

matplotlib.axis.XAxis.get_units

XAxis.get_units(self)
Return the units for axis.

matplotlib.axis.XAxis.get_view_interval

XAxis.get_view_interval(self)

matplotlib.axis.XAxis.grid

XAxis.grid(self, b=None, which='major', **kwargs)
Configure the grid lines.

Parameters

b [bool or None] Whether to show the grid lines. If any kwargs are supplied, it is assumed you want the grid on and \( b \) will be set to True.
If \( b \) is None and there are no kwargs, this toggles the visibility of the lines.

which [{‘major’, ‘minor’, ‘both’}] The grid lines to apply the changes on.

**kwargs [Line2D properties] Define the line properties of the grid, e.g.:

grid(color='r', linestyle='-', linewidth=2)
matplotlib.axis.XAxis.limit_range_for_scale

XAxis.limit_range_for_scale(self, vmin, vmax)

matplotlib.axis.XAxis.pan

XAxis.pan(self, numsteps)
   Pan by numsteps (can be positive or negative).

matplotlib.axis.XAxis.reset_ticks

XAxis.reset_ticks(self)
   Re-initialize the major and minor Tick lists.
   Each list starts with a single fresh Tick.

matplotlib.axis.XAxis.set_data_interval

XAxis.set_data_interval(self, vmin, vmax, ignore=False)

matplotlib.axis.XAxis.set_default_intervals

XAxis.set_default_intervals(self)
   Set the default limits for the axis data and view interval if they have not been not mutated yet.

matplotlib.axis.XAxis.set_label_coords

XAxis.set_label_coords(self, x, y, transform=None)
   Set the coordinates of the label.
   By default, the x coordinate of the y label is determined by the tick label bounding boxes, but this can lead to poor alignment of multiple ylabels if there are multiple axes. Ditto for the y coordinate of the x label.
   You can also specify the coordinate system of the label with the transform. If None, the default coordinate system will be the axes coordinate system (0,0) is (left,bottom), (0.5, 0.5) is middle, etc

matplotlib.axis.XAxis.set_label_position

XAxis.set_label_position(self, position)
   Set the label position (top or bottom)

   Parameters
   position [{‘top’, ‘bottom’}]
matplotlib.axis.XAxis.set_label_text

XAxis.set_label_text(self, label, fontdict=None, **kwargs)
    Set the text value of the axis label.

    Parameters
    ----------
    label : str
        Text string.
    fontdict : dict, optional
        Text properties.
    **kwargs
        Merged into fontdict.

matplotlib.axis.XAxis.set_major_formatter

XAxis.set_major_formatter(self, formatter)
    Set the formatter of the major ticker.

    Parameters
    ----------
    formatter : Formatter

matplotlib.axis.XAxis.set_major_locator

XAxis.set_major_locator(self, locator)
    Set the locator of the major ticker.

    Parameters
    ----------
    locator : Locator

matplotlib.axis.XAxis.set_minor_formatter

XAxis.set_minor_formatter(self, formatter)
    Set the formatter of the minor ticker.

    Parameters
    ----------
    formatter : Formatter

matplotlib.axis.XAxis.set_minor_locator

XAxis.set_minor_locator(self, locator)
    Set the locator of the minor ticker.

    Parameters
    ----------
    locator : Locator
matplotlib.axis.XAxis.set_pickradius

```
XAxis.set_pickradius(self, pickradius)
```

Set the depth of the axis used by the picker.

**Parameters**

pickradius [float]

matplotlib.axis.XAxis.set_smart_bounds

```
XAxis.set_smart_bounds(self, value)
```

Set the axis to have smart bounds.

matplotlib.axis.XAxis.set_tick_params

```
XAxis.set_tick_params(self, which='major', reset=False, **kw)
```

Set appearance parameters for ticks, ticklabels, and gridlines.

For documentation of keyword arguments, see `matplotlib.axes.Axes.tick_params()`.

matplotlib.axis.XAxis.set_ticklabels

```
XAxis.set_ticklabels(self, ticklabels, *args, minor=False, **kwargs)
```

Set the text values of the tick labels.

**Parameters**

ticklabels [sequence of str or of Texts] List of texts for tick labels; must include values for non-visible labels.

minor [bool] If True, set minor ticks instead of major ticks.

**kwargs Text properties.

**Returns**

labels [list of Texts] For each tick, includes tick.label1 if it is visible, then tick.label2 if it is visible, in that order.

matplotlib.axis.XAxis.set_ticks

```
XAxis.set_ticks(self, ticks, minor=False)
```

Set the locations of the tick marks from sequence ticks.

**Parameters**

ticks [sequence of floats]

minor [bool]
matplotlib.axis.XAxis.set_units

XAxis.set_units(self, u)
    Set the units for axis.

Parameters
    u [units tag]

matplotlib.axis.XAxis.set_view_interval

XAxis.set_view_interval(self, vmin, vmax, ignore=False)

matplotlib.axis.XAxis.update_units

XAxis.update_units(self, data)
    introspect data for units converter and update the axis.converter instance if necessary. Return True if data is registered for unit conversion.

matplotlib.axis.XAxis.zoom

XAxis.zoom(self, direction)
    Zoom in/out on axis; if direction is >0 zoom in, else zoom out.

Inherited from artist

Ticks

Tick.add_callback
Add a callback function that will be called whenever one of the Artist's properties changes.

Tick.axes
The Axes instance the artist resides in, or None.

Tick.contains
Test whether the mouse event occurred in the Tick marks.

Tick.convert_xunits
Convert x using the unit type of the xaxis.

Tick.convert_yunits
Convert y using the unit type of the yaxis.

Tick.draw
Draw the Artist using the given renderer.

Tick.findobj
Find artist objects.

Tick.format_cursor_data
Return a string representation of data.

Tick.get_agg_filter
Return filter function to be used for agg filter.

Tick.get_alpha
Return the alpha value used for blending - not supported on all backends

Tick.get_animated
Return the animated state.

Tick.get_children
Return a list of the child Artists of this Artist.

**matplotlib.axis.Tick.add_callback**

Tick.add_callback(*self, func*)

Add a callback function that will be called whenever one of the *Artist*’s properties changes.

**Parameters**

- **func** [callable] The callback function. It must have the signature:

  ```python
def func(artist: Artist) -> Any
  ```

  where *artist* is the calling *Artist*. Return values may exist but are ignored.

**Returns**

- **oid** [int] The observer id associated with the callback. This id can be used for removing the callback with *remove_callback* later.
See also:

remove_callback

matplotlib.axis.Tick.axes

Tick.axes
The Axes instance the artist resides in, or None.

matplotlib.axis.Tick.contains

Tick.contains(self, mouseevent)
Test whether the mouse event occurred in the Tick marks.
This function always returns false. It is more useful to test if the axis as a whole contains the mouse rather than the set of tick marks.

matplotlib.axis.Tick.convert_xunits

Tick.convert_xunits(self, x)
Convert x using the unit type of the xaxis.
If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

matplotlib.axis.Tick.convert_yunits

Tick.convert_yunits(self, y)
Convert y using the unit type of the yaxis.
If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.

matplotlib.axis.Tick.draw

Tick.draw(self, renderer)
Draw the Artist using the given renderer.
This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (Artist.get_visible is False).

Parameters

renderer [RendererBase subclass.]
Matplotlib, Release 3.1.1

matplotlib.axis.Tick.findobj

Tick.findobj(self, match=None, include_self=True)
Find artist objects.

Recursively find all Artist instances contained in the artist.

Parameters

**match**  A filter criterion for the matches. This can be
- None: Return all objects contained in artist.
- A function with signature def match(artist: Artist) → bool. The re-
  sult will only contain artists for which the function returns True.
- A class instance: e.g., Line2D. The result will only contain artists of this
  class or its subclasses (isinstance check).

**include_self**  [bool] Include self in the list to be checked for a match.

Returns

artists  [list of Artist]

matplotlib.axis.Tick.format_cursor_data

Tick.format_cursor_data(self, data)
Return a string representation of data.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of
Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a
comma-separated string enclosed in square brackets.

**See also:**

get_cursor_data

matplotlib.axis.Tick.get_agg_filter

Tick.get_agg_filter(self)
Return filter function to be used for agg filter.

matplotlib.axis.Tick.get_alpha

Tick.get_alpha(self)
Return the alpha value used for blending - not supported on all backends
matplotlib.axis.Tick.get_animated

Tick.get_animated(self)
    Return the animated state.

matplotlib.axis.Tick.get_children

Tick.get_children(self)
    Return a list of the child Artists of this Artist.

matplotlib.axis.Tick.get_clip_box

Tick.get_clip_box(self)
    Return the clipbox.

matplotlib.axis.Tick.get_clip_on

Tick.get_clip_on(self)
    Return whether the artist uses clipping.

matplotlib.axis.Tick.get_clip_path

Tick.get_clip_path(self)
    Return the clip path.

matplotlib.axis.Tick.get_contains

Tick.get_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:

    set_contains

matplotlib.axis.Tick.get_cursor_data

Tick.get_cursor_data(self, event)
    Return the cursor data for a given event.

    Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

    Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.
Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation. The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

`event` [matplotlib.backend_bases.MouseEvent]

**See also:**

`format_cursor_data`

```python
matplotlib.axis.Tick.get_figure

Tick.get_figure(self)
    Return the Figure instance the artist belongs to.
```

```python
matplotlib.axis.Tick.get_gid

Tick.get_gid(self)
    Return the group id.
```

```python
matplotlib.axis.Tick.get_label

Tick.get_label(self)
    Return the label used for this artist in the legend.
```

```python
matplotlib.axis.Tick.get_path_effects

Tick.get_path_effects(self)
```

```python
matplotlib.axis.Tick.get_picker

Tick.get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in `set_picker`.

**See also:**

`set_picker`, `pickable`, `pick`
```

```python
matplotlib.axis.Tick.get_rasterized

Tick.get_rasterized(self)
    Return whether the artist is to be rasterized.
```
matplotlib.axis.Tick.get_sketch_params

Tick.get_sketch_params(self)
    Returns the sketch parameters for the artist.

**Returns**

**sketch_params** [tuple or None] A 3-tuple with the following elements:

- *scale*: The amplitude of the wiggle perpendicular to the source line.
- *length*: The length of the wiggle along the line.
- *randomness*: The scale factor by which the length is shrunk or expanded.

Returns *None* if no sketch parameters were set.

matplotlib.axis.Tick.get_snap

Tick.get_snap(self)
    Returns the snap setting.

    See *set_snap* for details.

matplotlib.axis.Tick.get_transform

Tick.get_transform(self)
    Return the *Transform* instance used by this artist.

matplotlib.axis.Tick.get_transformed_clip_path_and_affine

Tick.get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

matplotlib.axis.Tick.get_url

Tick.get_url(self)
    Return the url.

matplotlib.axis.Tick.get_visible

Tick.get_visible(self)
    Return the visibility.
matplotlib.axis.Tick.get_window_extent

Tick.get_window_extent(self, renderer)
Get the axes bounding box in display space.

The bounding box’ width and height are nonnegative.

Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.

Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

matplotlib.axis.Tick.get_zorder

Tick.get_zorder(self)
Return the artist’s zorder.

matplotlib.axis.Tick.have_units

Tick.have_units(self)
Return True if units are set on the x or y axes.

matplotlib.axis.Tick.is_transform_set

Tick.is_transform_set(self)
Return whether the Artist has an explicitly set transform.

This is True after set_transform has been called.

matplotlib.axis.Tick.mouseover

Tick.mouseover

matplotlib.axis.Tick.pchanged

Tick.pchanged(self)
Call all of the registered callbacks.

This function is triggered internally when a property is changed.

See also:

add_callback
remove_callback
`matplotlib.axis.Tick.pick`

Tick.pick(self, mouseevent)
Process a pick event.

Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

See also:

`set_picker`, `get_picker`, `pickable`

`matplotlib.axis.Tick.pickable`

Tick.pickable(self)
Return whether the artist is pickable.

See also:

`set_picker`, `get_picker`, `pick`

`matplotlib.axis.Tick.properties`

Tick.properties(self)
Return a dictionary of all the properties of the artist.

`matplotlib.axis.Tick.remove`

Tick.remove(self)
Remove the artist from the figure if possible.

The effect will not be visible until the figure is redrawn, e.g., with `FigureCanvasBase.draw_idle`. Call `relim` to update the axes limits if desired.

Note: `relim` will not see collections even if the collection was added to the axes with `autolim = True`.

Note: there is no support for removing the artist’s legend entry.

`matplotlib.axis.Tick.remove_callback`

Tick.remove_callback(self, oid)
Remove a callback based on its observer id.

See also:

`add_callback`
matplotlib.axis.Tick.set

Tick.set(self, **kwargs)
A property batch setter. Pass kwargs to set properties.

matplotlib.axis.Tick.set_agg_filter

Tick.set_agg_filter(self, filter_func)
Set the agg filter.

Parameters

filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

matplotlib.axis.Tick.set_alpha

Tick.set_alpha(self, alpha)
Set the alpha value used for blending - not supported on all backends.

Parameters

alpha [float]

matplotlib.axis.Tick.set_animated

Tick.set_animated(self, b)
Set the artist's animation state.

Parameters

b [bool]

matplotlib.axis.Tick.set_clip_box

Tick.set_clip_box(self, clipbox)
Set the artist's clip Bbox.

Parameters

clipbox [Bbox]

matplotlib.axis.Tick.set_clip_on

Tick.set_clip_on(self, b)
Set whether the artist uses clipping.
When False artists will be visible out side of the axes which can lead to unexpected results.

Parameters

b [bool]
matplotlib.axis.Tick.set_clip_path

Tick.set_clip_path(self, clippath, transform=None)
Set the artist’s clip path, which may be:

• a Patch (or subclass) instance; or
• a Path instance, in which case a Transform instance, which will be applied to the path before using it for clipping, must be provided; or
• None, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

matplotlib.axis.Tick.setcontains

Tick.setcontains(self, picker)
Define a custom contains test for the artist.

The provided callable replaces the default contains method of the artist.

Parameters

picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

def contains(artist: Artist, event: MouseEvent) -> bool, dict

that returns:

• a bool indicating if the event is within the artist
• a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

matplotlib.axis.Tick.setfigure

Tick.setfigure(self, fig)
Set the Figure instance the artist belongs to.

Parameters

fig [Figure]

matplotlib.axis.Tick.setgid

Tick.setgid(self, gid)
Set the (group) id for the artist.

Parameters

gid [str]
matplotlib.axis.Tick.set_label

Tick.set_label(self, s)
Set the label1 text.

**Parameters**

- **s** [str]

matplotlib.axis.Tick.set_path_effects

Tick.set_path_effects(self, path_effects)
Set the path effects.

**Parameters**

- **path_effects** [AbstractPathEffect]

matplotlib.axis.Tick.set_picker

Tick.set_picker(self, picker)
Define the picking behavior of the artist.

**Parameters**

- **picker** [None or bool or float or callable] This can be one of the following:
  
  - *None*: Picking is disabled for this artist (default).
  
  - *A boolean*: If *True* then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
  
  - *A float*: If *picker* is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
  
  - *A function*: If *picker* is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

    ```python
    hit, props = picker(artist, mouseevent)
    ```

    to determine the hit test. if the mouse event is over the artist, return *hit=True* and *props* is a dictionary of properties you want added to the PickEvent attributes.

matplotlib.axis.Tick.set_rasterized

Tick.set_rasterized(self, rasterized)
Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

**Parameters**

- **rasterized** [bool or None]
**matplotlib.axis.Tick.set_sketch_params**

**Tick.set_sketch_params**(self, scale=None, length=None, randomness=None)

Sets the sketch parameters.

**Parameters**

- **scale** [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is `None`, or not provided, no sketch filter will be provided.
- **length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
- **randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

**matplotlib.axis.Tick.set_snap**

**Tick.set_snap**(self, snap)

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

- **snap** [bool or None] Possible values:
  - `True`: Snap vertices to the nearest pixel center.
  - `False`: Do not modify vertex positions.
  - `None`: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

**matplotlib.axis.Tick.set_transform**

**Tick.set_transform**(self, t)

Set the artist transform.

**Parameters**

- **t** [Transform]

**matplotlib.axis.Tick.set_url**

**Tick.set_url**(self, url)

Set the url for the artist.

**Parameters**
url [str]

```
matplotlib.axis.Tick.set_visible

Tick.set_visible(self, b)
    Set the artist’s visibility.

    Parameters
    ----------
    b [bool]
```

```
matplotlib.axis.Tick.set_zorder

Tick.set_zorder(self, level)
    Set the zorder for the artist. Artists with lower zorder values are drawn first.

    Parameters
    ----------
    level [float]
```

```
matplotlib.axis.Tick.stale

Tick.stale
    Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
```

```
matplotlib.axis.Tick.update

Tick.update(self, props)
    Update this artist’s properties from the dictionary props.
```

```
matplotlib.axis.Tick.update_from

Tick.update_from(self, other)
    Copy properties from other to self.
```

```
matplotlib.axis.Tick.zorder

Tick.zorder = 0
```

```
matplotlib.axis.XTick.add_callback

XTick.add_callback(self, func)
    Add a callback function that will be called whenever one of the Artist’s properties changes.

    Parameters
    ----------
```

1114 Chapter 17. Modules
**func** [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where *artist* is the calling *Artist*. Return values may exist but are ignored.

**Returns**

**oid** [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

**See also:**

`remove_callback`

---

**matplotlib.axis.XTick.axes**

`XTick.axes`

The *Axes* instance the artist resides in, or *None*.

---

**matplotlib.axis.XTick.contains**

`XTick.contains(self, mouseevent)`

Test whether the mouse event occurred in the Tick marks.

This function always returns false. It is more useful to test if the axis as a whole contains the mouse rather than the set of tick marks.

---

**matplotlib.axis.XTick.convert_xunits**

`XTick.convert_xunits(self, x)`

Convert *x* using the unit type of the *xaxis*.

If the artist is not in contained in an *Axes* or if the *xaxis* does not have units, *x* itself is returned.

---

**matplotlib.axis.XTick.convert_yunits**

`XTick.convert_yunits(self, y)`

Convert *y* using the unit type of the *yaxis*.

If the artist is not in contained in an *Axes* or if the *yaxis* does not have units, *y* itself is returned.

---

**matplotlib.axis.XTick.draw**

`XTick.draw(self, renderer)`

Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (*Artist.get_visible* is *False*).
**Parameters**

**renderer** [RendererBase subclass.]

**matplotlib.axis.XTick.findobj**

`XTick.findobj(self, match=None, include_self=True)`  
Find artist objects.

Recursively find all `Artist` instances contained in the artist.

**Parameters**

**match** A filter criterion for the matches. This can be

- `None`: Return all objects contained in artist.
- A function with signature `def match(artist: Artist) -> bool`. The result will only contain artists for which the function returns `True`.
- A class instance: e.g., `Line2D`. The result will only contain artists of this class or its subclasses (`isinstance` check).

**include_self** [bool] Include `self` in the list to be checked for a match.

**Returns**

**artists** [list of `Artist`]

**matplotlib.axis.XTick.format_cursor_data**

`XTick.format_cursor_data(self, data)`  
Return a string representation of `data`.

---

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

`get_cursor_data`

**matplotlib.axis.XTick.get_agg_filter**

`XTick.get_agg_filter(self)`  
Return filter function to be used for agg filter.

**matplotlib.axis.XTick.get_alpha**

`XTick.get_alpha(self)`  
Return the alpha value used for blending - not supported on all backends.
matplotlib.axis.XTick.get_animated

XTick.get_animated(self)
    Return the animated state.

matplotlib.axis.XTick.get_children

XTick.get_children(self)
    Return a list of the child Artists of this Artist.

matplotlib.axis.XTick.get_clip_box

XTick.get_clip_box(self)
    Return the clipbox.

matplotlib.axis.XTick.get_clip_on

XTick.get_clip_on(self)
    Return whether the artist uses clipping.

matplotlib.axis.XTick.get_clip_path

XTick.get_clip_path(self)
    Return the clip path.

matplotlib.axis.XTick.get_contains

XTick.get_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:

    set_contains

matplotlib.axis.XTick.get_cursor_data

XTick.get_cursor_data(self, event)
    Return the cursor data for a given event.

    Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

    Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.
Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation.

The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

- `event` ([`matplotlib.backend_bases.MouseEvent`]

**See also:**

- `format_cursor_data`

### `matplotlib.axis.XTick.get_figure`

`XTick.get_figure(self)`

Return the Figure instance the artist belongs to.

### `matplotlib.axis.XTick.get_gid`

`XTick.get_gid(self)`

Return the group id.

### `matplotlib.axis.XTick.get_label`

`XTick.get_label(self)`

Return the label used for this artist in the legend.

### `matplotlib.axis.XTick.get_path_effects`

`XTick.get_path_effects(self)`

### `matplotlib.axis.XTick.get_picker`

`XTick.get_picker(self)`

Return the picking behavior of the artist.

The possible values are described in `set_picker`.

**See also:**

- `set_picker`, `pickable`, `pick`

### `matplotlib.axis.XTick.get_rasterized`

`XTick.get_rasterized(self)`

Return whether the artist is to be rasterized.
XTick.get_sketch_params

Returns the sketch parameters for the artist.

**Returns**

**sketch_params** [tuple or None] A 3-tuple with the following elements:

• *scale*: The amplitude of the wiggle perpendicular to the source line.
• *length*: The length of the wiggle along the line.
• *randomness*: The scale factor by which the length is shrunken or expanded.

Returns *None* if no sketch parameters were set.

XTick.get_snap

Returns the snap setting.

See *set_snap* for details.

XTick.get_transform

Return the *Transform* instance used by this artist.

XTick.get_transformed_clip_path_and_affine

Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

XTick.get_url

Return the url.

XTick.get_visible

Return the visibility.
matplotlib.axis.XTick.get_window_extent

XTick.get_window_extent(self, renderer)

Get the axes bounding box in display space.

The bounding box’ width and height are nonnegative.

Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.

Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

matplotlib.axis.XTick.get_zorder

XTick.get_zorder(self)

Return the artist’s zorder.

matplotlib.axis.XTick.have_units

XTick.have_units(self)

Return True if units are set on the x or y axes.

matplotlib.axis.XTick.is_transform_set

XTick.is_transform_set(self)

Return whether the Artist has an explicitly set transform.

This is True after set_transform has been called.

matplotlib.axis.XTick.mouseover

XTick.mouseover

matplotlib.axis.XTick.pchanged

XTick.pchanged(self)

Call all of the registered callbacks.

This function is triggered internally when a property is changed.

See also:

add_callback
remove_callback
Matplotlib, Release 3.1.1

matplotlib.axis.XTick.pick

XTick.pick(self, mouseevent)
Process a pick event.

Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

**See also:**

set_picker, get_picker, pickable

matplotlib.axis.XTick.pickable

XTick.pickable(self)
Return whether the artist is pickable.

**See also:**

set_picker, get_picker, pick

matplotlib.axis.XTick.properties

XTick.properties(self)
Return a dictionary of all the properties of the artist.

matplotlib.axis.XTick.remove

XTick.remove(self)
Remove the artist from the figure if possible.

The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.draw_idle. Call relim to update the axes limits if desired.

Note: relim will not see collections even if the collection was added to the axes with autolim = True.

Note: there is no support for removing the artist’s legend entry.

matplotlib.axis.XTick.remove_callback

XTick.remove_callback(self, oid)
Remove a callback based on its observer id.

**See also:**

add_callback
**matplotlib.axis.XTick.set**

`XTick.set(self,**kwargs)`

A property batch setter. Pass `kwargs` to set properties.

**matplotlib.axis.XTick.set_agg_filter**

`XTick.set_agg_filter(self,filter_func)`

Set the agg filter.

**Parameters**

- `filter_func` [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

**matplotlib.axis.XTick.set_alpha**

`XTick.set_alpha(self,alpha)`

Set the alpha value used for blending - not supported on all backends.

**Parameters**

- `alpha` [float]

**matplotlib.axis.XTick.set_animated**

`XTick.set_animated(self,b)`

Set the artist’s animation state.

**Parameters**

- `b` [bool]

**matplotlib.axis.XTick.set_clip_box**

`XTick.set_clip_box(self,clipbox)`

Set the artist’s clip `Bbox`.

**Parameters**

- `clipbox` [Bbox]

**matplotlib.axis.XTick.set_clip_on**

`XTick.set_clip_on(self,b)`

Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

- `b` [bool]
**Matplotlib, Release 3.1.1**

**matplotlib.axis.XTick.set_clip_path**

`XTick.set_clip_path(self, clippath, transform=None)`

Set the artist’s clip path, which may be:

- a `Patch` (or subclass) instance; or
- a `Path` instance, in which case a `Transform` instance, which will be applied to the path before using it for clipping, must be provided; or
- `None`, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to `None`.

**ACCEPTS:** `[Path, Transform] | Patch | None]

**matplotlib.axis.XTick.set_contains**

`XTick.set_contains(self, picker)`

Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

- `picker` [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

  ```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
  ```

  that returns:
  - a bool indicating if the event is within the artist
  - a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

**matplotlib.axis.XTick.set_figure**

`XTick.set_figure(self, fig)`

Set the `Figure` instance the artist belongs to.

**Parameters**

- `fig` `[Figure]`

**matplotlib.axis.XTick.set_gid**

`XTick.set_gid(self, gid)`

Set the (group) id for the artist.

**Parameters**

- `gid` `[str]`
matplotlib.axis.XTick.set_label

XTick.set_label(self, s)
    Set the label text.

    **Parameters**
    s [str]

matplotlib.axis.XTick.set_path_effects

XTick.set_path_effects(self, path_effects)
    Set the path effects.

    **Parameters**
    path_effects [AbstractPathEffect]

matplotlib.axis.XTick.set_picker

XTick.set_picker(self, picker)
    Define the picking behavior of the artist.

    **Parameters**
    picker [None or bool or float or callable] This can be one of the following:
    - *None*: Picking is disabled for this artist (default).
    - A boolean: If *True* then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
    - A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event
    - A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

        ```python
        hit, props = picker(artist, mouseevent)
        ```

to determine the hit test. if the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes.

matplotlib.axis.XTick.set_rasterized

XTick.set_rasterized(self, rasterized)
    Force rasterized (bitmap) drawing in vector backend output.

    Defaults to None, which implies the backend’s default behavior.

    **Parameters**
    rasterized [bool or None]
matplotlib.axis.XTick.set_sketch_params

XTick.set_sketch_params(self, scale=None, length=None, randomness=None)

Sets the sketch parameters.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.

length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

randomness [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

matplotlib.axis.XTick.set_snap

XTick.set_snap(self, snap)

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

snap [bool or None] Possible values:

- True: Snap vertices to the nearest pixel center.
- False: Do not modify vertex positions.
- None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

matplotlib.axis.XTick.set_transform

XTick.set_transform(self, t)

Set the artist transform.

Parameters

t [Transform]

matplotlib.axis.XTick.set_url

XTick.set_url(self, url)

Set the url for the artist.

Parameters
url [str]

matplotlib.axis.XTick.set_visible

XTick.set_visible(self, b)
   Set the artist’s visibility.
   
   **Parameters**
   
   b [bool]

matplotlib.axis.XTick.set_zorder

XTick.set_zorder(self, level)
   Set the zorder for the artist. Artists with lower zorder values are drawn first.
   
   **Parameters**

   level [float]

matplotlib.axis.XTick.stale

XTick.stale
   Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

matplotlib.axis.XTick.update

XTick.update(self, props)
   Update this artist’s properties from the dictionary props.

matplotlib.axis.XTick.update_from

XTick.update_from(self, other)
   Copy properties from other to self.

matplotlib.axis.XTick.zorder

XTick.zorder = 0

matplotlib.axis.YTick.add_callback

YTick.add_callback(self, func)
   Add a callback function that will be called whenever one of the Artist’s properties changes.
   
   **Parameters**
**func** [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where `artist` is the calling `Artist`. Return values may exist but are ignored.

**Returns**

**oid** [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

**See also:**

`remove_callback`

```python
matplotlib.axis.YTick.axes
```

**YTick.axes**

The `Axes` instance the artist resides in, or `None`.

```python
matplotlib.axis.YTick.contains
```

**YTick.contains(self, mouseevent)**

Test whether the mouse event occurred in the Tick marks.

This function always returns false. It is more useful to test if the axis as a whole contains the mouse rather than the set of tick marks.

```python
matplotlib.axis.YTick.convert_xunits
```

**YTick.convert_xunits(self, x)**

Convert `x` using the unit type of the xaxis.

If the artist is not in contained in an Axes or if the xaxis does not have units, `x` itself is returned.

```python
matplotlib.axis.YTick.convert_yunits
```

**YTick.convert_yunits(self, y)**

Convert `y` using the unit type of the yaxis.

If the artist is not in contained in an Axes or if the yaxis does not have units, `y` itself is returned.

```python
matplotlib.axis.YTick.draw
```

**YTick.draw(self, renderer)**

Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (`Artist.get_visible` is `False`).
**Parameters**

**renderer** [RendererBase subclass.]

matplotlib.axis.YTick.findobj

**YTick.findobj**(self, match=None, include_self=True)
Find artist objects.

Recursively find all Artist instances contained in the artist.

**Parameters**

**match** A filter criterion for the matches. This can be

- None: Return all objects contained in artist.
- A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns True.
- A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

**include_self** [bool] Include self in the list to be checked for a match.

**Returns**

**artists** [list of Artist]

matplotlib.axis.YTick.format_cursor_data

**YTick.format_cursor_data**(self, data)
Return a string representation of data.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

get_cursor_data

matplotlib.axis.YTick.get_agg_filter

**YTick.get_agg_filter**(self)
Return filter function to be used for agg filter.

matplotlib.axis.YTick.get_alpha

**YTick.get_alpha**(self)
Return the alpha value used for blending - not supported on all backends
```

**matplotlib.axis.YTick.get_animated**

``YTick.get_animated(self)`

Return the animated state.

**matplotlib.axis.YTick.get_children**

``YTick.get_children(self)`

Return a list of the child *Artist* s of this *Artist*.

**matplotlib.axis.YTick.get_clip_box**

``YTick.get_clip_box(self)`

Return the clipbox.

**matplotlib.axis.YTick.get_clip_on**

``YTick.get_clip_on(self)`

Return whether the artist uses clipping.

**matplotlib.axis.YTick.get_clip_path**

``YTick.get_clip_path(self)`

Return the clip path.

**matplotlib.axis.YTick.get_contains**

``YTick.get_contains(self)`

Return the custom contains function of the artist if set, or *None*.

**See also:**

`set_contains`

**matplotlib.axis.YTick.get_cursor_data**

``YTick.get_cursor_data(self, event)`

Return the cursor data for a given event.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns *None*.
Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation.

The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

- `event` [matplotlib.backend_bases.MouseEvent]

**See also:**

`format_cursor_data`

```python
matplotlib.axis.YTick.get_figure

YTick.get_figure(self)
    Return the `Figure` instance the artist belongs to.
```

```python
matplotlib.axis.YTick.get_gid

YTick.get_gid(self)
    Return the group id.
```

```python
matplotlib.axis.YTick.get_label

YTick.get_label(self)
    Return the label used for this artist in the legend.
```

```python
matplotlib.axis.YTick.get_path_effects

YTick.get_path_effects(self)
```

```python
matplotlib.axis.YTick.get_picker

YTick.get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in `set_picker`.

**See also:**

`set_picker`, `pickable`, `pick`
```

```python
matplotlib.axis.YTick.get_rasterized

YTick.get_rasterized(self)
    Return whether the artist is to be rasterized.
```
matplotlib.axis.YTick.get_sketch_params

YTick.get_sketch_params(self)
Returns the sketch parameters for the artist.

**Returns**

**sketch_params** [tuple or None] A 3-tuple with the following elements:
- `scale`: The amplitude of the wiggle perpendicular to the source line.
- `length`: The length of the wiggle along the line.
- `randomness`: The scale factor by which the length is shrunken or expanded.

Returns `None` if no sketch parameters were set.

matplotlib.axis.YTick.get_snap

YTick.get_snap(self)
Returns the snap setting.
See `set_snap` for details.

matplotlib.axis.YTick.get_transform

YTick.get_transform(self)
Return the `Transform` instance used by this artist.

matplotlib.axis.YTick.get_transformed_clip_path_and_affine

YTick.get_transformed_clip_path_and_affine(self)
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

matplotlib.axis.YTick.get_url

YTick.get_url(self)
Return the url.

matplotlib.axis.YTick.get_visible

YTick.get_visible(self)
Return the visibility.
`matplotlib.axis.YTick.get_window_extent`

`YTick.get_window_extent(self, renderer)`
Get the axes bounding box in display space.

The bounding box width and height are nonnegative.

Subclasses should override for inclusion in the bounding box "tight" calculation. Default is to return an empty bounding box at 0, 0.

Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

`matplotlib.axis.YTick.get_zorder`

`YTick.get_zorder(self)`
Return the artist’s zorder.

`matplotlib.axis.YTick.have_units`

`YTick.have_units(self)`
Return `True` if units are set on the x or y axes.

`matplotlib.axis.YTick.is_transform_set`

`YTick.is_transform_set(self)`
Return whether the Artist has an explicitly set transform.

This is `True` after `set_transform` has been called.

`matplotlib.axis.YTick.mouseover`

`YTick.mouseover`

`matplotlib.axis.YTick.pchanged`

`YTick.pchanged(self)`
Call all of the registered callbacks.

This function is triggered internally when a property is changed.

**See also:**

- `add_callback`
- `remove_callback`
matplotlib.axis.YTick.pick

```
YTick.pick(self, mouseevent)
   Process a pick event.
      Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

See also:

    set_picker, get_picker, pickable
```

matplotlib.axis.YTick.pickable

```
YTick.pickable(self)
   Return whether the artist is pickable.

See also:

    set_picker, get_picker, pick
```

matplotlib.axis.YTick.properties

```
YTick.properties(self)
   Return a dictionary of all the properties of the artist.
```

matplotlib.axis.YTick.remove

```
YTick.remove(self)
   Remove the artist from the figure if possible.
      The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
draw_idle. Call relim to update the axes limits if desired.

Note: relim will not see collections even if the collection was added to the axes with
autolim = True.

Note: there is no support for removing the artist’s legend entry.
```

matplotlib.axis.YTick.remove_callback

```
YTick.remove_callback(self, oid)
   Remove a callback based on its observer id.

See also:

    add_callback
```
`matplotlib.axis.YTick.set`

`YTick.set(self, **kwargs)`

A property batch setter. Pass `kwargs` to set properties.

`matplotlib.axis.YTick.set_agg_filter`

`YTick.set_agg_filter(self, filter_func)`

Set the agg filter.

**Parameters**

- `filter_func` [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

`matplotlib.axis.YTick.set_alpha`

`YTick.set_alpha(self, alpha)`

Set the alpha value used for blending - not supported on all backends.

**Parameters**

- `alpha` [float]

`matplotlib.axis.YTick.set_animated`

`YTick.set_animated(self, b)`

Set the artist’s animation state.

**Parameters**

- `b` [bool]

`matplotlib.axis.YTick.set_clip_box`

`YTick.set_clip_box(self, clipbox)`

Set the artist’s clip `Bbox`.

**Parameters**

- `clipbox` [Bbox]

`matplotlib.axis.YTick.set_clip_on`

`YTick.set_clip_on(self, b)`

Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

- `b` [bool]
Matplotlib, Release 3.1.1

**matplotlib.axis.YTick.set_clip_path**

**YTick.set_clip_path(self, clippath, transform=None)**

Set the artist’s clip path, which may be:

- a `Patch` (or subclass) instance; or
- a `Path` instance, in which case a `Transform` instance, which will be applied to the path before using it for clipping, must be provided; or
- `None`, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to `None`.

**ACCEPTS:** `[Path, Transform] | Patch | None`

**matplotlib.axis.YTick.set_contains**

**YTick.set_contains(self, picker)**

Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

- **picker** [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```
def contains(artist: Artist, event: MouseEvent) -> bool, dict```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

**matplotlib.axis.YTick.set_figure**

**YTick.set_figure(self, fig)**

Set the `Figure` instance the artist belongs to.

**Parameters**

- **fig** `[Figure]`

**matplotlib.axis.YTick.set_gid**

**YTick.set_gid(self, gid)**

Set the (group) id for the artist.

**Parameters**

- **gid** `[str]`
**matplotlib.axis.YTick.set_label**

```
YTick.set_label(self, s)
```

Set the label text.

**Parameters**

- `s` [str]

**matplotlib.axis.YTick.set_path_effects**

```
YTick.set_path_effects(self, path_effects)
```

Set the path effects.

**Parameters**

- `path_effects` [AbstractPathEffect]

**matplotlib.axis.YTick.set_picker**

```
YTick.set_picker(self, picker)
```

Define the picking behavior of the artist.

**Parameters**

- `picker` [None or bool or float or callable] This can be one of the following:
  - `None`: Picking is disabled for this artist (default).
  - A boolean: If `True` then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
  - A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
  - A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

    ```python
    hit, props = picker(artist, mouseevent)
    ```

    to determine the hit test. if the mouse event is over the artist, return `hit=True` and props is a dictionary of properties you want added to the PickEvent attributes.

**matplotlib.axis.YTick.set_rasterized**

```
YTick.set_rasterized(self, rasterized)
```

Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

**Parameters**

- `rasterized` [bool or None]
**matplotlib.axis.YTick.set_sketch_params**

_YTick.set_sketch_params(self, scale=None, length=None, randomness=None)_

Sets the sketch parameters.

**Parameters**

- **scale** [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is `None`, or not provided, no sketch filter will be provided.
- **length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
- **randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

**matplotlib.axis.YTick.set_snap**

_YTick.set_snap(self, snap)_

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

- **snap** [bool or None] Possible values:
  - `True`: Snap vertices to the nearest pixel center.
  - `False`: Do not modify vertex positions.
  - `None`: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

**matplotlib.axis.YTick.set_transform**

_YTick.set_transform(self, t)_

Set the artist transform.

**Parameters**

- **t** [Transform]

**matplotlib.axis.YTick.set_url**

_YTick.set_url(self, url)_

Set the url for the artist.

**Parameters**
url [str]

matplotlib.axis.YTick.set_visible

YTick.set_visible(self, b)
   Set the artist’s visibility.

   **Parameters**
   
   b [bool]

matplotlib.axis.YTick.set_zorder

YTick.set_zorder(self, level)
   Set the zorder for the artist. Artists with lower zorder values are drawn first.

   **Parameters**
   
   level [float]

matplotlib.axis.YTick.stale

YTick.stale
   Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

matplotlib.axis.YTick.update

YTick.update(self, props)
   Update this artist’s properties from the dictionary props.

matplotlib.axis.YTick.update_from

YTick.update_from(self, other)
   Copy properties from other to self.

matplotlib.axis.YTick.zorder

YTick.zorder = 0

Axis

Axis.add_callback
Add a callback function that will be called whenever one of the Artist's properties changes.

**YAxes**

- mouseover: Call all of the registered callbacks.
- pchanged: Process a pick event.
- pickable: Return whether the artist is pickable.
- properties: Return a dictionary of all the properties of the artist.
- remove: Remove the artist from the figure if possible.
- remove_callback: Remove a callback based on its observer id.
- set: A property batch setter.
- set_agg_filter: Set the agg filter.
- set_alpha: Set the alpha value used for blending - not supported on all backends.
- set_animated: Set the artist’s animation state.
- set_clip_box: Set the artist’s clip Bbox.
- set_clip_on: Set whether the artist uses clipping.
- set_clip_path: Set the artist’s clip path, which may be:
- set_contains: Define a custom contains test for the artist.
- set_figure: Set the Figure instance the artist belongs to.
- set_gid: Set the (group) id for the artist.
- set_label: Set a label that will be displayed in the legend.
- set_path_effects: Set the path effects.
- set_picker: Define the picking behavior of the artist.
- set_rasterized: Force rasterized (bitmap) drawing in vector backend output.
- set_sketch_params: Sets the sketch parameters.
- set_snap: Set the snapping behavior.
- set_transform: Set the artist transform.
- set_url: Set the url for the artist.
- set_visible: Set the artist’s visibility.
- set_zorder: Set the zorder for the artist.
- stale: Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
- update: Update this artist’s properties from the dictionary props.
- update_from: Copy properties from other to self.
matplotlib.axis.Axis.add_callback

Axis.add_callback(self, func)
Add a callback function that will be called whenever one of the Artist’s properties changes.

Parameters
func [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where artist is the calling Artist. Return values may exist but are ignored.

Returns
oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

See also:
remove_callback

matplotlib.axis.Axis.axes

Axis.axes
The Axes instance the artist resides in, or None.

matplotlib.axis.Axis.contains

Axis.contains(self, mouseevent)
Test whether the artist contains the mouse event.

Parameters
mouseevent [matplotlib.backend_bases.MouseEvent]

Returns
contains [bool] Whether any values are within the radius.
details [dict] An artist-specific dictionary of details of the event context, such as which points are contained in the pick radius. See the individual Artist subclasses for details.

See also:
set_contains, get_contains
**matplotlib.axis.Axis.convert_xunits**

`Axis.convert_xunits(self, x)`  
Convert x using the unit type of the xaxis.  
If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

**matplotlib.axis.Axis.convert_yunits**

`Axis.convert_yunits(self, y)`  
Convert y using the unit type of the yaxis.  
If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.

**matplotlib.axis.Axis.draw**

`Axis.draw(self, renderer, *args, **kwargs)`  
Draw the axis lines, grid lines, tick lines and labels

**matplotlib.axis.Axis.findobj**

`Axis.findobj(self, match=None, include_self=True)`  
Find artist objects.  
Recursively find all Artist instances contained in the artist.  

**Parameters**

- **match** A filter criterion for the matches. This can be
  - `None`: Return all objects contained in artist.
  - A function with signature `def match(artist: Artist) -> bool`. The result will only contain artists for which the function returns `True`.
  - A class instance: e.g., `Line2D`. The result will only contain artists of this class or its subclasses (`isinstance` check).

- **include_self** [bool] Include `self` in the list to be checked for a match.

**Returns**

- **artists** [list of Artist]

**matplotlib.axis.Axis.format_cursor_data**

`Axis.format_cursor_data(self, data)`  
Return a string representation of `data`.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.
The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

`get_cursor_data`

```python
matplotlib.axis.Axis.get_agg_filter

Axis.get_agg_filter(self)
    Return filter function to be used for agg filter.

matplotlib.axis.Axis.get_alpha

Axis.get_alpha(self)
    Return the alpha value used for blending - not supported on all backends

matplotlib.axis.Axis.get_animated

Axis.get_animated(self)
    Return the animated state.

matplotlib.axis.Axis.get_children

Axis.get_children(self)
    Return a list of the child *Artists* of this *Artist*.

matplotlib.axis.Axis.get_clip_box

Axis.get_clip_box(self)
    Return the clipbox.

matplotlib.axis.Axis.get_clip_on

Axis.get_clip_on(self)
    Return whether the artist uses clipping.

matplotlib.axis.Axis.get_clip_path

Axis.get_clip_path(self)
    Return the clip path.
```
matplotlib.axis.Axis.get_contains

Axis.get_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:
    set_contains

matplotlib.axis.Axis.get_cursor_data

Axis.get_cursor_data(self, event)
    Return the cursor data for a given event.

    Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

    Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

    Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

    The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

    Parameters
    event [matplotlib.backend_bases.MouseEvent]

    See also:
    format_cursor_data

matplotlib.axis.Axis.get_figure

Axis.get_figure(self)
    Return the Figure instance the artist belongs to.

matplotlib.axis.Axis.get_gid

Axis.get_gid(self)
    Return the group id.

matplotlib.axis.Axis.get_label

Axis.get_label(self)
    Return the axis label as a Text instance
```python
matplotlib.axis.Axis.get_path_effects

Axis.get_path_effects(self)

matplotlib.axis.Axis.get_picker

Axis.get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.
    See also:
    set_picker, pickable, pick

matplotlib.axis.Axis.get_rasterized

Axis.get_rasterized(self)
    Return whether the artist is to be rasterized.

matplotlib.axis.Axis.get_sketch_params

Axis.get_sketch_params(self)
    Returns the sketch parameters for the artist.
    Returns
    sketch_params [tuple or None] A 3-tuple with the following elements:
    • scale: The amplitude of the wiggle perpendicular to the source line.
    • length: The length of the wiggle along the line.
    • randomness: The scale factor by which the length is shrunken or expanded.
    Returns None if no sketch parameters were set.

matplotlib.axis.Axis.get_snap

Axis.get_snap(self)
    Returns the snap setting.
    See set_snap for details.

matplotlib.axis.Axis.get_transform

Axis.get_transform(self)
    Return the Transform instance used by this artist.
```
matplotlib.axis.Axis.get_transformed_clip_path_and_affine

Axis.get_transformed_clip_path_and_affine(self)
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

matplotlib.axis.Axis.get_url

Axis.get_url(self)
Return the url.

matplotlib.axis.Axis.get_visible

Axis.get_visible(self)
Return the visibility.

matplotlib.axis.Axis.get_window_extent

Axis.get_window_extent(self, renderer)
Get the axes bounding box in display space.
The bounding box’ width and height are nonnegative.
Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.
Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

matplotlib.axis.Axis.get_zorder

Axis.get_zorder(self)
Return the artist’s zorder.

matplotlib.axis.Axis.have_units

Axis.have_units(self)
Return True if units are set on the x or y axes.

matplotlib.axis.Axis.is_transform_set

Axis.is_transform_set(self)
Return whether the Artist has an explicitly set transform.
This is True after set_transform has been called.
matplotlib.axis.Axis.mouseover

Axis.mouseover

matplotlib.axis.Axis.pchanged

Axis.pchanged(self)
   Call all of the registered callbacks.
   This function is triggered internally when a property is changed.
   See also:

   add_callback
   remove_callback

matplotlib.axis.Axis.pick

Axis.pick(self, mouseevent)
   Process a pick event.
   Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.
   See also:

   set_picker, get_picker, pickable

matplotlib.axis.Axis.pickable

Axis.pickable(self)
   Return whether the artist is pickable.
   See also:

   set_picker, get_picker, pick

matplotlib.axis.Axis.properties

Axis.properties(self)
   Return a dictionary of all the properties of the artist.

matplotlib.axis.Axis.remove

Axis.remove(self)
   Remove the artist from the figure if possible.
   The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase. draw_idle. Call relim to update the axes limits if desired.
Note: `relim` will not see collections even if the collection was added to the axes with `autolim = True`.

Note: there is no support for removing the artist’s legend entry.

```python
matplotlib.axis.Axis.remove_callback

Axis.remove_callback(self, oid)
    Remove a callback based on its observer id.

    See also:

    add_callback
```

```python
matplotlib.axis.Axis.set

Axis.set(self, **kwargs)
    A property batch setter. Pass `kwargs` to set properties.
```

```python
matplotlib.axis.Axis.set_agg_filter

Axis.set_agg_filter(self, filter_func)
    Set the agg filter.

    Parameters

    filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.
```

```python
matplotlib.axis.Axis.set_alpha

Axis.set_alpha(self, alpha)
    Set the alpha value used for blending - not supported on all backends.

    Parameters

    alpha [float]
```

```python
matplotlib.axis.Axis.set_animated

Axis.set_animated(self, b)
    Set the artist’s animation state.

    Parameters

    b [bool]
```
matplotlib.axis.Axis.set_clip_box

Axis.setClipBox(self, clipbox)

Set the artist’s clip Bbox.

Parameters

clipbox [Bbox]

matplotlib.axis.Axis.set_clip_on

Axis.setClipOn(self, b)

Set whether the artist uses clipping.

When False artists will be visible outside of the axes which can lead to unexpected results.

Parameters

b [bool]

matplotlib.axis.Axis.set_clip_path

Axis.setClipPath(self, clippath, transform=None)

Set the artist’s clip path, which may be:

• a Patch (or subclass) instance; or
• a Path instance, in which case a Transform instance, which will be applied to the path before using it for clipping, must be provided; or
• None, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

matplotlib.axis.Axis.set_contains

Axis.setContains(self, picker)

Define a custom contains test for the artist.

The provided callable replaces the default contains method of the artist.

Parameters

picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

• a bool indicating if the event is within the artist
• a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

```python
matplotlib.axis.Axis.set_figure

Axis.set_figure(self, fig)
   Set the Figure instance the artist belongs to.

   Parameters
   fig [Figure]
```

```python
matplotlib.axis.Axis.set_gid

Axis.set_gid(self, gid)
   Set the (group) id for the artist.

   Parameters
   gid [str]
```

```python
matplotlib.axis.Axis.set_label

Axis.set_label(self, s)
   Set a label that will be displayed in the legend.

   Parameters
   s [object] s will be converted to a string by calling str.
```

```python
matplotlib.axis.Axis.set_path_effects

Axis.set_path_effects(self, path_effects)
   Set the path effects.

   Parameters
   path_effects [AbstractPathEffect]
```

```python
matplotlib.axis.Axis.set_picker

Axis.set_picker(self, picker)
   Define the picking behavior of the artist.

   Parameters
   picker [None or bool or float or callable] This can be one of the following:
       • None: Picking is disabled for this artist (default).
       • A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
```
A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.

A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. If the mouse event is over the artist, return \(hit=True\) and \(props\) is a dictionary of properties you want added to the PickEvent attributes.

### `matplotlib.axis.Axis.set_rasterized`

**Axis.set_rasterized(self, rasterized)**

Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

**Parameters**

- **rasterized** [bool or None]

### `matplotlib.axis.Axis.set_sketch_params`

**Axis.set_sketch_params(self, scale=None, length=None, randomness=None)**

Sets the sketch parameters.

**Parameters**

- **scale** [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is \(None\), or not provided, no sketch filter will be provided.
- **length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
- **randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

### `matplotlib.axis.Axis.set_snap`

**Axis.set_snap(self, snap)**

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.
Parameters

snap [bool or None] Possible values:
- True: Snap vertices to the nearest pixel center.
- False: Do not modify vertex positions.
- None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

matplotlib.axis.Axis.set_transform

Axis.set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]

matplotlib.axis.Axis.set_url

Axis.set_url(self, url)
Set the url for the artist.

Parameters

url [str]

matplotlib.axis.Axis.set_visible

Axis.set_visible(self, b)
Set the artist’s visibility.

Parameters

b [bool]

matplotlib.axis.Axis.set_zorder

Axis.set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters

level [float]

matplotlib.axis.Axis.stale

Axis.stale
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
Axis.update(self, props)
    Update this artist’s properties from the dictionary props.

Axis.update_from(self, other)
    Copy properties from other to self.

Axis.zorder
    Axis.zorder = 0

XAxis.add_callback(self, func)
    Add a callback function that will be called whenever one of the Artist’s properties changes.

    Parameters
        func [callable] The callback function. It must have the signature:
        def func(artist: Artist) -> Any

        where artist is the calling Artist. Return values may exist but are ignored.

    Returns
        oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

    See also:
        remove_callback

XAxis.axes
    The Axes instance the artist resides in, or None.

XAxis.contains(self, mouseevent)
    Test whether the mouse event occurred in the x axis.
matplotlib.axis.XAxis.convert_xunits

XAxis.convert_xunits(self, x)
Convert x using the unit type of the xaxis.
If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

matplotlib.axis.XAxis.convert_yunits

XAxis.convert_yunits(self, y)
Convert y using the unit type of the yaxis.
If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.

matplotlib.axis.XAxis.draw

XAxis.draw(self, renderer, *args, **kwargs)
Draw the axis lines, grid lines, tick lines and labels

matplotlib.axis.XAxis.findobj

XAxis.findobj(self, match=None, include_self=True)
Find artist objects.
Recursively find all Artist instances contained in the artist.

Parameters

match A filter criterion for the matches. This can be
• None: Return all objects contained in artist.
• A function with signature def match(artist: Artist) -> bool. The re-
  sult will only contain artists for which the function returns True.
• A class instance: e.g., Line2D. The result will only contain artists of this
  class or its subclasses (isinstance check).

include_self [bool] Include self in the list to be checked for a match.

Returns

artists [list of Artist]

matplotlib.axis.XAxis.format_cursor_data

XAxis.format_cursor_data(self, data)
Return a string representation of data.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.
The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

get_cursor_data

```
matplotlib.axis.XAxis.get_agg_filter

XAxis.get_agg_filter(self)
    Return filter function to be used for agg filter.
```

```
matplotlib.axis.XAxis.get_alpha

XAxis.get_alpha(self)
    Return the alpha value used for blending - not supported on all backends
```

```
matplotlib.axis.XAxis.get_animated

XAxis.get_animated(self)
    Return the animated state.
```

```
matplotlib.axis.XAxis.get_children

XAxis.get_children(self)
    Return a list of the child Artists of this Artist.
```

```
matplotlib.axis.XAxis.get_clip_box

XAxis.get_clip_box(self)
    Return the clipbox.
```

```
matplotlib.axis.XAxis.get_clip_on

XAxis.get_clip_on(self)
    Return whether the artist uses clipping.
```

```
matplotlib.axis.XAxis.get_clip_path

XAxis.get_clip_path(self)
    Return the clip path.
```
`matplotlib.axis.XAxis.get_contains`

`XAxis.get_contains(self)`

Return the custom contains function of the artist if set, or `None`.

**See also:**

`set_contains`

`matplotlib.axis.XAxis.get_cursor_data`

`XAxis.get_cursor_data(self, event)`

Return the cursor data for a given event.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns `None`.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation.

The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

- `event`  
  `matplotlib.backend_bases.MouseEvent`

**See also:**

`format_cursor_data`

`matplotlib.axis.XAxis.get_figure`

`XAxis.get_figure(self)`

Return the `Figure` instance the artist belongs to.

`matplotlib.axis.XAxis.get_gid`

`XAxis.get_gid(self)`

Return the group id.

`matplotlib.axis.XAxis.get_label`

`XAxis.get_label(self)`

Return the axis label as a `Text` instance
Matplotlib, Release 3.1.1

matplotlib.axis.XAxis.get_path_effects

XAxis.get_path_effects(self)

matplotlib.axis.XAxis.get_picker

XAxis.get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.

See also:
    set_picker, pickable, pick

matplotlib.axis.XAxis.get_rasterized

XAxis.get_rasterized(self)
    Return whether the artist is to be rasterized.

matplotlib.axis.XAxis.get_sketch_params

XAxis.get_sketch_params(self)
    Returns the sketch parameters for the artist.

Returns
    sketch_params [tuple or None] A 3-tuple with the following elements:
        • scale: The amplitude of the wiggle perpendicular to the source line.
        • length: The length of the wiggle along the line.
        • randomness: The scale factor by which the length is shrunken or expanded.
    Returns None if no sketch parameters were set.

matplotlib.axis.XAxis.get_snap

XAxis.get_snap(self)
    Returns the snap setting.
    See set_snap for details.

matplotlib.axis.XAxis.get_transform

XAxis.get_transform(self)
    Return the Transform instance used by this artist.
matplotlib.axis.XAxis.get_transformed_clip_path_and_affine

XAxis.get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

matplotlib.axis.XAxis.get_url

XAxis.get_url(self)
    Return the url.

matplotlib.axis.XAxis.get_visible

XAxis.get_visible(self)
    Return the visibility.

matplotlib.axis.XAxis.get_window_extent

XAxis.get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box’ width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

matplotlib.axis.XAxis.get_zorder

XAxis.get_zorder(self)
    Return the artist’s zorder.

matplotlib.axis.XAxis.have_units

XAxis.have_units(self)
    Return True if units are set on the x or y axes.

matplotlib.axis.XAxis.is_transform_set

XAxis.is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.
matplotlib.axis.XAxis.mouseover

XAxis.mouseover

matplotlib.axis.XAxis.pchanged

XAxis.pchanged(self)
   Call all of the registered callbacks.
   This function is triggered internally when a property is changed.

   See also:

   add_callback
   remove_callback

matplotlib.axis.XAxis.pick

XAxis.pick(self, mouseevent)
   Process a pick event.
   Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

   See also:

   set_picker, get_picker, pickable

matplotlib.axis.XAxis.pickable

XAxis.pickable(self)
   Return whether the artist is pickable.

   See also:

   set_picker, get_picker, pick

matplotlib.axis.XAxis.properties

XAxis.properties(self)
   Return a dictionary of all the properties of the artist.

matplotlib.axis.XAxis.remove

XAxis.remove(self)
   Remove the artist from the figure if possible.
   The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase. draw_idle. Call relim to update the axes limits if desired.
Note: `relim` will not see collections even if the collection was added to the axes with `autolim = True`.

Note: there is no support for removing the artist’s legend entry.

```python
matplotlib.axis.XAxis.remove_callback

XAxis.remove_callback(self, oid)
    Remove a callback based on its observer id.
    
    **See also:**
    add_callback

matplotlib.axis.XAxis.set

XAxis.set(self, **kwargs)
    A property batch setter. Pass `kwargs` to set properties.

matplotlib.axis.XAxis.set_agg_filter

XAxis.set_agg_filter(self, filter_func)
    Set the agg filter.
    
    **Parameters**
    
    filter_func [callable] A filter function, which takes a (m, n, 3) float array 
    and a dpi value, and returns a (m, n, 3) array.

matplotlib.axis.XAxis.set_alpha

XAxis.set_alpha(self, alpha)
    Set the alpha value used for blending - not supported on all backends.
    
    **Parameters**
    
    alpha [float]

matplotlib.axis.XAxis.set_animated

XAxis.set_animated(self, b)
    Set the artist’s animation state.
    
    **Parameters**
    
    b [bool]
```
matplotlib.axis.XAxis.set_clip_box

XAxis.set_clip_box(self, clipbox)
Set the artist’s clip Bbox.

Parameters

clipbox [Bbox]

matplotlib.axis.XAxis.set_clip_on

XAxis.set_clip_on(self, b)
Set whether the artist uses clipping.
When False artists will be visible outside of the axes which can lead to unexpected results.

Parameters

b [bool]

matplotlib.axis.XAxis.set_clip_path

XAxis.set_clip_path(self, clippath, transform=None)
Set the artist’s clip path, which may be:
• a Patch (or subclass) instance; or
• a Path instance, in which case a Transform instance, which will be applied to the path before using it for clipping, must be provided; or
• None, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

matplotlib.axis.XAxis.set_contains

XAxis.set_contains(self, picker)
Define a custom contains test for the artist.
The provided callable replaces the default contains method of the artist.

Parameters

picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:
• a bool indicating if the event is within the artist
• a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

```python
matplotlib.axis.XAxis.set_figure
```

XAxis.set_figure(self, fig)

Set the Figure instance the artist belongs to.

**Parameters**

- `fig [Figure]`

```python
matplotlib.axis.XAxis.set_gid
```

XAxis.set_gid(self, gid)

Set the (group) id for the artist.

**Parameters**

- `gid [str]`

```python
matplotlib.axis.XAxis.set_label
```

XAxis.set_label(self, s)

Set a label that will be displayed in the legend.

**Parameters**

- `s [object] s will be converted to a string by calling str.`

```python
matplotlib.axis.XAxis.set_path_effects
```

XAxis.set_path_effects(self, path_effects)

Set the path effects.

**Parameters**

- `path_effects [AbstractPathEffect]`

```python
matplotlib.axis.XAxis.set_picker
```

XAxis.set_picker(self, picker)

Define the picking behavior of the artist.

**Parameters**

- `picker [None or bool or float or callable] This can be one of the following:
  - None: Picking is disabled for this artist (default).
  - A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
• A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it's data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.

• A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. If the mouse event is over the artist, return `hit=True` and `props` is a dictionary of properties you want added to the PickEvent attributes.

```python
matplotlib.axis.XAxis.set_rasterized
```

```python
XAxis.set_rasterized(self, rasterized)
```

Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

**Parameters**

- `rasterized` [bool or None]

```python
matplotlib.axis.XAxis.set_sketch_params
```

```python
XAxis.set_sketch_params(self, scale=None, length=None, randomness=None)
```

Sets the sketch parameters.

**Parameters**

- `scale` [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is `None`, or not provided, no sketch filter will be provided.

- `length` [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

- `randomness` [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

```python
matplotlib.axis.XAxis.set_snap
```

```python
XAxis.set_snap(self, snap)
```

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.
Parameters

**snap** [bool or None] Possible values:

- **True**: Snap vertices to the nearest pixel center.
- **False**: Do not modify vertex positions.
- **None**: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

```python
matplotlib.axis.XAxis.set_transform
```

```python
XAxis.set_transform(self, t)
```

Set the artist transform.

**Parameters**

- **t** [Transform]

```python
matplotlib.axis.XAxis.set_url
```

```python
XAxis.set_url(self, url)
```

Set the url for the artist.

**Parameters**

- **url** [str]

```python
matplotlib.axis.XAxis.set_visible
```

```python
XAxis.set_visible(self, b)
```

Set the artist’s visibility.

**Parameters**

- **b** [bool]

```python
matplotlib.axis.XAxis.set_zorder
```

```python
XAxis.set_zorder(self, level)
```

Set the zorder for the artist. Artists with lower zorder values are drawn first.

**Parameters**

- **level** [float]

```python
matplotlib.axis.XAxis.stale
```

```python
XAxis.stale
```

Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
matplotlib.axis.XAxis.update

XAxis.update(self, props)
    Update this artist’s properties from the dictionary props.

matplotlib.axis.XAxis.update_from

XAxis.update_from(self, other)
    Copy properties from other to self.

matplotlib.axis.XAxis.zorder

XAxis.zorder = 0

matplotlib.axis.YAxis.add_callback

YAxis.add_callback(self, func)
    Add a callback function that will be called whenever one of the Artist’s properties changes.

    Parameters
        func [callable] The callback function. It must have the signature:
        
        ```python
        def func(artist: Artist) -> Any
        ```
        
        where artist is the calling Artist. Return values may exist but are ignored.

    Returns
        oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

    See also:
        remove_callback

matplotlib.axis.YAxis.axes

YAxis.axes
    The Axes instance the artist resides in, or None.

matplotlib.axis.YAxis.contains

YAxis.contains(self, mouseevent)
    Test whether the mouse event occurred in the y axis.
    Returns True | False
matplotlib.axis.YAxis.convert_xunits

YAxis.convert_xunits(self, x)
Convert x using the unit type of the xaxis.
If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

matplotlib.axis.YAxis.convert_yunits

YAxis.convert_yunits(self, y)
Convert y using the unit type of the yaxis.
If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.

matplotlib.axis.YAxis.draw

YAxis.draw(self, renderer, *args, **kwargs)
Draw the axis lines, grid lines, tick lines and labels

matplotlib.axis.YAxis.findobj

YAxis.findobj(self, match=None, include_self=True)
Find artist objects.
Recursively find all Artist instances contained in the artist.

Parameters
match A filter criterion for the matches. This can be
• None: Return all objects contained in artist.
• A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns True.
• A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

include_self [bool] Include self in the list to be checked for a match.

Returns
artists [list of Artist]

matplotlib.axis.YAxis.format_cursor_data

YAxis.format_cursor_data(self, data)
Return a string representation of data.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.
The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

`get_cursor_data`

```python
matplotlib.axis.YAxis.get_agg_filter

YAxis.get_agg_filter(self)
    Return filter function to be used for agg filter.
```

```python
matplotlib.axis.YAxis.get_alpha

YAxis.get_alpha(self)
    Return the alpha value used for blending - not supported on all backends
```

```python
matplotlib.axis.YAxis.get_animated

YAxis.get_animated(self)
    Return the animated state.
```

```python
matplotlib.axis.YAxis.get_children

YAxis.get_children(self)
    Return a list of the child Artists of this Artist.
```

```python
matplotlib.axis.YAxis.get_clip_box

YAxis.get_clip_box(self)
    Return the clipbox.
```

```python
matplotlib.axis.YAxis.get_clip_on

YAxis.get_clip_on(self)
    Return whether the artist uses clipping.
```

```python
matplotlib.axis.YAxis.get_clip_path

YAxis.get_clip_path(self)
    Return the clip path.
```
matplotlib.axis.YAxis.get_contains

YAxis.get_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:
    set_contains

matplotlib.axis.YAxis.get_cursor_data

YAxis.get_cursor_data(self, event)
    Return the cursor data for a given event.

    Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

    Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

    Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

    The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

    Parameters
    event [matplotlib.backend_bases.MouseEvent]

    See also:
    format_cursor_data

matplotlib.axis.YAxis.get_figure

YAxis.get_figure(self)
    Return the Figure instance the artist belongs to.

matplotlib.axis.YAxis.get_gid

YAxis.get_gid(self)
    Return the group id.

matplotlib.axis.YAxis.get_label

YAxis.get_label(self)
    Return the axis label as a Text instance
YAxis.get_path_effects(self)

YAxis.get_picker(self)

Return the picking behavior of the artist.
The possible values are described in set_picker.
See also:

set_picker, pickable, pick

YAxis.get_rasterized(self)

Return whether the artist is to be rasterized.

YAxis.get_sketch_params(self)

Returns the sketch parameters for the artist.

Returns

sketch_params [tuple or None] A 3-tuple with the following elements:

- scale: The amplitude of the wiggle perpendicular to the source line.
- length: The length of the wiggle along the line.
- randomness: The scale factor by which the length is shrunken or expanded.

Returns None if no sketch parameters were set.

YAxis.get_snap(self)

Returns the snap setting.
See set_snap for details.

YAxis.get_transform(self)

Return the Transform instance used by this artist.
matplotlib.axis.YAxis.get_transformed_clip_path_and_affine

YAxis.get_transformed_clip_path_and_affine(self)
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

matplotlib.axis.YAxis.get_url

YAxis.get_url(self)
Return the url.

matplotlib.axis.YAxis.get_visible

YAxis.get_visible(self)
Return the visibility.

matplotlib.axis.YAxis.get_window_extent

YAxis.get_window_extent(self, renderer)
Get the axes bounding box in display space.
The bounding box’ width and height are nonnegative.
Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.
Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

matplotlib.axis.YAxis.get_zorder

YAxis.get_zorder(self)
Return the artist’s zorder.

matplotlib.axis.YAxis.have_units

YAxis.have_units(self)
Return True if units are set on the x or y axes.

matplotlib.axis.YAxis.is_transform_set

YAxis.is_transform_set(self)
Return whether the Artist has an explicitly set transform.
This is True after set_transform has been called.
YAxis.mouseover

Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:

add_callback
remove_callback

YAxis.pchanged

YAxis.pchanged(self)
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:

add_callback
remove_callback

YAxis.pick

YAxis.pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

See also:

set_picker, get_picker, pickable

YAxis.pickable

YAxis.pickable(self)
Return whether the artist is pickable.

See also:

set_picker, get_picker, pick

YAxis.properties

YAxis.properties(self)
Return a dictionary of all the properties of the artist.

YAxis.remove

YAxis.remove(self)
Remove the artist from the figure if possible.
The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.draw_idle. Call relim to update the axes limits if desired.
Note: `relim` will not see collections even if the collection was added to the axes with `autolim = True`.
Note: there is no support for removing the artist’s legend entry.

```python
matplotlib.axis.YAxis.remove_callback
```

`YAxis.remove_callback(self, oid)`
Remove a callback based on its observer id.

See also:

```
add_callback
```

```python
matplotlib.axis.YAxis.set
```

`YAxis.set(self, **kwargs)`
A property batch setter. Pass `kwargs` to set properties.

```python
matplotlib.axis.YAxis.set_agg_filter
```

`YAxis.set_agg_filter(self, filter_func)`
Set the agg filter.

Parameters

- `filter_func` [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

```python
matplotlib.axis.YAxis.set_alpha
```

`YAxis.set_alpha(self, alpha)`
Set the alpha value used for blending - not supported on all backends.

Parameters

- `alpha` [float]

```python
matplotlib.axis.YAxis.set_animated
```

`YAxis.set_animated(self, b)`
Set the artist’s animation state.

Parameters

- `b` [bool]
**matplotlib.axis.YAxis.set_clip_box**

```python
YAxis.set_clip_box(self, clipbox)
```

Set the artist’s clip `bbox`.

**Parameters**

- `clipbox [bbox]`

**matplotlib.axis.YAxis.set_clip_on**

```python
YAxis.set_clip_on(self, b)
```

Set whether the artist uses clipping.

When `False` artists will be visible outside of the axes which can lead to unexpected results.

**Parameters**

- `b [bool]`

**matplotlib.axis.YAxis.set_clip_path**

```python
YAxis.set_clip_path(self, clippath, transform=None)
```

Set the artist’s clip path, which may be:

- a `Path` (or subclass) instance; or
- a `Path` instance, in which case a `Transform` instance, which will be applied to the path before using it for clipping, must be provided; or
- `None`, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to `None`.

**ACCEPTS:** `[(Path, Transform) | Patch | None]`

**matplotlib.axis.YAxis.set_contains**

```python
YAxis.set_contains(self, picker)
```

Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

- `picker [callable]` A custom picker function to evaluate if an event is within the artist. The function must have the signature:

  ```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
  ```

  that returns:

  - a `bool` indicating if the event is within the artist
• a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

matplotlib.axis.YAxis.set_figure

YAxis.set_figure(self, fig)
Set the Figure instance the artist belongs to.

Parameters
fig [Figure]

matplotlib.axis.YAxis.set_gid

YAxis.set_gid(self, gid)
Set the (group) id for the artist.

Parameters
gid [str]

matplotlib.axis.YAxis.set_label

YAxis.set_label(self, s)
Set a label that will be displayed in the legend.

Parameters
s [object] s will be converted to a string by calling str.

matplotlib.axis.YAxis.set_path_effects

YAxis.set_path_effects(self, path_effects)
Set the path effects.

Parameters
path_effects [AbstractPathEffect]

matplotlib.axis.YAxis.set_picker

YAxis.set_picker(self, picker)
Define the picking behavior of the artist.

Parameters
picker [None or bool or float or callable] This can be one of the following:
• None: Picking is disabled for this artist (default).
• A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
• A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.

• A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. If the mouse event is over the artist, return \(hit=True\) and props is a dictionary of properties you want added to the PickEvent attributes.

```
matplotlib.axis.YAxis.set_rasterized
```

```
YAxis.set_rasterized(self, rasterized)
```

Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

**Parameters**

- **rasterized** [bool or None]

```
matplotlib.axis.YAxis.set_sketch_params
```

```
YAxis.set_sketch_params(self, scale=None, length=None, randomness=None)
```

Sets the sketch parameters.

**Parameters**

- **scale** [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.

- **length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

- **randomness** [float, optional] The scale factor by which the length is shrunk or expanded (default 16.0)

```
matplotlib.axis.YAxis.set_snap
```

```
YAxis.set_snap(self, snap)
```

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.
Parameters

snap [bool or None] Possible values:
  • True: Snap vertices to the nearest pixel center.
  • False: Do not modify vertex positions.
  • None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

matplotlib.axis.YAxis.set_transform

YAxis.set_transform(self, t)
Set the artist transform.

Parameters

  t [Transform]

matplotlib.axis.YAxis.set_url

YAxis.set_url(self, url)
Set the url for the artist.

Parameters

  url [str]

matplotlib.axis.YAxis.set_visible

YAxis.set_visible(self, b)
Set the artist’s visibility.

Parameters

  b [bool]

matplotlib.axis.YAxis.set_zorder

YAxis.set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters

  level [float]

matplotlib.axis.YAxis.stale

YAxis.stale
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
Matplotlib, Release 3.1.1

matplotlib.axis.YAxis.update

YAxis.update(self, props)

Update this artist’s properties from the dictionary props.

matplotlib.axis.YAxis.update_from

YAxis.update_from(self, other)

Copy properties from other to self.

matplotlib.axis.YAxis.zorder

YAxis.zorder = 0

17.7 matplotlib.backend_bases

Abstract base classes define the primitives that renderers and graphics contexts must implement to serve as a matplotlib backend

RendererBase An abstract base class to handle drawing/rendering operations.

FigureCanvasBase The abstraction layer that separates the matplotlib.figure.Figure from the backend specific details like a user interface drawing area

GraphicsContextBase An abstract base class that provides color, line styles, etc...

Event The base class for all of the matplotlib event handling. Derived classes such as KeyEvent and MouseEvent store the meta data like keys and buttons pressed, x and y locations in pixel and Axes coordinates.

ShowBase The base class for the Show class of each interactive backend; the ‘show’ callable is then set to Show.__call__, inherited from ShowBase.

ToolContainerBase The base class for the Toolbar class of each interactive backend.

StatusBarBase The base class for the messaging area.

class matplotlib.backend_bases.CloseEvent(name, canvas, guiEvent=None)

Bases: matplotlib.backend_bases.Event

An event triggered by a figure being closed.

class matplotlib.backend_bases.DrawEvent(name, canvas, renderer)

Bases: matplotlib.backend_bases.Event

An event triggered by a draw operation on the canvas

In most backends callbacks subscribed to this callback will be fired after the rendering is complete but before the screen is updated. Any extra artists drawn to the canvas’s renderer will be reflected without an explicit call to blit.

Warning: Calling canvas.draw and canvas.blit in these callbacks may not be safe with all backends and may cause infinite recursion.
In addition to the Event attributes, the following event attributes are defined:

Attributes

render [RendererBase] the renderer for the draw event

class matplotlib.backend_bases.Event(name, canvas, guiEvent=None)
Bases: object

A matplotlib event. Attach additional attributes as defined in FigureCanvasBase.
mpl_connect(). The following attributes are defined and shown with their default values

Attributes

name [str] the event name

canvas [FigureCanvasBase] the backend-specific canvas instance generating
the event

guiEvent the GUI event that triggered the matplotlib event

class matplotlib.backend_bases.FigureCanvasBase(figure)
Bases: object

The canvas the figure renders into.

Public attributes

Attributes

figure [matplotlib.figure.Figure] A high-level figure instance

blit(self, bbox=None)
Blit the canvas in bbox (default entire canvas).

button_press_event(self, x, y, button, dblclick=False, guiEvent=None)
Backend derived classes should call this function on any mouse button press. x,y are
the canvas coords: 0,0 is lower, left. button and key are as defined in MouseEvent.
This method will be call all functions connected to the 'button_press_event' with a
MouseEvent instance.

button_release_event(self, x, y, button, guiEvent=None)
Backend derived classes should call this function on any mouse button release.
This method will call all functions connected to the 'button_release_event' with a
MouseEvent instance.

Parameters

x [scalar] the canvas coordinates where 0=left

y [scalar] the canvas coordinates where 0=bottom

guiEvent the native UI event that generated the mpl event

close_event(self, guiEvent=None)
Pass a CloseEvent to all functions connected to close_event.

draw(self, *args, **kwargs)
Render the Figure.

draw_cursor(self, event)
Draw a cursor in the event.axes if inaxes is not None. Use native GUI drawing for
efficiency if possible
draw_event(self, renderer)
    Pass a DrawEvent to all functions connected to draw_event.

draw_idle(self, *args, **kwargs)
    Request a widget redraw once control returns to the GUI event loop.
    Even if multiple calls to draw_idle occur before control returns to the GUI event loop, the figure will only be rendered once.

Notes

Backends may choose to override the method and implement their own strategy to prevent multiple renderings.

derentify_event(self, guiEvent=None, xy=None)
    Backend derived classes should call this function when entering canvas

Parameters

    guiEvent  the native UI event that generated the mpl event
    xy        [float, float]) the coordinate location of the pointer when the canvas
               is entered

events = ['resize_event', 'draw_event', 'key_press_event', 'key_release_event', 'button_press_event', ...
filetypes = {'eps': 'Encapsulated Postscript', 'jpeg': 'Joint Photographic Experts Group', 'jpg':
fixed_dpi = None
flush_events(self)
    Flush the GUI events for the figure.
    Interactive backends need to reimplement this method.

get_default_filename(self)
    Return a string, which includes extension, suitable for use as a default filename.

classmethod get_default_filetype()
    Get the default savefig file format as specified in rcParam savefig.format. Returned
    string excludes period. Overridden in backends that only support a single file type.

classmethod get_supported_filetypes()
    Return dict of savefig file formats supported by this backend

classmethod get_supported_filetypes_grouped()
    Return a dict of savefig file formats supported by this backend, where the keys are
    a file type name, such as 'Joint Photographic Experts Group', and the values are a
    list of filename extensions used for that filetype, such as ['jpg', 'jpeg'].

get_width_height(self)
    Return the figure width and height in points or pixels (depending on the backend),
    truncated to integers

get_window_title(self)
    Get the title text of the window containing the figure. Return None if there is no
    window (e.g., a PS backend).

grab_mouse(self, ax)
    Set the child axes which are currently grabbing the mouse events. Usually called
    by the widgets themselves. It is an error to call this if the mouse is already grabbed
    by another axes.
inaxes(self, xy)
    Check if a point is in an axes.

Parameters
    xy [tuple or list] (x,y) coordinates. x position - pixels from left of canvas.
     y position - pixels from bottom of canvas.

Returns
    axes: topmost axes containing the point, or None if no axes.

is_saving(self)
    Returns whether the renderer is in the process of saving to a file, rather than render-
    dering for an on-screen buffer.

key_press_event(self, key, guiEvent=None)
    Pass a KeyEvent to all functions connected to key_press_event.

key_release_event(self, key, guiEvent=None)
    Pass a KeyEvent to all functions connected to key_release_event.

leave_notify_event(self, guiEvent=None)
    Backend derived classes should call this function when leaving canvas

Parameters
    guiEvent the native UI event that generated the mpl event

motion_notify_event(self, x, y, guiEvent=None)
    Backend derived classes should call this function on any motion-notify-event.
    This method will call all functions connected to the 'motion_notify_event' with a
    MouseEvent instance.

Parameters
    x [scalar] the canvas coordinates where 0=left
    y [scalar] the canvas coordinates where 0=bottom
    guiEvent the native UI event that generated the mpl event

mpl_connect(self, s, func)
    Connect event with string s to func. The signature of func is:

```python
def func(event)
```

where event is a matplotlib.backend_bases.Event. The following events are recog-
nized

- 'button_press_event'
- 'button_release_event'
- 'draw_event'
- 'key_press_event'
- 'key_release_event'
- 'motion_notify_event'
- 'pick_event'
- 'resize_event'
• 'scroll_event'
• 'figure_enter_event',
• 'figure_leave_event',
• 'axes_enter_event',
• 'axes_leave_event'
• 'close_event'

For the location events (button and key press/release), if the mouse is over the axes, the variable `event.inaxes` will be set to the `Axes` the event occurs over, and additionally, the variables `event.xdata` and `event.ydata` will be defined. This is the mouse location in data coords. See `KeyEvent` and `MouseEvent` for more info.

Return value is a connection id that can be used with `mpl_disconnect()`.

**Examples**

Usage:

```python
def on_press(event):
    print('you pressed', event.button, event.xdata, event.ydata)

cid = canvas.mpl_connect('button_press_event', on_press)
```

`mpl_disconnect(self, cid)`

Disconnect callback id `cid`

**Examples**

Usage:

```python
cid = canvas.mpl_connect('button_press_event', on_press)
#...later
canvas.mpl_disconnect(cid)
```

`new_timer(self, *args, **kwargs)`

Creates a new backend-specific subclass of `backend_bases.Timer`. This is useful for getting periodic events through the backend’s native event loop. Implemented only for backends with GUIs.

**Other Parameters**

- `interval` [scalar] Timer interval in milliseconds
- `callbacks` [List[Tuple[callable, Tuple, Dict]]] Sequence of (func, args, kwargs) where `func(*args, **kwargs)` will be executed by the timer every `interval`.

callbacks which return `False` or `0` will be removed from the timer.
Examples

```python
>>> timer = fig.canvas.new_timer(callbacks=[(f1, (1,), {'a': 3}),])
```

**pick(self, mouseevent)**

**pick_event(self, mouseevent, artist, **kwargs)**

This method will be called by artists who are picked and will fire off `PickEvent` callbacks registered listeners.

**print_figure(self, filename, dpi=None, facecolor=None, edgecolor=None, orientation='portrait', format=None, *, bbox_inches=None, **kwargs)**

Render the figure to hardcopy. Set the figure patch face and edge colors. This is useful because some of the GUIs have a gray figure face color background and you'll probably want to override this on hardcopy.

**Parameters**

- **filename** can also be a file object on image backends
- **orientation** [{‘landscape’, ‘portrait’}, optional] only currently applies to PostScript printing.
- **dpi** [scalar, optional] the dots per inch to save the figure in; if None, use `savefig.dpi`
- **facecolor** [color or None, optional] the facecolor of the figure; if None, defaults to `savefig.facecolor`
- **edgecolor** [color or None, optional] the edgecolor of the figure; if None, defaults to `savefig.edgecolor`
- **format** [str, optional] when set, forcibly set the file format to save to
- **bbox_inches** [str or `Bbox`, optional] Bbox in inches. Only the given portion of the figure is saved. If ‘tight’, try to figure out the tight bbox of the figure. If None, use `savefig.bbox`
- **pad_inches** [scalar, optional] Amount of padding around the figure when `bbox_inches` is ‘tight’. If None, use `savefig.pad_inches`
- **bbox_extra_artists** [list of `Artist`, optional] A list of extra artists that will be considered when the tight bbox is calculated.

**release_mouse(self, ax)**

Release the mouse grab held by the axes, ax. Usually called by the widgets. It is ok to call this even if you ax doesn’t have the mouse grab currently.

**resize(self, w, h)**

Set the canvas size in pixels.

**resize_event(self)**

Pass a `ResizeEvent` to all functions connected to `resize_event`.

**scroll_event(self, x, y, step, guiEvent=None)**

Backend derived classes should call this function on any scroll wheel event. x,y are the canvas coords: 0,0 is lower, left. button and key are as defined in `MouseEvent`.

This method will be call all functions connected to the ‘scroll_event’ with a `MouseEvent` instance.
set_window_title(self, title)
    Set the title text of the window containing the figure. Note that this has no effect if there is no window (e.g., a PS backend).

start_event_loop(self, timeout=0)
    Start a blocking event loop.
    Such an event loop is used by interactive functions, such as ginput and waitforbuttonpress, to wait for events.
    The event loop blocks until a callback function triggers stop_event_loop, or timeout is reached.
    If timeout is negative, never timeout.
    Only interactive backends need to reimplement this method and it relies on flush_events being properly implemented.
    Interactive backends should implement this in a more native way.

stop_event_loop(self)
    Stop the current blocking event loop.
    Interactive backends need to reimplement this to match start_event_loop

supports_blit = True

switch_backends(self, FigureCanvasClass)
    Instantiate an instance of FigureCanvasClass
    This is used for backend switching, e.g., to instantiate a FigureCanvasPS from a FigureCanvasGTK. Note, deep copying is not done, so any changes to one of the instances (e.g., setting figure size or line props), will be reflected in the other

class matplotlib.backend_bases.FigureManagerBase(canvas, num)
    Bases: object
    Helper class for pyplot mode, wraps everything up into a neat bundle

    Attributes
        canvas [FigureCanvasBase] The backend-specific canvas instance
        num [int or str] The figure number
        key_press_handler_id [int] The default key handler cid, when using the toolmanager. To disable the default key press handling use:
            figure.canvas.mpl_disconnect(
                figure.canvas.manager.key_press_handler_id)

        button_press_handler_id [int] The default mouse button handler cid, when using the toolmanager. To disable the default button press handling use:
            figure.canvas.mpl_disconnect(
                figure.canvas.manager.button_press_handler_id)

        button_press(self, event)
            The default Matplotlib button actions for extra mouse buttons.

        destroy(self)

        full_screen_toggle(self)
get_window_title(self)
    Get the title text of the window containing the figure.
    Return None for non-GUI (e.g., PS) backends.

key_press(self, event)
    Implement the default mpl key bindings defined at Navigation Keyboard Shortcuts

resize(self, w, h)
    “For GUI backends, resize the window (in pixels).

set_window_title(self, title)
    Set the title text of the window containing the figure.
    This has no effect for non-GUI (e.g., PS) backends.

show(self)
    For GUI backends, show the figure window and redraw. For non-GUI backends, raise an exception to be caught by show(), for an optional warning.

class matplotlib.backend_bases.GraphicsContextBase
    Bases: object
    An abstract base class that provides color, line styles, etc.

    copy_properties(self, gc)
        Copy properties from gc to self

    get_alpha(self)
        Return the alpha value used for blending - not supported on all backends.

    get_antialiased(self)
        Return whether the object should try to do antialiased rendering.

    get_capstyle(self)
        Return the capstyle as a string in ('butt', 'round', 'projecting').

    get_clip_path(self)
        Return the clip path in the form (path, transform), where path is a Path instance, and transform is an affine transform to apply to the path before clipping.

    get_clip_rectangle(self)
        Return the clip rectangle as a Bbox instance.

    get_dashes(self)
        Return the dash information as an offset dashlist tuple.
        The dash list is a even size list that gives the ink on, ink off in pixels.
        See p107 of to PostScript BLUEBOOK for more info.
        Default value is None

    get_forced_alpha(self)
        Return whether the value given by get_alpha() should be used to override any other alpha-channel values.

    get_gid(self)
        Return the object identifier if one is set, None otherwise.

    get_hatch(self)
        Get the current hatch style.

    get_hatch_color(self)
        Get the hatch color.
get_hatch_linewidth(self)
    Get the hatch linewidth.

get_hatch_path(self, density=6.0)
    Return a Path for the current hatch.

get_joinstyle(self)
    Return the line join style as one of ('miter', 'round', 'bevel').

get_linewidth(self)
    Return the line width in points.

get_rgb(self)
    Return a tuple of three or four floats from 0-1.

get_sketch_params(self)
    Return the sketch parameters for the artist.

    Returns

    sketch_params [tuple or None] A 3-tuple with the following elements:
       • scale: The amplitude of the wiggle perpendicular to the source line.
       • length: The length of the wiggle along the line.
       • randomness: The scale factor by which the length is shrunken or expanded.

    May return None if no sketch parameters were set.

get_snap(self)
    Returns the snap setting, which can be:
       • True: snap vertices to the nearest pixel center
       • False: leave vertices as-is
       • None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center

get_url(self)
    Return a url if one is set, None otherwise.

restore(self)
    Restore the graphics context from the stack - needed only for backends that save graphics contexts on a stack.

set_alpha(self, alpha)
    Set the alpha value used for blending - not supported on all backends.

    If alpha=None (the default), the alpha components of the foreground and fill colors will be used to set their respective transparencies (where applicable); otherwise, alpha will override them.

set_antialiased(self, b)
    Set whether object should be drawn with antialiased rendering.

set_capstyle(self, cs)
    Set the capstyle to be one of ('butt', 'round', 'projecting').

set_clip_path(self, path)
    Set the clip path and transformation. Path should be a TransformedPath instance.
**set_clip_rectangle**
Set the clip rectangle with sequence (left, bottom, width, height)

**set_dashes**
Set the dash style for the gc.

**Parameters**

- **dash_offset** [float] is the offset (usually 0).
- **dash_list** [array_like] specifies the on-off sequence as points. (None, None) specifies a solid line

**set_foreground**
Set the foreground color.

**Parameters**

- **fg** [color]
- **isRGBA** [bool] If fg is known to be an (r, g, b, a) tuple, isRGBA can be set to True to improve performance.

**set_gid**
Set the id.

**set_hatch**
Set the hatch style (for fills).

**set_hatch_color**
Set the hatch color.

**set_joinstyle**
Set the join style to be one of ('miter', 'round', 'bevel').

**set_linewidth**
Set the linewidth in points.

**set_sketch_params**
Set the sketch parameters.

**Parameters**

- **scale** [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.
- **length** [float, optional] The length of the wiggle along the line, in pixels (default 128).
- **randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16).

**set_snap**
Set the snap setting which may be:

- True: snap vertices to the nearest pixel center
- False: leave vertices as-is
- None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center

**set_url**
Set the url for links in compatible backends.
class matplotlib.backend_bases.KeyEvent(
    name, canvas, key, x=0, y=0, guiEvent=None)
Bases: matplotlib.backend_bases.LocationEvent

A key event (key press, key release).

Attach additional attributes as defined in FigureCanvasBase.mpl_connect().

In addition to the Event and LocationEvent attributes, the following attributes are defined:

Notes

Modifier keys will be prefixed to the pressed key and will be in the order “ctrl”, “alt”, “super”. The exception to this rule is when the pressed key is itself a modifier key, therefore “ctrl+alt” and “alt+control” can both be valid key values.

Examples

Usage:

```python
def on_key(event):
    print('you pressed', event.key, event.xdata, event.ydata)

cid = fig.canvas.mpl_connect('key_press_event', on_key)
```

Attributes

key [None or str] the key(s) pressed. Could be None, a single case sensitive ascii character ("g", "G", ",", etc.), a special key ("control", "shift", "f1", "up", etc.) or a combination of the above (e.g., "ctrl+alt+g", "ctrl+alt+G").

class matplotlib.backend_bases.LocationEvent(name, canvas, x, y, guiEvent=None)
Bases: matplotlib.backend_bases.Event

An event that has a screen location.

The following additional attributes are defined and shown with their default values.

In addition to the Event attributes, the following event attributes are defined:

Attributes

x [scalar] x position - pixels from left of canvas
y [scalar] y position - pixels from bottom of canvas
inaxes [bool] the Axes instance if mouse is over axes
xdata [scalar] x coord of mouse in data coords
ydata [scalar] y coord of mouse in data coords

x, y in figure coords, 0,0 = bottom, left
lastevent = None

class matplotlib.backend_bases.MouseEvent
Bases: enum.IntEnum

An enumeration.
BACK = 8
FORWARD = 9
LEFT = 1
MIDDLE = 2
RIGHT = 3

class matplotlib.backend_bases.MouseEvent(name, canvas, x, y, button=None, key=None, step=0, dblclick=False, guiEvent=None)
Bases: matplotlib.backend_bases.LocationEvent

A mouse event ('button_press_event', 'button_release_event', 'scroll_event', 'motion_notify_event').

In addition to the Event and LocationEvent attributes, the following attributes are defined:

Examples

Usage:

def on_press(event):
    print('you pressed', event.button, event.xdata, event.ydata)

cid = fig.canvas.mpl_connect('button_press_event', on_press)

Attributes

button [{None, MouseButton.LEFT, MouseButton.MIDDLE, MouseButton.RIGHT, 'up', 'down}] The button pressed. 'up' and 'down' are used for scroll events. Note that in the nbagg backend, both the middle and right clicks return RIGHT since right clicking will bring up the context menu in some browsers. Note that LEFT and RIGHT actually refer to the "primary" and "secondary" buttons, i.e. if the user inverts their left and right buttons ("left-handed setting") then the LEFT button will be the one physically on the right.

doubleclick [bool] Whether the event is a double-click. This applies only to 'button_press_event' and is False otherwise. In particular, it’s not used in ‘button_release_event’.

key [None or str] The key pressed when the mouse event triggered, e.g. ‘shift’. See KeyEvent.

step [scalar] The number of scroll steps (positive for ‘up’, negative for ‘down’). This applies only to ‘scroll_event’ and defaults to 0 otherwise.

x, y in figure coords, 0,0 = bottom, left button pressed None, 1, 2, 3, ‘up’, ‘down’

class matplotlib.backend_bases.NavigationToolbar2(canvas)
Bases: object

Base class for the navigation cursor, version 2

backends must implement a canvas that handles connections for ‘button_press_event’ and ‘button_release_event’. See FigureCanvasBase.mpl_connect() for more information

17.7. matplotlib.backend_bases
They must also define

- `save_figure()` to save the current figure
- `set_cursor()` if you want the pointer icon to change
- `_init_toolbar()` to create your toolbar widget
- `draw_rubberband()` (optional) to draw the zoom to rect “rubberband” rectangle
- `press()` (optional) whenever a mouse button is pressed, you’ll be notified with the event
- `release()` (optional) whenever a mouse button is released, you’ll be notified with the event
- `set_message()` (optional) to display a message
- `set_history_buttons()` (optional) to change the history back / forward buttons to indicate disabled / enabled state.

That’s it, we’ll do the rest!

- `back(self, *args)`
  - move back up the view lim stack
- `drag_pan(self, event)`
  - Callback for dragging in pan/zoom mode.
- `drag_zoom(self, event)`
  - Callback for dragging in zoom mode.
- `draw(self)`
  - Redraw the canvases, update the locators.
- `draw_rubberband(self, event, x0, y0, x1, y1)`
  - Draw a rectangle rubberband to indicate zoom limits.
  - Note that it is not guaranteed that $x_0 \leq x_1$ and $y_0 \leq y_1$.
- `forward(self, *args)`
  - Move forward in the view lim stack.
- `home(self, *args)`
  - Restore the original view.
- `mouse_move(self, event)`
- `pan(self, *args)`
  - Activate the pan/zoom tool. pan with left button, zoom with right
- `press(self, event)`
  - Called whenever a mouse button is pressed.
- `press_pan(self, event)`
  - Callback for mouse button press in pan/zoom mode.
- `press_zoom(self, event)`
  - Callback for mouse button press in zoom to rect mode.
- `push_current(self)`
  - Push the current view limits and position onto the stack.
- `release(self, event)`
  - Callback for mouse button release.
release_pan(self, event)
    Callback for mouse button release in pan/zoom mode.

release_zoom(self, event)
    Callback for mouse button release in zoom to rect mode.

remove_rubberband(self)
    Remove the rubberband.

save_figure(self, *args)
    Save the current figure.

set_cursor(self, cursor)
    Set the current cursor to one of the Cursors enums values.

    If required by the backend, this method should trigger an update in the backend
    event loop after the cursor is set, as this method may be called e.g. before a long-
    running task during which the GUI is not updated.

set_history_buttons(self)
    Enable or disable the back/forward button.

set_message(self, s)
    Display a message on toolbar or in status bar.

    Examples

    Usage:

    ax.plot(np.rand(100), 'o', picker=5)  # 5 points tolerance

    def on_pick(event):
        line = event.artist
        xdata, ydata = line.get_data()
        ind = event.ind
        print('on pick line:', np.array([xdata[ind], ydata[ind]]).T)

    cid = fig.canvas.mpl_connect('pick_event', on_pick)

Attributes
**mouseevent** [MouseEvent] the mouse event that generated the pick

**artist** [matplotlib.artist.Artist] the picked artist

**other** extra class dependent attrs - e.g., a Line2D pick may define different extra attributes than a PatchCollection pick event

class matplotlib.backend_bases.RendererBase

    Bases: object

    An abstract base class to handle drawing/rendering operations.

    The following methods must be implemented in the backend for full functionality (though just implementing `draw_path()` alone would give a highly capable backend):

    • `draw_path()`
    • `draw_image()`
    • `draw_gouraud_triangle()`

    The following methods *should* be implemented in the backend for optimization reasons:

    • `draw_text()`
    • `draw_markers()`
    • `draw_path_collection()`
    • `draw_quad_mesh()`

    `close_group(self, s)`

    Close a grouping element with label s

    Only used by the SVG renderer.

    `draw_gouraud_triangle(self, gc, points, colors, transform)`

    Draw a Gouraud-shaded triangle.

    **Parameters**

    - `points` [array_like, shape=(3, 2)] Array of (x, y) points for the triangle.
    - `colors` [array_like, shape=(3, 4)] RGBA colors for each point of the triangle.
    - `transform` [matplotlib.transforms.Transform] An affine transform to apply to the points.

    `draw_gouraud_triangles(self, gc, triangles_array, colors_array, transform)`

    Draws a series of Gouraud triangles.

    **Parameters**

    - `points` [array_like, shape=(N, 3, 2)] Array of N (x, y) points for the triangles.
    - `colors` [array_like, shape=(N, 3, 4)] Array of N RGBA colors for each point of the triangles.
    - `transform` [matplotlib.transforms.Transform] An affine transform to apply to the points.

    `draw_image(self, gc, x, y, im, transform=None)`

    Draw an RGBA image.

    **Parameters**
**gc** [GraphicsContextBase] a graphics context with clipping information.

**x** [scalar] the distance in physical units (i.e., dots or pixels) from the left hand side of the canvas.

**y** [scalar] the distance in physical units (i.e., dots or pixels) from the bottom side of the canvas.

**im** [array_like, shape=(N, M, 4), dtype=np.uint8] An array of RGBA pixels.

**transform** [matplotlib.transforms.Affine2DBase] If and only if the concrete backend is written such that `option_scale_image()` returns True, an affine transformation may be passed to `draw_image()`. It takes the form of a `Affine2DBase` instance. The translation vector of the transformation is given in physical units (i.e., dots or pixels). Note that the transformation does not override x and y, and has to be applied before translating the result by x and y (this can be accomplished by adding x and y to the translation vector defined by `transform`).

**draw_markers** *(self, gc, marker_path, marker_trans, path, trans, rgbFace=None)*

Draws a marker at each of the vertices in path. This includes all vertices, including control points on curves. To avoid that behavior, those vertices should be removed before calling this function.

This provides a fallback implementation of `draw_markers` that makes multiple calls to `draw_path()`. Some backends may want to override this method in order to draw the marker only once and reuse it multiple times.

**Parameters**

- **gc** [GraphicsContextBase] The graphics context
- **marker_trans** [matplotlib.transforms.Transform] An affine transform applied to the marker.
- **trans** [matplotlib.transforms.Transform] An affine transform applied to the path.

**draw_path** *(self, gc, path, transform, rgbFace=None)*

Draws a `Path` instance using the given affine transform.

**draw_path_collection** *(self, gc, master_transform, paths, all_transforms, offsets, offsetTrans, facecolors, edgecolors, linewidths, linestyles, antialiaseds, urls, offset_position)*

Draws a collection of paths selecting drawing properties from the lists `facecolors`, `edgecolors`, `linewidths`, `linestyles`, `antialiaseds`, `urls`, `offset_position`. `offsets` is a list of offsets to apply to each of the paths. The offsets in `offsets` are first transformed by `offsetTrans` before being applied. `offset_position` may be either "screen" or "data" depending on the space that the offsets are in.

This provides a fallback implementation of `draw_path_collection()` that makes multiple calls to `draw_path()`. Some backends may want to override this in order to render each set of path data only once, and then reference that path multiple times with the different offsets, colors, styles etc. The generator methods `_iter_collection_raw_paths()` and `_iter_collection()` are provided to help with (and standardize) the implementation across backends. It is highly recommended to use those generators, so that changes to the behavior of `draw_path_collection()` can be made globally.
draw_quad_mesh(self, gc, master_transform, meshWidth, meshHeight, coordinates,
    offsets, offsetTrans, facecolors, antialiased, edgecolors)
This provides a fallback implementation of draw_quad_mesh() that generates paths
and then calls draw_path_collection().
draw_tex(self, gc, x, y, s, prop, angle, ismath='TeX!', mtext=None)
draw_text(self, gc, x, y, s, prop, angle, ismath=False, mtext=None)
Draw the text instance.

Parameters

x [scalar] The x location of the text in display coords.
y [scalar] The y location of the text baseline in display coords.
s [str] The text string.
angle [scalar] The rotation angle in degrees.
mtext [matplotlib.text.Text] The original text object to be rendered.

Notes

backend implementers note
When you are trying to determine if you have gotten your bounding box right (which
is what enables the text layout/alignment to work properly), it helps to change the
line in text.py:

```python
if 0: bbox_artist(self, renderer)
```
to if 1, and then the actual bounding box will be plotted along with your text.

flipy(self)
Return whether y values increase from top to bottom.

Note that this only affects drawing of texts and images.

get_canvas_width_height(self)
Return the canvas width and height in display coords.

get_image_magnification(self)
Get the factor by which to magnify images passed to draw_image(). Allows a backend
to have images at a different resolution to other artists.

get_texmanager(self)
Return the TexManager instance.

get_text_width_height_descent(self, s, prop, ismath)
Get the width, height, and descent (offset from the bottom to the baseline), in display
coords, of the string s with FontProperties prop

new_gc(self)
Return an instance of a GraphicsContextBase.

open_group(self, s, gid=None)
Open a grouping element with label s and gid (if set) as id.
Only used by the SVG renderer.

```python
option_image_nocomposite(self)
    Return whether image composition by Matplotlib should be skipped.
    Raster backends should usually return False (letting the C-level rasterizer take care
    of image composition); vector backends should usually return not rcParams["image.
    composite_image"].
```

```python
option_scale_image(self)
    Return whether arbitrary affine transformations in draw_image() are supported (True
    for most vector backends).
```

```python
points_to_pixels(self, points)
    Convert points to display units.
    You need to override this function (unless your backend doesn’t have a dpi, e.g.,
    postscript or svg). Some imaging systems assume some value for pixels per inch:
    ```
    points to pixels = points * pixels_per_inch/72.0 * dpi/72.0
    ```
```

**Parameters**

- **points** [scalar or array_like] a float or a numpy array of float

**Returns**

Points converted to pixels

```python
start_filter(self)
    Switch to a temporary renderer for image filtering effects.
    Currently only supported by the agg renderer.
```

```python
start_rasterizing(self)
    Switch to the raster renderer.
    Used by MixedModeRenderer.
```

```python
stop_filter(self, filter_func)
    Switch back to the original renderer. The contents of the temporary renderer is
    processed with the filter_func and is drawn on the original renderer as an image.
    Currently only supported by the agg renderer.
```

```python
stop_rasterizing(self)
    Switch back to the vector renderer and draw the contents of the raster renderer as
    an image on the vector renderer.
    Used by MixedModeRenderer.
```

```python
strip_math(self, s)
    [Deprecated]
```

**Notes**

Deprecated since version 3.1:

```python
class matplotlib.backend_bases.ResizeEvent(name, canvas)
    Bases: matplotlib.backend_bases.Event
    An event triggered by a canvas resize
```
In addition to the Event attributes, the following event attributes are defined:

**Attributes**

- `width` [scalar] width of the canvas in pixels
- `height` [scalar] height of the canvas in pixels

```python
class matplotlib.backend_bases.ShowBase
    Bases: matplotlib.backend_bases._Backend
    Simple base class to generate a show() callable in backends.
    Subclass must override mainloop() method.
```

```python
class matplotlib.backend_bases.StatusbarBase(toolmanager)
    Bases: object
    Base class for the statusbar
    set_message(self, s)
        Display a message on toolbar or in status bar

    **Parameters**
    s [str] Message text
```

```python
class matplotlib.backend_bases.TimerBase(interval=None, callbacks=None)
    Bases: object
    A base class for providing timer events, useful for things animations. Backends need to implement a few specific methods in order to use their own timing mechanisms so that the timer events are integrated into their event loops.

    Mandatory functions that must be implemented:
    - `_timer_start`: Contains backend-specific code for starting the timer
    - `_timer_stop`: Contains backend-specific code for stopping the timer

    Optional overrides:
    - `_timer_set_single_shot`: Code for setting the timer to single shot operating mode, if supported by the timer object. If not, the Timer class itself will store the flag and the _on_timer method should be overridden to support such behavior.
    - `_timer_set_interval`: Code for setting the interval on the timer, if there is a method for doing so on the timer object.
    - `_on_timer`: This is the internal function that any timer object should call, which will handle the task of running all callbacks that have been set.

    **Attributes**
    - `interval` [scalar] The time between timer events in milliseconds. Default is 1000 ms.
    - `single_shot` [bool] Boolean flag indicating whether this timer should operate as single shot (run once and then stop). Defaults to `False`.
    - `callbacks` [List[Tuple[callable, Tuple, Dict]]] Stores list of (func, args, kwargs) tuples that will be called upon timer events. This list can be manipulated directly, or the functions `add_callback` and `remove_callback` can be used.
add_callback(self, func, *args, **kwargs)
    Register func to be called by timer when the event fires. Any additional arguments provided will be passed to func.

    This function returns func, which makes it possible to use it as a decorator.

interval
remove_callback(self, func, *args, **kwargs)
    Remove func from list of callbacks.

    args and kwargs are optional and used to distinguish between copies of the same function registered to be called with different arguments. This behavior is deprecated. In the future, *args, **kwargs won't be considered anymore; to keep a specific callback removable by itself, pass it to add_callback as a functools.partial object.

timeout
start(self, interval=None)
    Start the timer object.

    Parameters
    interval [int, optional] Timer interval in milliseconds; overrides a previously set interval if provided.

stop(self)
    Stop the timer.

class matplotlib.backend_bases.ToolContainerBase(toolmanager)
    Bases: object

    Base class for all tool containers, e.g. toolbars.

    Attributes
    toolmanager [ToolManager] The tools with which this ToolContainer wants to communicate.

add_tool(self, tool, group, position=-1)
    Adds a tool to this container

    Parameters
    tool [tool_like] The tool to add, see ToolManager.get_tool.
    group [str] The name of the group to add this tool to.
    position [int (optional)] The position within the group to place this tool. Defaults to end.

add_toolitem(self, name, group, position, image, description, toggle)
    Add a toolitem to the container

    This method must get implemented per backend

    The callback associated with the button click event, must be EXACTLY self.trigger_tool(name)

    Parameters
    name [string] Name of the tool to add, this gets used as the tool's ID and as the default label of the buttons
    group [String] Name of the group that this tool belongs to
**position** [Int] Position of the tool within its group, if -1 it goes at the End

**image_file** [String] Filename of the image for the button or None

**description** [String] Description of the tool, used for the tooltips

**toggle** [Bool]
- True: The button is a toggle (change the pressed/unpressed state between consecutive clicks)
- False: The button is a normal button (returns to unpressed state after release)

`remove_toolitem(self, name)`
Remove a toolitem from the ToolContainer
This method must get implemented per backend
Called when ToolManager emits a tool_removed_event

**Parameters**

- **name** [string] Name of the tool to remove

`toggle_toolitem(self, name, toggled)`
Toggle the toolitem without firing event

**Parameters**

- **name** [String] Id of the tool to toggle
- **toggled** [bool] Whether to set this tool as toggled or not.

`trigger_tool(self, name)`
Trigger the tool

**Parameters**

- **name** [string] Name (id) of the tool triggered from within the container

`matplotlib.backend_bases.button_press_handler(event, canvas, toolbar=None)`
The default Matplotlib button actions for extra mouse buttons.

`matplotlib.backend_bases.get_registered_canvas_class(format)`
Return the registered default canvas for given file format. Handles deferred import of required backend.

`matplotlib.backend_bases.key_press_handler(event, canvas, toolbar=None)`
Implement the default mpl key bindings for the canvas and toolbar described at Navigation Keyboard Shortcuts

**Parameters**

- **event** [KeyEvent] a key press/release event
- **canvas** [FigureCanvasBase] the backend-specific canvas instance
- **toolbar** [NavigationToolbar2] the navigation cursor toolbar

`matplotlib.backend_bases.register_backend(format, backend, description=None)`
Register a backend for saving to a given file format.

**Parameters**

- **format** [str] File extension
- **backend** [module string or canvas class] Backend for handling file output
description [str, optional] Description of the file type. Defaults to an empty string

17.8 matplotlib.backend_managers

class matplotlib.backend_managers.ToolEvent(name, sender, tool, data=None)
    Bases: object
    Event for tool manipulation (add/remove).

class matplotlib.backend_managers.ToolManager(figure=None)
    Bases: object
    Manager for actions triggered by user interactions (key press, toolbar clicks, ...) on a Figure.

    Attributes
    
    figure [Figure] Figure that holds the canvas.

    keypresslock [widgets.LockDraw] LockDraw object to know if the canvas key_press_event is locked

    messagelock [widgets.LockDraw] LockDraw object to know if the message is available to write

    active_toggle
    Currently toggled tools.

    add_tool(self, name, tool, *args, **kwargs)
    Add tool to ToolManager.

    If successful, adds a new event tool_trigger_{name} where {name} is the name of the tool; the event is fired everytime the tool is triggered.

    Parameters
    
    name [str] Name of the tool, treated as the ID, has to be unique.

    tool [class_like, i.e. str or type] Reference to find the class of the Tool to added.

    See also:

    matplotlib.backend_tools.ToolBase The base class for tools.

    Notes

    args and kwargs get passed directly to the tools constructor.

    canvas
    Canvas managed by FigureManager.

    figure
    Figure that holds the canvas.

    get_tool(self, name, warn=True)
    Return the tool object, also accepts the actual tool for convenience.

    Parameters
name [str, ToolBase] Name of the tool, or the tool itself

warn [bool, optional] If this method should give warnings.

get_tool_keymap(self, name)
Get the keymap associated with the specified tool.

Parameters

name [string] Name of the Tool

Returns

list [list of keys associated with the Tool]

message_event(self, message, sender=None)
Emit a ToolManagerMessageEvent.

remove_tool(self, name)
Remove tool named name.

Parameters

name [string] Name of the Tool

set_figure(self, figure, update_tools=True)
Bind the given figure to the tools.

Parameters

figure [Figure]
update_tools [bool] Force tools to update figure

toolmanager_connect(self, s, func)
Connect event with string s to func.

Parameters

s [String] Name of the event
The following events are recognized
• ‘tool_message_event’
• ‘tool_removed_event’
• ‘tool_added_event’
For every tool added a new event is created
• ‘tool_trigger.ToolNAME’ Where TOOLNAME is the id of the tool.

func [function] Function to be called with signature def func(event)

toolmanager_disconnect(self, cid)
Disconnect callback id cid.

Example usage:

cid = toolmanager.toolmanager_connect('tool_trigger_zoom', onpress)
#. . . later
toolmanager.toolmanager_disconnect(cid)

tools
A dict mapping tool name -> controlled tool.
trigger_tool(self, name, sender=None, canvasevent=None, data=None)
    Trigger a tool and emit the tool_trigger_{name} event.

    Parameters
    name [string] Name of the tool
    sender [object] Object that wishes to trigger the tool
    canvasevent [Event] Original Canvas event or None
    data [Object] Extra data to pass to the tool when triggering

update_keymap(self, name, *keys)
    Set the keymap to associate with the specified tool.

    Parameters
    name [string] Name of the Tool
    keys [keys to associate with the Tool]

class matplotlib.backend_managers.ToolManagerMessageEvent(name, sender, message)
Bases: object
    Event carrying messages from toolmanager.
    Messages usually get displayed to the user by the toolbar.

class matplotlib.backend_managers.ToolTriggerEvent(name, sender, tool, canvasevent=None, data=None)
    Bases: matplotlib.backend_managers.ToolEvent
    Event to inform that a tool has been triggered.

17.9 matplotlib.backend_tools

Abstract base classes define the primitives for Tools. These tools are used by matplotlib.backend_managers.ToolManager

ToolBase Simple stateless tool

ToolToggleBase Tool that has two states, only one Toggle tool can be active at any given time
    for the same matplotlib.backend_managers.ToolManager

class matplotlib.backend_tools.AxisScaleBase(*args, **kwargs)
Bases: matplotlib.backend_tools.ToolToggleBase
    Base Tool to toggle between linear and logarithmic

disable(self, event)
    Disable the toggle tool
    trigger call this method when toggled is True.
    This can happen in different circumstances
    • Click on the toolbar tool button
    • Call to matplotlib.backend_managers.ToolManager.trigger_tool
    • Another ToolToggleBase derived tool is triggered (from the same ToolManager)
enable(self, event)
    Enable the toggle tool

toggle calls this method when toggled is False

toggle(self, sender, event, data=None)
    Calls enable or disable based on toggled value

class matplotlib.backend_tools.ConfigureSubplotsBase(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase
    Base tool for the configuration of subplots
description = 'Configure subplots'
image = 'subplots'

class matplotlib.backend_tools.Cursors
    Bases: object
    Simple namespace for cursor reference
HAND = 0
MOVE = 3
POINTER = 1
SELECT_REGION = 2
WAIT = 4

class matplotlib.backend_tools.RubberbandBase(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase
    Draw and remove rubberband
draw_rubberband(self, *data)
    Draw rubberband
    This method must get implemented per backend
remove_rubberband(self)
    Remove rubberband
    This method should get implemented per backend
trigger(self, sender, event, data)
    Call draw_rubberband or remove_rubberband based on data

class matplotlib.backend_tools.SaveFigureBase(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase
    Base tool for figure saving
default_keymap = ['s', 'ctrl+s']
description = 'Save the figure'
image = 'filesave'

class matplotlib.backend_tools.SetCursorBase(*args, **kwargs)
    Bases: matplotlib.backend_tools.ToolBase
    Change to the current cursor while inaxes
    This tool, keeps track of all ToolToggleBase derived tools, and calls set_cursor when a tool gets triggered
set_cursor(self, cursor)
    Set the cursor

    This method has to be implemented per backend

set_figure(self, figure)
    Assign a figure to the tool

    Parameters
    
    figure [Figure]

class matplotlib.backend_tools.ToolBack(toolmanager, name)
    Bases: matplotlib.backend_tools.ViewsPositionsBase

    Move back up the view lim stack

    default_keymap = ['left', 'c', 'backspace', 'MouseButton.BACK']

    description = 'Back to previous view'

    image = 'back'

class matplotlib.backend_tools.ToolBase(toolmanager, name)
    Bases: object

    Base tool class

    A base tool, only implements trigger method or not method at all. The tool is instantiated by matplotlib.backend_managers.ToolManager

    Attributes

    toolmanager [matplotlib.backend_managers.ToolManager] ToolManager that controls this Tool

    figure [FigureCanvas] Figure instance that is affected by this Tool

    name [string] Tool Id

    canvas

    default_keymap = None
    Keymap to associate with this tool

    String: List of comma separated keys that will be used to call this tool when the keypress event of self.figure.canvas is emitted

    description = None
    Description of the Tool

    String: If the Tool is included in the Toolbar this text is used as a Tooltip

    destroy(self)
    Destroy the tool

    This method is called when the tool is removed by matplotlib.backend_managers.ToolManager.remove_tool

    figure

    image = None
    Filename of the image

    String: Filename of the image to use in the toolbar. If None, the name is used as a label in the toolbar button

17.9. matplotlib.backend_tools
name
Tool Id

```python
set_figure(self, figure)
    Assign a figure to the tool

    Parameters
    figure [Figure]
```

toolmanager

```python
trigger(self, sender, event, data=None)
    Called when this tool gets used

    This method is called by matplotlib.backend_managers.ToolManager.trigger_tool

    Parameters
    event [Event] The Canvas event that caused this tool to be called
    sender [object] Object that requested the tool to be triggered
    data [object] Extra data
```

```python
matplotlib.backend_tools.ToolCopyToClipboard
    alias of matplotlib.backend_tools.ToolCopyToClipboardBase

class matplotlib.backend_tools.ToolCopyToClipboardBase(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase
    Tool to copy the figure to the clipboard
    default_keymap = ['ctrl+c', 'cmd+c']
    description = 'Copy the canvas figure to clipboard'

    trigger(self, *args, **kwargs)
    Called when this tool gets used

    This method is called by matplotlib.backend_managers.ToolManager.trigger_tool

    Parameters
    event [Event] The Canvas event that caused this tool to be called
    sender [object] Object that requested the tool to be triggered
    data [object] Extra data
```

class matplotlib.backend_tools.ToolCursorPosition(*args, **kwargs)
    Bases: matplotlib.backend_tools.ToolBase
    Send message with the current pointer position
    This tool runs in the background reporting the position of the cursor

    send_message(self, event)
        Call matplotlib.backend_managers.ToolManager.message_event

    set_figure(self, figure)
        Assign a figure to the tool

    Parameters
    figure [Figure]
```
class matplotlib.backend_tools.ToolEnableAllNavigation(toolmanager, name)
Bases: matplotlib.backend_tools.ToolBase
Tool to enable all axes for toolmanager interaction

default_keymap = ['a']
description = 'Enable all axes toolmanager'

trigger(self, sender, event, data=None)
Called when this tool gets used

This method is called by matplotlib.backend_managers.ToolManager.trigger_tool

Parameters

- event [Event] The Canvas event that caused this tool to be called
- sender [object] Object that requested the tool to be triggered
- data [object] Extra data

class matplotlib.backend_tools.ToolEnableNavigation(toolmanager, name)
Bases: matplotlib.backend_tools.ToolBase
Tool to enable a specific axes for toolmanager interaction

default_keymap = (1, 2, 3, 4, 5, 6, 7, 8, 9)
description = 'Enable one axes toolmanager'

trigger(self, sender, event, data=None)
Called when this tool gets used

This method is called by matplotlib.backend_managers.ToolManager.trigger_tool

Parameters

- event [Event] The Canvas event that caused this tool to be called
- sender [object] Object that requested the tool to be triggered
- data [object] Extra data

class matplotlib.backend_tools.ToolForward(toolmanager, name)
Bases: matplotlib.backend_tools.ViewsPositionsBase
Move forward in the view lim stack

default_keymap = ['right', 'v', 'MouseButton.FORWARD']
description = 'Forward to next view'

image = 'forward'

class matplotlib.backend_tools.ToolFullScreen(*args, **kwargs)
Bases: matplotlib.backend_tools.ToolToggleBase
Tool to toggle full screen

default_keymap = ['f', 'ctrl+f']
description = 'Toggle fullscreen mode'

disable(self, event)
Disable the toggle tool

trigger call this method when toggled is True.
This can happen in different circumstances

- Click on the toolbar tool button
- Call to `matplotlib.backend_managers.ToolManager.trigger_tool`
- Another `ToolToggleBase` derived tool is triggered (from the same `ToolManager`)

```python
enable(self, event)
    Enable the toggle tool
    trigger calls this method when toggled is False
```

```python
class matplotlib.backend_tools.ToolGrid(toolmanager, name)
    Bases: matplotlib.backend_tools._ToolGridBase

    Tool to toggle the major grids of the figure
    default_keymap = ['g']
    description = 'Toggle major grids'
```

```python
class matplotlib.backend_tools.ToolHelpBase(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase

    default_keymap = ['f1']
    description = 'Print tool list, shortcuts and description'
    static formatShortcut(key_sequence)
        Converts a shortcut string from the notation used in rc config to the standard notation for displaying shortcuts, e.g. 'ctrl+a' -> 'Ctrl+A'.
    image = 'help.png'
```

```python
class matplotlib.backend_tools.ToolHome(toolmanager, name)
    Bases: matplotlib.backend_tools.ViewsPositionsBase

    Restore the original view lim
    default_keymap = ['h', 'r', 'home']
    description = 'Reset original view'
    image = 'home'
```

```python
class matplotlib.backend_tools.ToolMinorGrid(toolmanager, name)
    Bases: matplotlib.backend_tools._ToolGridBase

    Tool to toggle the major and minor grids of the figure
    default_keymap = ['G']
    description = 'Toggle major and minor grids'
```

```python
class matplotlib.backend_tools.ToolPan(*args)
    Bases: matplotlib.backend_tools.ZoomPanBase

    Pan axes with left mouse, zoom with right
    cursor = 3
    default_keymap = ['p']
    description = 'Pan axes with left mouse, zoom with right'
    image = 'move'
    radio_group = 'default'
```
class matplotlib.backend_tools.ToolQuit(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase
    Tool to call the figure manager destroy method
    default_keymap = ['ctrl+w', 'cmd+w', 'q']
    description = 'Quit the figure'
    trigger(self, sender, event, data=None)
        Called when this tool gets used
        This method is called by matplotlib.backend_managers.ToolManager.trigger_tool
        Parameters
        event [Event] The Canvas event that caused this tool to be called
        sender [object] Object that requested the tool to be triggered
        data [object] Extra data

class matplotlib.backend_tools.ToolQuitAll(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase
    Tool to call the figure manager destroy method
    default_keymap = ['W', 'cmd+W', 'Q']
    description = 'Quit all figures'
    trigger(self, sender, event, data=None)
        Called when this tool gets used
        This method is called by matplotlib.backend_managers.ToolManager.trigger_tool
        Parameters
        event [Event] The Canvas event that caused this tool to be called
        sender [object] Object that requested the tool to be triggered
        data [object] Extra data

class matplotlib.backend_tools.ToolToggleBase(*args, **kwargs)
    Bases: matplotlib.backend_tools.ToolBase
    Toggleable tool
    Every time it is triggered, it switches between enable and disable

    Parameters
    """*args" Variable length argument to be used by the Tool
    """**kwargs" toggled if present and True, sets the initial state of the Tool
    Arbitrary keyword arguments to be consumed by the Tool

cursor = None
    Cursor to use when the tool is active

default_toggled = False
    Default of toggled state

defable(self, event=None)
    Disable the toggle tool
    trigger call this method when toggled is True.
This can happen in different circumstances

- Click on the toolbar tool button
- Call to `matplotlib.backend_managers.ToolManager.trigger_tool`
- Another `ToolToggleBase` derived tool is triggered (from the same `ToolManager`)

```python
def enable(self, event=None):
    # Enable the toggle tool
    trigger calls this method when toggled is False

radio_group = None
    # Attribute to group 'radio' like tools (mutually exclusive)

class matplotlib.backend_tools.ToolViewsPositions(*args, **kwargs):
    # Bases: matplotlib.backend_tools.ToolBase
    # Auxiliary Tool to handle changes in views and positions
    # Runs in the background and should get used by all the tools that need to access the
    # figure's history of views and positions, e.g.

        - ToolZoom
        - ToolPan
        - ToolHome
        - ToolBack
        - ToolForward

    def add_figure(self, figure):
        # Add the current figure to the stack of views and positions

    def back(self):
        # Back one step in the stack of views and positions

    def clear(self, figure):
        # Reset the axes stack

    def forward(self):
        # Forward one step in the stack of views and positions

    def home(self):
        # Recall the first view and position from the stack

    def push_current(self, figure=None):
        # Push the current view limits and position onto their respective stacks
```
refresh_locators(self)
    Redraw the canvases, update the locators

update_home_views(self, figure=None)
    Make sure that self.home_views has an entry for all axes present in the figure

update_view(self)
    Update the view limits and position for each axes from the current stack position. If
    any axes are present in the figure that aren’t in the current stack position, use the
    home view limits for those axes and don’t update any positions.

class matplotlib.backend_tools.ToolXScale(*args, **kwargs)
    Bases: matplotlib.backend_tools.AxisScaleBase
    Tool to toggle between linear and logarithmic scales on the X axis
    default_keymap = ['k', 'L']
    description = 'Toggle scale X axis'
    set_scale(self, ax, scale)

class matplotlib.backend_tools.ToolYScale(*args, **kwargs)
    Bases: matplotlib.backend_tools.AxisScaleBase
    Tool to toggle between linear and logarithmic scales on the Y axis
    default_keymap = ['l']
    description = 'Toggle scale Y axis'
    set_scale(self, ax, scale)

class matplotlib.backend_tools.ToolZoom(*args)
    Bases: matplotlib.backend_tools.ZoomPanBase
    Zoom to rectangle
    cursor = 2
    default_keymap = ['o']
    description = 'Zoom to rectangle'
    image = 'zoom_to_rect'
    radio_group = 'default'

class matplotlib.backend_tools.ViewsPositionsBase(toolmanager, name)
    Bases: matplotlib.backend_tools.ToolBase
    Base class for ToolHome, ToolBack and ToolForward
    trigger(self, sender, event, data=None)
        Called when this tool gets used
        This method is called by matplotlib.backend_managers.ToolManager.trigger_tool

        Parameters
        event [Event] The Canvas event that caused this tool to be called
        sender [object] Object that requested the tool to be triggered
        data [object] Extra data
class matplotlib.backend_tools.ZoomPanBase(*args)
Bases: matplotlib.backend_tools.ToolToggleBase

Base class for ToolZoom and ToolPan

disable(self, event)
   Release the canvas and disconnect press/release events

enable(self, event)
   Connect press/release events and lock the canvas

scroll_zoom(self, event)

trigger(self, sender, event, data=None)
   Calls enable or disable based on toggled value

matplotlib.backend_tools.add_tools_to_container(container, tools=[['navigation', 'home', 'back', 'forward'], ['zoom-pan', 'pan', 'zoom', 'subplots'], ['io', 'save', 'help'])

Add multiple tools to the container.

Parameters

    container [Container] backend_bases.ToolContainerBase object that will get the tools added

    tools [list, optional] List in the form [[group1, [tool1, tool2 ...]], [group2, [...]]] Where the tools given by tool1, and tool2 will display in group1. See add_tool for details.

Add multiple tools to ToolManager

**Parameters**

- **toolmanager** [ToolManager] backend_managers.ToolManager object that will get the tools added
- **tools** [{str: class_like}, optional] The tools to add in a {name: tool} dict, see add_tool for more info.

matplotlib.backend_tools.default_toolbar_tools = [['navigation', ['home', 'back', 'forward']], ['zoompan', ['pan', 'zoom', 'subplots']], ['io', ['save', 'help']]

Default tools in the toolbar

Default tools
17.10 matplotlib.backends

17.10.1 matplotlib.backends.backend_mixed

class matplotlib.backends.backend_mixed.MixedModeRenderer(figure, width, height, 
dpi, vector_renderer, 
raster_renderer_class=None, 
bbox_inches_restore=None)

Bases: object

A helper class to implement a renderer that switches between vector and raster drawing. An example may be a PDF writer, where most things are drawn with PDF vector commands, but some very complex objects, such as quad meshes, are rasterised and then output as images.

Parameters

figure [matplotlib.figure.Figure] The figure instance.
width [scalar] The width of the canvas in logical units
height [scalar] The height of the canvas in logical units
dpi [scalar] The dpi of the canvas
vector_renderer [matplotlib.backend_bases.RendererBase] An instance of a subclass of RendererBase that will be used for the vector drawing.
raster_renderer_class [matplotlib.backend_bases.RendererBase] The renderer class to use for the raster drawing. If not provided, this will use the Agg backend (which is currently the only viable option anyway.)

start_rasterizing(self)
Enter “raster” mode. All subsequent drawing commands (until stop_rasterizing is called) will be drawn with the raster backend.

If start_rasterizing is called multiple times before stop_rasterizing is called, this method has no effect.

stop_rasterizing(self)
Exit “raster” mode. All of the drawing that was done since the last start_rasterizing command will be copied to the vector backend by calling draw_image.

If stop_rasterizing is called multiple times before start_rasterizing is called, this method has no effect.

17.10.2 matplotlib.backends.backend_agg

An agg http://antigrain.com/ backend

Features that are implemented

• capstyles and join styles
• dashes
• linewidth
• lines, rectangles, ellipses
• clipping to a rectangle
• output to RGBA and PNG, optionally JPEG and TIFF
• alpha blending
• DPI scaling properly - everything scales properly (dashes, linewidths, etc)
• draw polygon
• freetype2 w/ ft2font

TODO:
• integrate screen dpi w/ ppi and text

matplotlib.backends.backend_agg.FigureCanvas
alias of matplotlib.backends.backend_agg.FigureCanvasAgg
class matplotlib.backends.backend_agg.FigureCanvasAgg(figure)
Bases: matplotlib.backend_bases.FigureCanvasBase

The canvas the figure renders into. Calls the draw and print fig methods, creates the renderers, etc...

Attributes

figure [matplotlib.figure.Figure] A high-level Figure instance

buffer_rgba(self)
Get the image as a memoryview to the renderer’s buffer.

draw must be called at least once before this function will work and to update the renderer for any subsequent changes to the Figure.

Returns

memoryview

copy_from_bbox(self, bbox)
draw(self)
Draw the figure using the renderer.

get_renderer(self, cleared=False)

print_jpeg(self, filename_or_obj, *args, dryrun=False, pil_kwargs=None, **kwargs)
Write the figure to a JPEG file.

Parameters

filename_or_obj [str or PathLike or file-like object] The file to write to.

Other Parameters

quality [int] The image quality, on a scale from 1 (worst) to 100 (best). The default is rcParams["savefig.jpeg_quality"]. Values above 95 should be avoided; 100 completely disables the JPEG quantization stage.

optimize [bool] If present, indicates that the encoder should make an extra pass over the image in order to select optimal encoder settings.

progressive [bool] If present, indicates that this image should be stored as a progressive JPEG file.

pil_kwargs [dict, optional] Additional keyword arguments that are passed to PIL.Image.save when saving the figure. These take precedence over quality, optimize and progressive.
print_jpg(self, filename_or_obj, *args, dryrun=False, pil_kwargs=None, **kwargs)
Write the figure to a JPEG file.

Parameters

filename_or_obj [str or PathLike or file-like object] The file to write to.

Other Parameters

quality [int] The image quality, on a scale from 1 (worst) to 100 (best). The default is rcParams["savefig.jpeg_quality"]. Values above 95 should be avoided; 100 completely disables the JPEG quantization stage.

optimize [bool] If present, indicates that the encoder should make an extra pass over the image in order to select optimal encoder settings.

progressive [bool] If present, indicates that this image should be stored as a progressive JPEG file.

pil_kwargs [dict, optional] Additional keyword arguments that are passed to PIL.Image.save when saving the figure. These take precedence over quality, optimize and progressive.

print_png(self, filename_or_obj, *args, metadata=None, pil_kwargs=None, **kwargs)
Write the figure to a PNG file.

Parameters

filename_or_obj [str or PathLike or file-like object] The file to write to.

metadata [dict, optional] Metadata in the PNG file as key-value pairs of bytes or latin-1 encodable strings. According to the PNG specification, keys must be shorter than 79 chars.

The PNG specification defines some common keywords that may be used as appropriate:

• Title: Short (one line) title or caption for image.
• Author: Name of image’s creator.
• Description: Description of image (possibly long).
• Copyright: Copyright notice.
• Creation Time: Time of original image creation (usually RFC 1123 format).
• Software: Software used to create the image.
• Disclaimer: Legal disclaimer.
• Warning: Warning of nature of content.
• Source: Device used to create the image.
• Comment: Miscellaneous comment; conversion from other image format.

Other keywords may be invented for other purposes.
If ‘Software’ is not given, an autogenerated value for matplotlib will be used.
For more details see the PNG specification.

**pil_kwargs** [dict, optional] If set to a non-None value, use Pillow to save the figure instead of Matplotlib's builtin PNG support, and pass these keyword arguments to PIL.Image.save.

If the ‘pnginfo’ key is present, it completely overrides *metadata*, including the default ‘Software’ key.

```python
print_raw(self, filename_or_obj, *args, **kwargs)
print_rgba(self, filename_or_obj, *args, **kwargs)
print_tif(self, filename_or_obj, *args, dryrun=False, pil_kwargs=None, **kwargs)
print_tiff(self, filename_or_obj, *args, dryrun=False, pil_kwargs=None, **kwargs)
print_to_buffer(self)
restore_region(self, region, bbox=None, xy=None)
tostring_argb(self)
    Get the image as an ARGB byte string.
    *draw* must be called at least once before this function will work and to update the renderer for any subsequent changes to the Figure.

    **Returns**
    bytes

tostring_rgb(self)
    Get the image as an RGB byte string.
    *draw* must be called at least once before this function will work and to update the renderer for any subsequent changes to the Figure.

    **Returns**
    bytes
```

```python
class matplotlib.backends.backend_agg.RendererAgg(width, height, dpi)
    Bases: matplotlib.backend_bases.RendererBase

    The renderer handles all the drawing primitives using a graphics context instance that controls the colors/styles

    buffer_rgba(self)
    clear(self)

draw_mathtext(self, gc, x, y, s, prop, angle)
    Draw the math text using matplotlib.mathtext

draw_path(self, gc, path, transform, rgbFace=None)
    Draws a Path instance using the given affine transform.

draw_tex(self, gc, x, y, s, prop, angle, ismath='TeX!', mtext=None)
draw_text(self, gc, x, y, s, prop, angle, ismath=False, mtext=None)
    Draw the text instance.

    **Parameters**
    x [scalar] The x location of the text in display coords.
y  [scalar]  The y location of the text baseline in display coords.

s  [str]  The text string.

angle  [scalar]  The rotation angle in degrees.

mtext  [matplotlib.text.Text]  The original text object to be rendered.

Notes

backend implementers note

When you are trying to determine if you have gotten your bounding box right (which
is what enables the text layout/alignment to work properly), it helps to change the
line in text.py:

```python
if 0: bbox_artist(self, renderer)
```
to if 1, and then the actual bounding box will be plotted along with your text.

get_canvas_width_height(self)
Return the canvas width and height in display coords.

get_text_width_height_descent(self, s, prop, ismath)
Get the width, height, and descent (offset from the bottom to the baseline), in display
coords, of the string s with FontProperties prop

lock = <unlocked _thread.RLock object owner=0 count=0>

option_image_nocomposite(self)
Return whether image composition by Matplotlib should be skipped.

Raster backends should usually return False (letting the C-level rasterizer take care
of image composition); vector backends should usually return not rcParams["image.
composite_image"].

option_scale_image(self)
Return whether arbitrary affine transformations in draw_image() are supported (True
for most vector backends).

points_to_pixels(self, points)
Convert points to display units.

You need to override this function (unless your backend doesn’t have a dpi, e.g.,
postscript or svg). Some imaging systems assume some value for pixels per inch:

```python
points to pixels = points * pixels_per_inch/72.0 * dpi/72.0
```

Parameters

points  [scalar or array_like]  a float or a numpy array of float

Returns

Points converted to pixels

restore_region(self, region, bbox=None, xy=None)
Restore the saved region. If bbox (instance of BboxBase, or its extents) is given,
only the region specified by the bbox will be restored. xy (a pair of floats) optionally
specifies the new position (the LLC of the original region, not the LLC of the bbox) where the region will be restored.

```python
>>> region = renderer.copy_from_bbox()
>>> x1, y1, x2, y2 = region.get_extents()
>>> renderer.restore_region(region, bbox=(x1+dx, y1, x2, y2),
...     xy=(x1-dx, y1))
```

```python
start_filter(self)
    Start filtering. It simply create a new canvas (the old one is saved).

stop_filter(self, post_processing)
    Save the plot in the current canvas as a image and apply the post_processing function.

    def post_processing(image, dpi):
        # ny, nx, depth = image.shape  # image (numpy array) has RGBA channels and has a depth of 4. ...
        # create a new_image (numpy array of 4 channels, size can be # different). The resulting image may have offsets from # lower-left corner of the original image
        return new_image, offset_x, offset_y

    The saved renderer is restored and the returned image from post_processing is plotted (using draw_image) on it.

    tostring_argb(self)
    tostring_rgb(self)
    tostring_rgba_minimized(self)
```

17.10.3 matplotlib.backends.backend_cairo

A Cairo backend for matplotlib

Author Steve Chaplin and others

This backend depends on cairocffi or pycairo.

class matplotlib.backends.backend_cairo.ArrayWrapper(**kwargs)
    Bases: object

    [Deprecated] Thin wrapper around numpy ndarray to expose the interface expected by cairocffi. Basically replicates the array.array interface.

Notes

Deprecated since version 3.0.

buffer_info(self)

matplotlib.backends.backend_cairo.FigureCanvas
    alias of matplotlib.backends.backend_cairo.FigureCanvasCairo

class matplotlib.backends.backend_cairo.FigureCanvasCairo(figure)
    Bases: matplotlib.backend_bases.FigureCanvasBase

    print_pdf(self, fobj, *args, **kwargs)
print_png(self, fobj, *args, **kwargs)
print_ps(self, fobj, *args, **kwargs)
print_raw(self, fobj, *args, **kwargs)
print_rgba(self, fobj, *args, **kwargs)
print_svg(self, fobj, *args, **kwargs)
print_svgz(self, fobj, *args, **kwargs)
supports_blit = False

class matplotlib.backends.backend_cairo.GraphicsContextCairo(renderer)
    Bases: matplotlib.backend_bases.GraphicsContextBase

    get_rgb(self)
        Return a tuple of three or four floats from 0-1.

    restore(self)
        Restore the graphics context from the stack - needed only for backends that save
        graphics contexts on a stack.

    set_alpha(self, alpha)
        Set the alpha value used for blending - not supported on all backends.
        If alpha=None (the default), the alpha components of the foreground and fill colors
        will be used to set their respective transparencies (where applicable); otherwise,
        alpha will override them.

    set_capstyle(self, cs)
        Set the capstyle to be one of ('butt', 'round', 'projecting').

    set_clip_path(self, path)
        Set the clip path and transformation. Path should be a TransformedPath instance.

    set_clip_rectangle(self, rectangle)
        Set the clip rectangle with sequence (left, bottom, width, height)

    set_dashes(self, offset, dashes)
        Set the dash style for the gc.

        Parameters

        dash_offset [float] is the offset (usually 0).

        dash_list [array_like] specifies the on-off sequence as points. (None, None) specifies a solid line

    set_foreground(self, fg, isRGBA=None)
        Set the foreground color.

        Parameters

        fg [color]

        isRGBA [bool] If fg is known to be an (r, g, b, a) tuple, isRGBA can be
        set to True to improve performance.

    set_joinstyle(self, js)
        Set the join style to be one of ('miter', 'round', 'bevel').

    set_linewidth(self, w)
        Set the linewdth in points.
class matplotlib.backends.backend_cairo.RendererCairo(dpi)
    Bases: matplotlib.backend_bases.RendererBase

    static convert_path(ctx, path, transform, clip=None)
        [Deprecated]

    Notes

    Deprecated since version 3.0:

draw_image(self, gc, x, y, im)
    Draw an RGBA image.

    Parameters

    x [scalar] the distance in physical units (i.e., dots or pixels) from the left
    hand side of the canvas.
    y [scalar] the distance in physical units (i.e., dots or pixels) from the bottom
    side of the canvas.
    transform [matplotlib.transforms.Affine2DBase] If and only if the concrete
    backend is written such that option_scale_image() returns True, an affine
    transformation may be passed to draw_image(). It takes the
    form of a Affine2DBase instance. The translation vector of the transform-
    ation is given in physical units (i.e., dots or pixels). Note that the
    transformation does not override x and y, and has to be applied before
    translating the result by x and y (this can be accomplished by adding x
    and y to the translation vector defined by transform).

draw_markers(self, gc, marker_path, marker_trans, path, transform, rgbFace=None)
    Draws a marker at each of the vertices in path. This includes all vertices, including
    control points on curves. To avoid that behavior, those vertices should be removed
    before calling this function.

    This provides a fallback implementation of draw_markers that makes multiple calls
to draw_path(). Some backends may want to override this method in order to draw
the marker only once and reuse it multiple times.

    Parameters

    gc [GraphicsContextBase] The graphics context
    marker_trans [matplotlib.transforms.Transform] An affine transform ap-
    plied to the marker:
    trans [matplotlib.transforms.Transform] An affine transform applied to
    the path.

draw_path(self, gc, path, transform, rgbFace=None)
    Draws a Path instance using the given affine transform.

draw_text(self, gc, x, y, s, prop, angle, ismath=False, mtext=None)
    Draw the text instance.

    Parameters
The graphics context.

x [scalar] The x location of the text in display coords.

y [scalar] The y location of the text baseline in display coords.

s [str] The text string.

angle [scalar] The rotation angle in degrees.

mtext [matplotlib.text.Text] The original text object to be rendered.

Notes

backend implementers note

When you are trying to determine if you have gotten your bounding box right (which is what enables the text layout/alignment to work properly), it helps to change the line in text.py:

```python
if 0: bbox_artist(self, renderer)
```

to 1, and then the actual bounding box will be plotted along with your text.

```python
fontangles = {'italic': <MyCairoCffi name='mock.FONT_SLANT_ITALIC' id='140090861286512'>, 'normal': <MyCairoCffi name='mock.FONT_SLANT_NORMAL' id='140090854793112'>, 'oblique': <MyCairoCffi name='mock.FONT_SLANT_OBLIQUE' id='140090852270320'>}
fontweights = {100: <MyCairoCffi name='mock.FONT_WEIGHT_NORMAL' id='140090862217424'>, 200: <MyCairoCffi name='mock.FONT_WEIGHT_BOLD' id='140090861985352'>}
```

```python
get_canvas_width_height(self)
    Return the canvas width and height in display coords.
```

```python
get_text_width_height_descent(self, s, prop, ismath)
    Get the width, height, and descent (offset from the bottom to the baseline), in display coords, of the string s with FontProperties prop
```

```python
new_gc(self)
    Return an instance of a GraphicsContextBase.
```

```python
points_to_pixels(self, points)
    Convert points to display units.
    You need to override this function (unless your backend doesn’t have a dpi, e.g., postscript or svg). Some imaging systems assume some value for pixels per inch:
```

```python
points to pixels = points * pixels_per_inch/72.0 * dpi/72.0
```

Parameters

points [scalar or array_like] a float or a nump arrays of float

Returns

Points converted to pixels

```python
set_ctx_from_surface(self, surface)
```

```python
set_width_height(self, width, height)
```
17.10.4 matplotlib.backends.backend_gtk3agg

**TODO** We’ll add this later, importing the gtk3 backends requires an active X-session, which is not compatible with cron jobs.

17.10.5 matplotlib.backends.backend_gtk3cairo

**TODO** We’ll add this later, importing the gtk3 backends requires an active X-session, which is not compatible with cron jobs.

17.10.6 matplotlib.backends.backend_nbagg

Interactive figures in the IPython notebook

```python
class matplotlib.backends.backend_nbagg.CommSocket(manager)
    Bases: object
    Manages the Comm connection between IPython and the browser (client).
    Comms are 2 way, with the CommSocket being able to publish a message via the send_json method, and handle a message with on_message. On the JS side figure.send_message and figure.ws.onmessage do the sending and receiving respectively.

    is_open(self)
    on_close(self)
    on_message(self, message)
    send_binary(self, blob)
    send_json(self, content)
```

```python
matplotlib.backends.backend_nbagg.FigureCanvas
alias of matplotlib.backends.backend_nbagg.FigureCanvasNbAgg
class matplotlib.backends.backend_nbagg.FigureCanvasNbAgg(*args, **kwargs)
    Bases: matplotlib.backends.backend_webagg_core.FigureCanvasWebAggCore
    new_timer(self, *args, **kwargs)
    Creates a new backend-specific subclass of backend_bases.Timer. This is useful for getting periodic events through the backend’s native event loop. Implemented only for backends with GUIs.
```

**Other Parameters**

- `interval` [scalar] Timer interval in milliseconds
- `callbacks` [List[Tuple[callable, Tuple, Dict]]] Sequence of (func, args, kwargs) where func(*args, **kwargs) will be executed by the timer every interval.
  - callbacks which return False or 0 will be removed from the timer.
Examples

```python
>>> timer = fig.canvas.new_timer(callbacks=[[f1, (1, ), {'a': 3}]])
```

```
matplotlib.backends.backend_nbagg.FigureManager
    alias of matplotlib.backends.backend_nbagg.FigureManagerNbAgg
class matplotlib.backends.backend_nbagg.FigureManagerNbAgg(canvas, num)
    Bases: matplotlib.backends.backend_webagg_core.FigureManagerWebAgg
    ToolbarCls
        alias of NavigationIPy
clearup_closed(self)
    Clear up any closed Comms.
connected
destroy(self)
display_js(self)
classmethod get_javascript(stream=None)
remove_comm(self, comm_id)
reshape(self)
    A special method to re-show the figure in the notebook.
show(self)
    For GUI backends, show the figure window and redraw. For non-GUI backends,
    raise an exception to be caught by `show()`, for an optional warning.
class matplotlib.backends.backend_nbagg.NavigationIPy(canvas)
    Bases: matplotlib.backends.backend_webagg_core.NavigationToolbar2WebAgg
toolitems = [('Home', 'Reset original view', 'fa fa-home icon-home', 'home'), ('Back', 'Back to previous view', 'fa fa-reply icon-reply', 'back'), ('Forward', 'Forward to next view', 'fa fa-reply-all icon-replyall', 'forward'), ('Zoom', 'zoom in or out', 'fa fa-search-plus icon-search-plus', 'zoom'), (None, None, None, None), ('Download', 'Download plot', 'fa fa-floppy-o icon-save', 'download')]
connection_info()
    Return a string showing the figure and connection status for the backend.
    This is intended as a diagnostic tool, and not for general use.
class matplotlib.backends.backend_nbagg.new_figure_manager_given_figure(num, figure)
    Create a new figure manager instance for the given figure.
class matplotlib.backends.backend_nbagg.show(*args, block=None, **kwargs)
    Show all figures.
    `show` blocks by calling `mainloop` if `block` is True, or if it is `None` and we are neither in
    IPython’s `%pylab` mode, nor in interactive mode.
```

## 17.10.7 `matplotlib.backends.backend_pdf`

A PDF matplotlib backend Author: Jouni K Seppänen `<jks@iki.fi>`

```
matplotlib.backends.backend_pdf.FigureCanvas
    alias of matplotlib.backends.backend_pdf.FigureCanvasPdf
class matplotlib.backends.backend_pdf.FigureCanvasPdf(figure)
    Bases: matplotlib.backend_bases.FigureCanvasBase
```
The canvas the figure renders into. Calls the draw and print fig methods, creates the
renderers, etc...

Attributes

figure [matplotlib.figure.Figure] A high-level Figure instance
draw(self)
    Render the Figure.

filetypes = {'pdf': 'Portable Document Format'}
fixed_dpi = 72
gettext_default_filetype(self)
    Get the default savefig file format as specified in rcParam savefig.format. Returned
    string excludes period. Overridden in backends that only support a single file type.

print_pdf(self, filename, *, dpi=72, bbox_inches_restore=None, metadata=None,
          **kwargs)
class matplotlib.backends.backend_pdf.GraphicsContextPdf(file)
    Bases: matplotlib.backend_bases.GraphicsContextBase
    alpha_cmd(self, alpha, forced, effective_alphas)
    capstyle_cmd(self, style)
    capstyles = {'butt': 0, 'projecting': 2, 'round': 1}
    clip_cmd(self, cliprect, clippath)
        Set clip rectangle. Calls self.pop() and self.push().
    commands = ((('_cliprect', '_clippath'), <function GraphicsContextPdf.clip_cmd>),
                 ('_alpha', '_forced_alpha', ...<function GraphicsContextPdf.rgb_cmd>),
                 (('_hatch', '_hatch_color'), <function GraphicsContextPdf.hatch_cmd>))
    copy_properties(self, other)
        Copy properties of other into self.
    dash_cmd(self, dashes)
    delta(self, other)
        Copy properties of other into self and return PDF commands needed to transform
        self into other.
    fill(self, *args)
        Predicate: does the path need to be filled?
        An optional argument can be used to specify an alternative_fillcolor, as needed by
        RendererPdf draw_markers.
    fillcolor_cmd(self, rgb)
    finalize(self)
        Make sure every pushed graphics state is popped.
    hatch_cmd(self, hatch, hatch_color)
    joinstyle_cmd(self, style)
    joinstyles = {'bevel': 2, 'miter': 0, 'round': 1}
    linewidth_cmd(self, width)
    paint(self)
        Return the appropriate pdf operator to cause the path to be stroked, filled, or both.
    pop(self)
push(self)
rgb_cmd(self, rgb)
stroke(self)

Predicate: does the path need to be stroked (its outline drawn)? This tests for the various conditions that disable stroking the path, in which case it would presumably be filled.

class matplotlib.backends.backend_pdf.Name(name)
Bases: object

PDF name object.
static hexify(match)
name
pdfRepr(self)

class matplotlib.backends.backend_pdf.Operator(op)
Bases: object

PDF operator object.
op
pdfRepr(self)

class matplotlib.backends.backend_pdf.PdfFile(filename, metadata=None)
Bases: object

PDF file object.
addGouraudTriangles(self, points, colors)
alphaState(self, alpha)
    Return name of an ExtGState that sets alpha to the given value.
beginStream(self, id, len, extra=None, png=None)
close(self)
    Flush all buffers and free all resources.
createType1Descriptor(self, t1font, fontfile)
dviFontName(self, dvifont)
    Given a dvi font object, return a name suitable for Op.selectfont. This registers the font information in self.dviFontInfo if not yet registered.
embedTTF(self, filename, characters)
    Embed the TTF font from the named file into the document.
endStream(self)
finalize(self)
    Write out the various deferred objects and the pdf end matter.
fontName(self, fontprop)
    Select a font based on fontprop and return a name suitable for Op.selectfont. If fontprop is a string, it will be interpreted as the filename of the font.
hatchPattern(self, hatch_style)
imageObject(self, image)
    Return name of an image XObject representing the given image.
markerObject(self, path, trans, fill, stroke, lw, joinstyle, capstyle)
    Return name of a marker XObject representing the given path.

newPage(self, width, height)

newTextnote(self, text, positionRect=[-100, -100, 0, 0])

output(self, *data)

pathCollectionObject(self, gc, path, trans, padding, filled, stroked)

static pathOperations(path, transform, clip=None, simplify=None, sketch=None)

recordXref(self, id)

reserveObject(self, name="")
    Reserve an ID for an indirect object. The name is used for debugging in case we
    forget to print out the object with writeObject.

texFontMap

write(self, data)

writeFonts(self)

writeGouraudTriangles(self)

writeHatches(self)

writeImages(self)

writeInfoDict(self)
    Write out the info dictionary, checking it for good form

writeMarkers(self)

writeObject(self, object, contents)

writePath(self, path, transform, clip=False, sketch=None)

writePathCollectionTemplates(self)

writeTrailer(self)
    Write out the PDF trailer.

writeXref(self)
    Write out the xref table.

class matplotlib.backends.backend_pdf.PdfPages(filename, keep_empty=True, metadata=None)
    Bases: object

A multi-page PDF file.

Notes

In reality PdfPages is a thin wrapper around PdfFile, in order to avoid confusion when
using savefig() and forgetting the format argument.

Examples
Create a new PdfPages object.

**Parameters**

- `filename` [str] Plots using `PdfPages.savefig()` will be written to a file at this location. The file is opened at once and any older file with the same name is overwritten.

- `keep_empty` [bool, optional] If set to False, then empty pdf files will be deleted automatically when closed.

- `metadata` [dictionary, optional] Information dictionary object (see PDF reference section 10.2.1 'Document Information Dictionary'), e.g.:
  ```
  {'Creator': 'My software', 'Author': 'Me', 'Title': 'Awesome fig'}
  ```

  The standard keys are 'Title', 'Author', 'Subject', 'Keywords', 'Creator', 'Producer', 'CreationDate', 'ModDate', and 'Trapped'. Values have been predefined for 'Creator', 'Producer' and 'CreationDate'. They can be removed by setting them to `None`.

- `attach_note(self, text, positionRect=[-100, -100, 0, 0])`:

  Add a new text note to the page to be saved next. The optional positionRect specifies the position of the new note on the page. It is outside the page per default to make sure it is invisible on printouts.

- `close(self)`:

  Finalize this object, making the underlying file a complete PDF file.

- `get_pagecount(self)`:

  Returns the current number of pages in the multipage pdf file.

- `infodict(self)`:

  Return a modifiable information dictionary object (see PDF reference section 10.2.1 'Document Information Dictionary').

- `keep_empty`:

- `savefig(self, figure=None, **kwargs)`:

  Saves a `Figure` to this file as a new page.

  Any other keyword arguments are passed to `savefig()`.

**Parameters**

- `figure` [Figure or int, optional] Specifies what figure is saved to file. If not specified, the active figure is saved. If a `Figure` instance is provided, this figure is saved. If an int is specified, the figure instance to save is looked up by number.

---

```python
>>> import matplotlib.pyplot as plt
>>> # Initialize:
>>> with PdfPages('foo.pdf') as pdf:
...    # As many times as you like, create a figure fig and save it:
...    fig = plt.figure()
...    pdf.savefig(fig)
...    # When no figure is specified the current figure is saved
...    pdf.savefig()
```

Reference

Bases: object
PDF reference object. Use PdfFile.reserveObject() to create References.

```python
def pdfRepr(self)
    write(self, contents, file)
```

class matplotlib.backends.backend_pdf.RendererPdf(file, image_dpi, height, width)
    Bases: matplotlib.backends._backend_pdf_ps.RendererPDFPSBase

    afm_font_cache
        [Deprecated]

    Notes

    Deprecated since version 3.1:

    ```python
def check_gc(self, gc, fillcolor=None)
```

    ```python
def draw_gouraud_triangle(self, gc, points, colors, trans)
        Draw a Gouraud-shaded triangle.

        Parameters

        points [array_like, shape=(3, 2)] Array of (x, y) points for the triangle.
        colors [array_like, shape=(3, 4)] RGBA colors for each point of the triangle.
        transform [matplotlib.transforms.Transform] An affine transform to apply to the points.
```

    ```python
def draw_gouraud_triangles(self, gc, points, colors, trans)
        Draws a series of Gouraud triangles.

        Parameters

        points [array_like, shape=(N, 3, 2)] Array of N (x, y) points for the triangles.
        colors [array_like, shape=(N, 3, 4)] Array of N RGBA colors for each point of the triangles.
        transform [matplotlib.transforms.Transform] An affine transform to apply to the points.
```

    ```python
def draw_image(self, gc, x, y, im, transform=None)
        Draw an RGBA image.

        Parameters

        x [scalar] the distance in physical units (i.e., dots or pixels) from the left hand side of the canvas.
        y [scalar] the distance in physical units (i.e., dots or pixels) from the bottom side of the canvas.
        transform [matplotlib.transforms.Affine2DBase] If and only if the concrete backend is written such that option_scale_image() returns True, an affine transformation may be passed to draw_image(). It takes the
```
form of a `Affine2DBase` instance. The translation vector of the transformation is given in physical units (i.e., dots or pixels). Note that the transformation does not override $x$ and $y$, and has to be applied before translating the result by $x$ and $y$ (this can be accomplished by adding $x$ and $y$ to the translation vector defined by `transform`).

draw_markers(self, gc, marker_path, marker_trans, path, trans, rgbFace=None)

Draws a marker at each of the vertices in path. This includes all vertices, including control points on curves. To avoid that behavior, those vertices should be removed before calling this function.

This provides a fallback implementation of `draw_markers` that makes multiple calls to `draw_path()`. Some backends may want to override this method in order to draw the marker only once and reuse it multiple times.

**Parameters**

- **gc** [GraphicsContextBase] The graphics context
- **marker_trans** [`matplotlib.transforms.Transform`] An affine transform applied to the marker.
- **trans** [`matplotlib.transforms.Transform`] An affine transform applied to the path.

draw_mathtext(self, gc, x, y, s, prop, angle)

draw_path(self, gc, path, transform, rgbFace=None)

Draws a `Path` instance using the given affine transform.

draw_path_collection(self, gc, master_transform, paths, all_transforms, offsets, offsetTrans, facecolors, edgecolors, linewidths, linestyles, antialiaseds, urls, offset_position)

Draws a collection of paths selecting drawing properties from the lists `facecolors`, `edgecolors`, `linewidths`, `linestyles` and `antialiaseds`. `offsets` is a list of offsets to apply to each of the paths. The offsets in `offsets` are first transformed by `offsetTrans` before being applied. `offset_position` may be either "screen" or "data" depending on the space that the offsets are in.

This provides a fallback implementation of `draw_path_collection()` that makes multiple calls to `draw_path()`. Some backends may want to override this in order to render each set of path data only once, and then reference that path multiple times with the different offsets, colors, styles etc. The generator methods `_iter_collection_raw_paths()` and `_iter_collection()` are provided to help with (and standardize) the implementation across backends. It is highly recommended to use those generators, so that changes to the behavior of `draw_path_collection()` can be made globally.

draw_tex(self, gc, x, y, s, prop, angle, ismath='TeX!', mtext=None)

draw_text(self, gc, x, y, s, prop, angle, ismath=False, mtext=None)

Draw the text instance.

**Parameters**

- **x** [scalar] The x location of the text in display coords.
- **y** [scalar] The y location of the text baseline in display coords.
- **s** [str] The text string.
angle [scalar] The rotation angle in degrees.
mtext [matplotlib.text.Text] The original text object to be rendered.

Notes

backend implementers note
When you are trying to determine if you have gotten your bounding box right (which
is what enables the text layout/alignment to work properly), it helps to change the
line in text.py:

```python
if 0: bbox_artist(self, renderer)
```
to if 1, and then the actual bounding box will be plotted along with your text.

class matplotlib.backends.backend_pdf.Stream(id, len, file, extra=None, png=None)
   Bases: object

   PDF stream object.
   This has no pdfRepr method. Instead, call begin(), then output the contents of the stream
   by calling write(), and finally call end().

   id: object id of stream; len: an unused Reference object for the length of the stream,
   or None (to use a memory buffer); file: a PdfFile; extra: a dictionary of extra key-value
   pairs to include in the stream header; png: if the data is already png compressed, the
decode parameters

   compressobj
   end(self)
      Finalize stream.
```
extra
file
id
len
pdfFile
pos
write(self, data)
Write some data on the stream.

class matplotlib.backends.backend_pdf.Verbatim(x)
    Bases: object
    Store verbatim PDF command content for later inclusion in the stream.
    pdfRepr(self)
    matplotlib.backends.backend_pdf.fill(strings, linelen=75)
    Make one string from sequence of strings, with whitespace in between. The whitespace
is chosen to form lines of at most linelen characters, if possible.
    matplotlib.backends.backend_pdf.pdfRepr(obj)
    Map Python objects to PDF syntax.

17.10.8 matplotlib.backends.backend_pgf

matplotlib.backends.backend_pgf FigureCanvas
    alias of matplotlib.backends.backend_pgf.FigureCanvasPgf

class matplotlib.backends.backend_pgf.FigureCanvasPgf(figure)
    Bases: matplotlib.backend_bases.FigureCanvasBase
    filetypes = {'pdf': 'LaTeX compiled PGF picture', 'pgf': 'LaTeX PGF picture', 'png': 'Portable Network Graphics'}
    get_default_filetype(self)
        Get the default savefig file format as specified in rcParam savefig.format. Returned
string excludes period. Overridden in backends that only support a single file type.
    get_renderer(self)
    print_pdf(self, fname_or_fh, *args, **kwargs)
        Use LaTeX to compile a Pgf generated figure to PDF.
    print_pgf(self, fname_or_fh, *args, **kwargs)
        Output pgf commands for drawing the figure so it can be included and rendered in
latex documents.
    print_png(self, fname_or_fh, *args, **kwargs)
        Use LaTeX to compile a pgf figure to pdf and convert it to png.

matplotlib.backends.backend_pgf.FigureManager
    alias of matplotlib.backends.backend_pgf.FigureManagerPgf

class matplotlib.backends.backend_pgf.FigureManagerPgf(canvas, num)
    Bases: matplotlib.backend_bases.FigureManagerBase

class matplotlib.backends.backend_pgf.GraphicsContextPgf
    Bases: matplotlib.backend_bases.GraphicsContextBase

exception matplotlib.backends.backend_pgf.LatexError(message, latex_output="")
    Bases: Exception

class matplotlib.backends.backend_pgf.LatexManager
    Bases: object
    The LatexManager opens an instance of the LaTeX application for determining the met-
rics of text elements. The LaTeX environment can be modified by setting fonts and/or a
custom preamble in the rc parameters.
get_width_height_descent(self, text, prop)
Get the width, total height and descent for a text typeset by the current LaTeX environment.

class matplotlib.backends.backend_pgf.LatexManagerFactory(**kwargs)
Bases: object

[Deprecated]

Notes

Deprecated since version 3.1:

static get_latex_manager()

previous_instance = None
class matplotlib.backends.backend_pgf.PdfPages(filename, *, keep_empty=True, metadata=None)
Bases: object

A multi-page PDF file using the pgf backend

Examples

```python
>>> import matplotlib.pyplot as plt
>>> # Initialize:
>>> with PdfPages('foo.pdf') as pdf:
...    # As many times as you like, create a figure fig and save it:
...    fig = plt.figure()
...    pdf.savefig(fig)
...    # When no figure is specified the current figure is saved
...    pdf.savefig()
```

Create a new PdfPages object.

Parameters

filename [str] Plots using PdfPages.savefig() will be written to a file at this location. Any older file with the same name is overwritten.

keep_empty [bool, optional] If set to False, then empty pdf files will be deleted automatically when closed.

metadata [dictionary, optional] Information dictionary object (see PDF reference section 10.2.1 'Document Information Dictionary'), e.g.:

```python
{'Creator': 'My software', 'Author': 'Me', 'Title': 'Awesome fig'}
```

The standard keys are 'Title', 'Author', 'Subject', 'Keywords', 'Producer', 'Creator' and 'Trapped'. Values have been predefined for 'Creator' and 'Producer'. They can be removed by setting them to the empty string.

close(self)
Finalize this object, running LaTeX in a temporary directory and moving the final pdf file to filename.
get_pagecount(self)
    Returns the current number of pages in the multipage pdf file.

keep_empty

metadata

savefig(self, figure=None, **kwargs)
    Saves a Figure to this file as a new page.
    Any other keyword arguments are passed to savefig().

Parameters

    figure [Figure or int, optional] Specifies what figure is saved to file. If
    not specified, the active figure is saved. If a Figure instance is provided,
    this figure is saved. If an int is specified, the figure instance to save is
    looked up by number.

class matplotlib.backends.backend_pgf.RendererPgf(figure, fh, dummy=False)
    Bases: matplotlib.backend_bases.RendererBase

    Creates a new PGF renderer that translates any drawing instruction into text commands
    to be interpreted in a latex pgfpicture environment.

Attributes

    figure [matplotlib.figure.Figure] Matplotlib figure to initialize height,
    width and dpi from.

    fh [file-like] File handle for the output of the drawing commands.

draw_image(self, gc, x, y, im, transform=None)
    Draw an RGBA image.

Parameters

    x [scalar] the distance in physical units (i.e., dots or pixels) from the left
    hand side of the canvas.

    y [scalar] the distance in physical units (i.e., dots or pixels) from the bottom
    side of the canvas.

    im [array_like, shape=(N, M, 4), dtype=np.uint8] An array of RGBA pix-
    els.

    transform [matplotlib.transforms.Affine2DBase] If and only if the con-
    crete backend is written such that option_scale_image() returns True,
    an affine transformation may be passed to draw_image(). It takes the
    form of a Affine2DBase instance. The translation vector of the trans-
    formation is given in physical units (i.e., dots or pixels). Note that the
    transformation does not override x and y, and has to be applied before
    translating the result by x and y (this can be accomplished by adding x
    and y to the translation vector defined by transform).

draw_markers(self, gc, marker_path, marker_trans, path, trans, rgbFace=None)
    Draws a marker at each of the vertices in path. This includes all vertices, including
    control points on curves. To avoid that behavior, those vertices should be removed
    before calling this function.
This provides a fallback implementation of draw_markers that makes multiple calls
to draw_path(). Some backends may want to override this method in order to draw
the marker only once and reuse it multiple times.

**Parameters**

- **gc** [GraphicsContextBase] The graphics context
- **marker_trans** [matplotlib.transforms.Transform] An affine transform applied
to the marker.
- **trans** [matplotlib.transforms.Transform] An affine transform applied to
the path.

**draw_path**

```python
draw_path(self, gc, path, transform, rgbFace=None)
```

Draws a Path instance using the given affine transform.

**draw_tex**

```python
draw_tex(self, gc, x, y, s, prop, angle, ismath='TeX!', mtext=None)
```

Draw the text instance.

**Parameters**

- **x** [scalar] The x location of the text in display coords.
- **y** [scalar] The y location of the text baseline in display coords.
- **s** [str] The text string.
- **prop** [matplotlib.font_manager.FontProperties] The font properties.
- **angle** [scalar] The rotation angle in degrees.
- **mtext** [matplotlib.text.Text] The original text object to be rendered.

**Notes**

**backend implementers note**

When you are trying to determine if you have gotten your bounding box right (which
is what enables the text layout/alignment to work properly), it helps to change the
line in text.py:

```python
if 0: bbox_artist(self, renderer)
```

...to if 1, and then the actual bounding box will be plotted along with your text.

**flipy**

```python
flipy(self)
```

Return whether y values increase from top to bottom.

Note that this only affects drawing of texts and images.

**get_canvas_width_height**

```python
get_canvas_width_height(self)
```

Return the canvas width and height in display coords.

**get_text_width_height_descent**

```python
get_text_width_height_descent(self, s, prop, ismath)
```

Get the width, height, and descent (offset from the bottom to the baseline), in display
coords, of the string s with FontProperties prop

**new_gc**

```python
new_gc(self)
```

Return an instance of a GraphicsContextBase.
Matplotlib, Release 3.1.1

option_image_nocomposite(self)
Return whether image composition by Matplotlib should be skipped.
Raster backends should usually return False (letting the C-level rasterizer take care
of image composition); vector backends should usually return not rcParams["image.
composite_image"].

option_scale_image(self)
Return whether arbitrary affine transformations in draw_image() are supported (True
for most vector backends).

points_to_pixels(self, points)
Convert points to display units.
You need to override this function (unless your backend doesn’t have a dpi, e.g.,
postscript or svg). Some imaging systems assume some value for pixels per inch:

\[
\text{points to pixels} = \text{points} \times \text{pixels per inch} / 72.0 \times \text{dpi} / 72.0
\]

Parameters
points [scalar or array_like] a float or a numpy array of float

Returns
Points converted to pixels

class matplotlib.backends.backend_pgf.TmpDirCleaner
   Bases: object
   static add(tmpdir)
   static cleanup_remaining_tmpdirs()
   remaining_tmpdirs = {} 

matplotlib.backends.backend_pgf.common_texification(text)
   Do some necessary and/or useful substitutions for texts to be included in LaTeX docu-
   ments.

matplotlib.backends.backend_pgf.get_fontspec()
   Build fontspec preamble from rc.

matplotlib.backends.backend_pgf.get_preamble()
   Get LaTeX preamble from rc.

matplotlib.backends.backend_pgf.get_texcommand()
   [Deprecated] Get chosen TeX system from rc.

   Notes
   Depreciated since version 3.0.

matplotlib.backends.backend_pgf.make_pdf_to_png_converter()
   Returns a function that converts a pdf file to a png file.

matplotlib.backends.backend_pgf.repl_escapetext(m)
matplotlib.backends.backend_pgf.repl_mathdefault(m)
matplotlib.backends.backend_pgf.writeln(fh, line)
17.10.9 matplotlib.backends.backend_ps

A PostScript backend, which can produce both PostScript .ps and .eps.

```python
matplotlib.backends.backend_ps.FigureCanvas
alias of matplotlib.backends.backend_ps.FigureCanvasPS
```

class matplotlib.backends.backend_ps.FigureCanvasPS(figure)
Bases: matplotlib.backend_bases.FigureCanvasBase
draw(self)
    Render the Figure.
filetypes = {'eps': 'Encapsulated Postscript', 'ps': 'Postscript'}
fixed_dpi = 72
get_default_filetype(self)
    Get the default savefig file format as specified in rcParam savefig.format. Returned string excludes period. Overridden in backends that only support a single file type.
print_eps(self, outfile, *args, **kwargs)
print_ps(self, outfile, *args, **kwargs)
```

class matplotlib.backends.backend_ps.GraphicsContextPS
Bases: matplotlib.backend_bases.GraphicsContextBase
get_capstyle(self)
    Return the capstyle as a string in ('butt', 'round', 'projecting').
get_joinstyle(self)
    Return the line join style as one of ('miter', 'round', 'bevel').
shouldstroke(self)
    [Deprecated]
```

Notes

Deprecated since version 3.1:

class matplotlib.backends.backend_ps.PsBackendHelper
Bases: object
gs_exe
gs_version
supports_ps2write
```

class matplotlib.backends.backend_ps.RendererPS(width, height, pswriter, imagedpi=72)
Bases: matplotlib.backends._backend_pdf_ps.RendererPDFPSBase
```

The renderer handles all the drawing primitives using a graphics context instance that controls the colors/styles.

afmfontd
    [Deprecated]
Notes

Deprecated since version 3.1:

create_hatch(self, hatch)

draw_gouraud_triangle(self, gc, points, colors, trans)
    Draw a Gouraud-shaded triangle.

    Parameters
    
    points [array_like, shape=(3, 2)] Array of (x, y) points for the triangle.
    
    colors [array_like, shape=(3, 4)] RGBA colors for each point of the triangle.
    
    transform [matplotlib.transforms.Transform] An affine transform to apply to the points.

    draw_gouraud_triangles(self, gc, points, colors, trans)
    Draws a series of Gouraud triangles.

    Parameters
    
    points [array_like, shape=(N, 3, 2)] Array of N (x, y) points for the triangles.
    
    colors [array_like, shape=(N, 3, 4)] Array of N RGBA colors for each point of the triangles.
    
    transform [matplotlib.transforms.Transform] An affine transform to apply to the points.

    draw_image(self, gc, x, y, im, transform=None)
    Draw an RGBA image.

    Parameters
    
    
    x [scalar] the distance in physical units (i.e., dots or pixels) from the left hand side of the canvas.
    
    y [scalar] the distance in physical units (i.e., dots or pixels) from the bottom side of the canvas.
    
    
    transform [matplotlib.transforms.Affine2DBase] If and only if the concrete backend is written such that option_scale_image() returns True, an affine transformation may be passed to draw_image(). It takes the form of a Affine2DBase instance. The translation vector of the transformation is given in physical units (i.e., dots or pixels). Note that the transformation does not override x and y, and has to be applied before translating the result by x and y (this can be accomplished by adding x and y to the translation vector defined by transform).

    draw_markers(self, gc, marker_path, marker_trans, path, trans, rgbFace=None)
    Draws a marker at each of the vertices in path. This includes all vertices, including control points on curves. To avoid that behavior, those vertices should be removed before calling this function.
This provides a fallback implementation of `draw_markers` that makes multiple calls to `draw_path()`. Some backends may want to override this method in order to draw the marker only once and reuse it multiple times.

**Parameters**

**draw_math_text**

```python
def draw_math_text(self, gc, x, y, s, prop, angle)
    Draw the math text using matplotlib.mathtext.
```

**draw_path**

```python
def draw_path(self, gc, path, transform, rgbFace=None)
    Draws a Path instance using the given affine transform.
```

**draw_path_collection**

```python
def draw_path_collection(self, gc, master_transform, paths, all_transforms, offsets, offsetTrans, facecolors, edgecolors, linewidths, linestyles, antialiaseds, urls, offset_position)
    Draws a collection of paths selecting drawing properties from the lists facecolors, edgecolors, linewidths, linestyles and antialiaseds. offsets is a list of offsets to apply to each of the paths. The offsets in offsets are first transformed by offsetTrans before being applied. offset_position may be either "screen" or "data" depending on the space that the offsets are in.
```

This provides a fallback implementation of `draw_path_collection()` that makes multiple calls to `draw_path()`. Some backends may want to override this in order to render each set of path data only once, and then reference that path multiple times with the different offsets, colors, styles etc. The generator methods `_iter_collection_raw_paths()` and `_iter_collection()` are provided to help with (and standardize) the implementation across backends. It is highly recommended to use those generators, so that changes to the behavior of `draw_path_collection()` can be made globally.

**draw_tex**

```python
def draw_tex(self, gc, x, y, s, prop, angle, ismath='TeX!', mtext=None)
```

**draw_text**

```python
def draw_text(self, gc, x, y, s, prop, angle, ismath=False, mtext=None)
    Draw the text instance.
```

**Parameters**

- `x [scalar]` The x location of the text in display coords.
- `y [scalar]` The y location of the text baseline in display coords.
- `s [str]` The text string.
- `angle [scalar]` The rotation angle in degrees.
- `mtext [matplotlib.text.Text]` The original text object to be rendered.

**Notes**

**backend implementers note**
When you are trying to determine if you have gotten your bounding box right (which is what enables the text layout/alignment to work properly), it helps to change the line in text.py:

```python
if 0: bbox_artist(self, renderer)
```

to if 1, and then the actual bounding box will be plotted along with your text.

**get_image_magnification(self)**
Get the factor by which to magnify images passed to draw_image. Allows a backend to have images at a different resolution to other artists.

**merge_used_characters(self, other)**

**new_gc(self)**
Return an instance of a GraphicsContextBase.

**set_color(self, r, g, b, store=1)**

**set_font(self, fontname, fontsize, store=1)**

**set_linecap(self, linecap, store=1)**

**set_linedash(self, offset, seq, store=1)**

**set_linejoin(self, linejoin, store=1)**

**set_linewidth(self, linewidth, store=1)**

**track_characters(self, font, s)**
Keeps track of which characters are required from each font.

**matplotlib.backends.backend_ps.convert_psfrags(tmpfile, psfrags, font_preamble, custom_preamble, paperWidth, paperHeight, orientation)**
When we want to use the LaTeX backend with postscript, we write PSFrag tags to a temporary postscript file, each one marking a position for LaTeX to render some text. convert_psfrags generates a LaTeX document containing the commands to convert those tags to text. LaTeX/dvips produces the postscript file that includes the actual text.

**matplotlib.backends.backend_ps.get_bbox(tmpfile, bbox)**
[Deprecated] Use ghostscript’s bbox device to find the center of the bounding box. Return an appropriately sized bbox centered around that point. A bit of a hack.

**Notes**
Deprecated since version 3.0.

**matplotlib.backends.backend_ps.get_bbox_header(lbrt, rotated=False)**
return a postscript header string for the given bbox lbrt=(l, b, r, t). Optionally, return rotate command.

**matplotlib.backends.backend_ps.gs_distill(tmpfile, eps=False, ptype='letter', bbox=None, rotated=False)**
Use ghostscript’s pswrite or epswrite device to distill a file. This yields smaller files without illegal encapsulated postscript operators. The output is low-level, converting text to outlines.

**matplotlib.backends.backend_ps.pstoeps(tmpfile, bbox=None, rotated=False)**
Convert the postscript to encapsulated postscript. The bbox of the eps file will be replaced with the given bbox argument. If None, original bbox will be used.
Quote dangerous characters of S for use in a PostScript string constant.

Use ghostscript's ps2pdf and xpdf's/poppler's pdftops to distill a file. This yields smaller files without illegal encapsulated postscript operators. This distiller is preferred, generating high-level postscript output that treats text as text.

17.10.10 matplotlib.backends.backend_qt4agg

**NOTE** Not included, to avoid adding a dependency to building the docs.

17.10.11 matplotlib.backends.backend_qt4cairo

**NOTE** Not included, to avoid adding a dependency to building the docs.

17.10.12 matplotlib.backends.backend_qt5agg

**NOTE** Not included, to avoid adding a dependency to building the docs.

17.10.13 matplotlib.backends.backend_qt5cairo

**NOTE** Not included, to avoid adding a dependency to building the docs.

17.10.14 matplotlib.backends.backend_svg

**NOTE** Not included, to avoid adding a dependency to building the docs.
draw_gouraud_triangle(self, gc, points, colors, trans)
    Draw a Gouraud-shaded triangle.

    Parameters
    
    points [array_like, shape=(3, 2)] Array of (x, y) points for the triangle.
    
    colors [array_like, shape=(3, 4)] RGBA colors for each point of the triangle.
    
    transform [matplotlib.transforms.Transform] An affine transform to apply to the points.

draw_gouraud_triangles(self, gc, triangles_array, colors_array, transform)
    Draws a series of Gouraud triangles.

    Parameters
    
    points [array_like, shape=(N, 3, 2)] Array of N (x, y) points for the triangles.
    
    colors [array_like, shape=(N, 3, 4)] Array of N RGBA colors for each point of the triangles.
    
    transform [matplotlib.transforms.Transform] An affine transform to apply to the points.

draw_image(self, gc, x, y, im, transform=None)
    Draw an RGBA image.

    Parameters
    
    
    x [scalar] the distance in physical units (i.e., dots or pixels) from the left hand side of the canvas.
    
    y [scalar] the distance in physical units (i.e., dots or pixels) from the bottom side of the canvas.
    
    
    transform [matplotlib.transforms.Affine2DBase] If and only if the concrete backend is written such that option_scale_image() returns True, an affine transformation may be passed to draw_image(). It takes the form of a Affine2DBase instance. The translation vector of the transformation is given in physical units (i.e., dots or pixels). Note that the transformation does not override x and y, and has to be applied before translating the result by x and y (this can be accomplished by adding x and y to the translation vector defined by transform).

draw_markers(self, gc, marker_path, marker_trans, path, trans, rgbFace=None)
    Draws a marker at each of the vertices in path. This includes all vertices, including control points on curves. To avoid that behavior, those vertices should be removed before calling this function.

    This provides a fallback implementation of draw_markers that makes multiple calls to draw_path(). Some backends may want to override this method in order to draw the marker only once and reuse it multiple times.

    Parameters
    
    gc [GraphicsContextBase] The graphics context
**marker_trans** [matplotlib.transforms.Transform] An affine transform applied to the marker.

**trans** [matplotlib.transforms.Transform] An affine transform applied to the path.

draw_path(self, gc, path, transform, rgbFace=None)
Draws a Path instance using the given affine transform.

draw_path_collection(self, gc, master_transform, paths, all_transforms, offsets, offsetTrans, facecolors, edgecolors, linewidths, linestyles, antialiaseds, urls, offset_position)
Draws a collection of paths selecting drawing properties from the lists facecolors, edgecolors, linewidths, linestyles and antialiaseds. offsets is a list of offsets to apply to each of the paths. The offsets in offsets are first transformed by offsetTrans before being applied. offset_position may be either “screen” or “data” depending on the space that the offsets are in.

This provides a fallback implementation of draw_path_collection() that makes multiple calls to draw_path(). Some backends may want to override this in order to render each set of path data only once, and then reference that path multiple times with the different offsets, colors, styles etc. The generator methods _iter_collection_raw_paths() and _iter_collection() are provided to help with (and standardize) the implementation across backends. It is highly recommended to use those generators, so that changes to the behavior of draw_path_collection() can be made globally.

draw_tex(self, gc, x, y, s, prop, angle, ismath='TeX!', mtext=None)
draw_text(self, gc, x, y, s, prop, angle, ismath=False, mtext=None)
Draw the text instance.

**Parameters**

- **x** [scalar] The x location of the text in display coords.
- **y** [scalar] The y location of the text baseline in display coords.
- **s** [str] The text string.
- **prop** [matplotlib.font_manager.FontProperties] The font properties.
- **angle** [scalar] The rotation angle in degrees.
- **mtext** [matplotlib.text.Text] The original text object to be rendered.

**Notes**

**backend implementers note**

When you are trying to determine if you have gotten your bounding box right (which is what enables the text layout/alignment to work properly), it helps to change the line in text.py:

```python
if 0: bbox_artist(self, renderer)
```

to if 1, and then the actual bounding box will be plotted along with your text.

finalize(self)
flipy(self)
    Return whether y values increase from top to bottom.
    Note that this only affects drawing of texts and images.

get_canvas_width_height(self)
    Return the canvas width and height in display coords.

get_image_magnification(self)
    Get the factor by which to magnify images passed to draw_image(). Allows a backend
to have images at a different resolution to other artists.

get_text_width_height_descent(self, s, prop, ismath)
    Get the width, height, and descent (offset from the bottom to the baseline), in display
    coords, of the string s with FontProperties prop

open_group(self, s, gid=None)
    Open a grouping element with label s and gid (if set) as id.
    Only used by the SVG renderer.

option_image_nocomposite(self)
    Return whether image composition by Matplotlib should be skipped.
    Raster backends should usually return False (letting the C-level rasterizer take care
    of image composition); vector backends should usually return not rcParams["image.
    composite_image"].

option_scale_image(self)
    Return whether arbitrary affine transformations in draw_image() are supported (True
    for most vector backends).

class matplotlib.backends.backend_svg.XMLWriter(file)
    Bases: object

    Parameters
    ----------
    file [writable text file-like object]

close(self, id)
    Closes open elements, up to (and including) the element identified by the given
    identifier.

    Parameters
    ----------
    id Element identifier, as returned by the start() method.

comment(self, comment)
    Adds a comment to the output stream.

    Parameters
    ----------
    comment [str] Comment text.

data(self, text)
    Adds character data to the output stream.

    Parameters
    ----------
    text [str] Character data.

element(self, tag, text=None, attrib={}, **extra)
    Adds an entire element. This is the same as calling start(), data(), and end() in
    sequence. The text argument can be omitted.
end(self, tag=\texttt{None}, indent=\texttt{True})
Closes the current element (opened by the most recent call to \texttt{start()}).

\textbf{Parameters}

\textbf{tag} Element tag. If given, the tag must match the start tag. If omitted, the current element is closed.

\textbf{flush}(\texttt{self})
Flushes the output stream.

\textbf{start}(\texttt{self}, \texttt{tag}, \texttt{attrib=}\texttt{\{\}}, **\texttt{extra})
Opens a new element. Attributes can be given as keyword arguments, or as a string/string dictionary. The method returns an opaque identifier that can be passed to the \texttt{close()} method, to close all open elements up to and including this one.

\textbf{Parameters}

\textbf{tag} Element tag.

\textbf{attrib} Attribute dictionary. Alternatively, attributes can be given as keyword arguments.

\textbf{Returns}

\textbf{An element identifier.}

\texttt{matplotlib.backends.backend_svg.escape_attrib(s)}
\texttt{matplotlib.backends.backend_svg.escape_cdata(s)}
\texttt{matplotlib.backends.backend_svg.escape_comment(s)}
\texttt{matplotlib.backends.backend_svg.generate_css(\texttt{attrib=}\texttt{\{\}})}
\texttt{matplotlib.backends.backend_svg.generate_transform(\texttt{\texttt{transform_list=}\[\]}\})
\texttt{matplotlib.backends.backend_svg.short_float_fmt(x)}
Create a short string representation of a float, which is \%f formatting with trailing zeros and the decimal point removed.

\textbf{17.10.15 matplotlib.backends.backend_tkagg}

\texttt{matplotlib.backends.backend_tkagg.FigureCanvas}
alias of \texttt{matplotlib.backends.backend_tkagg.FigureCanvasTkAgg}

\textbf{class matplotlib.backends.backend_tkagg.FigureCanvasTkAgg(figure, master=\texttt{None}, resize_callback=\texttt{None})}
Bases: \texttt{matplotlib.backends.backend_agg.FigureCanvasAgg, matplotlib.backends._backend_tk.FigureCanvasTk}

\textbf{blit}(\texttt{self, bbox=}\texttt{\texttt{\{\}}})
Blit the canvas in bbox (default entire canvas).

\textbf{draw}(\texttt{self})
Draw the figure using the renderer.

\textbf{17.10.16 matplotlib.backends.backend_webagg}
**Note:** The WebAgg backend is not documented here, in order to avoid adding Tornado to the doc build requirements.

### 17.10.17 matplotlib.backends.backend_wxagg

**NOTE** Not included, to avoid adding a dependency to building the docs.

### 17.11 matplotlib.blocking_input

This provides several classes used for blocking interaction with figure windows:

- **BlockingInput** Creates a callable object to retrieve events in a blocking way for interactive sessions. Base class of the other classes listed here.
- **BlockingKeyMouseInput** Creates a callable object to retrieve key or mouse clicks in a blocking way for interactive sessions. Used by `waitforbuttonpress`.
- **BlockingMouseInput** Creates a callable object to retrieve mouse clicks in a blocking way for interactive sessions. Used by `ginput`.
- **BlockingContourLabeler** Creates a callable object to retrieve mouse clicks in a blocking way that will then be used to place labels on a `ContourSet`. Used by `clabel`.

```python
class matplotlib.blocking_input.BlockingContourLabeler(CS):
    Bases: matplotlib.blocking_input.BlockingMouseInput
    Callable for retrieving mouse clicks and key presses in a blocking way.
    Used to place contour labels.
    add_click(self, event)
        Add the coordinates of an event to the list of clicks.

    Parameters
    event [MouseEvent]

    button1(self, event)
        Process an button-1 event (add a label to a contour).

    Parameters
    event [MouseEvent]

    button3(self, event)
        Process an button-3 event (remove a label if not in inline mode).

    Unfortunately, if one is doing inline labels, then there is currently no way to fix the broken contour - once humpty-dumpty is broken, he can’t be put back together. In inline mode, this does nothing.

    Parameters
    event [MouseEvent]

    pop_click(self, event, index=-1)
        Remove a click (by default, the last) from the list of clicks.
```
Parameters

**event** [MouseEvent]

class matplotlib.blocking_input.BlockingInput(fig, eventslist=())
    Bases: object
    Callable for retrieving events in a blocking way.

    add_event(self, event)
        For base class, this just appends an event to events.

    cleanup(self)
        Disconnect all callbacks.

    on_event(self, event)
        Event handler; will be passed to the current figure to retrieve events.

    pop(self, index=-1)
        Remove an event from the event list – by default, the last.
        Note that this does not check that there are events, much like the normal pop
        method. If no events exist, this will throw an exception.

    pop_event(self, index=-1)
        Remove an event from the event list – by default, the last.
        Note that this does not check that there are events, much like the normal pop
        method. If no events exist, this will throw an exception.

    post_event(self)
        For baseclass, do nothing but collect events.

class matplotlib.blocking_input.BlockingKeyMouseInput(fig)
    Bases: matplotlib.blocking_input.BlockingInput
    Callable for retrieving mouse clicks and key presses in a blocking way.

    post_event(self)
        Determine if it is a key event.

class matplotlib.blocking_input.BlockingMouseInput(fig, mouse_add=1, mouse_pop=3, mouse_stop=2)
    Bases: matplotlib.blocking_input.BlockingInput
    Callable for retrieving mouse clicks in a blocking way.
    This class will also retrieve keypresses and map them to mouse clicks: delete and
    backspace are like mouse button 3, enter is like mouse button 2 and all others are like
    mouse button 1.

    add_click(self, event)
        Add the coordinates of an event to the list of clicks.

Parameters

**event** [MouseEvent]

button_add = 1
button_pop = 3
button_stop = 2
cleanup(self, event=None)
Parameters

- **event** [MouseEvent, optional] Not used

**key_event**(self)
Process a key press event, mapping keys to appropriate mouse clicks.

**mouse_event**(self)
Process a mouse click event.

**mouse_event_add**(self, event)
Process a button-1 event (add a click if inside axes).

Parameters

- **event** [MouseEvent]

**mouse_event_pop**(self, event)
Process a button-3 event (remove the last click).

Parameters

- **event** [MouseEvent]

**mouse_event_stop**(self, event)
Process a button-2 event (end blocking input).

Parameters

- **event** [MouseEvent]

**pop**(self, event, index=-1)
Removes a click and the associated event from the list of clicks.
Defaults to the last click.

**pop_click**(self, event, index=-1)
Remove a click (by default, the last) from the list of clicks.

Parameters

- **event** [MouseEvent]

**post_event**(self)
Process an event.

17.12 matplotlib.category

Module that allows plotting of string “category” data. i.e. `plot(['d', 'f', 'a'],[1, 2, 3])` will plot three points with x-axis values of ‘d’, ‘f’, ‘a’.

See `/gallery/lines_bars_and_markers/categorical_variables` for an example.

The module uses Matplotlib’s `matplotlib.units` mechanism to convert from strings to integers, provides a tick locator and formatter, and the class `UnitData` that creates and stores the string-to-integer mapping.

**class** matplotlib.category.StrCategoryConverter
    Bases: matplotlib.units.ConversionInterface

    **static axisinfo**(unit, axis)
    Sets the default axis ticks and labels
Parameters

- **unit** ([UnitData] object string unit information for value
- **axis** ([axis] axis for which information is being set

Returns

- **axisinfo** ([AxisInfo] Information to support default tick labeling

```python
def static convert(value, unit, axis):
    # Convert strings in value to floats using mapping information store in the unit object.
    # Parameters
    # value [string or iterable] Value or list of values to be converted.
    # unit [UnitData] An object mapping strings to integers.
    # axis [Axis] axis on which the converted value is plotted.
    
    # Note: axis is unused.
    
    Returns
    # mapped_value [float or ndarray[float]]
    
static default_units(data, axis)
    # Sets and updates the axis units.
    
Parameters

- **data** [string or iterable of strings]
- **axis** ([axis] axis on which the data is plotted

Returns

- **class** [UnitData] object storing string to integer mapping

```python
class matplotlib.category.StrCategoryFormatter(units_mapping):
    Bases: matplotlib.ticker.Formatter
    
    String representation of the data at every tick
    
Parameters

- **units_mapping** [Dict[Str, int]] string:integer mapping

```python
class matplotlib.category.StrCategoryLocator(units_mapping):
    Bases: matplotlib.ticker.Locator
    
    tick at every integer mapping of the string data
    
Parameters

- **units_mapping** [Dict[str, int]] string:integer mapping

```python
tick_values(self, vmin, vmax)
    # Return the values of the located ticks given vmin and vmax.
    
    # Note: To get tick locations with the vmin and vmax values defined automatically
    # for the associated axis simply call the Locator instance:
class matplotlib.category.UnitData(data=None)
    Bases: object

Create mapping between unique categorical values and integer ids.

    Parameters
    data [iterable] sequence of string values

update(self, data)
    Maps new values to integer identifiers.

    Parameters
    data [iterable] sequence of string values

    Raises
    TypeError If the value in data is not a string, unicode, bytes type

17.13 matplotlib.cbook

A collection of utility functions and classes. Originally, many (but not all) were from
the Python Cookbook – hence the name cbook.

This module is safe to import from anywhere within matplotlib; it imports matplotlib only at
time.

class matplotlib.cbook.Bunch(**kwargs)
    Bases: types.SimpleNamespace

    [Deprecated] Often we want to just collect a bunch of stuff together, naming each item
of the bunch; a dictionary’s OK for that, but a small do-nothing class is even handier,
and prettier to use. Whenever you want to group a few variables:

>>> point = Bunch(datum=2, squared=4, coord=12)
>>> point.datum

Notes

Depreciated since version 3.0.

class matplotlib.cbook.CallbackRegistry(exception_handler=<function _exception_printer>)
    Bases: object

Handle registering and disconnecting for a set of signals and callbacks:
In practice, one should always disconnect all callbacks when they are no longer needed to avoid dangling references (and thus memory leaks). However, real code in Matplotlib rarely does so, and due to its design, it is rather difficult to place this kind of code. To get around this, and prevent this class of memory leaks, we instead store weak references to bound methods only, so when the destination object needs to die, the CallbackRegistry won’t keep it alive.

**Parameters**

- **exception_handler** [callable, optional] If provided must have signature

  ```python
def handler(exc: Exception) -> None:
  ```

  If not None this function will be called with any `Exception` subclass raised by the callbacks in `CallbackRegistry.process`. The handler may either consume the exception or re-raise.

  The callable must be pickle-able.

  The default handler is

  ```python
def h(exc):
  traceback.print_exc()
  ```

- **connect(self, s, func)**
  Register `func` to be called when signal `s` is generated.

- **disconnect(self, cid)**
  Disconnect the callback registered with callback id `cid`.

- **process(self, s, *args, **kwargs)**
  Process signal `s`.
  All of the functions registered to receive callbacks on `s` will be called with `*args` and `**kwargs`.

**class** matplotlib.cbook.GetRealpathAndStat(**kwargs)**

Bases: `object`
[Deprecated]

Notes

Deprecated since version 3.0:

class matplotlib.cbook.Grouper(init=())

Bases: object

This class provides a lightweight way to group arbitrary objects together into disjoint sets when a full-blown graph data structure would be overkill.

Objects can be joined using `join()`, tested for connectedness using `joined()`, and all disjoint sets can be retrieved by using the object as an iterator.

The objects being joined must be hashable and weak-referenceable.

For example:

```python
>>> from matplotlib.cbook import Grouper
>>> class Foo(object):
...   def __init__(self, s):
...       self.s = s
...   def __repr__(self):
...       return self.s
...>>> a, b, c, d, e, f = [Foo(x) for x in 'abcdef']
>>> grp = Grouper()
>>> grp.join(a, b)
>>> grp.join(b, c)
>>> grp.join(d, e)
>>> sorted(map(tuple, grp))  
[(a, b, c), (d, e)]
>>> grp.joined(a, b)
True
>>> grp.joined(a, c)
True
>>> grp.joined(a, d)
False

clean(self)

Clean dead weak references from the dictionary.

get_siblings(self, a)

Return all of the items joined with a, including itself.

join(self, a, *args)

Join given arguments into the same set. Accepts one or more arguments.

joined(self, a, b)

Return whether a and b are members of the same set.

remove(self, a)

exception matplotlib.cbook.IgnoredKeywordWarning

Bases: UserWarning

A class for issuing warnings about keyword arguments that will be ignored by matplotlib
class matplotlib.cbook.Locked(**kwargs)
    Bases: object

    [Deprecated] Context manager to handle locks.
    Based on code from conda.

(c) 2012-2013 Continuum Analytics, Inc. / https://www.continuum.io/ All Rights Reserved
conda is distributed under the terms of the BSD 3-clause license. Consult LICENSE_CONDA or https://opensource.org/licenses/BSD-3-Clause.

Notes

Deprecated since version 3.0.

LOCKFN = '.matplotlib_lock'

exception TimeoutError
    Bases: RuntimeError

class matplotlib.cbook.Stack(default=None)
    Bases: object

    Stack of elements with a movable cursor.
    Mimics home/back/forward in a web browser.

    back(self)
        Move the position back and return the current element.

    bubble(self, o)
        Raise o to the top of the stack. o must be present in the stack.
        o is returned.

    clear(self)
        Empty the stack.

    empty(self)
        Return whether the stack is empty.

    forward(self)
        Move the position forward and return the current element.

    home(self)
        Push the first element onto the top of the stack.
        The first element is returned.

    push(self, o)
        Push o to the stack at current position. Discard all later elements.
        o is returned.

    remove(self, o)
        Remove o from the stack.

matplotlib.cbook.boxplot_stats(X, whis=1.5, bootstrap=None, labels=None, autorange=False)

    Returns list of dictionaries of statistics used to draw a series of box and whisker plots. The Returns section enumerates the required keys of the dictionary. Users can skip this
function and pass a user-defined set of dictionaries to the new `axes.bxp` method instead of relying on MPL to do the calculations.

**Parameters**

- **X** [array-like] Data that will be represented in the boxplots. Should have 2 or fewer dimensions.

- **whis** [float, string, or sequence (default = 1.5)] As a float, determines the reach of the whiskers beyond the first and third quartiles. In other words, where IQR is the interquartile range \((q3-q1)\), the upper whisker will extend to last datum less than \(q3 + \text{whis} \times \text{IQR}\). Similarly, the lower whisker will extend to the first datum greater than \(q1 - \text{whis} \times \text{IQR}\). Beyond the whiskers, data are considered outliers and are plotted as individual points. This can be set to an ascending sequence of percentiles (e.g., \([5, 95]\)) to set the whiskers at specific percentiles of the data. Finally, `whis` can be the string 'range' to force the whiskers to the minimum and maximum of the data. In the edge case that the 25th and 75th percentiles are equivalent, `whis` can be automatically set to 'range' via the autorange option.

- **bootstrap** [int, optional] Number of times the confidence intervals around the median should be bootstrapped (percentile method).

- **labels** [array-like, optional] Labels for each dataset. Length must be compatible with dimensions of `X`.

- **autorange** [bool, optional (False)] When True and the data are distributed such that the 25th and 75th percentiles are equal, `whis` is set to 'range' such that the whisker ends are at the minimum and maximum of the data.

**Returns**

- **bxpstats** [list of dict] A list of dictionaries containing the results for each column of data. Keys of each dictionary are the following:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>tick label for the boxplot</td>
</tr>
<tr>
<td>mean</td>
<td>arithmetic mean value</td>
</tr>
<tr>
<td>med</td>
<td>50th percentile</td>
</tr>
<tr>
<td>q1</td>
<td>first quartile (25th percentile)</td>
</tr>
<tr>
<td>q3</td>
<td>third quartile (75th percentile)</td>
</tr>
<tr>
<td>cilo</td>
<td>lower notch around the median</td>
</tr>
<tr>
<td>chih</td>
<td>upper notch around the median</td>
</tr>
<tr>
<td>whislo</td>
<td>end of the lower whisker</td>
</tr>
<tr>
<td>whishi</td>
<td>end of the upper whisker</td>
</tr>
<tr>
<td>fliers</td>
<td>outliers</td>
</tr>
</tbody>
</table>

**Notes**

Non-bootstrapping approach to confidence interval uses Gaussian-based asymptotic approximation:

\[
\text{med} \pm 1.57 \times \frac{\text{iqr}}{\sqrt{N}}
\]

```python
matplotlib.cbook.contiguous_regions(mask)
Return a list of (ind0, ind1) such that mask[ind0:ind1].all() is True and we cover all such regions
```

```python
matplotlib.cbook.dedent(s)
[Deprecated] Remove excess indentation from docstring s.
Discards any leading blank lines, then removes up to n whitespace characters from each line, where n is the number of leading whitespace characters in the first line. It differs from textwrap.dedent in its deletion of leading blank lines and its use of the first non-blank line to determine the indentation.
It is also faster in most cases.
```

**Notes**

Deprecated since version 3.1.

```python
matplotlib.cbook.delete_masked_points(*args)
Find all masked and/or non-finite points in a set of arguments, and return the arguments with only the unmasked points remaining.
Arguments can be in any of 5 categories:
1) 1-D masked arrays
2) 1-D ndarrays
3) ndarrays with more than one dimension
4) other non-string iterables
5) anything else
The first argument must be in one of the first four categories; any argument with a length differing from that of the first argument (and hence anything in category 5) then will be passed through unchanged.
Masks are obtained from all arguments of the correct length in categories 1, 2, and 4; a point is bad if masked in a masked array or if it is a nan or inf. No attempt is made to extract a mask from categories 2, 3, and 4 if np.isfinite() does not yield a Boolean array.
All input arguments that are not passed unchanged are returned as ndarrays after removing the points or rows corresponding to masks in any of the arguments.
A vastly simpler version of this function was originally written as a helper for Axes.scatter().
```

```python
matplotlib.cbook.file_requires_unicode(x)
Return whether the given writable file-like object requires Unicode to be written to it.
```

```python
matplotlib.cbook.flatten(seq, scalarp=<function is_scalar_or_string at 0x7f6976df8048>)
Return a generator of flattened nested containers
For example:
```
>>> from matplotlib.cbook import flatten
>>> l = (('John', ['Hunter']), (1, 23), [[[42, (5, 23)],]])
>>> print(list(flatten(l)))
['John', 'Hunter', 1, 23, 42, 5, 23]

matplotlib.cbook.get_label(y, default_name)

[Deprecated]

Notes

Deprecated since version 3.1:

matplotlib.cbook.get realpath_and_stat(path)

matplotlib.cbook.get sample_data(fname, asfileobj=True)
 Return a sample data file. fname is a path relative to the mpl-data/sample_data directory. If asfileobj is True return a file object, otherwise just a file path.

Set the rc parameter examples.directory to the directory where we should look, if sample data files are stored in a location different than default (which is 'mpl-data/sample_data' at the same level of 'matplotlib' Python module files).

If the filename ends in .gz, the file is implicitly ungzipped.

matplotlib.cbook.index_of(y)
 A helper function to get the index of an input to plot against if x values are not explicitly given.

Tries to get y.index (works if this is a pd.Series), if that fails, return np.arange(y.shape[0]).

This will be extended in the future to deal with more types of labeled data.

Parameters

y [scalar or array-like] The proposed y-value

Returns

x, y [ndarray] The x and y values to plot.

matplotlib.cbook.is hashable(obj)

[Deprecated] Returns true if obj can be hashed

Notes

Deprecated since version 3.1.

matplotlib.cbook.is math_text(s)

matplotlib.cbook.is numlike(obj)

[Deprecated] return true if obj looks like a number
Notes

Deprecated since version 3.0.

matplotlib.cbook.is_scalar_or_string(val)
Return whether the given object is a scalar or string like.

matplotlib.cbook.is_writable_file_like(obj)
Return whether obj looks like a file object with a write method.

matplotlib.cbook.iterable(obj)
[Depreciated] return true if obj is iterable

Notes

Deprecated since version 3.1.

matplotlib.cbook.listFiles(root, patterns='*', recurse=1, return_folders=0)
[Depreciated] Recursively list files
from Parmar and Martelli in the Python Cookbook

Notes

Deprecated since version 3.0.

matplotlib.cbook.local_over_kwdict(local_var, kwars, *keys)
Enforces the priority of a local variable over potentially conflicting argument(s) from a
kwars dict. The following possible output values are considered in order of priority:
local_var > kwars[keys[0]] > ... > kwars[keys[-1]]
The first of these whose value is not None will be returned. If all are None then None
will be returned. Each key in keys will be removed from the kwars dict in place.

Parameters

local_var [any object]
The local variable (highest priority)

kwars [dict] Dictionary of keyword arguments; modified in place
keys [str(s)] Name(s) of keyword arguments to process, in descending
order of priority

Returns

out [any object] Either local_var or one of kwars[key] for key in keys

Raises

IgnoredKeywordWarning For each key in keys that is removed from
kwars but not used as the output value

class matplotlib.cbook.maxdict(maxsize)
Bases: dict
A dictionary with a maximum size; this doesn’t override all the relevant methods to con-
strain the size, just setitem, so use with caution
Matplotlib, Release 3.1.1

matplotlib.cbook.mkdirs(newdir, mode=511)

[Deprecated] make directory newdir recursively, and set mode. Equivalent to

```bash
> mkdir -p NEWDIR
> chmod MODE NEWDIR
```

Notes

Deprecated since version 3.0.

matplotlib.cbook.normalize_kwargs(kw, alias_mapping=None, required=(), forbidden=(), allowed=None)

Helper function to normalize kwarg inputs

The order they are resolved are:

1. aliasing
2. required
3. forbidden
4. allowed

This order means that only the canonical names need appear in allowed, forbidden, required

Parameters

- **alias_mapping**, dict, optional A mapping between a canonical name to a list of aliases, in order of precedence from lowest to highest.
  
  If the canonical value is not in the list it is assumed to have the highest priority.
- **required** [iterable, optional] A tuple of fields that must be in kwars.
- **forbidden** [iterable, optional] A list of keys which may not be in kwars
- **allowed** [tuple, optional] A tuple of allowed fields. If this not None, then raise if kw contains any keys not in the union of required and allowed. To allow only the required fields pass in () for allowed

Raises

- **TypeError** To match what python raises if invalid args/kwargs are passed to a callable.

matplotlib.cbook.open_file_cm(path_or_file, mode='r', encoding=None)

Pass through file objects and context-manage PathLike.

matplotlib.cbook.print_cycles(objects, outstream=<_io.TextIOWrapper name='<stdout>' mode='w' encoding='UTF-8'>, show_progress=False)

- **objects** A list of objects to find cycles in. It is often useful to pass in gc.garbage to find the cycles that are preventing some objects from being garbage collected.
- **outstream** The stream for output.
- **show_progress** If True, print the number of objects reached as they are found.
Convert continuous line to mid-steps.

Given a set of \( N \) points convert to \( 2N \) points which when connected linearly give a step function which changes values at the middle of the intervals.

**Parameters**
- **x** [array] The x location of the steps. May be empty.
- **y1, ..., yp** [array] y arrays to be turned into steps; all must be the same length as x.

**Returns**
- **out** [array] The x and y values converted to steps in the same order as the input; can be unpacked as x_out, y1_out, ..., yp_out. If the input is length \( N \), each of these arrays will be length \( 2N \).

**Examples**

```python
>>> x_s, y1_s, y2_s = pts_to_midstep(x, y1, y2)
```

Convert continuous line to post-steps.

Given a set of \( N \) points convert to \( 2N + 1 \) points, which when connected linearly give a step function which changes values at the end of the intervals.

**Parameters**
- **x** [array] The x location of the steps. May be empty.
- **y1, ..., yp** [array] y arrays to be turned into steps; all must be the same length as x.

**Returns**
- **out** [array] The x and y values converted to steps in the same order as the input; can be unpacked as x_out, y1_out, ..., yp_out. If the input is length \( N \), each of these arrays will be length \( 2N + 1 \). For \( N=0 \), the length will be 0.

**Examples**

```python
>>> x_s, y1_s, y2_s = pts_to_poststep(x, y1, y2)
```

Convert continuous line to pre-steps.

Given a set of \( N \) points, convert to \( 2N - 1 \) points, which when connected linearly give a step function which changes values at the beginning of the intervals.

**Parameters**
- **x** [array] The x location of the steps. May be empty.
- **y1, ..., yp** [array] y arrays to be turned into steps; all must be the same length as x.

**Returns**

```python
>>> x_s, y1_s, y2_s = pts_to_prestep(x, y1, y2)
```
The x and y values converted to steps in the same order as the input; can be unpacked as `x_out, y1_out, ..., yp_out`. If the input is length `N`, each of these arrays will be length `2N + 1`. For `N=0`, the length will be 0.

**Examples**

```python
>>> x_s, y1_s, y2_s = pts_to_prestep(x, y1, y2)
```

```
matplotlib.cbook.report_memory(i=0)
  Return the memory consumed by the process.

matplotlib.cbook.safe_first_element(obj)

matplotlib.cbook.safe_masked_invalid(x, copy=False)

matplotlib.cbook.safezip(*args)
  [Deprecated] make sure args are equal len before zipping
```

**Notes**

Deprecated since version 3.1.

```python
matplotlib.cbooksanitize_sequence(data)
  Converts dictview object to list
```

```python
class matplotlib.cbook.silent_list(type, seq=None)
  Bases: list
  override repr when returning a list of matplotlib artists to prevent long, meaningless output. This is meant to be used for a homogeneous list of a given type
```

```python
matplotlib.cbook.simple_linear_interpolation(a, steps)
  Resample an array with `steps - 1` points between original point pairs.
```

**Parameters**

- `a` [array, shape (n, ...)]
- `steps` [int]

**Returns**

- `array, shape (n - 1) * steps + 1, ...`

**Along each column of** `a`, `(steps - 1)` points are introduced between each original values; the values are linearly interpolated.

```python
matplotlib.cbook.strip_math(s)
  Remove latex formatting from mathtext.
```

```
Only handles fully math and fully non-math strings.
```

```python
matplotlib.cbook.to_filehandle(fname, flag='r', return_opened=False, encoding=None)
  Convert a path to an open file handle or pass-through a file-like object.
```

```
Consider using `open_file_cm` instead, as it allows one to properly close newly created file objects more easily.
```

**Parameters**
fname [str or PathLike or file-like object] If str or os.PathLike, the file is opened using the flags specified by flag and encoding. If a file-like object, it is passed through.

flag [str, default ‘r’] Passed as the mode argument to open when fname is str or os.PathLike; ignored if fname is file-like.

return_opened [bool, default False] If True, return both the file object and a boolean indicating whether this was a new file (that the caller needs to close). If False, return only the new file.

encoding [str or None, default None] Passed as the mode argument to open when fname is str or os.PathLike; ignored if fname is file-like.

Returns

fh [file-like]

opened [bool] opened is only returned if return_opened is True.

matplotlib.cbook.unicode_safe(S)

[Deprecated]

Notes

Deprecated since version 3.0:

matplotlib.cbook.violin_stats(X, method, points=100)

Returns a list of dictionaries of data which can be used to draw a series of violin plots. See the Returns section below to view the required keys of the dictionary. Users can skip this function and pass a user-defined set of dictionaries to the axes.vplot method instead of using MPL to do the calculations.

Parameters

X [array-like] Sample data that will be used to produce the gaussian kernel density estimates. Must have 2 or fewer dimensions.

method [callable] The method used to calculate the kernel density estimate for each column of data. When called via method(v, coords), it should return a vector of the values of the KDE evaluated at the values specified in coords.

points [scalar, default = 100] Defines the number of points to evaluate each of the gaussian kernel density estimates at.

Returns

A list of dictionaries containing the results for each column of data.

The dictionaries contain at least the following:

• coords: A list of scalars containing the coordinates this particular kernel density estimate was evaluated at.

• vals: A list of scalars containing the values of the kernel density estimate at each of the coordinates given in coords.

• mean: The mean value for this column of data.

• median: The median value for this column of data.
Matplotlib, Release 3.1.1

- min: The minimum value for this column of data.
- max: The maximum value for this column of data.

17.14 matplotlib.cm

Builtin colormaps, colormap handling utilities, and the ScalarMappable mixin.

See also:
/gallery/color/colormap_reference for a list of builtin colormaps.
Creating Colormaps in Matplotlib for examples of how to make colormaps and
Choosing Colormaps in Matplotlib an in-depth discussion of choosing colormaps.

Colormap Normalization for more details about data normalization

class matplotlib.cm.ScalarMappable(norm=None, cmap=None)
  Bases: object

This is a mixin class to support scalar data to RGBA mapping. The ScalarMappable
makes use of data normalization before returning RGBA colors from the given colormap.

Parameters

  norm [matplotlib.colors.Normalize instance] The normalizing object which
      scales data, typically into the interval [0, 1]. If None, norm defaults to
      a colors.Normalize object which initializes its scaling based on the first
      data processed.

  cmap [str or Colormap instance] The colormap used to map normalized data
      values to RGBA colors.

  add_checker(self, checker)
      Add an entry to a dictionary of boolean flags that are set to True when the mappable
      is changed.

  autoscale(self)
      Autoscale the scalar limits on the norm instance using the current array

  autoscale_None(self)
      Autoscale the scalar limits on the norm instance using the current array, changing
      only limits that are None

  changed(self)
      Call this whenever the mappable is changed to notify all the callbackSM listeners to
      the ‘changed’ signal

  check_update(self, checker)
      If mappable has changed since the last check, return True; else return False

  cmap = None
      The Colormap instance of this ScalarMappable.

  colorbar = None
      The last colorbar associated with this ScalarMappable. May be None.

  get_alpha(self)

Returns

get_array(self)
    Return the array

get_clim(self)
    return the min, max of the color limits for image scaling

get_cmap(self)
    return the colormap

norm = None
    The Normalization instance of this ScalarMappable.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
    
    A [ndarray]

set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as (vmin, vmax) which is used to support setp

    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have vmin and vmax kwargs.

set_cmap(self, cmap)
    set the colormap for luminance data

    Parameters

    cmap [colormap or registered colormap name]

set_norm(self, norm)
    Set the normalization instance.

    Parameters

    norm [Normalize]

Notes

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

to_rgba(self, x, alpha=None, bytes=False, norm=True)
    Return a normalized rgba array corresponding to x.

    In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

    There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg
is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

```
matplotlib.cm.get_cmap(name=None, lut=None)
```

Get a colormap instance, defaulting to rc values if name is None.

Colormaps added with `register_cmap()` take precedence over built-in colormaps.

If name is a `matplotlib.colors.Colormap` instance, it will be returned.

If lut is not None it must be an integer giving the number of entries desired in the lookup table, and name must be a standard mpl colormap name.

```
matplotlib.cm.register_cmap(name=None, cmap=None, data=None, lut=None)
```

Add a colormap to the set recognized by `get_cmap()`.

It can be used in two ways:

```
register_cmap(name='swirly', cmap=swirly_cmap)

register_cmap(name='choppy', data=choppydata, lut=128)
```

In the first case, cmap must be a `matplotlib.colors.Colormap` instance. The name is optional; if absent, the name will be the name attribute of the cmap.

In the second case, the three arguments are passed to the `LinearSegmentedColormap` initializer, and the resulting colormap is registered.

```
matplotlib.cm.revcmap(data)
```

Can only handle specification data in dictionary format.

### 17.15 `matplotlib.collections`

Classes for the efficient drawing of large collections of objects that share most properties,
e.g., a large number of line segments or polygons.

The classes are not meant to be as flexible as their single element counterparts (e.g., you may not be able to select all line styles) but they are meant to be fast for common use cases (e.g., a large set of solid line segments).

class matplotlib.collections.AsteriskPolygonCollection(numsides, rotation=0, sizes=(1,), **kwargs)

Bases: matplotlib.collections.RegularPolyCollection

Draw a collection of regular asterisks with numsides points.

**numsides** the number of sides of the polygon

**rotation** the rotation of the polygon in radians

**sizes** gives the area of the circle circumscribing the regular polygon in points^2

Valid Collection keyword arguments:

- **edgecolors**: None
- **facecolors**: None
- **linewidths**: None
- **antialiaseds**: None
- **offsets**: None
- **transOffset**: transforms.IdentityTransform()
- **norm**: None (optional for matplotlib.cm.ScalarMappable)
- **cmap**: None (optional for matplotlib.cm.ScalarMappable)

**offsets** and **transOffset** are used to translate the patch after rendering (default no offsets)

If any of **edgecolors**, **facecolors**, **linewidths**, **antialiaseds** are None, they default to their matplotlib.rcParams patch setting, in sequence form.

Example: see /gallery/event_handling/lasso_demo for a complete example:

```python
offsets = np.random.rand(20, 2)
facecolors = [cm.jet(x) for x in np.random.rand(20)]
black = (0, 0, 0, 1)

collection = RegularPolyCollection(
    numsides=5, # a pentagon
    rotation=0, sizes=(50,),
    facecolors=facecolors,
    edgecolors=black,
    linewidths=(1,),
    offsets=offsets,
    transOffset=ax.transData,
)
```

**add_callback(self, func)**

Add a callback function that will be called whenever one of the Artist's properties changes.

**Parameters**
**func** [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where *artist* is the calling *Artist*. Return values may exist but are ignored.

**Returns**

**oid** [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

**See also:**

`remove_callback`

**add_checker**(self, checker)

Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

**aname**

**autoscale**(self)

Autoscale the scalar limits on the norm instance using the current array

**autoscale_None**(self)

Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

**axes**

The *Axes* instance the artist resides in, or *None*.

**changed**(self)

Call this whenever the mappable is changed to notify all the callback listeners to the ‘changed’ signal

**check_update**(self, checker)

If mappable has changed since the last check, return True; else return False

**contains**(self, mouseevent)

Test whether the mouse event occurred in the collection.

Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

**convert_xunits**(self, x)

Convert *x* using the unit type of the xaxis.

If the artist is not contained in an Axes or if the xaxis does not have units, *x* itself is returned.

**convert_yunits**(self, y)

Convert *y* using the unit type of the yaxis.

If the artist is not contained in an Axes or if the yaxis does not have units, *y* itself is returned.

**draw**(self, renderer)

Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (`Artist.get_visible` is `False`).

**Parameters**
renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
Find artist objects.
Recursively find all Artist instances contained in the artist.

Parameters

match A filter criterion for the matches. This can be
- None: Return all objects contained in artist.
- A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns True.
- A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

include_self [bool] Include self in the list to be checked for a match.

Returns

artists [list of Artist]

format_cursor_data(self, data)
Return a string representation of data.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

See also:

get_cursor_data

get_agg_filter(self)
Return filter function to be used for agg filter.

get_alpha(self)
Return the alpha value used for blending - not supported on all backends

get_animated(self)
Return the animated state.

get_array(self)
Return the array

get_capstyle(self)

get_children(self)
Return a list of the child Artists of this Artist.

get_clim(self)
return the min, max of the color limits for image scaling

get_clip_box(self)
Return the clipbox.

get_clip_on(self)
Return whether the artist uses clipping.
get_clip_path(self)
    Return the clip path.

get_cmap(self)
    return the colormap

get_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:

    set_contains

get_cursor_data(self, event)
    Return the cursor data for a given event.

    Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

Parameters

    event [matplotlib.backend_bases.MouseEvent]

    See also:

    format_cursor_data

get_dashes(self)
    Alias for get_linestyle.

get_datalim(self, transData)

get_ec(self)
    Alias for get_edgecolor.

get_edgecolor(self)

get_edgecolors(self)
    Alias for get_edgecolor.

get_facecolor(self)

get_facecolors(self)
    Alias for get_facecolor.

get_fc(self)
    Alias for get_facecolor.

get_figure(self)
    Return the Figure instance the artist belongs to.
get_fill(self)
    return whether fill is set

get_gid(self)
    Return the group id.

get_hatch(self)
    Return the current hatching pattern.

get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.

    E.g. Constrained Layout Guide, figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').

get_joinstyle(self)

get_label(self)
    Return the label used for this artist in the legend.

get_linestyle(self)

get_linestyles(self)
    Alias for get_linestyle.

get_linewidth(self)

get_linewidths(self)
    Alias for get_linewidth.

get_ls(self)
    Alias for get_linestyle.

get_lw(self)
    Alias for get_linewidth.

get_num_sides(self)

get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If offset_position is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
    Return the offsets for the collection.

get_path_effects(self)

get_paths(self)

get_picker(self)
    Return the picking behavior of the artist.

    The possible values are described in set_picker.

    See also:

    set_picker, pickable, pick

get_pick_radius(self)
get_rasterized(self)
    Return whether the artist is to be rasterized.

get_rotation(self)

get_sizes(self)
    Returns the sizes of the elements in the collection. The value represents the ‘area’ of the element.

    Returns

    sizes [array] The ‘area’ of each element.

get_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns

    sketch_params [tuple or None] A 3-tuple with the following elements:
    "scale": The amplitude of the wiggle perpendicular to the source line.
    "length": The length of the wiggle along the line.
    "randomness": The scale factor by which the length is shrunken or expanded.

    Returns None if no sketch parameters were set.

get_snap(self)
    Returns the snap setting.
    See set_snap for details.

get_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters

    renderer [RendererBase instance] renderer that will be used to draw the figures (i.e. fig.canvas.get_renderer())

    Returns

    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
    Return the Transform instance used by this artist.

get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

get_transforms(self)

get_url(self)
    Return the url.

get_urls(self)

get_visible(self)
    Return the visibility.

get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box’ width and height are nonnegative.
Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.

Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

\[ \text{get\_zorder}(self) \]
Return the artist’s zorder.

\[ \text{have\_units}(self) \]
Return True if units are set on the x or y axes.

\[ \text{is\_transform\_set}(self) \]
Return whether the Artist has an explicitly set transform.
This is True after set_transform has been called.

\[ \text{mouseover} \]

\[ \text{pchanged}(self) \]
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

\[ \text{See also:} \]

\[ \text{add\_callback} \]
\[ \text{remove\_callback} \]

\[ \text{pick}(self, mouseevent) \]
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

\[ \text{See also:} \]

\[ \text{set\_picker}, \text{get\_picker}, \text{pickable} \]

\[ \text{pickable}(self) \]
Return whether the artist is pickable.

\[ \text{See also:} \]

\[ \text{set\_picker}, \text{get\_picker}, \text{pick} \]

\[ \text{properties}(self) \]
Return a dictionary of all the properties of the artist.

\[ \text{remove}(self) \]
Remove the artist from the figure if possible.
The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
draw_idle. Call relim to update the axes limits if desired.

Note: relim will not see collections even if the collection was added to the axes with autolim = True.
Note: there is no support for removing the artist’s legend entry.

```python
remove_callback(self, oid)
    Remove a callback based on its observer id.

See also:
    add_callback
```

```python
set(self, **kwargs)
    A property batch setter. Pass `kwargs` to set properties.

set_aa(self, aa)
    Alias for `set_antialiased`.

set_agg_filter(self, filter_func)
    Set the agg filter.

Parameters
    filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.
```

```python
set_alpha(self, alpha)
    Set the alpha transparencies of the collection.

Parameters
    alpha [float or None]
```

```python
set_animated(self, b)
    Set the artist’s animation state.

Parameters
    b [bool]
```

```python
set_antialiased(self, aa)
    Set the antialiasing state for rendering.

Parameters
    aa [bool or sequence of bools]
```

```python
set_antialiaseds(self, aa)
    Alias for `set_antialiased`.
```

```python
set_array(self, A)
    Set the image array from numpy array `A`.

Parameters
    A [ndarray]
```

```python
set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

Parameters
    cs [{‘butt’, ‘round’, ‘projecting’}] The capstyle
```

```python
set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if `vmin` is a length2 sequence, interpret it as (vmin, vmax) which is used to support setp
```
 ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have vmin and vmax kwargs.

**set_clip_box**(self, clipbox)
Set the artist’s clip **bbox**.

**Parameters**

clipbox [**bbox**]

**set_clip_on**(self, b)
Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

b [bool]

**set_clip_path**(self, path, transform=None)
Set the artist’s clip path, which may be:

- a **Patch** (or subclass) instance; or
- a **Path** instance, in which case a **Transform** instance, which will be applied to the path before using it for clipping, must be provided; or
- **None**, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to **None**.

ACCEPTS: [(**Path**, **Transform**) | **Patch** | **None**]

**set_cmap**(self, cmap)
set the colormap for luminance data

**Parameters**

cmap [colormap or registered colormap name]

**set_color**(self, c)
Set both the edgecolor and the facecolor.

**Parameters**

c [color or sequence of rgba tuples]

**See also:**

*Collection.set_facecolor, Collection.set_edgecolor* For setting the edge or face color individually.

**set_contains**(self, picker)
Define a custom contains test for the artist.

The provided callable replaces the default **contains** method of the artist.

**Parameters**

picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:
```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:
- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

```python
set_dashes(self, ls)
    Alias for `set_linestyle`.

set_ec(self, c)
    Alias for `set_edgecolor`.

set_edgecolor(self, c)
    Set the edgecolor(s) of the collection.

    **Parameters**
    - c [color or sequence of colors or 'face'] The collection edgecolor(s). If a sequence, the patches cycle through it. If 'face', match the facecolor.

set_edgecolors(self, c)
    Alias for `set_edgecolor`.

set_facecolor(self, c)
    Set the facecolor(s) of the collection. c can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

    If c is 'none', the patch will not be filled.

    **Parameters**
    - c [color or sequence of colors]

set_facecolors(self, c)
    Alias for `set_facecolor`.

set_fc(self, c)
    Alias for `set_facecolor`.

set_figure(self, fig)
    Set the `Figure` instance the artist belongs to.

    **Parameters**
    - fig [Figure]

set_gid(self, gid)
    Set the (group) id for the artist.

    **Parameters**
    - gid [str]

set_hatch(self, hatch)
    Set the hatching pattern

    `hatch` can be one of:
Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

**Parameters**

- **hatch**
  - `hatch = ['\\', '\', '|', '-', '+', 'x', 'o', 'O', '.', '*']`

- **set_in_layout**
  - `set_in_layout(self, in_layout)`
  - Set if artist is to be included in layout calculations, E.g. Constrained Layout Guide, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

- **in_layout**
  - `in_layout = [bool]`

- **set_joinstyle**
  - `set_joinstyle(self, js)`
  - Set the joinstyle for the collection (for all its elements).

  - **Parameters**
    - **js**
      - `js = ['miter', 'round', 'bevel']` The joinstyle

- **set_label**
  - `set_label(self, s)`
  - Set a label that will be displayed in the legend.

  - **Parameters**
    - **s**
      - `s = [object]` s will be converted to a string by calling `str`.

- **set_linestyle**
  - `set_linestyle(self, ls)`
  - Set the linestyle(s) for the collection.

<table>
<thead>
<tr>
<th>linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'-'</code> or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td><code>'--'</code> or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td><code>'-.'</code> or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td><code>':.'</code> or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:

```python
(offset, onoffseq),
```

where `onoffseq` is an even length tuple of on and off ink in points.
Parameters

```
ls [‘-’, ‘–’, ‘.-’, ‘:\’, ‘”’, (offset, on-off-seq), ...]} The line style.
```

```
set_linestyles(self, ls)
Alias for set_linestyle.
```

```
set_linewidth(self, lw)
Set the linewidth(s) for the collection. lw can be a scalar or a sequence; if it is a
sequence the patches will cycle through the sequence.
```

Parameters

```
lw [float or sequence of floats]
```

```
set_linewidths(self, lw)
Alias for set_linewidth.
```

```
set_ls(self, ls)
Alias for set_linestyle.
```

```
set_lw(self, lw)
Alias for set_linewidth.
```

```
set_norm(self, norm)
Set the normalization instance.
```

Parameters

```
norm [Normalize]
```

Notes

If there are any colorbars using the mappable for this norm, setting the norm of the
mappable will reset the norm, locator, and formatters on the colorbar to default.

```
set_offset_position(self, offset_position)
Set how offsets are applied. If offset_position is ‘screen’ (default) the offset is applied
after the master transform has been applied, that is, the offsets are in screen coor-
dinates. If offset_position is ‘data’, the offset is applied before the master transform,
i.e., the offsets are in data coordinates.
```

Parameters

```
offset_position [{‘screen’, ‘data’}]
```

```
set_offsets(self, offsets)
Set the offsets for the collection.
```

Parameters

```
offsets [float or sequence of floats]
```

```
set_path_effects(self, path_effects)
Set the path effects.
```

Parameters

```
path_effects [AbstractPathEffect]
```

```
set_paths(self)
```

```
set_picker(self, picker)
Define the picking behavior of the artist.
```
Parameters

**picker** [None or bool or float or callable] This can be one of the following:

- *None*: Picking is disabled for this artist (default).
- A boolean: If `True` then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
- A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event
- A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

  ```python
def picker(artist, mouseevent):
    hit, props = picker(artist, mouseevent)
```

  to determine the hit test. If the mouse event is over the artist, return `hit=True` and `props` is a dictionary of properties you want added to the PickEvent attributes.

**set_pickradius** *(self, pr)*

Set the pick radius used for containment tests.

**Parameters**

- *d* [float] Pick radius, in points.

**set_rasterized** *(self, rasterized)*

Force rasterized (bitmap) drawing in vector backend output.

Defaults to `None`, which implies the backend’s default behavior.

**Parameters**

- *rasterized* [bool or None]

**set_sizes** *(self, sizes, dpi=72.0)*

Set the sizes of each member of the collection.

**Parameters**

- *sizes* [ndarray or None] The size to set for each element of the collection.
  The value is the ‘area’ of the element.
- *dpi* [float] The dpi of the canvas. Defaults to 72.0.

**set_sketch_params** *(self, scale=None, length=None, randomness=None)*

Sets the sketch parameters.

**Parameters**

- *scale* [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is `None`, or not provided, no sketch filter will be provided.
- *length* [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
- *randomness* [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)
set_snap(self, snap)
    Set the snapping behavior.

    Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

    Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

    snap [bool or None] Possible values:
    • True: Snap vertices to the nearest pixel center.
    • False: Do not modify vertex positions.
    • None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

set_transform(self, t)
    Set the artist transform.

Parameters

    t [Transform]

set_url(self, url)
    Set the url for the artist.

Parameters

    url [str]

set_urls(self, urls)

Parameters

    urls [List[str] or None]

set_visible(self, b)
    Set the artist’s visibility.

Parameters

    b [bool]

set_zorder(self, level)
    Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters

    level [float]

stale
    Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

sticky_edges
    x and y sticky edge lists for autoscaling.

    When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to
the edge. A typical use case is histograms, where one usually expects no margin on
the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in
place as needed.

Examples

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

`to_rgba(self, x, alpha=None, bytes=False, norm=True)`

Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding
ndarray of rgba values will be returned, based on the norm and colormap set for
this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as
might have been read from an image file. If x is an ndarray with 3 dimensions, and
the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array,
and no mapping will be done. The array can be uint8, or it can be floating point with
values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array,
the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to
1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg
is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if
the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range;
if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed
to be in the range (0-1).

`update(self, props)`

Update this artist’s properties from the dictionary props.

`update_from(self, other)`

copy properties from other to self

`update_scalarmappable(self)`

Update colors from the scalar mappable array, if it is not None.

`zorder = 0`

`class matplotlib.collections.BrokenBarHCollection(xranges, yrange, **kwargs)`

Bases: matplotlib.collections.PolyCollection

A collection of horizontal bars spanning yrange with a sequence of xranges.

`xranges` sequence of (xmin, xwidth)

`yrange` ymin, ywidth

Valid Collection keyword arguments:

- `edgecolors`: None
- `facecolors`: None
- `linewidths`: None
• antialiaseds: None
• offsets: None
• transOffset: transforms.IdentityTransform()
• norm: None (optional for matplotlib.cm.ScalarMappable)
• cmap: None (optional for matplotlib.cm.ScalarMappable)

offsets and transOffset are used to translate the patch after rendering (default no offsets)

If any of edgecolors, facecolors, linewidths, antialiaseds are None, they default to their matplotlib.rcParams patch setting, in sequence form.

add_callback(self, func)
Add a callback function that will be called whenever one of the Artist's properties changes.

Parameters

func [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where artist is the calling Artist. Return values may exist but are ignored.

Returns

oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

See also:

remove_callback

add_checker(self, checker)
Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

aname

autoscale(self)
Autoscale the scalar limits on the norm instance using the current array

autoscale_None(self)
Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

axes
The Axes instance the artist resides in, or None.

changed(self)
Call this whenever the mappable is changed to notify all the callback listeners to the 'changed' signal

check_update(self, checker)
If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
Test whether the mouse event occurred in the collection.
Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

**convert_xunits**(self, x)
Convert x using the unit type of the xaxis.

If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

**convert_yunits**(self, y)
Convert y using the unit type of the yaxis.

If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.

**draw**(self, renderer)
Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (Artist.get_visible is False).

**Parameters**

renderer [RendererBase subclass.]

**findobj**(self, match=None, include_self=True)
Find artist objects.

Recursively find all Artist instances contained in the artist.

**Parameters**

match A filter criterion for the matches. This can be

• None: Return all objects contained in artist.

• A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns True.

• A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

include_self [bool] Include self in the list to be checked for a match.

**Returns**

artists [list of Artist]

**format_cursor_data**(self, data)
Return a string representation of data.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

get_cursor_data

get_agg_filter(self)
Return filter function to be used for agg filter.
get_alpha(self)
    Return the alpha value used for blending - not supported on all backends

generate_animated(self)
    Return the animated state.

generate_array(self)
    Return the array

generate_capstyle(self)

generate_children(self)
    Return a list of the child Artists of this Artist.

generate_clim(self)
    return the min, max of the color limits for image scaling

generate_clip_box(self)
    Return the clipbox.

generate_clip_on(self)
    Return whether the artist uses clipping.

generate_clip_path(self)
    Return the clip path.

generate_cmap(self)
    return the colormap

generate_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:
    set_contains

generate_cursor_data(self, event)
    Return the cursor data for a given event.

    **Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

    Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

    Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

    The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

    **Parameters**

    event [matplotlib.backend_bases.MouseEvent]

    **See also:**

    format_cursor_data
get_dashes(self)
    Alias for get_linestyle.

get_dataLim(self, transData)

get_ec(self)
    Alias for get_edgecolor.

get_edgecolor(self)

get_edgecolors(self)
    Alias for get_edgecolor.

get_facecolor(self)

get_facecolors(self)
    Alias for get_facecolor.

gf(self)
    Alias for get_facecolor.

gf(self)
    Return the Figure instance the artist belongs to.

g_fill(self)
    return whether fill is set

g_gid(self)
    Return the group id.

g_hatch(self)
    Return the current hatching pattern.

g_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.
    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname,
    bbox_inches='tight').

g_joinstyle(self)

g_label(self)
    Return the label used for this artist in the legend.

g_linestyle(self)

g_linestyles(self)
    Alias for get_linestyle.

g_linewidth(self)

g_linewidths(self)
    Alias for get_linewidth.

g_ls(self)
    Alias for get_linestyle.

g_lw(self)
    Alias for get_linewidth.

g_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen',
    the offset is applied after the master transform has been applied, that is, the offsets
    are in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.
get_offset_transform(self)

detect_offsets(self)
    Return the offsets for the collection.
get_path_effects(self)
get_paths(self)
get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.
            See also:
                set_picker, pickable, pick

detect_pickradius(self)
detect_rasterized(self)
    Return whether the artist is to be rasterized.
detect_sizes(self)
    Returns the sizes of the elements in the collection. The value represents the ‘area’
    of the element.

    Returns

    sizes [array] The ‘area’ of each element.

detect_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns

    sketch_params [tuple or None] A 3-tuple with the following elements:
        • scale: The amplitude of the wiggle perpendicular to the source line.
        • length: The length of the wiggle along the line.
        • randomness: The scale factor by which the length is shrunken or expanded.

    Returns None if no sketch parameters were set.
detect_snap(self)
    Returns the snap setting.
    See set_snap for details.
detect_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters

    renderer [RendererBase instance] renderer that will be used to draw the
    figures (i.e. fig.canvas.get_renderer())

    Returns

    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

detect_transform(self)
    Return the Transform instance used by this artist.
get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the
    remaining affine part of its transformation.

get.transforms(self)

get_url(self)
    Return the url.

get_urls(self)

get_visible(self)
    Return the visibility.

get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box’ width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box “tight” calculation.
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window
    extent of the artist changes. The extent can change due to any changes in the transform
    stack, such as changing the axes limits, the figure size, or the canvas used (as is
    done when saving a figure). This can lead to unexpected behavior where interactive
    figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
    Return the artist’s zorder.

have_units(self)
    Return True if units are set on the x or y axes.

is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.

mouseover

pchanged(self)
    Call all of the registered callbacks.
    This function is triggered internally when a property is changed.

    See also:

    add_callback

    remove_callback

pick(self, mouseevent)
    Process a pick event.
    Each child artist will fire a pick event if mouseevent is over the artist and the artist
    has picker set.

    See also:

    set_picker, get_picker, pickable
pickable(self)
    Return whether the artist is pickable.

    See also:
    
    set_picker, get_picker, pick

properties(self)
    Return a dictionary of all the properties of the artist.

remove(self)
    Remove the artist from the figure if possible.
    
    The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
    draw_idle. Call relim to update the axes limits if desired.
    
    Note: relim will not see collections even if the collection was added to the axes with
    autolim = True.
    
    Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
    Remove a callback based on its observer id.

    See also:
    
    add_callback

set(self, **kwargs)
    A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
    Alias for set_antialiased.

set_agg_filter(self, filter_func)
    Set the agg filter.

    Parameters
    
    filter_func [callable] A filter function, which takes a (m, n, 3) float array
    and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
    Set the alpha transparencies of the collection.

    Parameters
    
    alpha [float or None]

set_animated(self, b)
    Set the artist’s animation state.

    Parameters
    
    b [bool]

set_antialiased(self, aa)
    Set the antialiasing state for rendering.

    Parameters
    
    aa [bool or sequence of bools]
set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    **Parameters**

    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

    **Parameters**

    cs [{‘butt’, ‘round’, ‘projecting’}] The capstyle

set_clim(self, vmin=None, vmax=None)
    Set the norm limits for image scaling; if vmin is a length 2 sequence, interpret it as
    (vmin, vmax) which is used to support setp

    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
    vmin and vmax kwargs.

set_clip_box(self, clipbox)
    Set the artist’s clip Bbox.

    **Parameters**

    clipbox [Bbox]

set_clip_on(self, b)
    Set whether the artist uses clipping.

    When False artists will be visible out side of the axes which can lead to unexpected
    results.

    **Parameters**

    b [bool]

set_clip_path(self, path, transform=None)
    Set the artist’s clip path, which may be:
    • a Patch (or subclass) instance; or
    • a Path instance, in which case a Transform instance, which will be applied to the
      path before using it for clipping, must be provided; or
    • None, to remove a previously set clipping path.

    For efficiency, if the path happens to be an axis-aligned rectangle, this method will
    set the clipping box to the corresponding rectangle and set the clipping path to None.

    ACCEPTS: [(Path, Transform) | Patch | None]

set_cmap(self, cmap)
    set the colormap for luminance data

    **Parameters**

    cmap [colormap or registered colormap name]

set_color(self, c)
    Set both the edgecolor and the facecolor.

    **Parameters**

    c [color]
See also:

*Collection.set_facecolor*, *Collection.set_edgecolor* For setting the edge or face color individually.

**set_contains**(self, picker)
Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

**set_dashes**(self, ls)
Alias for `set_linestyle`.

**set_ec**(self, c)
Alias for `set_edgecolor`.

**set_edgecolor**(self, c)
Set the edgecolor(s) of the collection.

**Parameters**

- **c** [color or sequence of colors or ‘face’] The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

**set_edgecolors**(self, c)
Alias for `set_edgecolor`.

**set_facecolor**(self, c)
Set the facecolor(s) of the collection. *c* can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If *c* is ‘none’, the patch will not be filled.

**Parameters**

- **c** [color or sequence of colors]

**set_facecolors**(self, c)
Alias for `set_facecolor`.

**set_fc**(self, c)
Alias for `set_facecolor`.

**set_figure**(self, fig)
Set the *Figure* instance the artist belongs to.
Paramaters

fig [Figure]

set_gid(self, gid)
Set the (group) id for the artist.

Parameters

gid [str]

set_hatch(self, hatch)
Set the hatching pattern

hatch can be one of:

/ - diagonal hatching
\ - back diagonal
| - vertical
- - horizontal
+ - crossed
x - crossed diagonal
o - small circle
O - large circle
. - dots
* - stars

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

Parameters

hatch [{', ', '\', '|', '-', '+', 'x', 'o', 'O', '(', ')', '/*'}]

set_in_layout(self, in_layout)
Set if artist is to be included in layout calculations, E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight')

Parameters

in_layout [bool]

set_joindstyle(self, js)
Set the joindstyle for the collection (for all its elements).

Parameters

js [{‘miter’, ‘round’, ‘bevel’}] The joindstyle

set_label(self, s)
Set a label that will be displayed in the legend.

Parameters

s [object] s will be converted to a string by calling str.

set_linestyle(self, ls)
Set the linestyle(s) for the collection.
Alternatively a dash tuple of the following form can be provided:

\[(offset, on-off-seq),\]

where on-off-seq is an even length tuple of on and off ink in points.

**Parameters**

- `ls` [`'-', '-', '-', '-', ':', (offset, on-off-seq), ...] The line style.

**set_linestyles**

- `self, ls`
  - Alias for `set_linestyle`.

**set_linewidth**

- `self, lw`
  - Set the linewidth(s) for the collection. `lw` can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence

**Parameters**

- `lw` [float or sequence of floats]

**set_linewidths**

- `self, lw`
  - Alias for `set_linewidth`.

**set_ls**

- `self, ls`
  - Alias for `set_linestyle`.

**set_lw**

- `self, lw`
  - Alias for `set_linewidth`.

**set_norm**

- `self, norm`
  - Set the normalization instance.

**Parameters**

- `norm` [Normalize]

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

**set_offset_position**

- `self, offset_position`
  - Set how offsets are applied. If `offset_position` is ‘screen’ (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is ‘data’, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- `offset_position` [{‘screen’, ‘data’}]

**set_offsets**

- `self, offsets`
  - Set the offsets for the collection.
Parameters

**offsets** [float or sequence of floats]

`set_path_effects(self, path_effects)`
Set the path effects.

Parameters

**path_effects** [AbstractPathEffect]

`set_paths(self, verts, closed=True)`
This allows one to delay initialization of the vertices.

**set_picker(self, picker)**
Define the picking behavior of the artist.

Parameters

**picker** [None or bool or float or callable] This can be one of the following:

- None: Picking is disabled for this artist (default).
- A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
- A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
- A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. if the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes.

`set_pickradius(self, pr)`
Set the pick radius used for containment tests.

Parameters

**d** [float] Pick radius, in points.

`set_rasterized(self, rasterized)`
Force rasterized (bitmap) drawing in vector backend output.
Defaults to None, which implies the backend’s default behavior.

Parameters

**rasterized** [bool or None]

`set_sizes(self, sizes, dpi=72.0)`
Set the sizes of each member of the collection.

Parameters

**sizes** [ndarray or None] The size to set for each element of the collection.
The value is the ‘area’ of the element.
dpi [float] The dpi of the canvas. Defaults to 72.0.

set_sketch_params(self, scale=None, length=None, randomness=None)
Sets the sketch parameters.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.

length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

randomness [float, optional] The scale factor by which the length is shrunk or expanded (default 16.0)

set_snap(self, snap)
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

snap [bool or None] Possible values:
• True: Snap vertices to the nearest pixel center.
• False: Do not modify vertex positions.
• None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]

set_url(self, url)
Set the url for the artist.

Parameters

url [str]

set_urls(self, urls)

Parameters

urls [List[str] or None]

set_verts(self, verts, closed=True)
This allows one to delay initialization of the vertices.

set_verts_and_codes(self, verts, codes)
This allows one to initialize vertices with path codes.
set_visible(self, b)
Set the artist’s visibility.

Parameters

  b [bool]

set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters

  level [float]

static span_where(x, ymin, ymax, where, **kwargs)
Create a BrokenBarHCollection to plot horizontal bars from over the regions in x
where where is True. The bars range on the y-axis from ymin to ymax
A BrokenBarHCollection is returned. kwags are passed on to the collection.

stale
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the
internal state of the artist.

sticky_edges
x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corre-
sponding sticky_edges list, then no margin will be added—the view limit “sticks” to
the edge. A typical use case is histograms, where one usually expects no margin on
the bottom edge (0) of the histogram.
This attribute cannot be assigned to; however, the x and y lists can be modified in
place as needed.

Examples

>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)

to_rgba(self, x, alpha=None, bytes=False, norm=True)
Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding
ndarray of rgba values will be returned, based on the norm and colormap set for
this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as
might have been read from an image file. If x is an ndarray with 3 dimensions, and
the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array,
and no mapping will be done. The array can be uint8, or it can be floating point with
values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array,
the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to
1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg
is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if
the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range;
if it is True, the returned rgba array will be uint8 in the 0 to 255 range.
If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

update(self, props)
   Update this artist's properties from the dictionary props.

update_from(self, other)
   copy properties from other to self

update_scalarmappable(self)
   Update colors from the scalar mappable array, if it is not None.

zorder = 0

class matplotlib.collections.CircleCollection(sizes, **kwargs)
   Bases: matplotlib.collections._CollectionWithSizes
   A collection of circles, drawn using splines.

sizes Gives the area of the circle in points^2

Valid Collection keyword arguments:

   •  edgecolors: None
   •  facecolors: None
   •  linewidths: None
   •  antialiaseds: None
   •  offsets: None
   •  transOffset: transforms.IdentityTransform()
   •  norm: None (optional for matplotlib.cm.ScalarMappable)
   •  cmap: None (optional for matplotlib.cm.ScalarMappable)

offsets and transOffset are used to translate the patch after rendering (default no offsets)

If any of edgecolors, facecolors, linewidths, antialiaseds are None, they default to their matplotlib.rcParams patch setting, in sequence form.

add_callback(self, func)
   Add a callback function that will be called whenever one of the Artist's properties changes.

Parameters

func [callable] The callback function. It must have the signature:

   def func(artist: Artist) -> Any

   where artist is the calling Artist. Return values may exist but are ignored.

Returns

oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

See also:

remove_callback
add_checker(self, checker)
    Add an entry to a dictionary of boolean flags that are set to True when the mappable
    is changed.

aname
autoscale(self)
    Autoscale the scalar limits on the norm instance using the current array
autoscale_None(self)
    Autoscale the scalar limits on the norm instance using the current array, changing
    only limits that are None

axes
    The Axes instance the artist resides in, or None.
changed(self)
    Call this whenever the mappable is changed to notify all the callbackSM listeners to
    the ‘changed’ signal
check_update(self, checker)
    If mappable has changed since the last check, return True; else return False
contains(self, mouseevent)
    Test whether the mouse event occurred in the collection.
    Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.
convert_xunits(self, x)
    Convert x using the unit type of the xaxis.
    If the artist is not in contained in an Axes or if the xaxis does not have units, x itself
    is returned.
convert_yunits(self, y)
    Convert y using the unit type of the yaxis.
    If the artist is not in contained in an Axes or if the yaxis does not have units, y itself
    is returned.
draw(self, renderer)
    Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented
to not have any effect if the Artist is not visible (Artist.get_visible is False).

    Parameters
    
    renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
    Find artist objects.
    Recursively find all Artist instances contained in the artist.

    Parameters
    
    match A filter criterion for the matches. This can be
    • None: Return all objects contained in artist.
    • A function with signature def match(artist: Artist) -> bool. The re-
      sult will only contain artists for which the function returns True.
• A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

**include_self** [bool] Include self in the list to be checked for a match.

**Returns**

**artists** [list of Artist]

**format_cursor_data**(self, data)

Return a string representation of data.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

* get_cursor_data

* get_agg_filter(self)
  Return filter function to be used for agg filter.

* get_alpha(self)
  Return the alpha value used for blending - not supported on all backends

* get_animated(self)
  Return the animated state.

* get_array(self)
  Return the array

* get_capstyle(self)

* get_children(self)
  Return a list of the child Artists of this Artist.

* get_clim(self)
  return the min, max of the color limits for image scaling

* get_clip_box(self)
  Return the clipbox.

* get_clip_on(self)
  Return whether the artist uses clipping.

* get_clip_path(self)
  Return the clip path.

* get_cmap(self)
  return the colormap

* get_contains(self)
  Return the custom contains function of the artist if set, or None.

**See also:**

* set_contains
get_cursor_data

Return the cursor data for a given event.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns `None`.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation.

The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

- **event** [matplotlib.backend_bases.MouseEvent]

**See also:**

format_cursor_data

g get_dashes

Alias for get_linestyle.

g get_datalim

get_ec

Alias for get_edgecolor.

g get_edgecolor

g get_edgecolors

Alias for get_edgecolor.

g get_facecolor

g get_facecolors

Alias for get_facecolor.

g get_fc

Alias for get_facecolor.

g get_figure

Return the Figure instance the artist belongs to.

g get_fill

return whether fill is set

g get_gid

Return the group id.

g get_hatch

Return the current hatching pattern.

g in_layout

Return boolean flag, True if artist is included in layout calculations.

E.g. *Constrained Layout Guide*, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

17.15. matplotlib.collections 1297
get_joinstyle(self)
get_label(self)
    Return the label used for this artist in the legend.
get_linestyle(self)
get_linestyles(self)
    Alias for get_linestyle.
get_linewidth(self)
get_linewidths(self)
    Alias for get_linewidth.
get_ls(self)
    Alias for get_linestyle.
get_lw(self)
    Alias for get_linewidth.
get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the
    offset is applied after the master transform has been applied, that is, the offsets are
    in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.
get_offset_transform(self)
get_offsets(self)
    Return the offsets for the collection.
get_path_effects(self)
get_paths(self)
get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.

    See also:

        set_picker, pickle, pick
get_pickradius(self)
get_rasterized(self)
    Return whether the artist is to be rasterized.
get_sizes(self)
    Returns the sizes of the elements in the collection. The value represents the 'area'
    of the element.

    Returns

        sizes [array] The 'area' of each element.
get_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns

        sketch_params [tuple or None] A 3-tuple with the following elements:
• **scale**: The amplitude of the wiggle perpendicular to the source line.
• **length**: The length of the wiggle along the line.
• **randomness**: The scale factor by which the length is shrunken or expanded.

Returns *None* if no sketch parameters were set.

```python
def get_snap(self):
    Returns the snap setting.
    See `set_snap` for details.

def get_tightbbox(self, renderer):
    Like `Artist.get_window_extent`, but includes any clipping.
    
    **Parameters**
    
    renderer : [RendererBase instance] renderer that will be used to draw the figures (i.e. `fig.canvas.get_renderer()`)
    
    **Returns**
    
    bbox : [BBox] The enclosing bounding box (in figure pixel co-ordinates).
```

```python
def get_transform(self):
    Return the `Transform` instance used by this artist.

def get_transformed_clip_path_and_affine(self):
    Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

def get_transforms(self):

def get_url(self):
    Return the url.

def get_urls(self):

def get_visible(self):
    Return the visibility.

def get_window_extent(self, renderer):
    Get the axes bounding box in display space.
    
    The bounding box' width and height are nonnegative.
    
    Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.
    
    Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

def get_zorder(self):
    Return the artist's zorder.

def have_units(self):
    Return `True` if units are set on the x or y axes.

def is_transform_set(self):
    Return whether the Artist has an explicitly set transform.
```
This is True after set_transform has been called.

mouseover

pchanged(self)
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:

add_callback
remove_callback

pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

See also:

set_picker, get_picker, pickable

pickable(self)
Return whether the artist is pickable.

See also:

set_picker, get_picker, pick

properties(self)
Return a dictionary of all the properties of the artist.

remove(self)
Remove the artist from the figure if possible.
The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
draw_idle. Call relim to update the axes limits if desired.

Note: relim will not see collections even if the collection was added to the axes with autolim = True.

Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
Remove a callback based on its observer id.

See also:

add_callback

set(self, **kwargs)
A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
Alias for set_antialiased.

set_agg_filter(self, filter_func)
Set the agg filter.
Parameters

*filter_func* [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

**set_alpha**(*self, alpha*)
Set the alpha transparencies of the collection.

**Parameters**

*alpha* [float or None]

**set_animated**(*self, b*)
Set the artist’s animation state.

**Parameters**

*b* [bool]

**set_antialiased**(*self, aa*)
Set the antialiasing state for rendering.

**Parameters**

*aa* [bool or sequence of bools]

**set_antialiaseds**(*self, aa*)
Alias for set_antialiased.

**set_array**(*self, A*)
Set the image array from numpy array A.

**Parameters**

*A* [ndarray]

**set_capstyle**(*self, cs*)
Set the capstyle for the collection (for all its elements).

**Parameters**

*cs* [{'butt', 'round', 'projecting'}] The capstyle

**set_clim**(*self, vmin=None, vmax=None*)
set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as (vmin, vmax) which is used to support setp

ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have vmin and vmax kwargs.

**set_clip_box**(*self, clipbox*)
Set the artist’s clip Bbox.

**Parameters**

*clipbox* [Bbox]

**set_clip_on**(*self, b*)
Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

*b* [bool]
set_clip_path(self, path, transform=None)
Set the artist’s clip path, which may be:

- a Patch (or subclass) instance; or
- a Path instance, in which case a Transform instance, which will be applied to the path before using it for clipping, must be provided; or
- None, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

set_cmap(self, cmap)
set the colormap for luminance data

Parameters

- cmap [colormap or registered colormap name]

set_color(self, c)
Set both the edgecolor and the facecolor.

Parameters

- c [color or sequence of rgba tuples]

See also:

Collection.set_facecolor, Collection.set_edgecolor For setting the edge or face color individually.

set_contains(self, picker)
Define a custom contains test for the artist.

The provided callable replaces the default contains method of the artist.

Parameters

- picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

set_dashes(self, ls)
Alias for set linestyle.

set_ec(self, c)
Alias for set_edgecolor.

set_edgecolor(self, c)
Set the edgecolor(s) of the collection.

Parameters
The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

```python
set_edgecolors(self, c)
    Alias for set_edgecolor.
```

```python
set_facecolor(self, c)
    Set the facecolor(s) of the collection. c can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.
    If c is ‘none’, the patch will not be filled.
```

**Parameters**

- `c` [color or sequence of colors]

```python
set_facecolors(self, c)
    Alias for set_facecolor.
```

```python
set_fc(self, c)
    Alias for set_facecolor.
```

```python
set_figure(self, fig)
    Set the Figure instance the artist belongs to.
```

**Parameters**

- `fig` [Figure]

```python
set_gid(self, gid)
    Set the (group) id for the artist.
```

**Parameters**

- `gid` [str]

```python
set_hatch(self, hatch)
    Set the hatching pattern
```

```python
hatch can be one of:
```

```
/    - diagonal hatching
\   - back diagonal
|    - vertical
|    - horizontal
+    - crossed
x    - crossed diagonal
o    - small circle
O    - large circle
.    - dots
*    - stars
```

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

**Parameters**

set_in_layout(self, in_layout)
    Set if artist is to be included in layout calculations, E.g. Constrained Layout Guide,
    Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').

    Parameters
    in_layout [bool]

set_joinstyle(self, js)
    Set the joinstyle for the collection (for all its elements).

    Parameters
    js [{‘miter’, ‘round’, ‘bevel’}] The joinstyle

set_label(self, s)
    Set a label that will be displayed in the legend.

    Parameters
    s [object] s will be converted to a string by calling str.

set_linestyle(self, ls)
    Set the linestyle(s) for the collection.

    Parameters
    ls [{‘-‘, ‘–’, ‘-.’, ‘:’, (offset, on-off-seq), ...}] The line style.

set_linestyles(self, ls)
    Alias for set_linestyle.

set_linewidth(self, lw)
    Set the linewidth(s) for the collection. lw can be a scalar or a sequence; if it is a
    sequence the patches will cycle through the sequence

    Parameters
    lw [float or sequence of floats]

set_linewidths(self, lw)
    Alias for set_linewidth.

set_ls(self, ls)
    Alias for set_linestyle.

set_lw(self, lw)
    Alias for set_linewidth.

set_norm(self, norm)
    Set the normalization instance.
Parameters

**norm** [Normalize]

Notes

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

```python
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is 'screen' (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

Parameters

**offset_position** [{'screen', 'data'}]

```python
set_offsets(self, offsets)
```

Set the offsets for the collection.

Parameters

**offsets** [float or sequence of floats]

```python
set_path_effects(self, path_effects)
```

Set the path effects.

Parameters

**path_effects** [AbstractPathEffect]

```python
set_paths(self)
```

```python
set_picker(self, picker)
```

Define the picking behavior of the artist.

Parameters

**picker** [None or bool or float or callable] This can be one of the following:

- *None:* Picking is disabled for this artist (default).
- A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
- A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it's data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
- A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. If the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes.
```
set_pickradius(self, pr)
    Set the pick radius used for containment tests.

    Parameters
    d [float] Pick radius, in points.

set_rasterized(self, rasterized)
    Force rasterized (bitmap) drawing in vector backend output.
    Defaults to None, which implies the backend’s default behavior.

    Parameters
    rasterized [bool or None]

set_sizes(self, sizes, dpi=72.0)
    Set the sizes of each member of the collection.

    Parameters
    sizes [ndarray or None] The size to set for each element of the collection.
    The value is the ‘area’ of the element.
    dpi [float] The dpi of the canvas. Defaults to 72.0.

set_sketch_params(self, scale=None, length=None, randomness=None)
    Sets the sketch parameters.

    Parameters
    scale [float, optional] The amplitude of the wiggle perpendicular to the
    source line, in pixels. If scale is None, or not provided, no sketch filter
    will be provided.
    length [float, optional] The length of the wiggle along the line, in pixels
    (default 128.0)
    randomness [float, optional] The scale factor by which the length is
    shrunken or expanded (default 16.0)

set_snap(self, snap)
    Set the snapping behavior.

    Snapping aligns positions with the pixel grid, which results in clearer images. For
    example, if a black line of 1px width was defined at a position in between two pixels,
    the resulting image would contain the interpolated value of that line in the pixel grid,
    which would be a grey value on both adjacent pixel positions. In contrast, snapping
    will move the line to the nearest integer pixel value, so that the resulting image will
    really contain a 1px wide black line.

    Snapping is currently only supported by the Agg and MacOSX backends.

    Parameters
    snap [bool or None] Possible values:
    • True: Snap vertices to the nearest pixel center.
    • False: Do not modify vertex positions.
    • None: (auto) If the path contains only rectilinear line segments, round
    to the nearest pixel center.

set_transform(self, t)
    Set the artist transform.
```
Parameters
  t [Transform]

set_url(self, url)
  Set the url for the artist.

Parameters
  url [str]

set_urls(self, urls)

Parameters
  urls [List[str] or None]

set_visible(self, b)
  Set the artist’s visibility.

Parameters
  b [bool]

set_zorder(self, level)
  Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters
  level [float]

stale
  Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

sticky_edges
  x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

Examples

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

to_rgba(self, x, alpha=None, bytes=False, norm=True)
  Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with
values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

update(self, props)
    Update this artist’s properties from the dictionary props.

update_from(self, other)
    copy properties from other to self

update_scalarmappable(self)
    Update colors from the scalar mappable array, if it is not None.

zorder = 0

class matplotlib.collections.Collection(edgecolors=None,            facecolors=None,            linewidths=None,            linestyles='solid',            capstyle=None,            joinstyle=None,            antialiaseds=None,            offsets=None,            transOffset=transforms.IdentityTransform(),            offset_position='screen',            zorder=1,            **kwargs)

Bases: matplotlib.artist.Artist, matplotlib.cm.ScalarMappable

Base class for Collections. Must be subclassed to be usable.

All properties in a collection must be sequences or scalars; if scalars, they will be converted to sequences. The property of the ith element of the collection is:

prop[i % len(props)]

Exceptions are capstyle and joinstyle properties, these can only be set globally for the whole collection.

Keyword arguments and default values:

• edgecolors: None
• facecolors: None
• linewidths: None
• linestyles: None
• capstyle: None
• joinstyle: None
• antialiaseds: None
• offsets: None
• transOffset: transforms.IdentityTransform()
• offset_position: ‘screen’ (default) or ‘data’
• norm: None (optional for matplotlib.cm.ScalarMappable)
• cmap: None (optional for matplotlib.cm.ScalarMappable)
• **hatch**: None

• **zorder**: 1

*offsets* and *transOffset* are used to translate the patch after rendering (default no offsets). If offset_position is ‘screen’ (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If offset_position is ‘data’, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

If any of *edgecolors*, *facecolors*, *linewidths*, *antialiaseds* are None, they default to their *matplotlib.rcParams* patch setting, in sequence form.

The use of *ScalarMappable* is optional. If the *ScalarMappable* matrix _A is not None (i.e., a call to *set_array* has been made), at draw time a call to scalar mappable will be made to set the face colors.

Create a Collection

%(*Collection)*

```
def func(artist: Artist) -> Any
```

where *artist* is the calling *Artist*. Return values may exist but are ignored.

**Returns**

*oid* [int] The observer id associated with the callback. This id can be used for removing the callback with *remove_callback* later.

**See also:**

*remove_callback*

```
add_checker(self, checker)
```

Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

```
aname
```

```
autoscale(self)
```

Autoscale the scalar limits on the norm instance using the current array

```
autoscale_None(self)
```

Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

```
axes
```

The *Axes* instance the artist resides in, or *None*.

```
changed(self)
```

Call this whenever the mappable is changed to notify all the callbackSM listeners to the ‘changed’ signal
check_update(self, checker)
    If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
    Test whether the mouse event occurred in the collection.
    Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

convert_xunits(self, x)
    Convert x using the unit type of the xaxis.
    If the artist is not in contained in an Axes or if the xaxis does not have units, x itself
    is returned.

convert_yunits(self, y)
    Convert y using the unit type of the yaxis.
    If the artist is not in contained in an Axes or if the yaxis does not have units, y itself
    is returned.

draw(self, renderer)
    Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented
to have any effect if the Artist is not visible (Artist.get_visible is False).

    Parameters
    renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
    Find artist objects.
    Recursively find all Artist instances contained in the artist.

    Parameters
    match A filter criterion for the matches. This can be
    • None: Return all objects contained in artist.
    • A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns True.
    • A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

    include_self [bool] Include self in the list to be checked for a match.

    Returns
    artists [list of Artist]

format_cursor_data(self, data)
    Return a string representation of data.

    Note: This method is intended to be overridden by artist subclasses. As an end-user
    of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into
a comma-separated string enclosed in square brackets.

See also:
get_cursor_data

get_agg_filter(self)
   Return filter function to be used for agg filter.

get_alpha(self)
   Return the alpha value used for blending - not supported on all backends

get_animated(self)
   Return the animated state.

get_array(self)
   Return the array

get_capstyle(self)

get_children(self)
   Return a list of the child Artists of this Artist.

get_clim(self)
   return the min, max of the color limits for image scaling

get_clip_box(self)
   Return the clipbox.

get_clip_on(self)
   Return whether the artist uses clipping.

get_clip_path(self)
   Return the clip path.

get_cmap(self)
   return the colormap

get_contains(self)
   Return the custom contains function of the artist if set, or None.

See also:

set_contains

get_cursor_data(self, event)
   Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user
of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a
given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when do-
ing so, they must ensure that format_cursor_data can convert the data to a string
representation.

The only current use case is displaying the z-value of an AxesImage in the status bar
of a plot window, while moving the mouse.

Parameters

   event [matplotlib.backend_bases.MouseEvent]
See also:

    format_cursor_data

get_dashes(self)
    Alias for get_linestyle.
get_datalim(self, transData)
get_ec(self)
    Alias for get_edgecolor.
get_edgecolor(self)
get_edgecolors(self)
    Alias for get_edgecolor.
get_facecolor(self)
get_facecolors(self)
    Alias for get_facecolor.
get_fc(self)
    Alias for get_facecolor.
get_facecolors(self)
    Alias for get_facecolor.
get_facecolor(self)
gec
    Alias for get_edgecolor.
get_ec
    Alias for get_edgecolor.
get_figure(self)
    Return the Figure instance the artist belongs to.
get_fill(self)
    return whether fill is set
get_gid(self)
    Return the group id.
get_hatch(self)
    Return the current hatching pattern.
get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.
    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').
gej
get_joinstyle(self)
get_label(self)
    Return the label used for this artist in the legend.
gej
get_linestyle(self)
gej
get_linestyles(self)
    Alias for get_linestyle.
gej
get_linewidth(self)
gej
get_linewidths(self)
    Alias for get_linewidth.
gej
get_ls
    Alias for get_linestyle.
gej
get_lw
    Alias for get_linewidth.
get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the
    offset is applied after the master transform has been applied, that is, the offsets are
    in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
    Return the offsets for the collection.

get_path_effects(self)

get_paths(self)

get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.

    See also:
    set_picker, pickable, pick

get_pickradius(self)

get_rasterized(self)
    Return whether the artist is to be rasterized.

get_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns
    sketch_params [tuple or None] A 3-tuple with the following elements:
        • scale: The amplitude of the wiggle perpendicular to the source line.
        • length: The length of the wiggle along the line.
        • randomness: The scale factor by which the length is shrunken or expanded.
    Returns None if no sketch parameters were set.

get_snap(self)
    Returns the snap setting.
    See set_snap for details.

get_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters
    renderer [RendererBase instance] renderer that will be used to draw the
    figures (i.e. fig.canvas.get_renderer())

    Returns
    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
    Return the Transform instance used by this artist.
get_transformed_clip_path_and_affine(self)
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

get_transforms(self)

get_url(self)
Return the url.

get_urls(self)

get_visible(self)
Return the visibility.

get_window_extent(self, renderer)
Get the axes bounding box in display space.
The bounding box' width and height are nonnegative.
Subclasses should override for inclusion in the bounding box "tight" calculation. Default is to return an empty bounding box at 0, 0.

Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
Return the artist's zorder.

have_units(self)
Return True if units are set on the x or y axes.

is_transform_set(self)
Return whether the Artist has an explicitly set transform.
This is True after set_transform has been called.

mouseover

pchanged(self)
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:

add_callback
remove_callback

pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

See also:

set_picker, get_picker, pickable
pickable(self)
    Return whether the artist is pickable.

See also:
    set_picker, get_picker, pick

properties(self)
    Return a dictionary of all the properties of the artist.

remove(self)
    Remove the artist from the figure if possible.
    The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.draw_idle. Call relim to update the axes limits if desired.
    Note: relim will not see collections even if the collection was added to the axes with autolim = True.
    Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
    Remove a callback based on its observer id.

See also:
    add_callback

set(self, **kwargs)
    A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
    Alias for set_antialiased.

set_agg_filter(self, filter_func)
    Set the agg filter.

    Parameters
    
    filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
    Set the alpha transparencies of the collection.

    Parameters
    
    alpha [float or None]

set_animated(self, b)
    Set the artist’s animation state.

    Parameters
    
    b [bool]

set_antialiased(self, aa)
    Set the antialiasing state for rendering.

    Parameters
    
    aa [bool or sequence of bools]
set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

    Parameters
    cs [ {'butt', 'round', 'projecting'} ] The capstyle

set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if vmin is a length 2 sequence, interpret it as
    (vmin, vmax) which is used to support setp

    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
    vmin and vmax kwargs.

set_clip_box(self, clipbox)
    Set the artist's clip Bbox.

    Parameters
    clipbox [ Bbox ]

set_clip_on(self, b)
    Set whether the artist uses clipping.

    When False artists will be visible out side of the axes which can lead to unexpected
    results.

    Parameters
    b [bool]

set_clip_path(self, path, transform=None)
    Set the artist's clip path, which may be:
    - a Patch (or subclass) instance; or
    - a Path instance, in which case a Transform instance, which will be applied to the
      path before using it for clipping, must be provided; or
    - None, to remove a previously set clipping path.

    For efficiency, if the path happens to be an axis-aligned rectangle, this method will
    set the clipping box to the corresponding rectangle and set the clipping path to None.

    ACCEPTS: [ ( Path, Transform ) | Patch | None ]

set_cmap(self, cmap)
    set the colormap for luminance data

    Parameters
    cmap [ colormap or registered colormap name ]

set_color(self, c)
    Set both the edgecolor and the facecolor.

    Parameters
c [color or sequence of rgba tuples]

See also:

Collection.set_facecolor, Collection.set_edgecolor For setting the edge or face color individually.

set_contains(self, picker)
    Define a custom contains test for the artist.
    
    The provided callable replaces the default contains method of the artist.

    Parameters

        picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

        def contains(artist: Artist, event: MouseEvent) -> bool, dict

    that returns:

    • a bool indicating if the event is within the artist
    • a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

set_dashes(self, ls)
    Alias for set_linestyle.

set_ec(self, c)
    Alias for set_edgecolor.

set_edgecolor(self, c)
    Set the edgecolor(s) of the collection.

    Parameters

        c [color or sequence of colors or ‘face’] The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

set_edgecolors(self, c)
    Alias for set_edgecolor.

set_facecolor(self, c)
    Set the facecolor(s) of the collection. c can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

    If c is ‘none’, the patch will not be filled.

    Parameters

        c [color or sequence of colors]

set_facecolors(self, c)
    Alias for set_facecolor.

set_fc(self, c)
    Alias for set_facecolor.

set_figure(self, fig)
    Set the Figure instance the artist belongs to.
Parameters

    fig [Figure]

set_gid(self, gid)
    Set the (group) id for the artist.

Parameters

    gid [str]

set_hatch(self, hatch)
    Set the hatching pattern

    hatch can be one of:

```
/ - diagonal hatching
\ - back diagonal
| - vertical
- - horizontal
+ - crossed
x - crossed diagonal
o - small circle
O - large circle
. - dots
* - stars
```

Letters can be combined, in which case all the specified hatchings are done. If same
letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified
for the collection as a whole, not separately for each member.

Parameters

set_in_layout(self, in_layout)
    Set if artist is to be included in layout calculations, E.g. Constrained Layout Guide,
    Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').

Parameters

    in_layout [bool]

set_joinstyle(self, js)
    Set the joinstyle for the collection (for all its elements).

Parameters

    js [{‘miter’, ‘round’, ‘bevel’}] The joinstyle

set_label(self, s)
    Set a label that will be displayed in the legend.

Parameters

    s [object] s will be converted to a string by calling str.

set_linestyle(self, ls)
    Set the linestyle(s) for the collection.
<table>
<thead>
<tr>
<th>linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-' or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--' or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-' or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>':' or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:

```
(offset, onoffseq),
```

where onoffseq is an even length tuple of on and off ink in points.

**Parameters**

- `ls` [{',', '–', '−', '·', 'ⁿ'}, (offset, on-off-seq), ...]} The line style.

**Examples**

```python
set_linestyles(self, ls)
```

Alias for `set_linestyle`.

```python
set_linewidths(self, lw)
```

Alias for `set_linewidth`.

```python
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is 'screen' (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

**Examples**

```python
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is 'screen' (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Examples**

```python
set_offset_position(self, offset_position)
```

Set the offsets for the collection.
Parameters

offsets [float or sequence of floats]

set_path_effects(self, path_effects)
    Set the path effects.

Parameters

path_effects [AbstractPathEffect]

set_paths(self)

set_picker(self, picker)
    Define the picking behavior of the artist.

Parameters

picker [None or bool or float or callable]
    This can be one of the following:
    • None: Picking is disabled for this artist (default).
    • A boolean: If True then picking will be enabled and the artist will fire
      a pick event if the mouse event is over the artist.
    • A float: If picker is a number it is interpreted as an epsilon toler-
      ance in points and the artist will fire off an event if it's data is within
      epsilon of the mouse event. For some artists like lines and patch col-
      lections, the artist may provide additional data to the pick event that
      is generated, e.g., the indices of the data within epsilon of the pick
      event
    • A function: If picker is callable, it is a user supplied function which
      determines whether the artist is hit by the mouse event:

        hit, props = picker(artist, mouseevent)

to determine the hit test. If the mouse event is over the artist, return
hit=True and props is a dictionary of properties you want added to
the PickEvent attributes.

set_pickradius(self, pr)
    Set the pick radius used for containment tests.

Parameters

d [float] Pick radius, in points.

set_rasterized(self, rasterized)
    Force rasterized (bitmap) drawing in vector backend output.
    Defaults to None, which implies the backend's default behavior.

Parameters

rasterized [bool or None]

set_sketch_params(self, scale=None, length=None, randomness=None)
    Sets the sketch parameters.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the
    source line, in pixels. If scale is None, or not provided, no sketch filter
    will be provided.
**length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

**randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

**set_snap(self, snap)**
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

**snap** [bool or None] Possible values:
- *True*: Snap vertices to the nearest pixel center.
- *False*: Do not modify vertex positions.
- *None*: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

**set_transform(self, t)**
Set the artist transform.

**Parameters**

**t** [Transform]

**set_url(self, url)**
Set the url for the artist.

**Parameters**

**url** [str]

**set_urls(self, urls)**

**Parameters**

**urls** [List[str] or None]

**set_visible(self, b)**
Set the artist’s visibility.

**Parameters**

**b** [bool]

**set_zorder(self, level)**
Set the zorder for the artist. Artists with lower zorder values are drawn first.

**Parameters**

**level** [float]

**stale**
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
**sticky_edges**

x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit "sticks" to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

**Examples**

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

to_rgba(self, x, alpha=None, bytes=False, norm=True)

Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

**update**(self, props)

Update this artist's properties from the dictionary props.

**update_from**(self, other)

copy properties from other to self

**update_scalarmappable**(self)

Update colors from the scalar mappable array, if it is not None.

zorder = 0

class matplotlib.collections.EllipseCollection(widths, heights, angles, units='points', **kwargs)

Bases: matplotlib.collections.Collection

A collection of ellipses, drawn using splines.

**Parameters**

- **widths** [array-like] The lengths of the first axes (e.g., major axis lengths).
**heights** [array-like] The lengths of second axes.

**angles** [array-like] The angles of the first axes, degrees CCW from the x-axis.

**units** [{'points', 'inches', 'dots', 'width', 'height', 'x', 'y', 'xy'}] The units in which majors and minors are given; 'width' and 'height' refer to the dimensions of the axes, while 'x' and 'y' refer to the offsets data units. 'xy' differs from all others in that the angle as plotted varies with the aspect ratio, and equals the specified angle only when the aspect ratio is unity. Hence it behaves the same as the *Ellipse* with *axes.transData* as its transform.

**Other Parameters**

**kwargs** Additional kwargs inherited from the base *Collection*.

Valid Collection keyword arguments:

- *edgecolors*: None
- *facecolors*: None
- *linewidths*: None
- *antialiaseds*: None
- *offsets*: None
- *transOffset*: *transforms.IdentityTransform()*
- *norm*: None (optional for *matplotlib.cm.ScalarMappable*)
- *cmap*: None (optional for *matplotlib.cm.ScalarMappable*)

*offsets* and *transOffset* are used to translate the patch after rendering (default no offsets)

If any of *edgecolors*, *facecolors*, *linewidths*, *antialiaseds* are None, they default to their *matplotlib.rcParams* patch setting, in sequence form.

add_callback(self, func)

Add a callback function that will be called whenever one of the *Artist*’s properties changes.

**Parameters**

**func** [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where *artist* is the calling *Artist*. Return values may exist but are ignored.

**Returns**

**oid** [int] The observer id associated with the callback. This id can be used for removing the callback with *remove_callback* later.

**See also:**

*remove_callback*
add_checker(self, checker)
    Add an entry to a dictionary of boolean flags that are set to True when the mappable
    is changed.

aname
autoscale(self)
    Autoscale the scalar limits on the norm instance using the current array
autoscale_None(self)
    Autoscale the scalar limits on the norm instance using the current array, changing
    only limits that are None

axes
    The Axes instance the artist resides in, or None.
changed(self)
    Call this whenever the mappable is changed to notify all the callbackSM listeners to
    the ‘changed’ signal
check_update(self, checker)
    If mappable has changed since the last check, return True; else return False
contains(self, mouseevent)
    Test whether the mouse event occurred in the collection.
    Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.
convert_xunits(self, x)
    Convert x using the unit type of the xaxis.
    If the artist is not in contained in an Axes or if the xaxis does not have units, x itself
    is returned.
convert_yunits(self, y)
    Convert y using the unit type of the yaxis.
    If the artist is not in contained in an Axes or if the yaxis does not have units, y itself
    is returned.
draw(self, renderer)
    Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented
to not have any effect if the Artist is not visible (Artist.get_visible is False).

Parameters
    renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
    Find artist objects.
    Recursively find all Artist instances contained in the artist.

Parameters
    match A filter criterion for the matches. This can be
        • None: Return all objects contained in artist.
        • A function with signature def match(artist: Artist) -> bool. The re-
          sult will only contain artists for which the function returns True.
• A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

**include_self**  [bool] Include self in the list to be checked for a match.

**Returns**

**artists**  [list of Artist]

**format_cursor_data**  *(self, data)*

Return a string representation of *data*.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

**get_cursor_data**

**get_agg_filter**(self)

Return filter function to be used for agg filter.

**get_alpha***(self)*

Return the alpha value used for blending - not supported on all backends

**get_animated**(self)

Return the animated state.

**get_array**(self)

Return the array

**get_capstyle**(self)

Return a list of the child Artists of this Artist.

**get_clim**(self)

return the min, max of the color limits for image scaling

**get_clip_box**(self)

Return the clipbox.

**get_clip_on**(self)

Return whether the artist uses clipping.

**get_clip_path**(self)

Return the clip path.

**get_cmap**(self)

return the colormap

**get_contains**(self)

Return the custom contains function of the artist if set, or None.

**See also:**

**set_contains**
get_cursor_data(self, event)
    Return the cursor data for a given event.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

**Parameters**

- **event**: [matplotlib.backend_bases.MouseEvent]

  See also:

  format_cursor_data

get_dashes(self)
    Alias for get_linestyle.

get_datalim(self, transData)

get_ec(self)
    Alias for get_edgecolor.

get_edgecolor(self)

get_edgecolors(self)
    Alias for get_edgecolor.

get_facecolor(self)

get_facecolors(self)
    Alias for get_facecolor.

get_fc(self)
    Alias for get_facecolor.

get_figure(self)
    Return the Figure instance the artist belongs to.

get_fill(self)
    return whether fill is set

get_gid(self)
    Return the group id.

get_hatch(self)
    Return the current hatching pattern.

get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.

    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').
get_joinstyle(self)

get_label(self)
    Return the label used for this artist in the legend.

get_linestyle(self)

get_linestyles(self)
    Alias for get_linestyle.

get_linewidth(self)

get_linewidths(self)
    Alias for get_linewidth.

get_ls(self)
    Alias for get_linestyle.

get_lw(self)
    Alias for get_linewidth.

get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If offset_position is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
    Return the offsets for the collection.

get_path_effects(self)

get_paths(self)

get_picker(self)
    Return the picking behavior of the artist.

    The possible values are described in set_picker.

    See also:

    set_picker, pickable, pick

get_pickradius(self)

get_rasterized(self)
    Return whether the artist is to be rasterized.

get_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns

    sketch_params [tuple or None] A 3-tuple with the following elements:
        • scale: The amplitude of the wiggle perpendicular to the source line.
        • length: The length of the wiggle along the line.
        • randomness: The scale factor by which the length is shrunken or expanded.

    Returns None if no sketch parameters were set.
get_snap(self)
    Returns the snap setting.
    See set_snap for details.

get_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters
    renderer [RendererBase instance] renderer that will be used to draw the
    figures (i.e. fig.canvas.get_renderer())

    Returns
    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
    Return the Transform instance used by this artist.

get_transposed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the
    remaining affine part of its transformation.

get_transforms(self)

get_url(self)
    Return the url.

get_urls(self)

get_visible(self)
    Return the visibility.

g_get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box' width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box "tight" calculation. 
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window
    extent of the artist changes. The extent can change due to any changes in the trans-
    form stack, such as changing the axes limits, the figure size, or the canvas used (as is
    done when saving a figure). This can lead to unexpected behavior where interactive
    figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
    Return the artist's zorder.

have_units(self)
    Return True if units are set on the x or y axes.

is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.

mouseover

pchanged(self)
    Call all of the registered callbacks.
    This function is triggered internally when a property is changed.
See also:

add_callback
remove_callback

pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.
See also:

set_picker, get_picker, pickable

pickable(self)
Return whether the artist is pickable.
See also:

set_picker, get_picker, pick

properties(self)
Return a dictionary of all the properties of the artist.
remove(self)
Remove the artist from the figure if possible.
The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.draw_idle. Call relim to update the axes limits if desired.
Note: relim will not see collections even if the collection was added to the axes with autolim = True.
Note: there is no support for removing the artist’s legend entry.
remove_callback(self, oid)
Remove a callback based on its observer id.
See also:

add_callback

set(self, **kwargs)
A property batch setter. Pass kwargs to set properties.
set_aa(self, aa)
Alias for set_antialiased.
set_agg_filter(self, filter_func)
Set the agg filter.

Parameters

filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
Set the alpha transparencies of the collection.

Parameters
alpha [float or None]

set_animated(self, b)
    Set the artist’s animation state.

    Parameters
    b [bool]

set_antialiased(self, aa)
    Set the antialiasing state for rendering.

    Parameters
    aa [bool or sequence of bools]

set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

    Parameters
    cs [{‘butt’, ‘round’, ‘projecting’}] The capstyle

set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as
    (vmin, vmax) which is used to support setp
    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
    vmin and vmax kwargs.

set_clip_box(self, clipbox)
    Set the artist’s clip Bbox.

    Parameters
    clipbox [Bbox]

set_clip_on(self, b)
    Set whether the artist uses clipping.
    When False artists will be visible out side of the axes which can lead to unexpected
    results.

    Parameters
    b [bool]

set_clip_path(self, path, transform=None)
    Set the artist’s clip path, which may be:
    • a Patch (or subclass) instance; or
    • a Path instance, in which case a Transform instance, which will be applied to the
      path before using it for clipping, must be provided; or
    • None, to remove a previously set clipping path.
For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

**ACCEPTS:** [(Path, Transform) | Patch | None]

```python
set_cmap(self, cmap)
```

set the colormap for luminance data

**Parameters**

- **cmap [colormap or registered colormap name]**

```python
set_color(self, c)
```

Set both the edgecolor and the facecolor.

**Parameters**

- **c [color or sequence of rgba tuples]**

**See also:**

`Collection.set_facecolor, Collection.set_edgecolor` For setting the edge or face color individually.

```python
set_contains(self, picker)
```

Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

- **picker [callable]** A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

```python
set_dashes(self, ls)
```

Alias for `set_linestyle`.

```python
set_ec(self, c)
```

Alias for `set_edgecolor`.

```python
set_edgecolor(self, c)
```

Set the edgecolor(s) of the collection.

**Parameters**

- **c [color or sequence of colors or ‘face’]** The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

```python
set_edgecolors(self, c)
```

Alias for `set_edgecolor`.

```python
set_facecolor(self, c)
```

Set the facecolor(s) of the collection. `c` can be a matplotlib color spec (all patches
have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If c is 'none', the patch will not be filled.

**Parameters**

- **c** [color or sequence of colors]

```python
set_facecolors(self, c)
```

Alias for `set_facecolor`.

```python
set_fc(self, c)
```

Alias for `set_facecolor`.

```python
set_figure(self, fig)
```

Set the `Figure` instance the artist belongs to.

**Parameters**

- **fig** [Figure]

```python
set_gid(self, gid)
```

Set the (group) id for the artist.

**Parameters**

- **gid** [str]

```python
set_hatch(self, hatch)
```

Set the hatching pattern

- **hatch** can be one of:

```
/ - diagonal hatching
\ - back diagonal
| - vertical
- - horizontal
+ - crossed
x - crossed diagonal
o - small circle
O - large circle
. - dots
* - stars
```

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

**Parameters**

- **hatch** [\{ '/', '\', '|', '-', '+', 'x', 'o', 'O', '.', '*\}]

```python
set_in_layout(self, in_layout)
```

Set if artist is to be included in layout calculations, E.g. `Constrained Layout Guide`, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

**Parameters**

- **in_layout** [bool]
**set_joinstyle** *(self, js)*  
Set the joinstyle for the collection (for all its elements).

**Parameters**
- **js** ['miter', 'round', 'bevel'] The joinstyle

**set_label** *(self, s)*  
Set a label that will be displayed in the legend.

**Parameters**
- **s** [object] s will be converted to a string by calling **str**.

**set_linestyle** *(self, ls)*  
Set the linestyle(s) for the collection.

<table>
<thead>
<tr>
<th>linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-' or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--' or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.' or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>':' or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:

```python
( offset, onoffseq),
```

where `onoffseq` is an even length tuple of on and off ink in points.

**Parameters**
- **ls** ['--', ' -', '-..', ':', ' (offset, on-off-seq), ...] The line style.

**set_linestyles** *(self, ls)*  
Alias for **set_linestyle**.

**set_linewidth** *(self, lw)*  
Set the linewidth(s) for the collection. *lw* can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence.

**Parameters**
- **lw** [float or sequence of floats]

**set_linewidths** *(self, lw)*  
Alias for **set_linewidth**.

**set_ls** *(self, ls)*  
Alias for **set_linestyle**.

**set_lw** *(self, lw)*  
Alias for **set_linewidth**.

**set_norm** *(self, norm)*  
Set the normalization instance.

**Parameters**
- **norm** [Normalize]
Notes

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

**set_offset_position** *(self, offset_position)*
Set how offsets are applied. If *offset_position* is ‘screen’ (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If *offset_position* is ‘data’, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- **offset_position** [‘screen’, ‘data’]

**set_offsets** *(self, offsets)*
Set the offsets for the collection.

**Parameters**

- **offsets** [float or sequence of floats]

**set_path_effects** *(self, path_effects)*
Set the path effects.

**Parameters**

- **path_effects** [AbstractPathEffect]

**set_paths** *(self)*

**set_picker** *(self, picker)*
Define the picking behavior of the artist.

**Parameters**

- **picker** [None or bool or float or callable] This can be one of the following:
  - *None*: Picking is disabled for this artist (default).
  - A boolean: If *True* then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
  - A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
  - A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:
    ```python
    hit, props = picker(artist, mouseevent)
    ```
    to determine the hit test. if the mouse event is over the artist, return *hit=True* and props is a dictionary of properties you want added to the PickEvent attributes.

**set_pickradius** *(self, pr)*
Set the pick radius used for containment tests.

**Parameters**
Pick radius, in points.

**set_rasterized**

Force rasterized (bitmap) drawing in vector backend output.

Defaults to `None`, which implies the backend’s default behavior.

**Parameters**

- **rasterized** [bool or None]

**set_sketch_params**

Sets the sketch parameters.

**Parameters**

- **scale** [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is `None`, or not provided, no sketch filter will be provided.
- **length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
- **randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

**set_snap**

Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

- **snap** [bool or None] Possible values:
  - `True`: Snap vertices to the nearest pixel center.
  - `False`: Do not modify vertex positions.
  - `None`: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

**set_transform**

Set the artist transform.

**Parameters**

- **t** [Transform]

**set_url**

Set the url for the artist.

**Parameters**

- **url** [str]

**set_urls**

Parameters
urls [List[str] or None]

set_visible(self, b)
Set the artist’s visibility.

Parameters
b [bool]

set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters
level [float]

stale
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

sticky_edges
x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

Examples

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

to_rgba(self, x, alpha=None, bytes=False, norm=True)
Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).
update(self, props)
    Update this artist’s properties from the dictionary props.

update_from(self, other)
    copy properties from other to self

update_scalarmappable(self)
    Update colors from the scalar mappable array, if it is not None.

zorder = 0
class matplotlib.collections.EventCollection(positions, orientation=None, lineoffset=0, linelength=1, linewidth=None, color=None, linestyle='solid', antialiased=None, **kwargs)

Bases: matplotlib.collections.LineCollection

A collection of discrete events.

The events are given by a 1-dimensional array, usually the position of something along an axis, such as time or length. They do not have an amplitude and are displayed as vertical or horizontal parallel bars.

Parameters

positions [1D array-like object] Each value is an event.

orientation [{None, ‘horizontal’, ‘vertical’}, optional] The orientation of the collection (the event bars are along the orthogonal direction). Defaults to ‘horizontal’ if not specified or None.

lineoffset [scalar, optional, default: 0] The offset of the center of the markers from the origin, in the direction orthogonal to orientation.

linelength [scalar, optional, default: 1] The total height of the marker (i.e. the marker stretches from lineoffset - linelength/2 to lineoffset + linelength/2).

linewidth [scalar or None, optional, default: None] If it is None, defaults to its rcParams setting, in sequence form.

color [color, sequence of colors or None, optional, default: None] If it is None, defaults to its rcParams setting, in sequence form.

linestyle [str or tuple, optional, default: ‘solid’] Valid strings are [‘solid’, ‘dashed’, ‘dashdot’, ‘dotted’, ‘-‘, ‘-’, ‘-‘, ‘-‘, ‘:‘]. Dash tuples should be of the form:

    (offset, onoffseq),

where onoffseq is an even length tuple of on and off ink in points.

antialiased [{None, 1, 2}, optional] If it is None, defaults to its rcParams setting, in sequence form.

**kwargs [optional] Other keyword arguments are line collection properties. See LineCollection for a list of the valid properties.
Examples

add_callback(self, func)

Add a callback function that will be called whenever one of the Artist's properties changes.

Parameters

  func [callable] The callback function. It must have the signature:

  ```python
  def func(artist: Artist) -> Any
  ```

  where artist is the calling Artist. Return values may exist but are ignored.

Returns

  oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

See also:

remove_callback

add_checker(self, checker)

Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.
add_positions(self, position)
    add one or more events at the specified positions

append_positions(self, position)
    add one or more events at the specified positions

autoscale(self)
    Autoscale the scalar limits on the norm instance using the current array

autoscale_None(self)
    Autoscale the scalar limits on the norm instance using the current array, changing
    only limits that are None

axes
    The Axes instance the artist resides in, or None.

changed(self)
    Call this whenever the mappable is changed to notify all the callback listeners to
    the 'changed' signal

check_update(self, checker)
    If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
    Test whether the mouse event occurred in the collection.
    Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

convert_xunits(self, x)
    Convert x using the unit type of the xaxis.
    If the artist is not in contained in an Axes or if the xaxis does not have units, x itself
    is returned.

convert_yunits(self, y)
    Convert y using the unit type of the yaxis.
    If the artist is not in contained in an Axes or if the yaxis does not have units, y itself
    is returned.

draw(self, renderer)
    Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented
to not have any effect if the Artist is not visible (Artist.get_visible is False).

    Parameters

    renderer [RendererBase subclass.]

extend_positions(self, position)
    add one or more events at the specified positions

findobj(self, match=None, include_self=True)
    Find artist objects.
    Recursively find all Artist instances contained in the artist.

    Parameters

    match A filter criterion for the matches. This can be
      • None: Return all objects contained in artist.
• A function with signature `def match(artist: Artist) -> bool`. The result will only contain artists for which the function returns `True`.

• A class instance: e.g., `Line2D`. The result will only contain artists of this class or its subclasses (`isinstance` check).

`include_self` [bool] Include `self` in the list to be checked for a match.

**Returns**

`artists` [list of `Artist`]

`format_cursor_data(self, data)`

Return a string representation of `data`.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

`get_cursor_data`

`get_agg_filter(self)`

Return filter function to be used for agg filter.

`get_alpha(self)`

Return the alpha value used for blending - not supported on all backends

`get_animated(self)`

Return the animated state.

`get_array(self)`

Return the array

`get_capstyle(self)`

`get_children(self)`

Return a list of the child `Artist`s of this `Artist`.

`get_clim(self)`

Return the min, max of the color limits for image scaling

`get_clip_box(self)`

Return the clipbox.

`get_clip_on(self)`

Return whether the artist uses clipping.

`get_clip_path(self)`

Return the clip path.

`get_cmap(self)`

Return the colormap

`get_color(self)`

Get the color of the lines used to mark each event

`get_colors(self)`
get_contains(self)
Return the custom contains function of the artist if set, or None.

See also:

set_contains

get_cursor_data(self, event)
Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

Parameters

event [matplotlib.backend_bases.MouseEvent]

See also:

format_cursor_data

get_dashes(self)
Alias for get_linestyle.

get_datalim(self, transData)

get_ec(self)
Alias for get_edgecolor.

get_edgecolor(self)

get_edgecolors(self)
Alias for get_edgecolor.

get_facecolor(self)

get_facecolors(self)
Alias for get_facecolor.

get_fc(self)
Alias for get_facecolor.

get_figure(self)
Return the Figure instance the artist belongs to.

get_fill(self)
return whether fill is set

get_gid(self)
Return the group id.
get_hatch(self)
    Return the current hatching pattern.

get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.

    E.g. *Constrained Layout Guide*, Figure.tight_layout(), and fig.savefig(fname,
         bbox_inches='tight').

get_joinstyle(self)

get_label(self)
    Return the label used for this artist in the legend.

get_linelength(self)
    get the length of the lines used to mark each event

get_lineoffset(self)
    get the offset of the lines used to mark each event

get_linestyle(self)

get_linestyles(self)
    Alias for get_linestyle.

get_linewidth(self)
    Get the width of the lines used to mark each event.

get_linewidths(self)
    Alias for get_linewidth.

get_ls(self)
    Alias for get_linestyle.

get_lw(self)
    Alias for get_linewidth.

get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the
    offset is applied after the master transform has been applied, that is, the offsets are
    in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
    Return the offsets for the collection.

get_orientation(self)
    get the orientation of the event line, may be: [ 'horizontal' | 'vertical' ]

get_path_effects(self)

get_paths(self)

get_picker(self)
    Return the picking behavior of the artist.

    The possible values are described in set_picker.

    See also:

    set_picker, pickable, pick
get_pickradius(self)

get_positions(self)
    return an array containing the floating-point values of the positions

get_rasterized(self)
    Return whether the artist is to be rasterized.

get_segments(self)
    Returns
    segments [list] List of segments in the LineCollection. Each list item contains an array of vertices.

get_sketch_params(self)
    Returns the sketch parameters for the artist.
    Returns
    sketch_params [tuple or None] A 3-tuple with the following elements:
    • scale: The amplitude of the wiggle perpendicular to the source line.
    • length: The length of the wiggle along the line.
    • randomness: The scale factor by which the length is shrunken or expanded.
    Returns None if no sketch parameters were set.

get_snap(self)
    Returns the snap setting.
    See set_snap for details.

get_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters
    renderer [RendererBase instance] renderer that will be used to draw the figures (i.e. fig.canvas.get_renderer())

    Returns
    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
    Return the Transform instance used by this artist.

get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

get_transforms(self)

get_url(self)
    Return the url.

get_urls(self)

get_visible(self)
    Return the visibility.
get_window_extent(self, renderer)
Get the axes bounding box in display space.
The bounding box’ width and height are nonnegative.
Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.
Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
Return the artist’s zorder.

have_units(self)
Return True if units are set on the x or y axes.

is_horizontal(self)
True if the eventcollection is horizontal, False if vertical

is_transform_set(self)
Return whether the Artist has an explicitly set transform.
This is True after set_transform has been called.

mouseover

pchanged(self)
Call all of the registered callbacks.
This function is triggered internally when a property is changed.
See also:
add_callback
remove_callback

pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.
See also:
set_picker, get_picker, pickable

pickable(self)
Return whether the artist is pickable.
See also:
set_picker, get_picker, pick

properties(self)
Return a dictionary of all the properties of the artist.
remove(self)
    Remove the artist from the figure if possible.

    The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
    draw_idle. Call relim to update the axes limits if desired.

    Note: relim will not see collections even if the collection was added to the axes with
    autolim = True.

    Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
    Remove a callback based on its observer id.

    See also:

    add_callback

set(self, **kwargs)
    A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
    Alias for set_antialiased.

set_agg_filter(self, filter_func)
    Set the agg filter.

    Parameters

    filter_func [callable] A filter function, which takes a (m, n, 3) float array
    and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
    Set the alpha transparencies of the collection.

    Parameters

    alpha [float or None]

set_animated(self, b)
    Set the artist’s animation state.

    Parameters

    b [bool]

set_antialiased(self, aa)
    Set the antialiasing state for rendering.

    Parameters

    aa [bool or sequence of bools]

set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters

    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).
**Parameters**

**cs** ['butt', 'round', 'projecting'] The capstyle

**set_clim**(self, vmin=None, vmax=None)
set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as (vmin, vmax) which is used to support setp

ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have vmin and vmax kwargs.

**set_clip_box**(self, clipbox)
Set the artist’s clip Bbox.

**Parameters**

**clipbox** [Bbox]

**set_clip_on**(self, b)
Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

**b** [bool]

**set_clip_path**(self, path, transform=None)
Set the artist’s clip path, which may be:
- a Patch (or subclass) instance; or
- a Path instance, in which case a Transform instance, which will be applied to the path before using it for clipping, must be provided; or
- None, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

**set_cmap**(self, cmap)
set the colormap for luminance data

**Parameters**

**cmap** [colormap or registered colormap name]

**set_color**(self, c)
Set the color(s) of the LineCollection.

**Parameters**

**c** [color or list of colors] Matplotlib color argument (all patches have same color), or a sequence or rgba tuples; if it is a sequence the patches will cycle through the sequence.

**set_contains**(self, picker)
Define a custom contains test for the artist.

The provided callable replaces the default contains method of the artist.

**Parameters**
**picker** [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

```python
set_dashes(self, ls)
    Alias for set_linstyle.

set_ec(self, c)
    Alias for set_edgecolor.

set_edgecolor(self, c)
    Set the edgecolor(s) of the collection.

    **Parameters**
    
    c [color or sequence of colors or ‘face’] The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

set_edgecolors(self, c)
    Alias for set_edgecolor.

set_facecolor(self, c)
    Set the facecolor(s) of the collection. c can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If c is ‘none’, the patch will not be filled.

    **Parameters**
    
    c [color or sequence of colors]

set_facecolors(self, c)
    Alias for set_facecolor.

set_fc(self, c)
    Alias for set_facecolor.

set_figure(self, fig)
    Set the Figure instance the artist belongs to.

    **Parameters**
    
    fig [Figure]

set_gid(self, gid)
    Set the (group) id for the artist.

    **Parameters**
    
    gid [str]

set_hatch(self, hatch)
    Set the hatching pattern

    hatch can be one of:
Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

**Parameters**

- **hatch**
  
  `hatch [{'/', '\', '|', '-', '+', 'x', 'o', 'O', '.', '*'}]`

- **set_in_layout**
  
  `set_in_layout(self, in_layout)`
  
  Set if artist is to be included in layout calculations, E.g. *Constrained Layout Guide*, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

**Parameters**

- **in_layout**
  
  `[bool]`

- **set_joinstyle**
  
  `set_joinstyle(self, js)`
  
  Set the joinstyle for the collection (for all its elements).

**Parameters**

- **js**
  
  `[{'miter', 'round', 'bevel'}]` The joinstyle

- **set_label**
  
  `set_label(self, s)`
  
  Set a label that will be displayed in the legend.

**Parameters**

- **s**
  
  `[object] s will be converted to a string by calling `str`.

- **set_linelength**
  
  `set_linelength(self, linelength)`
  
  set the length of the lines used to mark each event

- **set_lineoffset**
  
  `set_lineoffset(self, lineoffset)`
  
  set the offset of the lines used to mark each event

- **set_linestyle**
  
  `set_linestyle(self, ls)`
  
  Set the linestyle(s) for the collection.

<table>
<thead>
<tr>
<th>linestyle</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-' or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--' or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.' or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>':' or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:
where onoffseq is an even length tuple of on and off ink in points.

**Parameters**

- **ls** [{‘-’, ‘–’, ‘-.’, ‘:’, ”, (offset, on-off-seq), ...}] The line style.

**set_linestyles**(self, ls)
Alias for **set_linestyle**.

**set_linewidth**(self, lw)
Set the linewidth(s) for the collection. lw can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence

**Parameters**

- **lw** [float or sequence of floats]

**set_linewidths**(self, lw)
Alias for **set_linewidth**.

**set_ls**(self, ls)
Alias for **set_linestyle**.

**set_lw**(self, lw)
Alias for **set_linewidth**.

**set_norm**(self, norm)
Set the normalization instance.

**Parameters**

- **norm** [Normalize]

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

**set_offset_position**(self, offset_position)
Set how offsets are applied. If offset_position is ‘screen’ (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If offset_position is ‘data’, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- **offset_position** [{‘screen’, ‘data’}]

**set_offsets**(self, offsets)
Set the offsets for the collection.

**Parameters**

- **offsets** [float or sequence of floats]

**set_orientation**(self, orientation=None)
set the orientation of the event line [ ‘horizontal’ | ‘vertical’ | None ] defaults to ‘horizontal’ if not specified or None
set_path_effects(self, path_effects)

Set the path effects.

Parameters
path_effects [AbstractPathEffect]

set_paths(self, segments)

set_picker(self, picker)

Define the picking behavior of the artist.

Parameters
picker [None or bool or float or callable] This can be one of the following:

• None: Picking is disabled for this artist (default).
• A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
• A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event
• A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

\[
\text{hit, props} = \text{picker(artist, mouseevent)}
\]

to determine the hit test. If the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes.

set_pickradius(self, pr)

Set the pick radius used for containment tests.

Parameters
d [float] Pick radius, in points.

set_positions(self, positions)

set the positions of the events to the specified value

set_rasterized(self, rasterized)

Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

Parameters
rasterized [bool or None]

set_segments(self, segments)

set_sketch_params(self, scale=None, length=None, randomness=None)

Sets the sketch parameters.

Parameters
scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.

length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

randomness [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

set_snap(self, snap)
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

snap [bool or None] Possible values:

- True: Snap vertices to the nearest pixel center.
- False: Do not modify vertex positions.
- None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]

set_url(self, url)
Set the url for the artist.

Parameters

url [str]

set_urls(self, urls)

Parameters

urls [List[str] or None]

set_verts(self, segments)

set_visible(self, b)
Set the artist’s visibility.

Parameters

b [bool]

set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters
level [float]

stale
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

sticky_edges
x and y sticky edge lists for autoscaling.
When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.
This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

Examples

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

switch_orientation(self)
switch the orientation of the event line, either from vertical to horizontal or vice versa

to_rgba(self, x, alpha=None, bytes=False, norm=True)
Return a normalized rgba array corresponding to x.
In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.
There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.
In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.
If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

update(self, props)
Update this artist’s properties from the dictionary props.

update_from(self, other)
copy properties from other to self

update_sclarmappable(self)
Update colors from the scalar mappable array, if it is not None.

zorder = 0
class matplotlib.collections.LineCollection(segments,  
linewidths=None,  
colors=None,  
antialiaseds=None,  
linestyles='solid',  
offsets=None,  
transOffset=None,  
norm=None,  
cmap=None,  
pickradius=5,  
zorder=2,  
facecolors='none', **kwargs)

Bases: matplotlib.collections.Collection

All parameters must be sequences or scalars; if scalars, they will be converted to sequences. The property of the ith line segment is:

prop[i % len(props)]

i.e., the properties cycle if the len of props is less than the number of segments.

Parameters

segments A sequence of (line0, line1, line2), where:

linen = (x0, y0), (x1, y1), ... (xm, ym)

or the equivalent numpy array with two columns. Each line can be a different length.

colors [sequence, optional] A sequence of RGBA tuples (e.g., arbitrary color strings, etc, not allowed).

antialiaseds [sequence, optional] A sequence of ones or zeros.

linestyles [string, tuple, optional] Either one of [ ‘solid’ | ‘dashed’ | ‘dash-dot’ | ‘dotted’ ], or a dash tuple. The dash tuple is:

(offset, onoffseq)

where onoffseq is an even length tuple of on and off ink in points.

norm [Normalize, optional] Normalize instance.

cmap [string or Colormap, optional] Colormap name or Colormap instance.

pickradius [float, optional] The tolerance in points for mouse clicks picking a line. Default is 5 pt.

facecolors [optional] The facecolors of the LineCollection. Default is ‘none’. Setting to a value other than ‘none’ will lead to a filled polygon being drawn between points on each line.

Notes

If linewidths, colors, or antialiaseds is None, they default to their rcParams setting, in sequence form.

If offsets and transOffset are not None, then offsets are transformed by transOffset and applied after the segments have been transformed to display coordinates.

If offsets is not None but transOffset is None, then the offsets are added to the segments before any transformation. In this case, a single offset can be specified as:
and this value will be added cumulatively to each successive segment, so as to produce a set of successively offset curves.

The use of `ScalarMappable` is optional. If the `ScalarMappable` array `_A` is not None (i.e., a call to `set_array()` has been made), at draw time a call to scalar mappable will be made to set the colors.

```python
add_callback(self, func)
```

Add a callback function that will be called whenever one of the `Artist`'s properties changes.

**Parameters**

- `func` [callable] The callback function. It must have the signature:

  ```python
def func(artist: Artist) -> Any
  ```

  where `artist` is the calling `Artist`. Return values may exist but are ignored.

**Returns**

- `oid` [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

**See also:**

- `remove_callback`

```python
add_checker(self, checker)
```

Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

```python
autoscale(self)
```

Autoscale the scalar limits on the norm instance using the current array

```python
autoscale_None(self)
```

Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

```python
axes
```

The `Axes` instance the artist resides in, or `None`.

```python
changed(self)
```

Call this whenever the mappable is changed to notify all the callbackSM listeners to the ‘changed’ signal

```python
check_update(self, checker)
```

If mappable has changed since the last check, return True; else return False

```python
contains(self, mouseevent)
```

Test whether the mouse event occurred in the collection.

Returns `bool`, `dict(ind=itemlist)`, where every item in itemlist contains the event.

```python
convert_xunits(self, x)
```

Convert x using the unit type of the xaxis.
If the artist is not contained in an Axes or if the xaxis does not have units, \( x \) itself is returned.

\[
\text{convert \_ units}(self, y)
\]
Convert \( y \) using the unit type of the yaxis.

If the artist is not contained in an Axes or if the yaxis does not have units, \( y \) itself is returned.

\[
\text{draw}(self, renderer)
\]
Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (\( \text{Artist}.get\_visible \) is \( \text{False} \)).

**Parameters**

- **renderer** [\( \text{RendererBase} \) subclass.]

\[
\text{findobj}(self, match=None, include\_self=True)
\]
Find artist objects.

Recursively find all \( \text{Artist} \) instances contained in the artist.

**Parameters**

- **match** A filter criterion for the matches. This can be
  - \( \text{None} \): Return all objects contained in artist.
  - A function with signature \( \text{def \_ match(artist: \text{Artist}) \rightarrow bool} \). The result will only contain artists for which the function returns \( \text{True} \).
  - A class instance: e.g., \( \text{Line2D} \). The result will only contain artists of this class or its subclasses (\( \text{isinstance} \) check).

- **include\_self** [bool] Include \( self \) in the list to be checked for a match.

**Returns**

- **artists** [list of \( \text{Artist} \)]

\[
\text{format\_cursor\_data}(self, data)
\]
Return a string representation of \( data \).

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

\[
\text{get\_cursor\_data}
\]

\[
\text{get\_agg\_filter}(self)
\]
Return filter function to be used for agg filter.

\[
\text{get\_alpha}(self)
\]
Return the alpha value used for blending - not supported on all backends

\[
\text{get\_animated}(self)
\]
Return the animated state.
get_array(self)
    Return the array

get_capstyle(self)

get_children(self)
    Return a list of the child Artists of this Artist.

get_clim(self)
    return the min, max of the color limits for image scaling

get_clip_box(self)
    Return the clipbox.

get_clip_on(self)
    Return whether the artist uses clipping.

get_clip_path(self)
    Return the clip path.

get_cmap(self)
    return the colormap

get_color(self)

get_colors(self)

get_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:

    set_contains

get_cursor_data(self, event)
    Return the cursor data for a given event.

    Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

    Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

    Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

    The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

    Parameters

    event [matplotlib.backend_bases.MouseEvent]

    See also:

    format_cursor_data

get_dashes(self)
    Alias for get_linestyle.
get_datalim(self, transData)

get_ec(self)
    Alias for get_edgecolor.

get_edgecolor(self)

get_edgecolors(self)
    Alias for get_edgecolor.

get_facecolor(self)

get_facecolors(self)
    Alias for get_facecolor.

gf(self)
    Alias for get_facecolor.

get_facecolor(self)

gfcs(self)
    Alias for get_facecolor.

get_fill(self)
    return whether fill is set

get_gid(self)
    Return the group id.

g_hatch(self)
    Return the current hatching pattern.

get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.
    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname,
    bbox_inches='tight').

get_joinstyle(self)

get_label(self)
    Return the label used for this artist in the legend.

get_linestyle(self)

glss(self)
    Alias for get_linestyle.

get_linewidth(self)

glw(self)
    Alias for get_linewidth.

get_lw(self)
    Alias for get_linewidth.

g_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the
    offset is applied after the master transform has been applied, that is, the offsets are
    in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.

g_offset_transform(self)
get_offsets(self)
    Return the offsets for the collection.

g et_path_effects(self)

g et_paths(self)

g et_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.
    See also:

    set_picker, pickable, pick

g et_pickradius(self)

g et_rasterized(self)
    Return whether the artist is to be rasterized.

g et_segments(self)

    Returns

    segments [list] List of segments in the LineCollection. Each list item
    contains an array of vertices.

g et_s ketch_params(self)
    Returns the sketch parameters for the artist.
    Returns

    sketch_params [tuple or None] A 3-tuple with the following elements:
    • scale: The amplitude of the wiggle perpendicular to the source line.
    • length: The length of the wiggle along the line.
    • randomness: The scale factor by which the length is shrunken or ex-
    panded.
    Returns None if no sketch parameters were set.

g et_snap(self)
    Returns the snap setting.
    See set_snap for details.

g et_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters

    renderer [RendererBase instance] renderer that will be used to draw the
    figures (i.e. fig.canvas.get_renderer())

    Returns

    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

g et_transf orm(self)
    Return the Transform instance used by this artist.
get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the
    remaining affine part of its transformation.

get_transforms(self)

get_url(self)
    Return the url.

get_urls(self)

get_visible(self)
    Return the visibility.

get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box’ width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box “tight” calculation.
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window
    extent of the artist changes. The extent can change due to any changes in the trans-  
    form stack, such as changing the axes limits, the figure size, or the canvas used (as is
    done when saving a figure). This can lead to unexpected behavior where interactive
    figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
    Return the artist’s zorder.

have_units(self)
    Return True if units are set on the x or y axes.

is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.

mouseover

pchanged(self)
    Call all of the registered callbacks.
    This function is triggered internally when a property is changed.

    See also:

    add_callback

    remove_callback

pick(self, mouseevent)
    Process a pick event.
    Each child artist will fire a pick event if mouseevent is over the artist and the artist
    has picker set.

    See also:

    set_picker, get_picker, pickable
Matplotlib, Release 3.1.1

**pickable**(self)
Return whether the artist is pickable.

**See also:**
set_picker, get_picker, pick

**properties**(self)
Return a dictionary of all the properties of the artist.

**remove**(self)
Remove the artist from the figure if possible.

The effect will not be visible until the figure is redrawn, e.g., with `FigureCanvasBase.draw_idle`. Call `relim` to update the axes limits if desired.

Note: `relim` will not see collections even if the collection was added to the axes with `autolim = True`.

Note: there is no support for removing the artist’s legend entry.

**remove_callback**(self, oid)
Remove a callback based on its observer id.

**See also:**
add_callback

**set**(self, **kwargs)
A property batch setter. Pass `kwargs` to set properties.

**set_aa**(self, aa)
Alias for `set_antialiased`.

**set_agg_filter**(self, filter_func)
Set the agg filter.

**Parameters**

`filter_func` [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

**set_alpha**(self, alpha)
Set the alpha transparencies of the collection.

**Parameters**

`alpha` [float or None]

**set_animated**(self, b)
Set the artist’s animation state.

**Parameters**

`b` [bool]

**set_antialiased**(self, aa)
Set the antialiasing state for rendering.

**Parameters**

`aa` [bool or sequence of bools]
set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

    Parameters
    cs [{'butt', 'round', 'projecting'}] The capstyle

set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as
    (vmin, vmax) which is used to support setp

    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
    vmin and vmax kwargs.

set_clip_box(self, clipbox)
    Set the artist's clip Bbox.

    Parameters
    clipbox [Bbox]

set_clip_on(self, b)
    Set whether the artist uses clipping.

    When False artists will be visible out side of the axes which can lead to unexpected
    results.

    Parameters
    b [bool]

set_clip_path(self, path, transform=None)
    Set the artist’s clip path, which may be:
- a Patch (or subclass) instance; or
- a Path instance, in which case a Transform instance, which will be applied to the
  path before using it for clipping, must be provided; or
- None, to remove a previously set clipping path.

    For efficiency, if the path happens to be an axis-aligned rectangle, this method will
    set the clipping box to the corresponding rectangle and set the clipping path to None.

    ACCEPTS: [(Path, Transform) | Patch | None]

set_cmap(self, cmap)
    set the colormap for luminance data

    Parameters
    cmap [colormap or registered colormap name]

set_color(self, c)
    Set the color(s) of the LineCollection.

    Parameters
c [color or list of colors] Matplotlib color argument (all patches have same color), or a sequence or rgba tuples; if it is a sequence the patches will cycle through the sequence.

```
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

set_contains(self, picker)
Define a custom contains test for the artist.
The provided callable replaces the default `contains` method of the artist.

Parameters

**picker** [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

that returns:
• a bool indicating if the event is within the artist
• a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

set_dashes(self, ls)
Alias for `set_linestyle`.

set_ec(self, c)
Alias for `set_edgecolor`.

set_edgecolor(self, c)
Set the edgecolor(s) of the collection.

Parameters

c [color or sequence of colors or 'face'] The collection edgecolor(s). If a sequence, the patches cycle through it. If 'face', match the facecolor.

set_edgecolors(self, c)
Alias for `set_edgecolor`.

set_facecolor(self, c)
Set the facecolor(s) of the collection. `c` can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If `c` is 'none', the patch will not be filled.

Parameters

c [color or sequence of colors]

set_facecolors(self, c)
Alias for `set_facecolor`.

set_fc(self, c)
Alias for `set_facecolor`.

set_figure(self, fig)
Set the `Figure` instance the artist belongs to.

Parameters

**fig** [Figure]
set_gid(self, gid)
    Set the (group) id for the artist.

Parameters
    gid [str]

set_hatch(self, hatch)
    Set the hatching pattern

hatch can be one of:

/  - diagonal hatching
\  - back diagonal
|  - vertical
-  - horizontal
+  - crossed
x  - crossed diagonal
o  - small circle
O  - large circle
.  - dots
*  - stars

Letters can be combined, in which case all the specified hatchings are done. If same
letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified
for the collection as a whole, not separately for each member.

Parameters
    hatch [{'/', '\', '|', '-', '+', 'x', 'o', 'O', '.', '*'}]

set_in_layout(self, in_layout)
    Set if artist is to be included in layout calculations, E.g. Constrained Layout Guide,
    Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').

Parameters
    in_layout [bool]

set_joinstyle(self, js)
    Set the joinstyle for the collection (for all its elements).

Parameters
    js [{'miter', 'round', 'bevel'}] The joinstyle

set_label(self, s)
    Set a label that will be displayed in the legend.

Parameters
    s [object] s will be converted to a string by calling str.

set_linestyle(self, ls)
    Set the linestyle(s) for the collection.
# Matplotlib, Release 3.1.1

<table>
<thead>
<tr>
<th>linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-' or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--' or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.' or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>':' or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:

```
(offset, onoffseq),
```

where `onoffseq` is an even length tuple of on and off ink in points.

**Parameters**

- `ls` [{',-', '-', '-', '-', ':', '', (offset, on-off-seq), ...}] The line style.

```
set_linestyles(self, ls)
```

Alias for `set_linestyle`.

```
set_linewidth(self, lw)
```

Set the linewidth(s) for the collection. `lw` can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence.

**Parameters**

- `lw` [float or sequence of floats]

```
set_linewidths(self, lw)
```

Alias for `set_linewidth`.

```
set_ls(self, ls)
```

Alias for `set_linestyle`.

```
set_lw(self, lw)
```

Alias for `set_linewidth`.

```
set_norm(self, norm)
```

Set the normalization instance.

**Parameters**

- `norm` [Normalize]

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

```
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is 'screen' (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- `offset_position` [{'screen', 'data'}]

```
set_offsets(self, offsets)
```

Set the offsets for the collection.
Parameters

offsets [float or sequence of floats]

set_path_effects(self, path_effects)
Set the path effects.

Parameters

path_effects [AbstractPathEffect]

set_paths(self, segments)

set_picker(self, picker)
Define the picking behavior of the artist.

Parameters

picker [None or bool or float or callable] This can be one of the following:

• None: Picking is disabled for this artist (default).
• A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
• A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event
• A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

hit, props = picker(artist, mouseevent)

to determine the hit test. if the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes.

set_pickradius(self, pr)
Set the pick radius used for containment tests.

Parameters

d [float] Pick radius, in points.

set_rasterized(self, rasterized)
Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

Parameters

rasterized [bool or None]

set_segments(self, segments)

set_sketch_params(self, scale=None, length=None, randomness=None)
Sets the sketch parameters.

Parameters
scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.

length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

randomness [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

set_snap(self, snap)
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

snap [bool or None] Possible values:

- True: Snap vertices to the nearest pixel center.
- False: Do not modify vertex positions.
- None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]

set_url(self, url)
Set the url for the artist.

Parameters

url [str]

set_urls(self, urls)

Parameters

urls [List[str] or None]

set_verts(self, segments)

set_visible(self, b)
Set the artist’s visibility.

Parameters

b [bool]

set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters
level [float]

stale
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the
internal state of the artist.

sticky_edges
x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corre-
sponding sticky_edges list, then no margin will be added—the view limit “sticks” to
the edge. A typical use case is histograms, where one usually expects no margin on
the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in
place as needed.

Examples

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

to_rgba(self, x, alpha=None, bytes=False, norm=True)
Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding
ndarray of rgba values will be returned, based on the norm and colormap set for
this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as
might have been read from an image file. If x is an ndarray with 3 dimensions, and
the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array,
and no mapping will be done. The array can be uint8, or it can be floating point with
values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array,
the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to
1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg
is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if
the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range;
if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed
to be in the range (0-1).

update(self, props)
Update this artist’s properties from the dictionary props.

update_from(self, other)
copy properties from other to self

update_scalarmappable(self)
Update colors from the scalar mappable array, if it is not None.

zorder = 0

class matplotlib.collections.PatchCollection(patches, match_original=False,
**kwargs)

Bases: matplotlib.collections.Collection
A generic collection of patches.
This makes it easier to assign a color map to a heterogeneous collection of patches.
This also may improve plotting speed, since PatchCollection will draw faster than a large number of patches.

**patches** a sequence of Patch objects. This list may include a heterogeneous assortment of different patch types.

**match_original** If True, use the colors and linewidths of the original patches. If False, new colors may be assigned by providing the standard collection arguments, facecolor, edgecolor, linewidths, norm or cmap.

If any of `edgecolors`, `facecolors`, `linewidths`, `antialiaseds` are None, they default to their `matplotlib.rcParams` patch setting, in sequence form.

The use of `ScalarMappable` is optional. If the `ScalarMappable` matrix _A is not None (i.e., a call to set_array has been made), at draw time a call to scalar mappable will be made to set the face colors.

```
def add_callback(self, func)
    Add a callback function that will be called whenever one of the Artist's properties changes.

    Parameters

    func [callable] The callback function. It must have the signature:

        def func(artist: Artist) -> Any

    where artist is the calling Artist. Return values may exist but are ignored.

    Returns

    oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

    See also:

    remove_callback

add_checker(self, checker)
    Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

aname
autoscale(self)
    Autoscale the scalar limits on the norm instance using the current array
autoscale_None(self)
    Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

axes
    The Axes instance the artist resides in, or None.

changed(self)
    Call this whenever the mappable is changed to notify all the callbackSM listeners to the ‘changed’ signal
check_update(self, checker)
    If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
    Test whether the mouse event occurred in the collection.
    Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

convert_xunits(self, x)
    Convert x using the unit type of the xaxis.
    If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

convert_yunits(self, y)
    Convert y using the unit type of the yaxis.
    If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.

draw(self, renderer)
    Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (Artist.get_visible is False).

    Parameters
    ----------
    renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
    Find artist objects.
    Recursively find all Artist instances contained in the artist.

    Parameters
    ----------
    match A filter criterion for the matches. This can be
    • None: Return all objects contained in artist.
    • A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns True.
    • A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

    include_self [bool] Include self in the list to be checked for a match.

    Returns
    -------
    artists [list of Artist]

format_cursor_data(self, data)
    Return a string representation of data.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

See also:
get_cursor_data

get_agg_filter(self)
    Return filter function to be used for agg filter.

get_alpha(self)
    Return the alpha value used for blending - not supported on all backends

get_animated(self)
    Return the animated state.

get_array(self)
    Return the array

get_capstyle(self)

get_children(self)
    Return a list of the child Artists of this Artist.

get_clim(self)
    return the min, max of the color limits for image scaling

get_clip_box(self)
    Return the clipbox.

get_clip_on(self)
    Return whether the artist uses clipping.

g_get_clip_path(self)
    Return the clip path.

get_cmap(self)
    return the colormap

get_contains(self)
    Return the custom contains function of the artist if set, or None.

    See also:

    set_contains

get_cursor_data(self, event)
    Return the cursor data for a given event.

    Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

Parameters

    event [matplotlib.backend_bases.MouseEvent]
See also:

format_cursor_data

get_dashes(self)
   Alias for get_linestyle.
get_datalim(self, transData)
get_ec(self)
   Alias for get_edgecolor.
get_edgecolor(self)
get_edgecolors(self)
   Alias for get_edgecolor.
get_facecolor(self)
get_facecolors(self)
   Alias for get_facecolor.
get_fc(self)
   Alias for get_facecolor.
get_figure(self)
   Return the Figure instance the artist belongs to.
get_fill(self)
   return whether fill is set
get_gid(self)
   Return the group id.
get_hatch(self)
   Return the current hatching pattern.
get_in_layout(self)
   Return boolean flag, True if artist is included in layout calculations.
   E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname,
   bbox_inches='tight').
get_joinstyle(self)
get_label(self)
   Return the label used for this artist in the legend.
get_linestyle(self)
get_linestyles(self)
   Alias for get_linestyle.
get_linewidth(self)
get_linewidths(self)
   Alias for get_linewidth.
get_ls(self)
   Alias for get_linestyle.
get_lw(self)
   Alias for get_linewidth.
get_offset_position(self)
Returns how offsets are applied for the collection. If offset_position is 'screen', the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If offset_position is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
Return the offsets for the collection.

get_path_effects(self)

get_paths(self)

get_picker(self)
Return the picking behavior of the artist.
The possible values are described in set_picker.

See also:
set_picker, pickable, pick

get_pickradius(self)

get_rasterized(self)
Return whether the artist is to be rasterized.

get_sketch_params(self)
Returns the sketch parameters for the artist.

Returns
sketch_params [tuple or None] A 3-tuple with the following elements:
• scale: The amplitude of the wiggle perpendicular to the source line.
• length: The length of the wiggle along the line.
• randomness: The scale factor by which the length is shrunked or expanded.

Returns None if no sketch parameters were set.

get_snap(self)
Returns the snap setting.
See set_snap for details.

get_tightbbox(self, renderer)
Like Artist.get_window_extent, but includes any clipping.

Parameters
renderer [RendererBase instance] renderer that will be used to draw the figures (i.e. fig.canvas.get_renderer())

Returns
bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
Return the Transform instance used by this artist.
get_transformed_clip_path_and_affine(self)
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

get_transforms(self)

get_url(self)
Return the url.

get_urls(self)

get_visible(self)
Return the visibility.

get_window_extent(self, renderer)
Get the axes bounding box in display space.
The bounding box' width and height are nonnegative.
Subclasses should override for inclusion in the bounding box "tight" calculation. Default is to return an empty bounding box at 0, 0.
Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
Return the artist's zorder.

have_units(self)
Return True if units are set on the x or y axes.

is_transform_set(self)
Return whether the Artist has an explicitly set transform.
This is True after set_transform has been called.

mouseover

pchanged(self)
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:

add_callback
remove_callback

pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

See also:

set_picker, get_picker, pickable
pickable(self)
Return whether the artist is pickable.

See also:
set_picker, get_picker, pick

properties(self)
Return a dictionary of all the properties of the artist.

remove(self)
Remove the artist from the figure if possible.
The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
draw_idle. Call relim to update the axes limits if desired.
Note: relim will not see collections even if the collection was added to the axes with
autolim = True.
Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
Remove a callback based on its observer id.

See also:
add_callback

set(self, **kwargs)
A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
Alias for set_antialiased.

set_agg_filter(self, filter_func)
Set the agg filter.

Parameters

filter_func [callable] A filter function, which takes a (m, n, 3) float array
and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
Set the alpha transparencies of the collection.

Parameters

alpha [float or None]

set_animated(self, b)
Set the artist’s animation state.

Parameters

b [bool]

set_antialiased(self, aa)
Set the antialiasing state for rendering.

Parameters

aa [bool or sequence of bools]
set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

    Parameters
    cs [{'butt', 'round', 'projecting'}] The capstyle

set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as
    (vmin, vmax) which is used to support setp

    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
    vmin and vmax kwargs.

set_clip_box(self, clipbox)
    Set the artist’s clip Bbox.

    Parameters
    clipbox [Bbox]

set_clip_on(self, b)
    Set whether the artist uses clipping.

    When False artists will be visible out side of the axes which can lead to unexpected
    results.

    Parameters
    b [bool]

set_clip_path(self, path, transform=None)
    Set the artist’s clip path, which may be:
    • a Patch (or subclass) instance; or
    • a Path instance, in which case a Transform instance, which will be applied to the
      path before using it for clipping, must be provided; or
    • None, to remove a previously set clipping path.

    For efficiency, if the path happens to be an axis-aligned rectangle, this method will
    set the clipping box to the corresponding rectangle and set the clipping path to None.

    ACCEPTS: [(Path, Transform) | Patch | None]

set_cmap(self, cmap)
    set the colormap for luminance data

    Parameters
    cmap [colormap or registered colormap name]

set_color(self, c)
    Set both the edgecolor and the facecolor.

    Parameters
**See also:**

`Collection.set_facecolor`, `Collection.set_edgecolor` For setting the edge or face color individually.

### set_contains

Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

- **picker** [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

### set_dashes

Alias for `set_linestyle`.

### set_ec

Alias for `set_edgecolor`.

### set_edgecolor

Set the edgecolor(s) of the collection.

**Parameters**

- **c** [color or sequence of colors or 'face'] The collection edgecolor(s). If a sequence, the patches cycle through it. If 'face', match the facecolor.

### set_edgecolors

Alias for `set_edgecolor`.

### set_facecolor

Set the facecolor(s) of the collection. `c` can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If `c` is 'none', the patch will not be filled.

**Parameters**

- **c** [color or sequence of colors]

### set_facecolors

Alias for `set_facecolor`.

### set_fc

Alias for `set_facecolor`.

### set_figure

Set the `Figure` instance the artist belongs to.
Parameters

fig [Figure]

set_gid(self, gid)
Set the (group) id for the artist.

Parameters

gid [str]

set_hatch(self, hatch)
Set the hatching pattern

hatch can be one of:

/  - diagonal hatching
\  - back diagonal
|  - vertical
-  - horizontal
+  - crossed
x  - crossed diagonal
O  - small circle
0  - large circle
.  - dots
*  - stars

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

Parameters

hatch [{'/', '\', '|', '-', '+', 'x', 'o', 'O', ',', '*'}]

set_in_layout(self, in_layout)
Set if artist is to be included in layout calculations, E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname, bbox_inches='tight').

Parameters

in_layout [bool]

set_joinstyle(self, js)
Set the joinstyle for the collection (for all its elements).

Parameters

js [{'miter', 'round', 'bevel'}] The joinstyle

set_label(self, s)
Set a label that will be displayed in the legend.

Parameters

s [object] s will be converted to a string by calling str.

set_linestyle(self, ls)
Set the linestyle(s) for the collection.
<table>
<thead>
<tr>
<th>linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'-'</code> or <code>'solid'</code></td>
<td>solid line</td>
</tr>
<tr>
<td><code>'--'</code> or <code>'dashed'</code></td>
<td>dashed line</td>
</tr>
<tr>
<td><code>'-.'</code> or <code>'dashdot'</code></td>
<td>dash-dotted line</td>
</tr>
<tr>
<td><code>':'</code> or <code>'dotted'</code></td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:

```
(offset, onoffseq),
```

where `onoffseq` is an even length tuple of on and off ink in points.

**Parameters**

- `ls` 
  `['-', '-', '-', '-', ',', (offset, on-off-seq), ...]` The line style.

```
set_linestyles(self, ls)
```

Alias for `set_linestyle`.

```
set_linewidth(self, lw)
```

Set the linewidth(s) for the collection. `lw` can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence.

**Parameters**

- `lw` 
  `[float or sequence of floats]`

```
set_linewidths(self, lw)
```

Alias for `set_linewidth`.

```
set_ls(self, ls)
```

Alias for `set_linestyle`.

```
set_lw(self, lw)
```

Alias for `set_linewidth`.

```
set_norm(self, norm)
```

Set the normalization instance.

**Parameters**

- `norm` 
  `[Normalize]`

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

```
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is `screen` (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is `data`, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- `offset_position` 
  `[{'screen', 'data'}]`

```
set_offsets(self, offsets)
```

Set the offsets for the collection.
Parameters

offsets [float or sequence of floats]

set_path_effects(self, path_effects)
Set the path effects.

Parameters

path_effects [AbstractPathEffect]

set_paths(self, patches)

set_picker(self, picker)
Define the picking behavior of the artist.

Parameters

picker [None or bool or float or callable] This can be one of the following:

• None: Picking is disabled for this artist (default).

• A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.

• A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.

• A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```
hit, props = picker(artist, mouseevent)
```
to determine the hit test. if the mouse event is over the artist, return $hit=True$ and props is a dictionary of properties you want added to the PickEvent attributes.

set_pickradius(self, pr)
Set the pick radius used for containment tests.

Parameters

d [float] Pick radius, in points.

set_rasterized(self, rasterized)
Force rasterized (bitmap) drawing in vector backend output.
Defaults to None, which implies the backend’s default behavior.

Parameters

rasterized [bool or None]

set_sketch_params(self, scale=None, length=None, randomness=None)
Sets the sketch parameters.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.
**length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

**randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

```python
set_snap(self, snap)
```
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

**snap** [bool or None] Possible values:

- *True*: Snap vertices to the nearest pixel center.
- *False*: Do not modify vertex positions.
- *None*: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

```python
set_transform(self, t)
```
Set the artist transform.

**Parameters**

**t** [Transform]

```python
set_url(self, url)
```
Set the url for the artist.

**Parameters**

**url** [str]

```python
set_urls(self, urls)
```
Parameters

**urls** [List[str] or None]

```python
set_visible(self, b)
```
Set the artist’s visibility.

**Parameters**

**b** [bool]

```python
set_zorder(self, level)
```
Set the zorder for the artist. Artists with lower zorder values are drawn first.

**Parameters**

**level** [float]

**stale**
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
**sticky_edges**

x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

**Examples**

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

**to_rgba**(self, x, alpha=None, bytes=False, norm=True)

Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

**update**(self, props)

Update this artist’s properties from the dictionary props.

**update_from**(self, other)

copy properties from other to self

**update_scalarmappable**(self)

Update colors from the scalar mappable array, if it is not None.

zorder = 0

**class** matplotlib.collections.PathCollection(paths, sizes=None, **kwargs)

Bases: matplotlib.collections._CollectionWithSizes

This is the most basic Collection subclass. A PathCollection is e.g. created by a scatter() plot.

paths is a sequence of matplotlib.path.Path instances.

Valid Collection keyword arguments:
• `edgecolors`: None
• `facecolors`: None
• `linewdths`: None
• `antialiaseds`: None
• `offsets`: None
• `transOffset`: `transforms.IdentityTransform()`
• `norm`: None (optional for `matplotlib.cm.ScalarMappable`)
• `cmap`: None (optional for `matplotlib.cm.ScalarMappable`)

`offsets` and `transOffset` are used to translate the patch after rendering (default no offsets)

If any of `edgecolors`, `facecolors`, `linewdths`, `antialiaseds` are None, they default to their `matplotlib.rcParams` patch setting, in sequence form.

`add_callback(self, func)`
Add a callback function that will be called whenever one of the `Artist`'s properties changes.

**Parameters**

`func`  [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where `artist` is the calling `Artist`. Return values may exist but are ignored.

**Returns**

`oid` [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

**See also:**

`remove_callback`

`add_checker(self, checker)`
Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

`aname`

`autoscale(self)`
Autoscale the scalar limits on the norm instance using the current array

`autoscale_None(self)`
Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

`axes`
The `Axes` instance the artist resides in, or `None`.

`changed(self)`
Call this whenever the mappable is changed to notify all the callbackSM listeners to the 'changed' signal
check_update(self, checker)
If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
Test whether the mouse event occurred in the collection.
Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

convert_xunits(self, x)
Convert x using the unit type of the xaxis.
If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

convert_yunits(self, y)
Convert y using the unit type of the yaxis.
If the artist is not in contained in an Axes or if the yaxis does not have units, y itself is returned.

draw(self, renderer)
Draw the Artist using the given renderer.
This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (Artist.get_visible is False).

Parameters

renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
Find artist objects.
Recursively find all Artist instances contained in the artist.

Parameters

match A filter criterion for the matches. This can be
• None: Return all objects contained in artist.
• A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns True.
• A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

include_self [bool] Include self in the list to be checked for a match.

Returns

artists [list of Artist]

format_cursor_data(self, data)
Return a string representation of data.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

See also:
get_cursor_data

def get_agg_filter(self):
    Return filter function to be used for agg filter.

def get_alpha(self):
    Return the alpha value used for blending - not supported on all backends.

def get_animated(self):
    Return the animated state.

def get_array(self):
    Return the array.

def get_capstyle(self):

def get_children(self):
    Return a list of the child Artists of this Artist.

def get_clim(self):
    return the min, max of the color limits for image scaling.

def get_clip_box(self):
    Return the clipbox.

def get_clip_on(self):
    Return whether the artist uses clipping.

def get_clip_path(self):
    Return the clip path.

def get_cmap(self):
    return the colormap.

def get_contains(self):
    Return the custom contains function of the artist if set, or None.

See also:

set_contains

def get_cursor_data(self, event):
    Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

Parameters

    event [matplotlib.backend_bases.MouseEvent]
See also:

format_cursor_data

get_dashes(self)
    Alias for get_linestyle.
get_datalim(self, transData)

get_ec(self)
    Alias for get_edgecolor.
get_edgecolor(self)

get_edgecolors(self)
    Alias for get_edgecolor.
get_facecolor(self)

get_facecolors(self)
    Alias for get_facecolor.
g.get_fc(self)
    Alias for get_facecolor.
g.get_fill(self)
    return whether fill is set
g.get_gid(self)
    Return the group id.
g.get_hatch(self)
    Return the current hatching pattern.
g.get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.
    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname,
    bbox_inches='tight').
g.get_joinstyle(self)

g.get_label(self)
    Return the label used for this artist in the legend.
g.get_linestyle(self)

g.get_linestyles(self)
    Alias for get_linestyle.
g.get_linewidth(self)

g.get_linewidths(self)
    Alias for get_linewidth.
g.get_ls(self)
    Alias for get_linestyle.
g.get_lw(self)
    Alias for get_linewidth.
get_offset_position(self)
Returns how offsets are applied for the collection. If offset_position is 'screen', the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If offset_position is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
Return the offsets for the collection.

get_path_effects(self)

get_paths(self)

get_picker(self)
Return the picking behavior of the artist.
The possible values are described in set_picker.

See also:
set_picker, pickable, pick

get_pickradius(self)

get_rasterized(self)
Return whether the artist is to be rasterized.

get_sizes(self)
Returns the sizes of the elements in the collection. The value represents the 'area' of the element.

Returns

sizes [array] The 'area' of each element.

get_sketch_params(self)
Returns the sketch parameters for the artist.

Returns

sketch_params [tuple or None] A 3-tuple with the following elements:
• scale: The amplitude of the wiggle perpendicular to the source line.
• length: The length of the wiggle along the line.
• randomness: The scale factor by which the length is shrunken or expanded.

Returns None if no sketch parameters were set.

get_snap(self)
Returns the snap setting.

See set_snap for details.

get_tightbbox(self, renderer)
Like Artist.get_window_extent, but includes any clipping.

Parameters

renderer [RendererBase instance] renderer that will be used to draw the figures (i.e. fig.canvas.get_renderer())
Returns

bbox (BBox) The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
Return the Transform instance used by this artist.

get_transformed_clip_path_and_affine(self)
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

get_transforms(self)

get_url(self)
Return the url.

get_urls(self)

get_visible(self)
Return the visibility.

get_window_extent(self, renderer)
Get the axes bounding box in display space.
The bounding box' width and height are nonnegative.
Subclasses should override for inclusion in the bounding box "tight" calculation.
Default is to return an empty bounding box at 0, 0.
Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
Return the artist's zorder.

have_units(self)
Return True if units are set on the x or y axes.

is_transform_set(self)
Return whether the Artist has an explicitly set transform.
This is True after set_transform has been called.

legend_elements(self, prop='colors', num='auto', fmt=None, func=<function PathCollection.<lambda> at 0x7f6988bd1378>, **kwargs)
Creates legend handles and labels for a PathCollection. This is useful for obtaining a legend for a scatter() plot. E.g.:

```python
scatter = plt.scatter([1,2,3], [4,5,6], c=[7,2,3])
plt.legend(*scatter.legend_elements())
```

Also see the automatedlegendcreation example.

Parameters

prop (string, optional, default "colors") Can be "colors" or "sizes". In case of "colors", the legend handles will show the different colors of the collection. In case of "sizes", the legend will show the different sizes.
num [int, None, “auto” (default), array-like, or Locator,] optional Target number of elements to create. If None, use all unique elements of the mappable array. If an integer, target to use num elements in the normed range. If “auto”, try to determine which option better suits the nature of the data. The number of created elements may slightly deviate from num due to a Locator being used to find useful locations. If a list or array, use exactly those elements for the legend. Finally, a Locator can be provided.

fmt [string, Formatter, or None (default)] The format or formatter to use for the labels. If a string must be a valid input for a StrMethodFormatter. If None (the default), use a ScalarFormatter.

func [function, default lambda x: x] Function to calculate the labels. Often the size (or color) argument to scatter() will have been preprocessed by the user using a function s = f(x) to make the markers visible; e.g. size = np.log10(x). Providing the inverse of this function here allows that pre-processing to be inverted, so that the legend labels have the correct values; e.g. func = np.exp(x, 10).

kwargs [further parameters] Allowed kwargs are color and size. E.g. it may be useful to set the color of the markers if prop="sizes" is used; similarly to set the size of the markers if prop="colors" is used. Any further parameters are passed onto the Line2D instance. This may be useful to e.g. specify a different markeredgecolor or alpha for the legend handles.

Returns
tuple (handles, labels) with handles being a list of Line2D objects and labels a matching list of strings.

mouseover

pchanged(self)
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

See also:
add_callback
remove_callback

pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.

See also:
set_picker, get_picker, pickable

pickable(self)
Return whether the artist is pickable.

See also:
set_picker, get_picker, pick

properties(self)
Return a dictionary of all the properties of the artist.

remove(self)
Remove the artist from the figure if possible.
The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
draw_idle. Call relim to update the axes limits if desired.
Note: relim will not see collections even if the collection was added to the axes with autolim = True.
Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
Remove a callback based on its observer id.

See also:
add_callback

set(self, **kwargs)
A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
Alias for set_antialiased.

set_agg_filter(self, filter_func)
Set the agg filter.

Parameters

filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
Set the alpha transparencies of the collection.

Parameters

alpha [float or None]

set_animated(self, b)
Set the artist’s animation state.

Parameters

b [bool]

set_antialiased(self, aa)
Set the antialiasing state for rendering.

Parameters

aa [bool or sequence of bools]

set_antialiaseds(self, aa)
Alias for set_antialiased.

set_array(self, A)
Set the image array from numpy array A.

Parameters
A [ndarray]

set_capstyle(self, cs)
Set the capstyle for the collection (for all its elements).

Parameters

cs [{'butt', 'round', 'projecting'}] The capstyle

set_clim(self, vmin=\text{n}one, vmax=\text{n}one)
set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as
(vmin, vmax) which is used to support setp

ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
vmin and vmax kwargs.

set_clip_box(self, clipbox)
Set the artist's clip Bbox.

Parameters

clipbox [Bbox]

set_clip_on(self, b)
Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected
results.

Parameters

b [bool]

set_clip_path(self, path, transform=\text{n}one)
Set the artist's clip path, which may be:

• a Patch (or subclass) instance; or

• a Path instance, in which case a Transform instance, which will be applied to the
  path before using it for clipping, must be provided; or

• \text{n}one, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will
set the clipping box to the corresponding rectangle and set the clipping path to \text{n}one.

ACCEPTS: [(\text{Path}, \text{Transform}) | \text{Patch} | \text{n}one]

set_cmap(self, cmap)
set the colormap for luminance data

Parameters

cmap [colormap or registered colormap name]

set_color(self, c)
Set both the edgecolor and the facecolor.

Parameters

c [color or sequence of rgba tuples]

See also:

Collection.set_facecolor, Collection.set_edgecolor For setting the edge or face
color individually.
set_contains(self, picker)
    Define a custom contains test for the artist.
    The provided callable replaces the default contains method of the artist.

    Parameters
    picker [callable] A custom picker function to evaluate if an event is
    within the artist. The function must have the signature:
    
    ```python
    def contains(artist: Artist, event: MouseEvent) -> bool, dict
    ```
    that returns:
    • a bool indicating if the event is within the artist
    • a dict of additional information. The dict should at least return the
      same information as the default contains() implementation of the re-
      spective artist, but may provide additional information.

set_dashes(self, ls)
    Alias for set_linestyle.

set_ec(self, c)
    Alias for set_edgecolor.

set_edgecolor(self, c)
    Set the edgecolor(s) of the collection.

    Parameters
    c [color or sequence of colors or ‘face’] The collection edgecolor(s). If a
    sequence, the patches cycle through it. If ‘face’, match the facecolor.

set_edgecolors(self, c)
    Alias for set_edgecolor.

set_facecolor(self, c)
    Set the facecolor(s) of the collection. c can be a matplotlib color spec (all patches
    have same color), or a sequence of specs; if it is a sequence the patches will cycle
    through the sequence.

    If c is ‘none’, the patch will not be filled.

    Parameters
    c [color or sequence of colors]

set_facecolors(self, c)
    Alias for set_facecolor.

set_fc(self, c)
    Alias for set_facecolor.

set_figure(self, fig)
    Set the Figure instance the artist belongs to.

    Parameters
    fig [Figure]

set_gid(self, gid)
    Set the (group) id for the artist.

    Parameters
**gid** [str]

```python
set_hatch(self, hatch)
```

Set the hatching pattern

`hatch` can be one of:

```
/  - diagonal hatching
\  - back diagonal
|  - vertical
-  - horizontal
+  - crossed
x  - crossed diagonal
0  - large circle
.  - dots
*  - stars
```

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

**Parameters**

- **hatch** [{'/', '\', '|', '-', '+', 'x', 'o', 'O', '.', '*'}]

**set_in_layout** (self, in_layout)

Set if artist is to be included in layout calculations, E.g. *Constrained Layout Guide*, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

**Parameters**

- **in_layout** [bool]

**set_joinstyle** (self, js)

Set the joinstyle for the collection (for all its elements).

**Parameters**

- **js** [{‘miter’, ‘round’, ‘bevel’}] The joinstyle

**set_label** (self, s)

Set a label that will be displayed in the legend.

**Parameters**

- **s** [object] s will be converted to a string by calling `str`.

**set_linestyle** (self, ls)

Set the linestyle(s) for the collection.

<table>
<thead>
<tr>
<th>linestyle</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-' or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--' or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.' or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>':' or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:
where \texttt{onoffseq} is an even length tuple of on and off ink in points.

**Parameters**

\texttt{ls} \{‘-‘, ‘-‘, ‘-, ‘:’, ‘,’\} The line style.

\begin{verbatim}
set_linestyles(self, ls)
\end{verbatim}

Alias for \texttt{set_linestyle}.

\begin{verbatim}
set_linewidth(self, lw)
\end{verbatim}

Set the linewidth(s) for the collection. \texttt{lw} can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence.

**Parameters**

\texttt{lw} [float or sequence of floats]

\begin{verbatim}
set_linewidths(self, lw)
\end{verbatim}

Alias for \texttt{set_linewidth}.

\begin{verbatim}
set_ls(self, ls)
\end{verbatim}

Alias for \texttt{set_linestyle}.

\begin{verbatim}
set_lw(self, lw)
\end{verbatim}

Alias for \texttt{set_linewidth}.

\begin{verbatim}
set_norm(self, norm)
\end{verbatim}

Set the normalization instance.

**Parameters**

\texttt{norm} [\texttt{Normalize}]

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

\begin{verbatim}
set_offset_position(self, offset_position)
\end{verbatim}

Set how offsets are applied. If \texttt{offset_position} is ‘screen’ (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If \texttt{offset_position} is ‘data’, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

\texttt{offset_position} \{'screen’, ‘data’\}

\begin{verbatim}
set_offsets(self, offsets)
\end{verbatim}

Set the offsets for the collection.

**Parameters**

\texttt{offsets} [float or sequence of floats]

\begin{verbatim}
set_path_effects(self, path_effects)
\end{verbatim}

Set the path effects.

**Parameters**

\texttt{path_effects} [\texttt{AbstractPathEffect}]
set_paths(self, paths)

set_picker(self, picker)
    Define the picking behavior of the artist.

Parameters

   picker [None or bool or float or callable] This can be one of the following:

   • None: Picking is disabled for this artist (default).
   • A boolean: If True then picking will be enabled and the artist will fire
     a pick event if the mouse event is over the artist.
   • A float: If picker is a number it is interpreted as an epsilon toler-
     ance in points and the artist will fire off an event if it’s data is within
     epsilon of the mouse event. For some artists like lines and patch col-
     lections, the artist may provide additional data to the pick event that
     is generated, e.g., the indices of the data within epsilon of the pick
     event.
   • A function: If picker is callable, it is a user supplied function which
     determines whether the artist is hit by the mouse event:

     ```python
     hit, props = picker(artist, mouseevent)
     ```

     to determine the hit test. if the mouse event is over the artist, return
     hit=True and props is a dictionary of properties you want added to
     the PickEvent attributes.

set_pickradius(self, pr)
    Set the pick radius used for containment tests.

Parameters

   d [float] Pick radius, in points.

set_rasterized(self, rasterized)
    Force rasterized (bitmap) drawing in vector backend output.
    Defaults to None, which implies the backend’s default behavior.

Parameters

   rasterized [bool or None]

set_sizes(self, sizes, dpi=72.0)
    Set the sizes of each member of the collection.

Parameters

   sizes [ndarray or None] The size to set for each element of the collection.
   The value is the ‘area’ of the element.

   dpi [float] The dpi of the canvas. Defaults to 72.0.

set_sketch_params(self, scale=None, length=None, randomness=None)
    Sets the sketch parameters.

Parameters

   scale [float, optional] The amplitude of the wiggle perpendicular to the
   source line, in pixels. If scale is None, or not provided, no sketch filter
   will be provided.
length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

randomness [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

set_snap(self, snap)
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

snap [bool or None] Possible values:

• True: Snap vertices to the nearest pixel center.
• False: Do not modify vertex positions.
• None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]

set_url(self, url)
Set the url for the artist.

Parameters

url [str]

set_urls(self, urls)

Parameters

urls [List[str] or None]

set_visible(self, b)
Set the artist’s visibility.

Parameters

b [bool]

set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters

level [float]

stale
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.
**sticky_edges**

x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

**Examples**

```python
>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)
```

to_rgba

```python
to_rgba(self, x, alpha=None, bytes=False, norm=True)
```

Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

**update**

```python
update(self, props)
```

Update this artist’s properties from the dictionary props.

**update_from**

```python
update_from(self, other)
```

copy properties from other to self

**update_scalarmappable**

```python
update_scalarmappable(self)
```

Update colors from the scalar mappable array, if it is not None.

**zorder = 0**

**class matplotlib.collections.PolyCollection(verts, sizes=None, closed=True, **kwargs)**

Bases: matplotlib.collections._CollectionWithSizes

verts is a sequence of (verts0, verts1, ...) where verts.i is a sequence of xy tuples of vertices, or an equivalent numpy array of shape (nv, 2).

sizes is None (default) or a sequence of floats that scale the corresponding verts.i. The scaling is applied before the Artist master transform; if the latter is an identity transform,
then the overall scaling is such that if \( \text{verts}_i \) specify a unit square, then \( \text{sizes}_i \) is the area of that square in points\(^2\). If \( \text{len}(\text{sizes}) < n_v \), the additional values will be taken cyclically from the array.

*closed*, when *True*, will explicitly close the polygon.

Valid Collection keyword arguments:

- *edgecolors*: None
- *facecolors*: None
- *linewidths*: None
- *antialiaseds*: None
- *offsets*: None
- *transOffset*: `transforms.IdentityTransform()`
- *norm*: None (optional for `matplotlib.cm.ScalarMappable`)
- *cmap*: None (optional for `matplotlib.cm.ScalarMappable`)

*offsets* and *transOffset* are used to translate the patch after rendering (default no offsets)

If any of *edgecolors*, *facecolors*, *linewidths*, *antialiaseds* are None, they default to their `matplotlib.rcParams` patch setting, in sequence form.

add_callback(*self, func*)

Add a callback function that will be called whenever one of the *Artist*’s properties changes.

**Parameters**

- **func** [callable] The callback function. It must have the signature:

  ```python
def func(artist: Artist) -> Any
  ```

  where *artist* is the calling *Artist*. Return values may exist but are ignored.

**Returns**

- **oid** [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

**See also:**

- `remove_callback`

add_checker(*self, checker*)

Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

aname

autoscale(*self*)

Autoscale the scalar limits on the norm instance using the current array

autoscale_None(*self*)

Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None
axes
   The Axes instance the artist resides in, or None.

called(self)
   Call this whenever the mappable is changed to notify all the callback listeners to
   the ‘changed’ signal

calculate_update(self, checker)
   If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
   Test whether the mouse event occurred in the collection.
   Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

convert_xunits(self, x)
   Convert x using the unit type of the xaxis.
   If the artist is not in contained in an Axes or if the xaxis does not have units, x itself
   is returned.

convert_yunits(self, y)
   Convert y using the unit type of the yaxis.
   If the artist is not in contained in an Axes or if the yaxis does not have units, y itself
   is returned.

draw(self, renderer)
   Draw the Artist using the given renderer.
   This method will be overridden in the Artist subclasses. Typically, it is implemented
to not have any effect if the Artist is not visible (Artist.get_visible is False).

   Parameters
      renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
   Find artist objects.
   Recursively find all Artist instances contained in the artist.

   Parameters
      match A filter criterion for the matches. This can be
      • None: Return all objects contained in artist.
      • A function with signature def match(artist: Artist) -> bool. The re-
        sult will only contain artists for which the function returns True.
      • A class instance: e.g., Line2D. The result will only contain artists of
        this class or its subclasses (isinstance check).

      include_self [bool] Include self in the list to be checked for a match.

   Returns
      artists [list of Artist]

format_cursor_data(self, data)
   Return a string representation of data.
**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

`get_cursor_data`

`get_agg_filter(self)`  
Return filter function to be used for agg filter.

`get_alpha(self)`  
Return the alpha value used for blending - not supported on all backends

`get_animated(self)`  
Return the animated state.

`get_array(self)`  
Return the array

`get_capstyle(self)`

`get_children(self)`  
Return a list of the child *Artists* of this *Artist*.

`get_clim(self)`  
return the min, max of the color limits for image scaling

`get_clip_box(self)`  
Return the clipbox.

`get_clip_on(self)`  
Return whether the artist uses clipping.

`get_clip_path(self)`  
Return the clip path.

`get_cmap(self)`  
return the colormap

`get_contains(self)`  
Return the custom contains function of the artist if set, or *None*.

**See also:**

`set_contains`

`get_cursor_data(self, event)`  
Return the cursor data for a given event.

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns *None*.
Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation.

The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

- `event [matplotlib.backend_bases.MouseEvent]`  

**See also:**

`format_cursor_data`

```
get_dashes(self)
    Alias for `get_linestyle`.
get_datalim(self, transData)
get_ec(self)
    Alias for `get_edgecolor`.
get_edgecolor(self)
get_edgecolors(self)
    Alias for `get_edgecolor`.
get_facecolor(self)
get_facecolors(self)
    Alias for `get_facecolor`.
gt_fcc(self)
    Alias for `get_facecolor`.
gt_fi(self)
    Return the `Figure` instance the artist belongs to.
get_fill(self)
    return whether fill is set
```

```
gt_gid(self)
    Return the group id.
get_hatch(self)
    Return the current hatching pattern.
get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.
    E.g. `Constrained Layout Guide`, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.
get_joinstyle(self)
get_label(self)
    Return the label used for this artist in the legend.
get_linestyle(self)
```

```
get_linestyles(self)
    Alias for `get_linestyle`.
get_linewidth(self)
```
get_linewidths(self)
    Alias for get_linewidth.

get_ls(self)
    Alias for get_linestyle.

get_lw(self)
    Alias for get_linewidth.

get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the
    offset is applied after the master transform has been applied, that is, the offsets are
    in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
    Return the offsets for the collection.

get_path_effects(self)

get_paths(self)

get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.

    See also:

    set_picker, pickable, pick

get_pickradius(self)

get_rasterized(self)
    Return whether the artist is to be rasterized.

get_sizes(self)
    Returns the sizes of the elements in the collection. The value represents the 'area'
    of the element.

    Returns

    sizes [array] The 'area' of each element.

get_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns

    sketch_params [tuple or None] A 3-tuple with the following elements:

    • scale: The amplitude of the wiggle perpendicular to the source line.
    • length: The length of the wiggle along the line.
    • randomness: The scale factor by which the length is shrunken or ex-
       panded.

    Returns None if no sketch parameters were set.

get_snap(self)
    Returns the snap setting.
See `set_snap` for details.

**get_tightbbox** *(self, renderer)*
Like `Artist.get_window_extent`, but includes any clipping.

**Parameters**

**renderer** ([`RendererBase` instance]) renderer that will be used to draw the figures (i.e. `fig.canvas.get_renderer()`)

**Returns**

**bbox** ([`BBox`]) The enclosing bounding box (in figure pixel co-ordinates).

**get_transform** *(self)*
Return the `Transform` instance used by this artist.

**get_transformed_clip_path_and_affine** *(self)*
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

**get_transforms** *(self)*

**get_url** *(self)*
Return the url.

**get_urls** *(self)*

**get_visible** *(self)*
Return the visibility.

**get_window_extent** *(self, renderer)*
Get the axes bounding box in display space.
The bounding box’ width and height are nonnegative.
Subclasses should override for inclusion in the bounding box “tight” calculation.
Default is to return an empty bounding box at 0, 0.

Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

**get_zorder** *(self)*
Return the artist’s zorder.

**have_units** *(self)*
Return `True` if units are set on the x or y axes.

**is_transform_set** *(self)*
Return whether the Artist has an explicitly set transform.
This is `True` after `set_transform` has been called.

**mouseover**

**pchanged** *(self)*
Call all of the registered callbacks.
This function is triggered internally when a property is changed.

**See also:**
`add_callback`

`remove_callback`

`pick(self, mouseevent)`  
Process a pick event.  
Each child artist will fire a pick event if `mouseevent` is over the artist and the artist has picker set.  

**See also:**

`set_picker`, `get_picker`, `pickable`

`pickable(self)`  
Return whether the artist is pickable.  

**See also:**

`set_picker`, `get_picker`, `pick`

`properties(self)`  
Return a dictionary of all the properties of the artist.

`remove(self)`  
Remove the artist from the figure if possible.  
The effect will not be visible until the figure is redrawn, e.g., with `FigureCanvasBase.draw_idle`. Call `relim` to update the axes limits if desired.  
Note: `relim` will not see collections even if the collection was added to the axes with `autolim=True`.  
Note: there is no support for removing the artist’s legend entry.

`remove_callback(self, oid)`  
Remove a callback based on its observer id.  

**See also:**

`add_callback`

`set(self, **kwargs)`  
A property batch setter. Pass `kwargs` to set properties.

`set_aa(self, aa)`  
Alias for `set_antialiased`.

`set_agg_filter(self, filter_func)`  
Set the agg filter.  

**Parameters**

`filter_func` [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

`set_alpha(self, alpha)`  
Set the alpha transparencies of the collection.  

**Parameters**

`alpha` [float or None]
set_animated(self, b)
    Set the artist’s animation state.

    Parameters
    b [bool]

set_antialiased(self, aa)
    Set the antialiasing state for rendering.

    Parameters
    aa [bool or sequence of bools]

set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

    Parameters
    cs [{'butt', 'round', 'projecting'}] The capstyle

set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as
    (vmin, vmax) which is used to support setp
    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
    vmin and vmax kwargs.

set_clip_box(self, clipbox)
    Set the artist’s clip Bbox.

    Parameters
    clipbox [Bbox]

set_clip_on(self, b)
    Set whether the artist uses clipping.

    When False artists will be visible out side of the axes which can lead to unexpected
    results.

    Parameters
    b [bool]

set_clip_path(self, path, transform=None)
    Set the artist’s clip path, which may be:
    • a Patch (or subclass) instance; or
    • a Path instance, in which case a Transform instance, which will be applied to the
      path before using it for clipping, must be provided; or
    • None, to remove a previously set clipping path.
For efficiency, if the path happens to be an axis-aligned rectangle, this method will
set the clipping box to the corresponding rectangle and set the clipping path to None.

**ACCEPTS:** [(Path, Transform) | Patch | None]

```python
set_cmap(self, cmap)
```
set the colormap for luminance data

**Parameters**

- **cmap** [colormap or registered colormap name]

```python
set_color(self, c)
```
Set both the edgecolor and the facecolor.

**Parameters**

- **c** [color or sequence of rgba tuples]

**See also:**

Collection.set_facecolor, Collection.set_edgecolor For setting the edge or face
color individually.

```python
set_contains(self, picker)
```
Define a custom contains test for the artist.

The provided callable replaces the default contains method of the artist.

**Parameters**

- **picker** [callable] A custom picker function to evaluate if an event is
  within the artist. The function must have the signature:

```
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the
  same information as the default contains() implementation of the re-
  spective artist, but may provide additional information.

```python
set_dashes(self, ls)
```
Alias for set_linestyle.

```python
set_ec(self, c)
```
Alias for set_edgecolor.

```python
set_edgecolor(self, c)
```
Set the edgecolor(s) of the collection.

**Parameters**

- **c** [color or sequence of colors or ‘face’) The collection edgecolor(s). If a
  sequence, the patches cycle through it. If ‘face’, match the facecolor.

```python
set_edgecolors(self, c)
```
Alias for set_edgecolor.

```python
set_facecolor(self, c)
```
Set the facecolor(s) of the collection. c can be a matplotlib color spec (all patches
have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If c is 'none', the patch will not be filled.

**Parameters**

- **c** [color or sequence of colors]

```python
set_facecolors(self, c)
```

Alias for `set_facecolor`.

```python
set_tc(self, c)
```

Alias for `set_facecolor`.

```python
set_figure(self, fig)
```

Set the `Figure` instance the artist belongs to.

**Parameters**

- **fig** [Figure]

```python
set_gid(self, gid)
```

Set the (group) id for the artist.

**Parameters**

- **gid** [str]

```python
set_hatch(self, hatch)
```

Set the hatching pattern

- **hatch** can be one of:

```
/ - diagonal hatching
\ - back diagonal
| - vertical
- - horizontal
+ - crossed
x - crossed diagonal
o - small circle
O - large circle
. - dots
* - stars
```

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

**Parameters**

```python
set_in_layout(self, in_layout)
```

Set if artist is to be included in layout calculations, E.g. `Constrained Layout Guide`, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

**Parameters**

- **in_layout** [bool]
set_joinstyle(self, js)
    Set the joinstyle for the collection (for all its elements).

    Parameters
    js [‘miter’, ‘round’, ‘bevel’] The joinstyle

set_label(self, s)
    Set a label that will be displayed in the legend.

    Parameters
    s [object] s will be converted to a string by calling str.

set_linestyle(self, ls)
    Set the linestyle(s) for the collection.

    Parameters
    ls [‘-’, ‘–’, ‘.-’, ‘:’, (offset, on-off-seq), ...] The line style.

    Alternatively a dash tuple of the following form can be provided:

    (offset, onoffseq),

    where onoffseq is an even length tuple of on and off ink in points.

set_linestyles(self, ls)
    Alias for set_linestyle.

set_linewidth(self, lw)
    Set the linewidth(s) for the collection. lw can be a scalar or a sequence; if it is a
    sequence the patches will cycle through the sequence

    Parameters
    lw [float or sequence of floats]

set_linewidths(self, lw)
    Alias for set_linewidth.

set_ls(self, ls)
    Alias for set_linestyle.

set_lw(self, lw)
    Alias for set_linewidth.

set_norm(self, norm)
    Set the normalization instance.

    Parameters
    norm [Normalize]
Notes

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

```python
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is ‘screen’ (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is ‘data’, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- `offset_position` [{‘screen’, ‘data’}]

```python
set_offsets(self, offsets)
```

Set the offsets for the collection.

**Parameters**

- `offsets` [float or sequence of floats]

```python
set_path_effects(self, path_effects)
```

Set the path effects.

**Parameters**

- `path_effects` [AbstractPathEffect]

```python
set_paths(self, verts, closed=True)
```

This allows one to delay initialization of the vertices.

```python
set_picker(self, picker)
```

Define the picking behavior of the artist.

**Parameters**

- `picker` [None or bool or float or callable] This can be one of the following:
  - `None`: Picking is disabled for this artist (default).
  - A boolean: If `True` then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
  - A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
  - A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. If the mouse event is over the artist, return `hit=True` and props is a dictionary of properties you want added to the PickEvent attributes.

```python
set_pickradius(self, pr)
```

Set the pick radius used for containment tests.
Parameters

d [float] Pick radius, in points.

set_rasterized(self, rasterized)
Force rasterized (bitmap) drawing in vector backend output.
Defaults to None, which implies the backend’s default behavior.

Parameters

rasterized [bool or None]

set_sizes(self, sizes, dpi=72.0)
Set the sizes of each member of the collection.

Parameters

sizes [ndarray or None] The size to set for each element of the collection.
The value is the ‘area’ of the element.
dpi [float] The dpi of the canvas. Defaults to 72.0.

set_sketch_params(self, scale=None, length=None, randomness=None)
Sets the sketch parameters.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the
source line, in pixels. If scale is None, or not provided, no sketch filter
will be provided.
length [float, optional] The length of the wiggle along the line, in pixels
(default 128.0)
randomness [float, optional] The scale factor by which the length is
shrunk or expanded (default 16.0)

set_snap(self, snap)
Set the snapping behavior.
Snapping aligns positions with the pixel grid, which results in clearer images. For
example, if a black line of 1px width was defined at a position in between two pixels,
the resulting image would contain the interpolated value of that line in the pixel grid,
which would be a grey value on both adjacent pixel positions. In contrast, snapping
will move the line to the nearest integer pixel value, so that the resulting image will
really contain a 1px wide black line.
Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

snap [bool or None] Possible values:
• True: Snap vertices to the nearest pixel center.
• False: Do not modify vertex positions.
• None: (auto) If the path contains only rectilinear line segments, round
to the nearest pixel center.

set_transform(self, t)
Set the artist transform.

Parameters
t [Transform]

set_url(self, url)
    Set the url for the artist.

    Parameters
    url [str]

set_urls(self, urls)
    Parameters
    urls [List[str] or None]

set_verts(self, verts, closed=True)
    This allows one to delay initialization of the vertices.

set_verts_and_codes(self, verts, codes)
    This allows one to initialize vertices with path codes.

set_visible(self, b)
    Set the artist's visibility.

    Parameters
    b [bool]

set_zorder(self, level)
    Set the zorder for the artist. Artists with lower zorder values are drawn first.

    Parameters
    level [float]

stale
    Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

sticky_edges
    x and y sticky edge lists for autoscaling.

    When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit "sticks" to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

    This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

Examples

>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)

to_rgba(self, x, alpha=None, bytes=False, norm=True)
    Return a normalized rgba array corresponding to x.

    In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.
There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If \( x \) is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the `alpha` kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the `alpha` kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if `bytes` is `False` (default), the rgba array will be floats in the 0-1 range; if it is `True`, the returned rgba array will be uint8 in the 0 to 255 range.

If `norm` is `False`, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

```python
update(self, props)
    Update this artist’s properties from the dictionary `props`.

update_from(self, other)
    copy properties from other to self

update_scalarmappable(self)
    Update colors from the scalar mappable array, if it is not None.

zorder = 0
```

class matplotlib.collections.QuadMesh(meshWidth, meshHeight, coordinates, antialiased=True, shading='flat', **kwargs)

Bases: matplotlib.collections.Collection

Class for the efficient drawing of a quadrilateral mesh.

A quadrilateral mesh consists of a grid of vertices. The dimensions of this array are \((meshWidth + 1, meshHeight + 1)\). Each vertex in the mesh has a different set of “mesh coordinates” representing its position in the topology of the mesh. For any values \((m, n)\) such that \(0 \leq m \leq meshWidth\) and \(0 \leq n \leq meshHeight\), the vertices at mesh coordinates \((m, n), (m, n + 1), (m + 1, n + 1),\) and \((m + 1, n)\) form one of the quadrilaterals in the mesh. There are thus \((meshWidth * meshHeight)\) quadrilaterals in the mesh. The mesh need not be regular and the polygons need not be convex.

A quadrilateral mesh is represented by a \((2 \times ((meshWidth + 1) \times (meshHeight + 1)))\) numpy array `coordinates`, where each row is the \(x\) and \(y\) coordinates of one of the vertices. To define the function that maps from a data point to its corresponding color, use the `set_cmap()` method. Each of these arrays is indexed in row-major order by the mesh coordinates of the vertex (or the mesh coordinates of the lower left vertex, in the case of the colors).

For example, the first entry in `coordinates` is the coordinates of the vertex at mesh coordinates \((0, 0)\), then the one at \((0, 1)\), then at \((0, 2) \ldots (0, meshWidth)\), \((1, 0), (1, 1),\) and so on.

`shading` may be ‘flat’, or ‘gouraud’

```python
add_callback(self, func)
    Add a callback function that will be called whenever one of the Artist’s properties changes.
```

**Parameters**

- `func` [callable] The callback function. It must have the signature:
def func(artist: Artist) -> Any

where artist is the calling Artist. Return values may exist but are ignored.

Returns

oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

See also:

remove_callback

add_checker(self, checker)
Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

aname

autoscale(self)
Autoscale the scalar limits on the norm instance using the current array

autoscale_None(self)
Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

axes
The Axes instance the artist resides in, or None.

changed(self)
Call this whenever the mappable is changed to notify all the callback listeners to the 'changed' signal

check_update(self, checker)
If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
Test whether the mouse event occurred in the collection.

Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

static convert_mesh_to_paths(meshWidth, meshHeight, coordinates)
Converts a given mesh into a sequence of Path objects.

This function is primarily of use to implementers of backends that do not directly support quadmeshes.

convert_mesh_to_triangles(self, meshWidth, meshHeight, coordinates)
Converts a given mesh into a sequence of triangles, each point with its own color. This is useful for experiments using draw_gouraud_triangle.

convert_xunits(self, x)
Convert x using the unit type of the xaxis.

If the artist is not in contained in an Axes or if the xaxis does not have units, x itself is returned.

convert_yunits(self, y)
Convert y using the unit type of the yaxis.
If the artist is not contained in an Axes or if the yaxis does not have units, \( y \) itself is returned.

\( \text{draw}(\text{self}, \text{renderer}) \)

Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (\( \text{Artist.get_visible} \) is \( False \)).

**Parameters**

**renderer** [\( \text{RendererBase} \) subclass.]

\( \text{findobj}(\text{self}, \text{match}=\text{None}, \text{include_self}=\text{True}) \)

Find artist objects.

Recursively find all \( \text{Artist} \) instances contained in the artist.

**Parameters**

**match** A filter criterion for the matches. This can be

- **None**: Return all objects contained in artist.
- A function with signature \( \text{def match(style: Artist) -> bool} \). The result will only contain artists for which the function returns **True**.
- A class instance: e.g., \( \text{Line2D} \). The result will only contain artists of this class or its subclasses (\( \text{isinstance} \) check).

**include_self** [bool] Include \( \text{self} \) in the list to be checked for a match.

**Returns**

**artists** [list of \( \text{Artist} \)]

\( \text{format_cursor_data}(\text{self}, \text{data}) \)

Return a string representation of \( \text{data} \).

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

\( \text{get_cursor_data} \)

\( \text{get_agg_filter}(\text{self}) \)

Return filter function to be used for agg filter.

\( \text{get_alpha}(\text{self}) \)

Return the alpha value used for blending - not supported on all backends

\( \text{get_animated}(\text{self}) \)

Return the animated state.

\( \text{get_array}(\text{self}) \)

Return the array

\( \text{get_capstyle}(\text{self}) \)
get_children(self)
   Return a list of the child Artists of this Artist.

get_clim(self)
   return the min, max of the color limits for image scaling

get_clip_box(self)
   Return the clipbox.

get_clip_on(self)
   Return whether the artist uses clipping.

get_clip_path(self)
   Return the clip path.

get_cmap(self)
   return the colormap

get_contains(self)
   Return the custom contains function of the artist if set, or None.

See also:
   set_contains

get_cursor_data(self, event)
   Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

Parameters
   event [matplotlib.backend_bases.MouseEvent]

See also:
   format_cursor_data

get_dashes(self)
   Alias for get_linestyle.

get_datalim(self, transData)

get_ec(self)
   Alias for get_edgecolor.

get_edgecolor(self)

get_edgecolors(self)
   Alias for get_edgecolor.
get_facecolor(self)
get_facecolors(self)
    Alias for get_facecolor.
get_fc(self)
    Alias for get_facecolor.
get_figure(self)
    Return the Figure instance the artist belongs to.
get_fill(self)
    return whether fill is set
get_gid(self)
    Return the group id.
get_hatch(self)
    Return the current hatching pattern.
get_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.
    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname,
         bbox_inches='tight').
get_joinstyle(self)
get_label(self)
    Return the label used for this artist in the legend.
get_linestyle(self)
get_linestyles(self)
    Alias for get_linestyle.
get_linewidth(self)
get_linewidths(self)
    Alias for get_linewidth.
get_ls(self)
    Alias for get_linestyle.
get_lw(self)
    Alias for get_linewidth.
get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen',
    the offset is applied after the master transform has been applied, that is, the offsets
    are in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.
get_offset_transform(self)
get_offsets(self)
    Return the offsets for the collection.
get_path_effects(self)
get_paths(self)
get_picker(self)
    Return the picking behavior of the artist.
The possible values are described in `set_picker`.

**See also:**

`set_picker`, `pickable`, `pick`

`get_pickradius(self)`

`get_rasterized(self)`

Return whether the artist is to be rasterized.

`get_sketch_params(self)`

Returns the sketch parameters for the artist.

**Returns**

`sketch_params` [tuple or None] A 3-tuple with the following elements:

- `scale`: The amplitude of the wiggle perpendicular to the source line.
- `length`: The length of the wiggle along the line.
- `randomness`: The scale factor by which the length is shrunk or expanded.

Returns `None` if no sketch parameters were set.

`get_snap(self)`

Returns the snap setting.

See `set_snap` for details.

`get_tightbbox(self, renderer)`

Like `Artist.get_window_extent`, but includes any clipping.

**Parameters**

`renderer` [RendererBase instance] renderer that will be used to draw the figures (i.e. `fig.canvas.get_renderer()`)

**Returns**

`bbox` [BBox] The enclosing bounding box (in figure pixel co-ordinates).

`get_transform(self)`

Return the `Transform` instance used by this artist.

`get_transformed_clip_path_and_affine(self)`

Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

`get_transforms(self)`

`get_url(self)`

Return the url.

`get_urls(self)`

`get_visible(self)`

Return the visibility.

`get_window_extent(self, renderer)`

Get the axes bounding box in display space.

The bounding box' width and height are nonnegative.
Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.

Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

```python
get_zorder(self)
    Return the artist’s zorder.

have_units(self)
    Return True if units are set on the x or y axes.

is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.
```

```python
mouseover

pchanged(self)
    Call all of the registered callbacks.
    This function is triggered internally when a property is changed.
    See also:

    add_callback
    remove_callback
```

```python
pick(self, mouseevent)
    Process a pick event.
    Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.
    See also:

    set_picker, get_picker, pickable
```

```python
pickable(self)
    Return whether the artist is pickable.
    See also:

    set_picker, get_picker, pick
```

```python
properties(self)
    Return a dictionary of all the properties of the artist.

remove(self)
    Remove the artist from the figure if possible.
    The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.draw_idle. Call relim to update the axes limits if desired.
    Note: relim will not see collections even if the collection was added to the axes with autolim = True.
```
Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
Remove a callback based on its observer id.

See also:
add_callback

set(self, **kwargs)
A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
Alias for set_antialiased.

set_agg_filter(self, filter_func)
Set the agg filter.

Parameters

filter_func [callable] A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
Set the alpha transparencies of the collection.

Parameters

alpha [float or None]

set_animated(self, b)
Set the artist’s animation state.

Parameters

b [bool]

set_antialiased(self, aa)
Set the antialiasing state for rendering.

Parameters

aa [bool or sequence of bools]

set_antialiaseds(self, aa)
Alias for set_antialiased.

set_array(self, A)
Set the image array from numpy array A.

Parameters

A [ndarray]

set_capstyle(self, cs)
Set the capstyle for the collection (for all its elements).

Parameters

cs [{'butt', 'round', 'projecting'}] The capstyle

set_clim(self, vmin=None, vmax=None)
Set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as (vmin, vmax) which is used to support setp
set_clip_box(self, clipbox)
Set the artist's clip Bbox.

Parameters

    clipbox [Bbox]

set_clip_on(self, b)
Set whether the artist uses clipping.
When False artists will be visible outside of the axes which can lead to unexpected results.

Parameters

    b [bool]

set_clip_path(self, path, transform=None)
Set the artist's clip path, which may be:

- a Patch (or subclass) instance; or
- a Path instance, in which case a Transform instance, which will be applied to the path before using it for clipping, must be provided; or
- None, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

set_cmap(self, cmap)
set the colormap for luminance data

Parameters

    cmap [colormap or registered colormap name]

set_color(self, c)
Set both the edgecolor and the facecolor.

Parameters

    c [color or sequence of rgba tuples]

See also:

Collection.set_facecolor, Collection.set_edgecolor For setting the edge or face color individually.

set_contains(self, picker)
Define a custom contains test for the artist.
The provided callable replaces the default contains method of the artist.

Parameters

    picker [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:
```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the
  same information as the default `contains()` implementation of the re-
  spective artist, but may provide additional information.

```python
set_dashes(self, ls)
    Alias for `set_linestyle`.
```

```python
set_ec(self, c)
    Alias for `set_edgecolor`.
```

```python
set_edgecolor(self, c)
    Set the edgecolor(s) of the collection.

    Parameters
    ===========
    c [color or sequence of colors or ‘face’] The collection edgecolor(s). If a
    sequence, the patches cycle through it. If ‘face’, match the facecolor.
```

```python
set_edgecolors(self, c)
    Alias for `set_edgecolor`.
```

```python
set_facecolor(self, c)
    Set the facecolor(s) of the collection. `c` can be a matplotlib color spec (all patches
    have same color), or a sequence of specs; if it is a sequence the patches will cycle
    through the sequence.

    If `c` is ‘none’, the patch will not be filled.

    Parameters
    ===========
    c [color or sequence of colors]
```

```python
set_facecolors(self, c)
    Alias for `set_facecolor`.
```

```python
set_fc(self, c)
    Alias for `set_facecolor`.
```

```python
set_figure(self, fig)
    Set the `Figure` instance the artist belongs to.

    Parameters
    ===========
    fig [Figure]
```

```python
set_gid(self, gid)
    Set the (group) id for the artist.

    Parameters
    ===========
    gid [str]
```

```python
set_hatch(self, hatch)
    Set the hatching pattern

    `hatch` can be one of:
```
Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

Parameters

**hatch** [{`} , {`'`, `\`, `|`, `-`, `+`, `x`, `'o`, `'O`, `.` , `*`}]

`set_in_layout(self, in_layout)`  
Set if artist is to be included in layout calculations, E.g. *Constrained Layout Guide*, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

Parameters

**in_layout** [bool]

`set_joinstyle(self, js)`  
Set the joinstyle for the collection (for all its elements).

Parameters

**js** [{`miter`, `round`, `bevel`}]. The joinstyle

`set_label(self, s)`  
Set a label that will be displayed in the legend.

Parameters

**s** [object] s will be converted to a string by calling *str*.

`set_linestyle(self, ls)`  
Set the linestyle(s) for the collection.

```
<table>
<thead>
<tr>
<th>linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-</code> or `'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td><code>'--'</code> or `'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td><code>'-.'</code> or `'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td><code>':'</code> or `'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>
```

Alternatively a dash tuple of the following form can be provided:

```
(offset, onoffseq),
```

where `onoffseq` is an even length tuple of on and off ink in points.
Parameters

ls [‘-’, ‘–’, ‘.-’, ‘:’, ‘’, (offset, on-off-seq), …}] The line style.

set_linestyles(self, ls)
   Alias for set_linestyle.

set_linewidth(self, lw)
   Set the linewidth(s) for the collection. lw can be a scalar or a sequence; if it is a
   sequence the patches will cycle through the sequence

Parameters

lw [float or sequence of floats]

set_linewidths(self, lw)
   Alias for set_linewidth.

set_ls(self, ls)
   Alias for set_linestyle.

set_lw(self, lw)
   Alias for set_linewidth.

set_norm(self, norm)
   Set the normalization instance.

Parameters

norm [Normalize]

Notes

If there are any colorbars using the mappable for this norm, setting the norm of the
mappable will reset the norm, locator, and formatters on the colorbar to default.

set_offset_position(self, offset_position)
   Set how offsets are applied. If offset_position is ‘screen’ (default) the offset is applied
   after the master transform has been applied, that is, the offsets are in screen coor-
   dinates. If offset_position is ‘data’, the offset is applied before the master transform,
   i.e., the offsets are in data coordinates.

Parameters

offset_position [{‘screen’, ‘data’}]

set_offsets(self, offsets)
   Set the offsets for the collection.

Parameters

offsets [float or sequence of floats]

set_path_effects(self, path_effects)
   Set the path effects.

Parameters

path_effects [AbstractPathEffect]

set_paths(self)

set_picker(self, picker)
   Define the picking behavior of the artist.
Parameters

picker [None or bool or float or callable] This can be one of the following:

- None: Picking is disabled for this artist (default).
- A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
- A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
- A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

  ```
  hit, props = picker(artist, mouseevent)
  ```

to determine the hit test. If the mouse event is over the artist, return hit=True and props is a dictionary of properties you want added to the PickEvent attributes.

set_pickradius(self, pr)
Set the pick radius used for containment tests.

Parameters
d [float] Pick radius, in points.

set_rasterized(self, rasterized)
Force rasterized (bitmap) drawing in vector backend output.

Defaults to None, which implies the backend’s default behavior.

Parameters

rasterized [bool or None]

set_sketch_params(self, scale=None, length=None, randomness=None)
Sets the sketch parameters.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.

length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)

randomness [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

set_snap(self, snap)
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping
will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

**snap** [bool or None] Possible values:

- **True**: Snap vertices to the nearest pixel center.
- **False**: Do not modify vertex positions.
- **None**: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

`set_transform(self, t)`
Set the artist transform.

**Parameters**

**t** [Transform]

`set_url(self, url)`
Set the url for the artist.

**Parameters**

**url** [str]

`set_urls(self, urls)`

**Parameters**

**urls** [List[str] or None]

`set_visible(self, b)`
Set the artist’s visibility.

**Parameters**

**b** [bool]

`set_zorder(self, level)`
Set the zorder for the artist. Artists with lower zorder values are drawn first.

**Parameters**

**level** [float]

**stale**
Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

**sticky_edges**

x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.
Examples

```python
>>> artist.sticky_edges.x[:1] = (xmin, xmax)
>>> artist.sticky_edges.y[:1] = (ymin, ymax)
```

to_rgba(self, x, alpha=None, bytes=False, norm=True)

Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding
ndarray of rgba values will be returned, based on the norm and colormap set for
this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as
might have been read from an image file. If x is an ndarray with 3 dimensions, and
the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array,
and no mapping will be done. The array can be uint8, or it can be floating point with
values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array,
the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to
1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg
is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if
the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgb array will be floats in the 0-1 range;
if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed
to be in the range (0-1).

update(self, props)

Update this artist’s properties from the dictionary props.

update_from(self, other)

copy properties from other to self

update_scalarmappable(self)

Update colors from the scalar mappable array, if it is not None.

zorder = 0

class matplotlib.collections.RegularPolyCollection

Bases: matplotlib.collections._CollectionWithSizes

Draw a collection of regular polygons with numsides.

numsides the number of sides of the polygon

rotation the rotation of the polygon in radians

sizes gives the area of the circle circumscribing the regular polygon in points^2

Valid Collection keyword arguments:

• edgecolors: None
• facecolors: None
• linewidths: None
• antialiaseds: None
• offsets: None
• transOffset: transforms.IdentityTransform()
• norm: None (optional for matplotlib.cm.ScalarMappable)
• cmap: None (optional for matplotlib.cm.ScalarMappable)

offsets and transOffset are used to translate the patch after rendering (default no offsets)

If any of edgecolors, facecolors, linewidths, antialiaseds are None, they default to their matplotlib.rcParams patch setting, in sequence form.

Example: see /gallery/event_handling/lasso_demo for a complete example:

```python
def func(artist: Artist) -> Any
```

where artist is the calling Artist. Return values may exist but are ignored.

Returns

**oid** [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

See also:

remove_callback

add_checker(self, checker)

Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

aname

autoscale(self)

Autoscale the scalar limits on the norm instance using the current array

autoscale_None(self)

Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None
axes

The `Axes` instance the artist resides in, or `None`.

`changed(self)`

Call this whenever the mappable is changed to notify all the callback listeners to the 'changed' signal.

`check_update(self, checker)`

If mappable has changed since the last check, return `True`; else return `False`.

`contains(self, mouseevent)`

Test whether the mouse event occurred in the collection.

Returns `bool`, `dict(ind=itemlist)`, where every item in `itemlist` contains the event.

`convert_xunits(self, x)`

Convert `x` using the unit type of the xaxis.

If the artist is not in contained in an Axes or if the xaxis does not have units, `x` itself is returned.

`convert_yunits(self, y)`

Convert `y` using the unit type of the yaxis.

If the artist is not in contained in an Axes or if the yaxis does not have units, `y` itself is returned.

`draw(self, renderer)`

Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (`Artist.get_visible` is `False`).

`findobj(self, match=None, include_self=True)`

Find artist objects.

Recursively find all `Artist` instances contained in the artist.

`format_cursor_data(self, data)`

Return a string representation of `data`.

`renderers` [RendererBase subclass.]
Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

See also:

get_cursor_data

get_agg_filter(self)
    Return filter function to be used for agg filter.

get_alpha(self)
    Return the alpha value used for blending - not supported on all backends

get_animated(self)
    Return the animated state.

get_array(self)
    Return the array

get_capstyle(self)

get_children(self)
    Return a list of the child Artists of this Artist.

get_clim(self)
    return the min, max of the color limits for image scaling

get_clip_box(self)
    Return the clipbox.

get_clip_on(self)
    Return whether the artist uses clipping.

get_clip_path(self)
    Return the clip path.

get_cmap(self)
    return the colormap

get_contains(self)
    Return the custom contains function of the artist if set, or None.

See also:

set_contains

get_cursor_data(self, event)
    Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.
Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that `format_cursor_data` can convert the data to a string representation.

The only current use case is displaying the z-value of an `AxesImage` in the status bar of a plot window, while moving the mouse.

**Parameters**

- `event` ([`matplotlib.backend_bases.MouseEvent`])

**See also:**

- `format_cursor_data`

- `get_dashes`
  - Alias for `get_linestyle`.

- `get_datalim`
  - `get_datalim(self, transData)`

- `get_ec`
  - Alias for `get_edgecolor`.

- `get_edgecolor`

- `get_edgecolors`
  - Alias for `get_edgecolor`.

- `get_facecolor`

- `get_facecolors`
  - Alias for `get_facecolor`.

- `get_fc`
  - Alias for `get_facecolor`.

- `get_figure`
  - Return the `Figure` instance the artist belongs to.

- `get_fill`
  - Return whether fill is set.

- `get_gid`
  - Return the group id.

- `get_hatch`
  - Return the current hatching pattern.

- `get_in_layout`
  - Return boolean flag, True if artist is included in layout calculations.

  E.g. *Constrained Layout Guide*, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

- `get_joinstyle`

- `get_label`
  - Return the label used for this artist in the legend.

- `get_linestyle`

- `get_linestyles`
  - Alias for `get_linestyle`.

- `get_linewidth`
get_linewidths(self)
    Alias for get_linewidth.

get_ls(self)
    Alias for get_linestyle.

get_lw(self)
    Alias for get_linewidth.

get_numsides(self)

get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen', the
    offset is applied after the master transform has been applied, that is, the offsets are
    in screen coordinates. If offset_position is 'data', the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
    Return the offsets for the collection.

get_path_effects(self)

get_paths(self)

get_picker(self)
    Return the picking behavior of the artist.
    
    The possible values are described in set_picker.

    See also:

    set_picker, pickable, pick

get_pickradius(self)

get_rasterized(self)
    Return whether the artist is to be rasterized.

get_rotation(self)

get_sizes(self)
    Returns the sizes of the elements in the collection. The value represents the ‘area’
    of the element.

    Returns

    sizes [array] The ‘area’ of each element.

get_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns

    sketch_params [tuple or None] A 3-tuple with the following elements:
    
    • scale: The amplitude of the wiggle perpendicular to the source line.
    • length: The length of the wiggle along the line.
    • randomness: The scale factor by which the length is shrunken or expanded.

    Returns None if no sketch parameters were set.
get_snap(self)
    Returns the snap setting.
    See set_snap for details.

get_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters
    
    renderer [RendererBase instance] renderer that will be used to draw the
    figures (i.e. fig.canvas.get_renderer())

    Returns
    
    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

g_get_transform(self)
    Return the Transform instance used by this artist.

g_get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the
    remaining affine part of its transformation.

g_get_transforms(self)

g_get_url(self)
    Return the url.

g_get_urls(self)

g_get_visible(self)
    Return the visibility.

g_get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    
    The bounding box’ width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box “tight” calculation.
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window
    extent of the artist changes. The extent can change due to any changes in the trans-
    form stack, such as changing the axes limits, the figure size, or the canvas used (as is
done when saving a figure). This can lead to unexpected behavior where interactive
    figures will look fine on the screen, but will save incorrectly.

g_get_zorder(self)
    Return the artist’s zorder.

have_units(self)
    Return True if units are set on the x or y axes.

is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.

mouseover

pchanged(self)
    Call all of the registered callbacks.
    This function is triggered internally when a property is changed.
See also:

add_callback
remove_callback

pick(self, mouseevent)
Process a pick event.
Each child artist will fire a pick event if mouseevent is over the artist and the artist has picker set.
See also:

set_picker, get_picker, pickable

pickable(self)
Return whether the artist is pickable.
See also:

set_picker, get_picker, pick

properties(self)
Return a dictionary of all the properties of the artist.

remove(self)
Remove the artist from the figure if possible.
The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.draw_idle. Call relim to update the axes limits if desired.
Note: relim will not see collections even if the collection was added to the axes with autolim = True.
Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
Remove a callback based on its observer id.
See also:

add_callback

set(self, **kwargs)
A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
Alias for set_antialiased.

set_agg_filter(self, filter_func)
Set the agg filter.

Parameters

filter_func (callable) A filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
Set the alpha transparencies of the collection.

Parameters
**alpha** [float or None]

```python
set_animated(self, b)
```

Set the artist’s animation state.

**Parameters**

- **b** [bool]

```python
set_antialiased(self, aa)
```

Set the antialiasing state for rendering.

**Parameters**

- **aa** [bool or sequence of bools]

```python
set_antialiaseds(self, aa)
```

Alias for `set_antialiased`.

```python
set_array(self, A)
```

Set the image array from numpy array `A`.

**Parameters**

- **A** [ndarray]

```python
set_capstyle(self, cs)
```

Set the capstyle for the collection (for all its elements).

**Parameters**

- **cs** [{'butt', 'round', 'projecting'}] The capstyle

```python
set_clim(self, vmin=None, vmax=None)
```

Set the norm limits for image scaling; if `vmin` is a length2 sequence, interpret it as `(vmin, vmax)` which is used to support `setp` ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have `vmin` and `vmax` kwargs.

```python
set_clip_box(self, clipbox)
```

Set the artist’s clip `Bbox`.

**Parameters**

- **clipbox** [Bbox]

```python
set_clip_on(self, b)
```

Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

- **b** [bool]

```python
set_clip_path(self, path, transform=None)
```

Set the artist’s clip path, which may be:

- a `Patch` (or subclass) instance; or
- a `Path` instance, in which case a `Transform` instance, which will be applied to the path before using it for clipping, must be provided; or
- None, to remove a previously set clipping path.
For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

`set_cmap(self, cmap)`
set the colormap for luminance data

**Parameters**

- `cmap` [colormap or registered colormap name]

`set_color(self, c)`
Set both the edgecolor and the facecolor.

**Parameters**

- `c` [color or sequence of rgba tuples]

See also:

- `Collection.set_facecolor`, `Collection.set_edgecolor` For setting the edge or face color individually.

`set_contains(self, picker)`
Define a custom contains test for the artist.

The provided callable replaces the default contains method of the artist.

**Parameters**

- `picker` [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

  ```python
  def contains(artist: Artist, event: MouseEvent) -> bool, dict
  ```

  that returns:
  - a bool indicating if the event is within the artist
  - a dict of additional information. The dict should at least return the same information as the default contains() implementation of the respective artist, but may provide additional information.

`set_dashes(self, ls)`
Alias for `set_linestyle`.

`set_ec(self, c)`
Alias for `set_edgecolor`.

`set_edgecolor(self, c)`
Set the edgecolor(s) of the collection.

**Parameters**

- `c` [color or sequence of colors or ‘face’] The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

`set_edgecolors(self, c)`
Alias for `set_edgecolor`.

`set_facecolor(self, c)`
Set the facecolor(s) of the collection. `c` can be a matplotlib color spec (all patches
have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If \( c \) is 'none', the patch will not be filled.

**Parameters**

- \( c \) [color or sequence of colors]

```
set_facecolors(self, c)
```

Alias for `set_facecolor`.

```
set_tc(self, c)
```

Alias for `set_facecolor`.

```
set_figure(self, fig)
```

Set the Figure instance the artist belongs to.

**Parameters**

- \( fig \) [Figure]

```
set_gid(self, gid)
```

Set the (group) id for the artist.

**Parameters**

- \( gid \) [str]

```
set_hatch(self, hatch)
```

Set the hatching pattern

\( hatch \) can be one of:

```
/  - diagonal hatching
\  - back diagonal
|  - vertical
-  - horizontal
+  - crossed
x  - crossed diagonal
o  - small circle
O  - large circle
.  - dots
*  - stars
```

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

**Parameters**

```
set_in_layout(self, in_layout)
```

Set if artist is to be included in layout calculations, E.g. *Constrained Layout Guide*, `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

**Parameters**

- \( in\text{\_}layout \) [bool]
set_joinstyle(self, js)
Set the joinstyle for the collection (for all its elements).

Parameters
    js [{'miter', 'round', 'bevel'}] The joinstyle

set_label(self, s)
Set a label that will be displayed in the legend.

Parameters
    s [object] s will be converted to a string by calling str.

set_linestyle(self, ls)
Set the linestyle(s) for the collection.

<table>
<thead>
<tr>
<th>linestyle</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-' or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--' or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.' or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>':' or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:

{(offset, onoffseq),}

where onoffseq is an even length tuple of on and off ink in points.

Parameters
    ls [{'-','-','--','-.','..', (offset, on-off-seq), ...}] The line style.

set_linestyles(self, ls)
Alias for set_linestyle.

set_linewidth(self, lw)
Set the linewidth(s) for the collection. lw can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence

Parameters
    lw [float or sequence of floats]

set_linewidths(self, lw)
Alias for set_linewidth.

set_ls(self, ls)
Alias for set_linestyle.

set_lw(self, lw)
Alias for set_linewidth.

set_norm(self, norm)
Set the normalization instance.

Parameters
    norm [Normalize]
Notes

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

`set_offset_position(self, offset_position)`
Set how offsets are applied. If `offset_position` is `‘screen’` (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is `‘data’`, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- `offset_position` [‘screen’, ‘data’]

`set_offsets(self, offsets)`
Set the offsets for the collection.

**Parameters**

- `offsets` [float or sequence of floats]

`set_path_effects(self, path_effects)`
Set the path effects.

**Parameters**

- `path_effects` [AbstractPathEffect]

`set_paths(self)`

`set_picker(self, picker)`
Define the picking behavior of the artist.

**Parameters**

- `picker` [None or bool or float or callable] This can be one of the following:
  - `None`: Picking is disabled for this artist (default).
  - A boolean: If `True` then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
  - A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it’s data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
  - A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

    ```python
    hit, props = picker(artist, mouseevent)
    ```

to determine the hit test. If the mouse event is over the artist, return `hit=True` and `props` is a dictionary of properties you want added to the PickEvent attributes.

`set_pickradius(self, pr)`
Set the pick radius used for containment tests.

**Parameters**
**set_rasterized**

- **set_rasterized** *(self, rasterized)*
  - Force rasterized (bitmap) drawing in vector backend output.
  - Defaults to None, which implies the backend’s default behavior.

**Parameters**

- **rasterized** [bool or None]

**set_sizes** *(self, sizes, dpi=72.0)*

- Set the sizes of each member of the collection.

**Parameters**

- **sizes** [ndarray or None] The size to set for each element of the collection.
  - The value is the ‘area’ of the element.
- **dpi** [float] The dpi of the canvas. Defaults to 72.0.

**set_sketch_params** *(self, scale=None, length=None, randomness=None)*

- Sets the sketch parameters.

**Parameters**

- **scale** [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.
- **length** [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
- **randomness** [float, optional] The scale factor by which the length is shrunken or expanded (default 16.0)

**set_snap** *(self, snap)*

- Set the snapping behavior.

  - Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

  - Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

- **snap** [bool or None] Possible values:
  - True: Snap vertices to the nearest pixel center.
  - False: Do not modify vertex positions.
  - None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

**set_transform** *(self, t)*

- Set the artist transform.

**Parameters**

- **t** [Transform]
set_url(self, url)
    Set the url for the artist.

    Parameters
    url [str]

set_urls(self, urls)
    Parameters
    urls [List[str] or None]

set_visible(self, b)
    Set the artist’s visibility.

    Parameters
    b [bool]

set_zorder(self, level)
    Set the zorder for the artist. Artists with lower zorder values are drawn first.

    Parameters
    level [float]

stale
    Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the internal state of the artist.

sticky_edges
    x and y sticky edge lists for autoscaling.

    When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.

    This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

Examples

>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)

to_rgba(self, x, alpha=None, bytes=False, norm=True)
    Return a normalized rgba array corresponding to x.

    In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

    There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg
is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

```python
update(self, props)
    Update this artist’s properties from the dictionary props.

update_from(self, other)
    copy properties from other to self

update_scalarmappable(self)
    Update colors from the scalar mappable array, if it is not None.
```

```python
zorder = 0
class matplotlib.collections.StarPolygonCollection(numsides, rotation=0, sizes=(1,), **kwargs)
```

Bases: matplotlib.collections.RegularPolyCollection

Draw a collection of regular stars with numsides points.

**numsides**  the number of sides of the polygon

**rotation**  the rotation of the polygon in radians

**sizes**  gives the area of the circle circumscribing the regular polygon in points^2

Valid Collection keyword arguments:

- **edgecolors**: None
- **facecolors**: None
- **linewidths**: None
- **antialiaseds**: None
- **offsets**: None
- **transOffset**: transforms.IdentityTransform()
- **norm**: None (optional for matplotlib.cm.ScalarMappable)
- **cmap**: None (optional for matplotlib.cm.ScalarMappable)

**offsets** and **transOffset** are used to translate the patch after rendering (default no offsets)

If any of **edgecolors**, **facecolors**, **linewidths**, **antialiaseds** are None, they default to their matplotlib.rcParams patch setting, in sequence form.

Example: see /gallery/event_handling/lasso_demo for a complete example:

```python
offsets = np.random.rand(20,2)
facecolors = [cm.jet(x) for x in np.random.rand(20)]
black = (0,0,0,1)

collection = RegularPolyCollection(
    numsides=5, # a pentagon
    rotation=0, sizes=(50,),
```

(continues on next page)
add_callback(self, func)
Add a callback function that will be called whenever one of the Artist's properties changes.

Parameters

func [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where artist is the calling Artist. Return values may exist but are ignored.

Returns

oid [int] The observer id associated with the callback. This id can be used for removing the callback with remove_callback later.

See also:

remove_callback

add_checker(self, checker)
Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

aname

autoscale(self)
Autoscale the scalar limits on the norm instance using the current array

autoscale_None(self)
Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

axes
The Axes instance the artist resides in, or None.

changed(self)
Call this whenever the mappable is changed to notify all the callback listeners to the ‘changed’ signal

check_update(self, checker)
If mappable has changed since the last check, return True; else return False

contains(self, mouseevent)
Test whether the mouse event occurred in the collection.

Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

convert_xunits(self, x)
Convert x using the unit type of the xaxis.
If the artist is not in contained in an Axes or if the xaxis does not have units, \( x \) itself is returned.

\[
\text{convert_yunits}(self, y)
\]
Convert \( y \) using the unit type of the yaxis.

If the artist is not in contained in an Axes or if the yaxis does not have units, \( y \) itself is returned.

\[
\text{draw}(self, renderer)
\]
Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (\( \text{Artist}.\text{get_visible} \) is \( \text{False} \)).

**Parameters**

- **renderer** [RendererBase subclass.]

\[
\text{findobj}(self, match=None, include_self=True)
\]
Find artist objects.

Recursively find all \( \text{Artist} \) instances contained in the artist.

**Parameters**

- **match** A filter criterion for the matches. This can be
  - None: Return all objects contained in artist.
  - A function with signature \( \text{def } \text{match}(\text{artist}: \text{Artist}) \rightarrow \text{bool} \). The result will only contain artists for which the function returns \( \text{True} \).
  - A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (\( \text{isinstance} \) check).

- **include_self** [bool] Include \( \text{self} \) in the list to be checked for a match.

**Returns**

- **artists** [list of \( \text{Artist} \)]

\[
\text{format_cursor_data}(self, data)
\]
Return a string representation of \( data \).

**Note:** This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

**See also:**

- \( \text{get_cursor_data} \)
- \( \text{get_agg_filter} \)
  Return filter function to be used for agg filter.
- \( \text{get_alpha} \)
  Return the alpha value used for blending - not supported on all backends
- \( \text{get_animated} \)
  Return the animated state.
get_array(self)
    Return the array

get_capstyle(self)

get_children(self)
    Return a list of the child Artists of this Artist.

get_clim(self)
    return the min, max of the color limits for image scaling

get_clip_box(self)
    Return the clip box.

get_clip_on(self)
    Return whether the artist uses clipping.

get_clip_path(self)
    Return the clip path.

get_cmap(self)
    return the colormap

get.contains(self)
    Return the custom contains function of the artist if set, or None.

See also:

set.contains

get.cursor_data(self, event)
    Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user
of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a
given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when do-
ing so, they must ensure that format_cursor_data can convert the data to a string
representation.

The only current use case is displaying the z-value of an AxesImage in the status bar
of a plot window, while moving the mouse.

Parameters

    event [matplotlib.backend_bases.MouseEvent]

See also:

format.cursor_data

get.dashes(self)
    Alias for get_linestyle.

getdatalim(self, transData)

get.ec(self)
    Alias for get_edgecolor.
get_edgecolor(self)
get_edgecolors(self)
    Alias for get_edgecolor.
get_facecolor(self)
get_facecolors(self)
    Alias for get_facecolor.
get.fc(self)
    Alias for get_facecolor.
get.figure(self)
    Return the Figure instance the artist belongs to.
get.fill(self)
    return whether fill is set
get_gid(self)
    Return the group id.
get.hatch(self)
    Return the current hatching pattern.
get.in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.
    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname,
    bbox_inches='tight').
get.joinstyle(self)
get.label(self)
    Return the label used for this artist in the legend.
get.linestyle(self)
get.linestyles(self)
    Alias for get_linestyle.
get.linewidth(self)
get.linewidths(self)
    Alias for get_linewidth.
get.ls(self)
    Alias for get_linestyle.
get.lw(self)
    Alias for get_linewidth.
get.numsides(self)
get.offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is ‘screen’, the
    offset is applied after the master transform has been applied, that is, the offsets are
    in screen coordinates. If offset_position is ‘data’, the offset is applied before the
    master transform, i.e., the offsets are in data coordinates.
get.offset_transform(self)
get.offsets(self)
    Return the offsets for the collection.
get_path_effects(self)
get_paths(self)
get_picker(self)
    Return the picking behavior of the artist.
    The possible values are described in set_picker.
    
    See also:
    
    set_picker, pickable, pick

get_pickradius(self)
get_rasterized(self)
    Return whether the artist is to be rasterized.
get_rotation(self)
get_sizes(self)
    Returns the sizes of the elements in the collection. The value represents the ‘area’
    of the element.

    Returns
    
    sizes [array] The ‘area’ of each element.

get_sketch_params(self)
    Returns the sketch parameters for the artist.

    Returns
    
    sketch_params [tuple or None] A 3-tuple with the following elements:
    • scale: The amplitude of the wiggle perpendicular to the source line.
    • length: The length of the wiggle along the line.
    • randomness: The scale factor by which the length is shrunken or expanded.

    Returns None if no sketch parameters were set.

get_snap(self)
    Returns the snap setting.
    See set_snap for details.

get_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

    Parameters
    
    renderer [RendererBase instance] renderer that will be used to draw the
    figures (i.e. fig.canvas.get_renderer())

    Returns
    
    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
    Return the Transform instance used by this artist.
get_transformed_clip_path_and_affine(self)
    Return the clip path with the non-affine part of its transformation applied, and the
    remaining affine part of its transformation.

get_transforms(self)

get_url(self)
    Return the url.

get_urls(self)

get_visible(self)
    Return the visibility.

get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box’ width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box “tight” calculation.
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window
    extent of the artist changes. The extent can change due to any changes in the trans-
    form stack, such as changing the axes limits, the figure size, or the canvas used (as is
done when saving a figure). This can lead to unexpected behavior where interactive
figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
    Return the artist’s zorder.

have_units(self)
    Return True if units are set on the x or y axes.

is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.

mouseover

pchanged(self)
    Call all of the registered callbacks.
    This function is triggered internally when a property is changed.

    See also:

        add_callback

        remove_callback

pick(self, mouseevent)
    Process a pick event.
    Each child artist will fire a pick event if mouseevent is over the artist and the artist
    has picker set.

    See also:

        set_picker, get_picker, pickable
pickleable(self)
    Return whether the artist is pickable.

    See also:
    
    set_picker, get_picker, pick

properties(self)
    Return a dictionary of all the properties of the artist.

remove(self)
    Remove the artist from the figure if possible.
    
    The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
    draw_idle. Call relim to update the axes limits if desired.
    
    Note: relim will not see collections even if the collection was added to the axes with
    autolim = True.
    
    Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
    Remove a callback based on its observer id.

    See also:
    
    add_callback

set(self, **kwargs)
    A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
    Alias for set_antialiased.

set_agg_filter(self, filter_func)
    Set the agg filter.

    Parameters
    
    filter_func [callable] A filter function, which takes a (m, n, 3) float array
    and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
    Set the alpha transparencies of the collection.

    Parameters
    
    alpha [float or None]

set_animated(self, b)
    Set the artist’s animation state.

    Parameters
    
    b [bool]

set_antialiased(self, aa)
    Set the antialiasing state for rendering.

    Parameters
    
    aa [bool or sequence of bools]
set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
    A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).

    Parameters
    cs [{'butt', 'round', 'projecting'}] The capstyle

set_clim(self, vmin=None, vmax=None)
    set the norm limits for image scaling; if vmin is a length2 sequence, interpret it as
    (vmin, vmax) which is used to support setp

    ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have
    vmin and vmax kwargs.

set_clip_box(self, clipbox)
    Set the artist’s clip Bbox.

    Parameters
    clipbox [Bbox]

set_clip_on(self, b)
    Set whether the artist uses clipping.

    When False artists will be visible out side of the axes which can lead to unexpected
    results.

    Parameters
    b [bool]

set_clip_path(self, path, transform=None)
    Set the artist’s clip path, which may be:
    • a Patch (or subclass) instance; or
    • a Path instance, in which case a Transform instance, which will be applied to the
      path before using it for clipping, must be provided; or
    • None, to remove a previously set clipping path.

    For efficiency, if the path happens to be an axis-aligned rectangle, this method will
    set the clipping box to the corresponding rectangle and set the clipping path to None.

    ACCEPTS: [(Path, Transform) | Patch | None]

set_cmap(self, cmap)
    set the colormap for luminance data

    Parameters
    cmap [colormap or registered colormap name]

set_color(self, c)
    Set both the edgecolor and the facecolor.

    Parameters
c [color or sequence of rgba tuples]

See also:

```
Collection.set_facecolor, Collection.set_edgecolor
```

For setting the edge or face color individually.

**set_contains** *(self, picker)*

Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.

**Parameters**

- **picker** [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

**set_dashes** *(self, ls)*

Alias for `set_linestyle`.

**set_ec** *(self, c)*

Alias for `set_edgecolor`.

**set_edgecolor** *(self, c)*

Set the edgecolor(s) of the collection.

**Parameters**

- **c** [color or sequence of colors or ‘face’] The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

**set_edgecolors** *(self, c)*

Alias for `set_edgecolor`.

**set_facecolor** *(self, c)*

Set the facecolor(s) of the collection. `c` can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If `c` is ‘none’, the patch will not be filled.

**Parameters**

- **c** [color or sequence of colors]

**set_facecolors** *(self, c)*

Alias for `set_facecolor`.

**set_fc** *(self, c)*

Alias for `set_facecolor`.

**set_figure** *(self, fig)*

Set the `Figure` instance the artist belongs to.
Parameters

**fig** [Figure]

`set_gid(self, gid)`

Set the (group) id for the artist.

Parameters

**gid** [str]

`set_hatch(self, hatch)`

Set the hatching pattern

`hatch` can be one of:

```
/ - diagonal hatching
\ - back diagonal
| - vertical
- - horizontal
+ - crossed
dx - crossed diagonal
o - small circle
O - large circle
. - dots
* - stars
```

Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

Unlike other properties such as linewidth and colors, hatching can only be specified for the collection as a whole, not separately for each member.

Parameters

`set_in_layout(self, in_layout)`

Set if artist is to be included in layout calculations, e.g. `Constrained Layout Guide`, `Figure.tight_layout()` and `fig.savefig(fname, bbox_inches='tight')`.

Parameters

**in_layout** [bool]

`set_joinstyle(self, js)`

Set the joinstyle for the collection (for all its elements).

Parameters

**js** [{‘miter’, ‘round’, ‘bevel’}] The joinstyle

`set_label(self, s)`

Set a label that will be displayed in the legend.

Parameters

**s** [object] s will be converted to a string by calling `str`.

`set_linestyle(self, ls)`

Set the linestyle(s) for the collection.
<table>
<thead>
<tr>
<th>linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-' or 'solid'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--' or 'dashed'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.' or 'dashdot'</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>':' or 'dotted'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Alternatively a dash tuple of the following form can be provided:

```
(offset, on-off-seq),
```

where `on-off-seq` is an even length tuple of on and off ink in points.

**Parameters**

- `ls` [{',', '-', '.', ':', '', (offset, on-off-seq), ...}] The line style.

```python
set_linestyles(self, ls)
```

Alias for `set_linestyle`.

```python
set_linewidth(self, lw)
```

Set the linewidth(s) for the collection. `lw` can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence.

**Parameters**

- `lw` [float or sequence of floats]

```python
set_linewidths(self, lw)
```

Alias for `set_linewidth`.

```python
set_ls(self, ls)
```

Alias for `set_linestyle`.

```python
set_lw(self, lw)
```

Alias for `set_linewidth`.

```python
set_norm(self, norm)
```

Set the normalization instance.

**Parameters**

- `norm` [Normalize]

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

```python
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is 'screen' (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is 'data', the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- `offset_position` [{‘screen’, ‘data’}]

```python
set_offsets(self, offsets)
```

Set the offsets for the collection.
Parameters

**offsets** [float or sequence of floats]

`set_path_effects(self, path_effects)`
Set the path effects.

Parameters

**path_effects** [AbstractPathEffect]

`set_paths(self)`

`set_picker(self, picker)`
Define the picking behavior of the artist.

Parameters

**picker** [None or bool or float or callable] This can be one of the following:

- *None*: Picking is disabled for this artist (default).
- A boolean: If True then picking will be enabled and the artist will fire a pick event if the mouse event is over the artist.
- A float: If picker is a number it is interpreted as an epsilon tolerance in points and the artist will fire off an event if it's data is within epsilon of the mouse event. For some artists like lines and patch collections, the artist may provide additional data to the pick event that is generated, e.g., the indices of the data within epsilon of the pick event.
- A function: If picker is callable, it is a user supplied function which determines whether the artist is hit by the mouse event:

```python
hit, props = picker(artist, mouseevent)
```

to determine the hit test. if the mouse event is over the artist, return `hit=True` and props is a dictionary of properties you want added to the PickEvent attributes.

`set_pickradius(self, pr)`
Set the pick radius used for containment tests.

Parameters

**d** [float] Pick radius, in points.

`set_rasterized(self, rasterized)`
Force rasterized (bitmap) drawing in vector backend output.
Defaults to None, which implies the backend’s default behavior.

Parameters

**rasterized** [bool or None]

`set_sizes(self, sizes, dpi=72.0)`
Set the sizes of each member of the collection.

Parameters

**sizes** [ndarray or None] The size to set for each element of the collection. The value is the ‘area’ of the element.

**dpi** [float] The dpi of the canvas. Defaults to 72.0.
set_sketch_params(self, scale=None, length=None, randomness=None)
Sets the sketch parameters.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the source line, in pixels. If scale is None, or not provided, no sketch filter will be provided.
length [float, optional] The length of the wiggle along the line, in pixels (default 128.0)
randomness [float, optional] The scale factor by which the length is shrunk or expanded (default 16.0)

set_snap(self, snap)
Set the snapping behavior.

Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

Parameters

snap [bool or None] Possible values:
- True: Snap vertices to the nearest pixel center.
- False: Do not modify vertex positions.
- None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.

set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]

set_url(self, url)
Set the url for the artist.

Parameters

url [str]

set_urls(self, urls)

Parameters

urls [List[str] or None]

set_visible(self, b)
Set the artist's visibility.

Parameters

b [bool]
set_zorder(self, level)
    Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters
    level [float]

stale
    Whether the artist is ‘stale’ and needs to be re-drawn for the output to match the
    internal state of the artist.

sticky_edges
    x and y sticky edge lists for autoscaling.
    When performing autoscaling, if a data limit coincides with a value in the corres-
    ponding sticky_edges list, then no margin will be added–the view limit “sticks” to
    the edge. A typical use case is histograms, where one usually expects no margin on
    the bottom edge (0) of the histogram.

    This attribute cannot be assigned to; however, the x and y lists can be modified in
    place as needed.

Examples

>>> artist.sticky_edges.x[:] = (xmin, xmax)
>>> artist.sticky_edges.y[:] = (ymin, ymax)

to_rgba(self, x=None, alpha=None, bytes=False, norm=True)
    Return a normalized rgba array corresponding to x.
    In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding
    ndarray of rgba values will be returned, based on the norm and colormap set for
    this ScalarMappable.
    There is one special case, for handling images that are already rgb or rgba, such as
    might have been read from an image file. If x is an ndarray with 3 dimensions, and
    the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array,
    and no mapping will be done. The array can be uint8, or it can be floating point with
    values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array,
    the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to
    1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg
    is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if
    the third dimension is other than 3 or 4.
    In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range;
    if it is True, the returned rgba array will be uint8 in the 0 to 255 range.
    If norm is False, no normalization of the input data is performed, and it is assumed
    to be in the range (0-1).

update(self, props)
    Update this artist’s properties from the dictionary props.

update_from(self, other)
    copy properties from other to self

update_scalarmappable(self)
    Update colors from the scalar mappable array, if it is not None.

zorder = 0
class `matplotlib.collections.TriMesh(triangulation, **kwargs)`

Bases: `matplotlib.collections.Collection`

Class for the efficient drawing of a triangular mesh using Gouraud shading.

A triangular mesh is a `Triangulation` object.

`add_callback(self, func)`

Add a callback function that will be called whenever one of the `Artist`'s properties changes.

**Parameters**

`func` [callable] The callback function. It must have the signature:

```python
def func(artist: Artist) -> Any
```

where `artist` is the calling `Artist`. Return values may exist but are ignored.

**Returns**

`oid` [int] The observer id associated with the callback. This id can be used for removing the callback with `remove_callback` later.

**See also:**

`remove_callback`

`add_checker(self, checker)`

Add an entry to a dictionary of boolean flags that are set to True when the mappable is changed.

`aname`

`autoscale(self)`

Autoscale the scalar limits on the norm instance using the current array

`autoscale_None(self)`

Autoscale the scalar limits on the norm instance using the current array, changing only limits that are None

`axes`

The `Axes` instance the artist resides in, or `None`.

`changed(self)`

Call this whenever the mappable is changed to notify all the callback listeners to the ‘changed’ signal

`check_update(self, checker)`

If mappable has changed since the last check, return True; else return False

`contains(self, mouseevent)`

Test whether the mouse event occurred in the collection.

Returns bool, dict(ind=itemlist), where every item in itemlist contains the event.

static `convert_mesh_to_paths(tri)`

Converts a given mesh into a sequence of `Path` objects.

This function is primarily of use to implementers of backends that do not directly support meshes.
convert_xunits(self, x)
    Convert x using the unit type of the xaxis.
    If the artist is not in contained in an Axes or if the xaxis does not have units, x itself
    is returned.

convert_yunits(self, y)
    Convert y using the unit type of the yaxis.
    If the artist is not in contained in an Axes or if the yaxis does not have units, y itself
    is returned.

draw(self, renderer)
    Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented
to not have any effect if the Artist is not visible (Artist.get_visible is False).

    Parameters
    
    renderer [RendererBase subclass.]

findobj(self, match=None, include_self=True)
    Find artist objects.
    Recursively find all Artist instances contained in the artist.

    Parameters
    
    match A filter criterion for the matches. This can be
    • None: Return all objects contained in artist.
    • A function with signature def match(artist: Artist) -> bool. The re-
      sult will only contain artists for which the function returns True.
    • A class instance: e.g., Line2D. The result will only contain artists of
      this class or its subclasses (isinstance check).

    include_self [bool] Include self in the list to be checked for a match.

    Returns
    
    artists [list of Artist]

format_cursor_data(self, data)
    Return a string representation of data.

    Note: This method is intended to be overridden by artist subclasses. As an end-user
    of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into
a comma-separated string enclosed in square brackets.

See also:

    get_cursor_data

get_agg_filter(self)
    Return filter function to be used for agg filter.

geta lpha(self)
    Return the alpha value used for blending - not supported on all backends
get_animated(self)
    Return the animated state.

go_array(self)
    Return the array

go_capstyle(self)

go_children(self)
    Return a list of the child Artists of this Artist.

go_clim(self)
    return the min, max of the color limits for image scaling

go_clip_box(self)
    Return the clipbox.

go_clip_on(self)
    Return whether the artist uses clipping.

go_clip_path(self)
    Return the clip path.

go_cmap(self)
    return the colormap

go_contains(self)
    Return the custom contains function of the artist if set, or None.

See also:

set_contains

go_cursor_data(self, event)
    Return the cursor data for a given event.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

Cursor data can be used by Artists to provide additional context information for a given event. The default implementation just returns None.

Subclasses can override the method and return arbitrary data. However, when doing so, they must ensure that format_cursor_data can convert the data to a string representation.

The only current use case is displaying the z-value of an AxesImage in the status bar of a plot window, while moving the mouse.

Parameters

event [matplotlib.backend_bases.MouseEvent]

See also:

format_cursor_data

go_dashes(self)
    Alias for get_linestyle.

go_datalim(self, transData)
get_ec(self)
    Alias for get_edgecolor.

get_edgecolor(self)

get_edgecolors(self)
    Alias for get_edgecolor.

get_facecolor(self)

get_facecolors(self)
    Alias for get_facecolor.

g_f(self)
    Alias for get_facecolor.

g_figure(self)
    Return the Figure instance the artist belongs to.

g_fill(self)
    return whether fill is set

g_gid(self)
    Return the group id.

get_hatch(self)
    Return the current hatching pattern.

g_in_layout(self)
    Return boolean flag, True if artist is included in layout calculations.

    E.g. Constrained Layout Guide, Figure.tight_layout(), and fig.savefig(fname,
        bbox_inches='tight').

g_joinstyle(self)

g_label(self)
    Return the label used for this artist in the legend.

g_linestyle(self)

g_linestyles(self)
    Alias for get_linestyle.

g_linewidth(self)

g_linewidths(self)
    Alias for get_linewidth.

g_ls(self)
    Alias for get_linestyle.

g_lw(self)
    Alias for get_linewidth.

get_offset_position(self)
    Returns how offsets are applied for the collection. If offset_position is 'screen',
    the offset is applied after the master transform has been applied, that is, the offsets
    are in screen coordinates. If offset_position is 'data', the offset is applied before
    the master transform, i.e., the offsets are in data coordinates.

get_offset_transform(self)

get_offsets(self)
    Return the offsets for the collection.
get_path_effects(self)
get_paths(self)
get_picker(self)
Return the picking behavior of the artist.
The possible values are described in set_picker.

See also:

set_picker, pickable, pick

get_pickradius(self)
get_rasterized(self)
Return whether the artist is to be rasterized.

get_sketch_params(self)
Returns the sketch parameters for the artist.

Returns

sketch_params [tuple or None] A 3-tuple with the following elements:
• scale: The amplitude of the wiggle perpendicular to the source line.
• length: The length of the wiggle along the line.
• randomness: The scale factor by which the length is shrunken or expanded.

Returns None if no sketch parameters were set.

get_snap(self)
Returns the snap setting.
See set_snap for details.

get_tightbbox(self, renderer)
Like Artist.get_window_extent, but includes any clipping.

Parameters

renderer [RendererBase instance] renderer that will be used to draw the figures (i.e. fig.canvas.get_renderer())

Returns

bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
Return the Transform instance used by this artist.

get_transformed_clip_path_and_affine(self)
Return the clip path with the non-affine part of its transformation applied, and the remaining affine part of its transformation.

get_transforms(self)

get_url(self)
Return the url.

get_urls(self)
get_visible(self)
    Return the visibility.

get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box’ width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box ”tight” calculation.
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window
extent of the artist changes. The extent can change due to any changes in the trans-
form stack, such as changing the axes limits, the figure size, or the canvas used (as is
done when saving a figure). This can lead to unexpected behavior where interactive
figures will look fine on the screen, but will save incorrectly.

get_zorder(self)
    Return the artist’s zorder.

have_units(self)
    Return True if units are set on the x or y axes.

is_transform_set(self)
    Return whether the Artist has an explicitly set transform.
    This is True after set_transform has been called.

mouseover

pchanged(self)
    Call all of the registered callbacks.
    This function is triggered internally when a property is changed.
    See also:

        add_callback

        remove_callback

pick(self, mouseevent)
    Process a pick event.
    Each child artist will fire a pick event if mouseevent is over the artist and the artist
has picker set.
    See also:

        set_picker, get_picker, pickable

pickable(self)
    Return whether the artist is pickable.
    See also:

        set_picker, get_picker, pick

properties(self)
    Return a dictionary of all the properties of the artist.
remove(self)
    Remove the artist from the figure if possible.

    The effect will not be visible until the figure is redrawn, e.g., with FigureCanvasBase.
    draw_idle. Call relim to update the axes limits if desired.

    Note: relim will not see collections even if the collection was added to the axes with autolim = True.

    Note: there is no support for removing the artist’s legend entry.

remove_callback(self, oid)
    Remove a callback based on its observer id.

See also:
    add_callback

set(self, **kwargs)
    A property batch setter. Pass kwargs to set properties.

set_aa(self, aa)
    Alias for set_antialiased.

set_agg_filter(self, filter_func)
    Set the agg filter.

    Parameters
        filter_func [callable] A filter function, which takes a (m, n, 3) float array
        and a dpi value, and returns a (m, n, 3) array.

set_alpha(self, alpha)
    Set the alpha transparencies of the collection.

    Parameters
        alpha [float or None]

set_animated(self, b)
    Set the artist’s animation state.

    Parameters
        b [bool]

set_antialiased(self, aa)
    Set the antialiasing state for rendering.

    Parameters
        aa [bool or sequence of bools]

set_antialiaseds(self, aa)
    Alias for set_antialiased.

set_array(self, A)
    Set the image array from numpy array A.

    Parameters
        A [ndarray]

set_capstyle(self, cs)
    Set the capstyle for the collection (for all its elements).
**Parameters**

cs [{'butt', 'round', 'projecting'}] The capstyle

`set_clim(self, vmin=None, vmax=None)`

set the norm limits for image scaling; if `vmin` is a length2 sequence, interpret it as `(vmin, vmax)` which is used to support setp

ACCEPTS: a length 2 sequence of floats; may be overridden in methods that have `vmin` and `vmax` kwargs.

`set_clip_box(self, clipbox)`

Set the artist’s clip `Bbox`.

**Parameters**

clipbox [Bbox]

`set_clip_on(self, b)`

Set whether the artist uses clipping.

When False artists will be visible out side of the axes which can lead to unexpected results.

**Parameters**

b [bool]

`set_clip_path(self, path, transform=None)`

Set the artist’s clip path, which may be:

- a `Patch` (or subclass) instance; or
- a `Path` instance, in which case a `Transform` instance, which will be applied to the path before using it for clipping, must be provided; or
- `None`, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will set the clipping box to the corresponding rectangle and set the clipping path to `None`.

ACCEPTS: [(Path, Transform) | Path | None]

`set_cmap(self, cmap)`

set the colormap for luminance data

**Parameters**

cmap [colormap or registered colormap name]

`set_color(self, c)`

Set both the edgecolor and the facecolor.

**Parameters**

c [color or sequence of rgba tuples]

See also:

`Collection.set_facecolor`, `Collection.set_edgecolor` For setting the edge or face color individually.

`set_contains(self, picker)`

Define a custom contains test for the artist.

The provided callable replaces the default `contains` method of the artist.
Parameters

**picker** [callable] A custom picker function to evaluate if an event is within the artist. The function must have the signature:

```python
def contains(artist: Artist, event: MouseEvent) -> bool, dict
```

that returns:

- a bool indicating if the event is within the artist
- a dict of additional information. The dict should at least return the same information as the default `contains()` implementation of the respective artist, but may provide additional information.

**set_dashes** *(self, ls)*

Alias for `set_linestyle`.

**set_ec** *(self, c)*

Alias for `set_edgecolor`.

**set_edgecolor** *(self, c)*

Set the edgecolor(s) of the collection.

**Parameters**

- **c** [color or sequence of colors or ‘face’] The collection edgecolor(s). If a sequence, the patches cycle through it. If ‘face’, match the facecolor.

**set_edgecolors** *(self, c)*

Alias for `set_edgecolor`.

**set_facecolor** *(self, c)*

Set the facecolor(s) of the collection. `c` can be a matplotlib color spec (all patches have same color), or a sequence of specs; if it is a sequence the patches will cycle through the sequence.

If `c` is ‘none’, the patch will not be filled.

**Parameters**

- **c** [color or sequence of colors]

**set_facecolors** *(self, c)*

Alias for `set_facecolor`.

**set_fc** *(self, c)*

Alias for `set_facecolor`.

**set_figure** *(self, fig)*

Set the `Figure` instance the artist belongs to.

**Parameters**

- **fig** [`Figure`]

**set_gid** *(self, gid)*

Set the (group) id for the artist.

**Parameters**

- **gid** [str]
set_hatch(self, hatch)
    Set the hatching pattern

    `hatch` can be one of:

    / - diagonal hatching
    \ - back diagonal
    | - vertical
    - - horizontal
    + - crossed
    x - crossed diagonal
    o - small circle
    O - large circle
    . - dots
    * - stars

    Letters can be combined, in which case all the specified hatchings are done. If same
    letter repeats, it increases the density of hatching of that pattern.

    Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

    Unlike other properties such as linewidth and colors, hatching can only be specified
    for the collection as a whole, not separately for each member.

    Parameters

set_in_layout(self, in_layout)
    Set if artist is to be included in layout calculations, E.g. `Constrained Layout Guide`,
    `Figure.tight_layout()`, and `fig.savefig(fname, bbox_inches='tight')`.

    Parameters

    `in_layout` [bool]

set_joinstyle(self, js)
    Set the joinstyle for the collection (for all its elements).

    Parameters

    `js` [{‘miter’, ‘round’, ‘bevel’}] The joinstyle

set_label(self, s)
    Set a label that will be displayed in the legend.

    Parameters

    `s` [object] s will be converted to a string by calling `str`.

set_linestyle(self, ls)
    Set the linestyle(s) for the collection.

    linestyle | description
    1 'solid' | solid line
    2 'dashed' | dashed line
    3 'dashdot' | dash-dotted line
    4 'dotted' | dotted line

    Alternatively a dash tuple of the following form can be provided:
where \( \text{onoffseq} \) is an even length tuple of on and off ink in points.

**Parameters**

- **ls** [\{ '-', '–', '––', ':', ', (offset, on-off-seq), ... \}] The line style.

**set_linestyles**

```python
set_linestyles(self, ls)
```

Alias for `set_linestyle`.

**set_linewidth**

```python
set_linewidth(self, lw)
```

Set the linewidth(s) for the collection. \( \text{lw} \) can be a scalar or a sequence; if it is a sequence the patches will cycle through the sequence.

**Parameters**

- **lw** [float or sequence of floats]

**set_linewidths**

```python
set_linewidths(self, lw)
```

Alias for `set_linewidth`.

**set_ls**

```python
set_ls(self, ls)
```

Alias for `set_linestyle`.

**set_lw**

```python
set_lw(self, lw)
```

Alias for `set_linewidth`.

**set_norm**

```python
set_norm(self, norm)
```

Set the normalization instance.

**Parameters**

- **norm** (`Normalize`)

**Notes**

If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

**set_offset_position**

```python
set_offset_position(self, offset_position)
```

Set how offsets are applied. If `offset_position` is ‘screen’ (default) the offset is applied after the master transform has been applied, that is, the offsets are in screen coordinates. If `offset_position` is ‘data’, the offset is applied before the master transform, i.e., the offsets are in data coordinates.

**Parameters**

- **offset_position** [\{‘screen’, ‘data’\}]

**set_offsets**

```python
set_offsets(self, offsets)
```

Set the offsets for the collection.

**Parameters**

- **offsets** [float or sequence of floats]

**set_path_effects**

```python
set_path_effects(self, path_effects)
```

Set the path effects.

**Parameters**

- **path_effects** [AbstractPathEffect]
set_paths(self)

set_picker(self, picker)
    Define the picking behavior of the artist.

    **Parameters**

    picker [None or bool or float or callable] This can be one of the following:
    - None: Picking is disabled for this artist (default).
    - A boolean: If True then picking will be enabled and the artist will fire
      a pick event if the mouse event is over the artist.
    - A float: If picker is a number it is interpreted as an epsilon toler-
      ance in points and the artist will fire off an event if it’s data is within
      epsilon of the mouse event. For some artists like lines and patch col-
      lections, the artist may provide additional data to the pick event that
      is generated, e.g., the indices of the data within epsilon of the pick
      event
    - A function: If picker is callable, it is a user supplied function which
      determines whether the artist is hit by the mouse event:

        ```python
        hit, props = picker(artist, mouseevent)
        ```

      to determine the hit test. if the mouse event is over the artist, return
      hit=True and props is a dictionary of properties you want added to
      the PickEvent attributes.

    set_pickradius(self, pr)
        Set the pick radius used for containment tests.

    **Parameters**

    d [float] Pick radius, in points.

    set_rasterized(self, rasterized)
        Force rasterized (bitmap) drawing in vector backend output.

        Defaults to None, which implies the backend’s default behavior.

    **Parameters**

    rasterized [bool or None]

    set_sketch_params(self, scale=None, length=None, randomness=None)
        Sets the sketch parameters.

    **Parameters**

    scale [float, optional] The amplitude of the wiggle perpendicular to the
    source line, in pixels. If scale is None, or not provided, no sketch filter
    will be provided.

    length [float, optional] The length of the wiggle along the line, in pixels
    (default 128.0)

    randomness [float, optional] The scale factor by which the length is
    shrunken or expanded (default 16.0)

    set_snap(self, snap)
        Set the snapping behavior.
Snapping aligns positions with the pixel grid, which results in clearer images. For example, if a black line of 1px width was defined at a position in between two pixels, the resulting image would contain the interpolated value of that line in the pixel grid, which would be a grey value on both adjacent pixel positions. In contrast, snapping will move the line to the nearest integer pixel value, so that the resulting image will really contain a 1px wide black line.

Snapping is currently only supported by the Agg and MacOSX backends.

**Parameters**

```
snap [bool or None] Possible values:
• True: Snap vertices to the nearest pixel center.
• False: Do not modify vertex positions.
• None: (auto) If the path contains only rectilinear line segments, round to the nearest pixel center.
```

```
set_transform(self, t)
Set the artist transform.

Parameters

t [Transform]
```

```
set_url(self, url)
Set the url for the artist.

Parameters

url [str]
```

```
set_urls(self, urls)

Parameters

urls [List[str] or None]
```

```
set_visible(self, b)
Set the artist’s visibility.

Parameters

b [bool]
```

```
set_zorder(self, level)
Set the zorder for the artist. Artists with lower zorder values are drawn first.

Parameters

level [float]
```

```
sticky_edges
x and y sticky edge lists for autoscaling.

When performing autoscaling, if a data limit coincides with a value in the corresponding sticky_edges list, then no margin will be added—the view limit “sticks” to the edge. A typical use case is histograms, where one usually expects no margin on the bottom edge (0) of the histogram.
This attribute cannot be assigned to; however, the x and y lists can be modified in place as needed.

Examples

```python
def artist.sticky_edges.x[:]:
    x = (xmin, xmax)
def artist.sticky_edges.y[:]:
    y = (ymin, ymax)
```

to_rgba

```
to_rgba(self, x, alpha=None, bytes=False, norm=True)
```
Return a normalized rgba array corresponding to x.

In the normal case, x is a 1-D or 2-D sequence of scalars, and the corresponding ndarray of rgba values will be returned, based on the norm and colormap set for this ScalarMappable.

There is one special case, for handling images that are already rgb or rgba, such as might have been read from an image file. If x is an ndarray with 3 dimensions, and the last dimension is either 3 or 4, then it will be treated as an rgb or rgba array, and no mapping will be done. The array can be uint8, or it can be floating point with values in the 0-1 range; otherwise a ValueError will be raised. If it is a masked array, the mask will be ignored. If the last dimension is 3, the alpha kwarg (defaulting to 1) will be used to fill in the transparency. If the last dimension is 4, the alpha kwarg is ignored; it does not replace the pre-existing alpha. A ValueError will be raised if the third dimension is other than 3 or 4.

In either case, if bytes is False (default), the rgba array will be floats in the 0-1 range; if it is True, the returned rgba array will be uint8 in the 0 to 255 range.

If norm is False, no normalization of the input data is performed, and it is assumed to be in the range (0-1).

update

```
update(self, props)
```
Update this artist’s properties from the dictionary props.

update_from

```
update_from(self, other)
```
copy properties from other to self

update_scalarmappable

```
update_scalarmappable(self)
```
Update colors from the scalar mappable array, if it is not None.

zorder = 0

17.16 matplotlib.colorbar

Colorbar toolkit with two classes and a function:

ColorbarBase the base class with full colorbar drawing functionality. It can be used as-is to make a colorbar for a given colormap; a mappable object (e.g., image) is not needed.

Colorbar the derived class for use with images or contour plots.

make_axes() a function for resizing an axes and adding a second axes suitable for a colorbar
The `colorbar()` method uses `make_axes()` and `Colorbar`; the `colorbar()` function is a thin wrapper over `colorbar()`.

```python
class matplotlib.colorbar.Colorbar(ax, mappable, **kw)
    Bases: matplotlib.colorbar.ColorbarBase

This class connects a `ColorbarBase` to a `ScalarMappable` such as a `AxesImage` generated via `imshow()`.

It is not intended to be instantiated directly; instead, use `colorbar()` or `colorbar()` to make your colorbar.
```

```python
add_lines(self, CS, erase=True)
    Add the lines from a non-filled `ContourSet` to the colorbar.

    Set `erase` to False if these lines should be added to any pre-existing lines.
```

```python
on_mappable_changed(self, mappable)
    Updates this colorbar to match the mappable's properties.

    Typically this is automatically registered as an event handler by `colorbar_factory()`
    and should not be called manually.
```

```python
remove(self)
    Remove this colorbar from the figure. If the colorbar was created with
    use_gridspec=True then restore the gridspec to its previous value.
```

```python
update_bruteforce(self, mappable)
    Destroy and rebuild the colorbar. This is intended to become obsolete, and will
    probably be deprecated and then removed. It is not called when the pyplot.colorbar
    function or the Figure.colorbar method are used to create the colorbar.
```

```python
update_normal(self, mappable)
    Update solid patches, lines, etc.

    Unlike `update_bruteforce`, this does not clear the axes. This is meant to be called
    when the norm of the image or contour plot to which this colorbar belongs changes.

    If the norm on the mappable is different than before, this resets the locator and
    formatter for the axis, so if these have been customized, they will need to be cus-
    tomized again. However, if the norm only changes values of `vmin`, `vmax` or `cmap`
    then the old formatter and locator will be preserved.
```

```python
class matplotlib.colorbar.ColorbarBase(ax, cmap=None, norm=None, alpha=None,
    values=None, boundaries=None, orientation='vertical', ticklocation='auto',
    extend='neither', spacing='uniform', ticks=None, format=None, drawedges=False,
    filled=True, extendfrac=None, extendrect=False, label='')
    Bases: matplotlib.colorbar._ColorbarMappableDummy
```

Draw a colorbar in an existing axes.

This is a base class for the `Colorbar` class, which is the basis for the `colorbar()` function
and the `colorbar()` method, which are the usual ways of creating a colorbar.

It is also useful by itself for showing a colormap. If the `cmap` kwarg is given but `bound-
aries` and `values` are left as `None`, then the colormap will be displayed on a 0-1 scale. To
show the under- and over-value colors, specify the `norm` as:
To show the colors versus index instead of on the 0-1 scale, use:

```python
colors.Normalize(clip=False)
```

Useful public methods are `set_label()` and `add_lines()`.

**Attributes**

- **ax** [Axes] The `Axes` instance in which the colorbar is drawn.
- **lines** [list] A list of `LineCollection` if lines were drawn, otherwise an empty list.
- **dividers** [LineCollection] A `LineCollection` if `drawedges` is `True`, otherwise `None`.

```python
add_lines(self, levels, colors, linewidths, erase=True)
```

Draw lines on the colorbar:

- `colors` and `linewidths` must be scalars or sequences the same length as `levels`.
- Set `erase` to `False` to add lines without first removing any previously added lines.

```python
ax = None
```

The axes that this colorbar lives in.

```python
config_axis(self)
```

```python
draw_all(self)
```

Calculate any free parameters based on the current `cmap` and `norm`, and do all the drawing.

```python
get_ticks(self, minor=False)
```

Return the x ticks as a list of locations.

```python
minorticks_off(self)
```

Turns off the minor ticks on the colorbar.

```python
minorticks_on(self)
```

Turns on the minor ticks on the colorbar without extruding into the “extend regions”.

```python
n_rasterize = 50
```

```python
remove(self)
```

Remove this colorbar from the figure.

```python
set_alpha(self, alpha)
```

```python
set_label(self, label, **kw)
```

Label the long axis of the colorbar.

```python
set_ticklabels(self, ticklabels, update_ticks=True)
```

Set tick labels.

- Tick labels are updated immediately unless `update_ticks` is `False`, in which case one should call `update_ticks` explicitly.

```python
set_ticks(self, ticks, update_ticks=True)
```

Set tick locations.

**Parameters**
ticks [{None, sequence, Locator instance}] If None, a default Locator will be used.

update_ticks [{True, False}, optional] If True, tick locations are updated immediately. If False, use update_ticks() to manually update the ticks.

update_ticks(self)
    Force the update of the ticks and ticklabels. This must be called whenever the tick locator and/or tick formatter changes.

class matplotlib.colorbar.ColorbarPatch(ax, mappable, **kw)
    Bases: matplotlib.colorbar.Colorbar

    A Colorbar which is created using Patch rather than the default pcolor(). It uses a list of Patch instances instead of a PatchCollection because the latter does not allow the hatch pattern to vary among the members of the collection.

    matplotlib.colorbar.colorbar_factory(cax, mappable, **kwargs)
    Creates a colorbar on the given axes for the given mappable. Typically, for automatic colorbar placement given only a mappable use colorbar().

    matplotlib.colorbar.make_axes(parents, location=None, orientation=None, fraction=0.15, shrink=1.0, aspect=20, **kw)
    Resize and reposition parent axes, and return a child axes suitable for a colorbar. Keyword arguments may include the following (with defaults):

    location [[None|’left’|’right’|’top’|’bottom’]] The position, relative to parents, where the colorbar axes should be created. If None, the value will either come from the given orientation, else it will default to ’right’.

    orientation [[None|’vertical’|’horizontal’]] The orientation of the colorbar. Typically, this keyword shouldn’t be used, as it can be derived from the location keyword.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orientation</td>
<td>vertical or horizontal</td>
</tr>
<tr>
<td>fraction</td>
<td>0.15; fraction of original axes to use for colorbar</td>
</tr>
<tr>
<td>pad</td>
<td>0.05 if vertical, 0.15 if horizontal; fraction of original axes between colorbar and new image axes</td>
</tr>
<tr>
<td>shrink</td>
<td>1.0; fraction by which to multiply the size of the colorbar</td>
</tr>
<tr>
<td>aspect</td>
<td>20; ratio of long to short dimensions</td>
</tr>
<tr>
<td>anchor</td>
<td>(0.0, 0.5) if vertical; (0.5, 1.0) if horizontal; the anchor point of the colorbar axes</td>
</tr>
<tr>

<td>(1.0, 0.5) if vertical; (0.5, 0.0) if horizontal; the anchor point of the colorbar parent axes. If False, the parent axes’ anchor will be unchanged</td>
</tr>
</tbody>
</table>

Returns (cax, kw), the child axes and the reduced kw dictionary to be passed when creating the colorbar instance.

    matplotlib.colorbar.make_axes_gridspec(parent, *, fraction=0.15, shrink=1.0, aspect=20, **kw)
Resize and reposition a parent axes, and return a child axes suitable for a colorbar. This function is similar to make_axes. Primary differences are

- `make_axes_gridspec` only handles the `orientation` keyword and cannot handle the “location” keyword.
- `make_axes_gridspec` should only be used with a subplot parent.
- `make_axes` creates an instance of Axes. `make_axes_gridspec` creates an instance of Subplot.
- `make_axes` updates the position of the parent. `make_axes_gridspec` replaces the grid_spec attribute of the parent with a new one.

While this function is meant to be compatible with `make_axes`, there could be some minor differences.

Keyword arguments may include the following (with defaults):

- `orientation` ‘vertical’ or ‘horizontal’

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>orientation</code></td>
<td>vertical or horizontal</td>
</tr>
<tr>
<td><code>fraction</code></td>
<td>0.15; fraction of original axes to use for colorbar</td>
</tr>
<tr>
<td><code>pad</code></td>
<td>0.05 if vertical, 0.15 if horizontal; fraction of original axes between colorbar and new image axes</td>

</tr>
</tbody>
</table>

All but the first of these are stripped from the input kw set.

Returns (cax, kw), the child axes and the reduced kw dictionary to be passed when creating the colorbar instance.

### 17.17 `matplotlib.colors`

For a visual representation of the Matplotlib colormaps, see:

- The `color_examples` examples for examples of controlling color with Matplotlib.
- The `Colors` tutorial for an in-depth guide on controlling color.

A module for converting numbers or color arguments to `RGB` or `RGBA`.

`RGB` and `RGBA` are sequences of, respectively, 3 or 4 floats in the range 0-1.

This module includes functions and classes for color specification conversions, and for mapping numbers to colors in a 1-D array of colors called a colormap.
Mapping data onto colors using a colormap typically involves two steps: a data array is first mapped onto the range 0-1 using a subclass of `Normalize`, then this number is mapped to a color using a subclass of `Colormap`. Two are provided here: `LinearSegmentedColormap`, which uses piecewise-linear interpolation to define colormaps, and `ListedColormap`, which makes a colormap from a list of colors.

**See also:**

*Creating Colormaps in Matplotlib* for examples of how to make colormaps and

*Choosing Colormaps in Matplotlib* for a list of built-in colormaps.

*Colormap Normalization* for more details about data normalization

More colormaps are available at [palettable](https://pypi.org/project/palettable/).

The module also provides functions for checking whether an object can be interpreted as a color (`is_color_like()`), for converting such an object to an RGBA tuple (`to_rgba()`) or to an HTML-like hex string in the #rrggbb format (`to_hex()`), and a sequence of colors to an (n, 4) RGBA array (`to_rgba_array()`). Caching is used for efficiency.

Matplotlib recognizes the following formats to specify a color:

- an RGB or RGBA tuple of float values in [0, 1] (e.g., (0.1, 0.2, 0.5) or (0.1, 0.2, 0.5, 0.3));
- a hex RGB or RGBA string (e.g., '#0f0f0f' or '#0f0f0f80'; case-insensitive);
- a string representation of a float value in [0, 1] inclusive for gray level (e.g., '0.5');
- one of {'b', 'g', 'r', 'c', 'm', 'y', 'k', 'w'};
- a X11/CSS4 color name (case-insensitive);
- a name from the [xkcd color survey](https://xkcd.com/color/), prefixed with 'xkcd:' (e.g., 'xkcd:sky blue'; case-insensitive);
- a "CN" color spec, i.e. 'C' followed by a number, which is an index into the default property cycle (matplotlib.rcParams['axes.prop_cycle']); the indexing is intended to occur at rendering time, and defaults to black if the cycle does not include color.

### 17.17.1 Classes

<table>

<td>The symmetrical logarithmic scale is logarithmic in both the positive and negative directions from the origin.</td>
</tr>
</tbody>
</table>

**matplotlib.colors.BoundaryNorm**

class `matplotlib.colors.BoundaryNorm(boundaries, ncolors, clip=False)`

Bases: `matplotlib.colors.Normalize`

Generate a colormap index based on discrete intervals.

Unlike `Normalize` or `LogNorm`, `BoundaryNorm` maps values to integers instead of to the interval 0-1.

Mapping to the 0-1 interval could have been done via piece-wise linear interpolation, but using integers seems simpler, and reduces the number of conversions back and forth between integer and floating point.

**Parameters**

- `boundaries` [array-like] Monotonically increasing sequence of boundaries
- `ncolors` [int] Number of colors in the colormap to be used
- `clip` [bool, optional] If clip is True, out of range values are mapped to 0 if they are below `boundaries[0]` or mapped to `ncolors - 1` if they are above `boundaries[-1]`.
  
  If clip is False, out of range values are mapped to -1 if they are below `boundaries[0]` or mapped to `ncolors` if they are above `boundaries[-1]`. These are then converted to valid indices by `Colormap.__call__()`.  

**Notes**

`boundaries` defines the edges of bins, and data falling within a bin is mapped to the color with the same index.

If the number of bins doesn’t equal `ncolors`, the color is chosen by linear interpolation of the bin number onto color numbers.

**inverse(self, value)**

**Raises**

- `ValueError` BoundaryNorm is not invertible, so calling this method will always raise an error
Examples using `matplotlib.colors.BoundaryNorm`

- sphx_glr_gallery_userdemo_colormap_normalizations_bounds.py
- Customized Colorbars Tutorial
- Colormap Normalization

`matplotlib.colors.Colormap`

class `matplotlib.colors.Colormap(name, N=256)`

Bases: `object`

Baseclass for all scalar to RGBA mappings.

Typically Colormap instances are used to convert data values (floats) from the interval \([0, 1]\) to the RGBA color that the respective Colormap represents. For scaling of data into the \([0, 1]\) interval see `matplotlib.colors.Normalize`. It is worth noting that `matplotlib.cm.ScalarMappable` subclasses make heavy use of this `data->normalize->map-to-color` processing chain.

Parameters

- **name** [str] The name of the colormap.
- **N** [int] The number of rgb quantization levels.

`colorbar_extend = None`

When this colormap exists on a scalar mappable and colorbar_extend is not False, colorbar creation will pick up colorbar_extend as the default value for the extend keyword in the `matplotlib.colorbar.Colorbar` constructor.

`is_gray(self)`

`reversed(self, name=None)`

Make a reversed instance of the Colormap.

---

**Note:**  Function not implemented for base class.

---

Parameters

- **name** [str, optional] The name for the reversed colormap. If it’s None the name will be the name of the parent colormap + "_r".

See also:

`LinearSegmentedColormap.reversed`
ListedColormap.reversed

```python
set_bad(self, color='k', alpha=None)
```

Set color to be used for masked values.

```python
set_over(self, color='k', alpha=None)
```

Set color to be used for high out-of-range values. Requires norm.clip = False

```python
set_under(self, color='k', alpha=None)
```

Set color to be used for low out-of-range values. Requires norm.clip = False

**Examples using** matplotlib.colors.Colormap

- sphx_glr_gallery_images_contours_and_fields_contourf_demo.py

**matplotlib.colors.DivergingNorm**

```python
class matplotlib.colors.DivergingNorm(vcenter, vmin=None, vmax=None)
```

Bases: matplotlib.colors.Normalize

Normalize data with a set center.

Useful when mapping data with an unequal rates of change around a conceptual center, e.g., data that range from -2 to 4, with 0 as the midpoint.

**Parameters**

- **vcenter** [float] The data value that defines 0.5 in the normalization.
- **vmin** [float, optional] The data value that defines 0.0 in the normalization. Defaults to the min value of the dataset.
- **vmax** [float, optional] The data value that defines 1.0 in the normalization. Defaults to the max value of the dataset.

**Examples**

This maps data value -4000 to 0., 0 to 0.5, and +10000 to 1.0; data between is linearly interpolated:

```python
>>> import matplotlib.colors as mcolors
>>> offset = mcolors.DivergingNorm(vmin=-4000.,
                                  vcenter=0., vmax=10000)
>>> data = [-4000., -2000., 0., 2500., 5000., 7500., 10000.]
>>> offset(data)
array([0., 0.25, 0.5, 0.625, 0.75, 0.875, 1.0])
```

```python
autoscale_None(self, A)
```

Get vmin and vmax, and then clip at vcenter

**Examples using** matplotlib.colors.DivergingNorm

- sphx_glr_gallery_userdemo_colormap_normalizations_diverging.py
• Colormap Normalization

```python
class matplotlib.colors.LightSource(azdeg=315, altdeg=45, hsv_min_val=0, hsv_max_val=1, hsv_min_sat=1, hsv_max_sat=0)
Bases: object

Create a light source coming from the specified azimuth and elevation. Angles are in degrees, with the azimuth measured clockwise from north and elevation up from the zero plane of the surface.

The `shade()` is used to produce “shaded” rgb values for a data array. `shade_rgb()` can be used to combine an rgb image with The `shade_rgb()` The `hillshade()` produces an illumination map of a surface.

Specify the azimuth (measured clockwise from south) and altitude (measured up from the plane of the surface) of the light source in degrees.

**Parameters**

- **azdeg** [number, optional] The azimuth (0-360, degrees clockwise from North) of the light source. Defaults to 315 degrees (from the northwest).
- **altdeg** [number, optional] The altitude (0-90, degrees up from horizontal) of the light source. Defaults to 45 degrees from horizontal.

**Notes**

For backwards compatibility, the parameters `hsv_min_val`, `hsv_max_val`, `hsv_min_sat`, and `hsv_max_sat` may be supplied at initialization as well. However, these parameters will only be used if “blend_mode='hsv'” is passed into `shade()` or `shade_rgb()`. See the documentation for `blend_hsv()` for more details.

```python
blend_hsv(self, rgb, intensity, hsv_max_sat=None, hsv_max_val=None, hsv_min_val=None, hsv_min_sat=None)
```

Take the input data array, convert to HSV values in the given colormap, then adjust those color values to give the impression of a shaded relief map with a specified light source. RGBA values are returned, which can then be used to plot the shaded image with imshow.

The color of the resulting image will be darkened by moving the (s,v) values (in hsv colorspace) toward (hsv_min_sat, hsv_min_val) in the shaded regions, or lightened by sliding (s,v) toward (hsv_max_sat hsv_max_val) in regions that are illuminated. The default extremes are chose so that completely shaded points are nearly black (s = 1, v = 0) and completely illuminated points are nearly white (s = 0, v = 1).

**Parameters**

- **rgb** [ndarray] An MxNx3 RGB array of floats ranging from 0 to 1 (color image).
- **intensity** [ndarray] An MxNx1 array of floats ranging from 0 to 1 (grayscale image).
- **hsv_max_sat** [number, optional] The maximum saturation value that the intensity map can shift the output image to. Defaults to 1.
Matplotlib, Release 3.1.1

**hsv_min_sat** [number, optional] The minimum saturation value that the intensity map can shift the output image to. Defaults to 0.

**hsv_max_val** [number, optional] The maximum value (“v” in “hsv”) that the intensity map can shift the output image to. Defaults to 1.

**hsv_min_val** [number, optional] The minimum value (“v” in “hsv”) that the intensity map can shift the output image to. Defaults to 0.

**Returns**

**rgb** [ndarray] An MxNx3 RGB array representing the combined images.

**blend_overlay**(self, rgb, intensity)
Combines an rgb image with an intensity map using “overlay” blending.

**Parameters**

**rgb** [ndarray] An MxNx3 RGB array of floats ranging from 0 to 1 (color image).

**intensity** [ndarray] An MxNx1 array of floats ranging from 0 to 1 (grayscale image).

**Returns**

**rgb** [ndarray] An MxNx3 RGB array representing the combined images.

**blend_soft_light**(self, rgb, intensity)
Combines an rgb image with an intensity map using “soft light” blending. Uses the “pegtop” formula.

**Parameters**

**rgb** [ndarray] An MxNx3 RGB array of floats ranging from 0 to 1 (color image).

**intensity** [ndarray] An MxNx1 array of floats ranging from 0 to 1 (grayscale image).

**Returns**

**rgb** [ndarray] An MxNx3 RGB array representing the combined images.

**direction**
The unit vector direction towards the light source.

**hillshade**(self, elevation, vert_exag=1, dx=1, dy=1, fraction=1.0)
Calculates the illumination intensity for a surface using the defined azimuth and elevation for the light source.

This computes the normal vectors for the surface, and then passes them on to **shade_normals**.

**Parameters**

**elevation** [array-like] A 2d array (or equivalent) of the height values used to generate an illumination map.

**vert_exag** [number, optional] The amount to exaggerate the elevation values by when calculating illumination. This can be used either to correct for differences in units between the x-y coordinate system and the elevation coordinate system (e.g. decimal degrees vs meters) or to exaggerate or de-emphasize topographic effects.
dx [number, optional] The x-spacing (columns) of the input elevation grid.

dy [number, optional] The y-spacing (rows) of the input elevation grid.

fraction [number, optional] Increases or decreases the contrast of the hillshade. Values greater than one will cause intermediate values to move closer to full illumination or shadow (and clipping any values that move beyond 0 or 1). Note that this is not visually or mathematically the same as vertical exaggeration.

Returns

intensity [ndarray] A 2d array of illumination values between 0-1, where 0 is completely in shadow and 1 is completely illuminated.

shade(self, data, cmap, norm=None, blend_mode='overlay', vmin=None, vmax=None, vert_exag=1, dx=1, dy=1, fraction=1, **kwargs)

Combine colormapped data values with an illumination intensity map (a.k.a. “hillshade”) of the values.

Parameters

data [array-like] A 2d array (or equivalent) of the height values used to generate a shaded map.

cmap [Colormap instance] The colormap used to color the data array. Note that this must be a Colormap instance. For example, rather than passing in cmap='gist_earth', use cmap=plt.get_cmap('gist_earth') instead.

norm [Normalize instance, optional] The normalization used to scale values before colormapping. If None, the input will be linearly scaled between its min and max.

blend_mode [{‘hsv’, ‘overlay’, ‘soft’} or callable, optional] The type of blending used to combine the colormapped data values with the illumination intensity. Default is “overlay”. Note that for most topographic surfaces, “overlay” or “soft” appear more visually realistic. If a user-defined function is supplied, it is expected to combine an MxNx3 RGB array of floats (ranging 0 to 1) with an MxNx1 hillshade array (also 0 to 1). (Call signature func(rgb, illum, **kwargs)) Additional kwargs supplied to this function will be passed on to the blend_mode function.

vmin [scalar or None, optional] The minimum value used in colormapping data. If None the minimum value in data is used. If norm is specified, then this argument will be ignored.

vmax [scalar or None, optional] The maximum value used in colormapping data. If None the maximum value in data is used. If norm is specified, then this argument will be ignored.

vert_exag [number, optional] The amount to exaggerate the elevation values by when calculating illumination. This can be used either to correct for differences in units between the x-y coordinate system and the elevation coordinate system (e.g. decimal degrees vs meters) or to exaggerate or de-emphasize topography.

dx [number, optional] The x-spacing (columns) of the input elevation grid.

dy [number, optional] The y-spacing (rows) of the input elevation grid.
**shade_normals**

Calculates the illumination intensity for the normal vectors of a surface using the defined azimuth and elevation for the light source.

Imagine an artificial sun placed at infinity in some azimuth and elevation position illuminating our surface. The parts of the surface that slope toward the sun should brighten while those sides facing away should become darker.

**Parameters**

- **fraction** [number, optional] Increases or decreases the contrast of the hillshade. Values greater than one will cause intermediate values to move closer to full illumination or shadow (and clipping any values that move beyond 0 or 1). Note that this is not visually or mathematically the same as vertical exaggeration.

**Returns**

- **intensity** [ndarray] A 2d array of illumination values between 0-1, where 0 is completely in shadow and 1 is completely illuminated.

**shade_rgb**

Use this light source to adjust the colors of the *rgb* input array to give the impression of a shaded relief map with the given *elevation*.

**Parameters**

- **rgb** [array-like] An (M, N, 3) RGB array, assumed to be in the range of 0 to 1.
- **elevation** [array-like] An (M, N) array of the height values used to generate a shaded map.
- **fraction** [number] Increases or decreases the contrast of the hillshade. Values greater than one will cause intermediate values to move closer to full illumination or shadow (and clipping any values that move beyond 0 or 1). Note that this is not visually or mathematically the same as vertical exaggeration.
- **blend_mode** [{‘hsv’, ‘overlay’, ‘soft’} or callable, optional] The type of blending used to combine the colormapped data values with the illumination intensity. For backwards compatibility, this defaults to “hsv”. Note that for most topographic surfaces, “overlay” or “soft” appear more visually realistic. If a user-defined function is supplied, it is expected to combine an MxNx3 RGB array of floats (ranging 0 to 1) with an MxNx1 hillshade array (also 0 to 1). (Call signature func(rgb, illum, **kwargs)) Additional kwargs supplied to this function will be passed on to the *blend_mode* function.
vert_exag [number, optional] The amount to exaggerate the elevation values by when calculating illumination. This can be used either to correct for differences in units between the x-y coordinate system and the elevation coordinate system (e.g. decimal degrees vs meters) or to exaggerate or de-emphasize topography.

dx [number, optional] The x-spacing (columns) of the input elevation grid.

dy [number, optional] The y-spacing (rows) of the input elevation grid.

Additional kwargs are passed on to the *blend_mode* function.

Returns

shaded_rgb [ndarray] An (m, n, 3) array of floats ranging between 0-1.

matplotlib.colors.LinearSegmentedColormap

class matplotlib.colors.LinearSegmentedColormap(name, segmentdata, N=256, gamma=1.0)

Bases: matplotlib.colors.Colormap

Colormap objects based on lookup tables using linear segments.

The lookup table is generated using linear interpolation for each primary color, with the
0-1 domain divided into any number of segments.

Create color map from linear mapping segments

segmentdata argument is a dictionary with a red, green and blue entries. Each entry
should be a list of x, y0, y1 tuples, forming rows in a table. Entries for alpha are optional.

Example: suppose you want red to increase from 0 to 1 over the bottom half, green to
do the same over the middle half, and blue over the top half. Then you would use:

cdict = {'red': [(0.0, 0.0, 0.0),
(0.5, 1.0, 1.0),
(1.0, 1.0, 1.0)],

'green': [(0.0, 0.0, 0.0),
(0.25, 0.0, 0.0),
(0.75, 1.0, 1.0),
(1.0, 1.0, 1.0)],

(continues on next page)
Each row in the table for a given color is a sequence of \(x, y0, y1\) tuples. In each sequence, \(x\) must increase monotonically from 0 to 1. For any input value \(z\) falling between \(x[i]\) and \(x[i+1]\), the output value of a given color will be linearly interpolated between \(y1[i]\) and \(y0[i+1]\):

<table>
<thead>
<tr>
<th>row i: x</th>
<th>y0</th>
<th>y1</th>
</tr>
</thead>
<tbody>
<tr>
<td>row i+1: x</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Hence \(y0\) in the first row and \(y1\) in the last row are never used.

**See also:**

*LinearSegmentedColormap.from_list* Static method; factory function for generating a smoothly-varying LinearSegmentedColormap.

*makeMappingArray* For information about making a mapping array.

*static* from_list*(name, colors, N=256, gamma=1.0)*

Make a linear segmented colormap with *name* from a sequence of *colors* which evenly transitions from colors[0] at val=0 to colors[-1] at val=1. *N* is the number of rgb quantization levels. Alternatively, a list of (value, color) tuples can be given to divide the range unevenly.

*reversed*(self, name=None)*

Make a reversed instance of the Colormap.

**Parameters**

- **name** [str, optional] The name for the reversed colormap. If it’s None the name will be the name of the parent colormap + "_r".

**Returns**

*LinearSegmentedColormap* The reversed colormap.

*set_gamma*(self, gamma)*

Set a new gamma value and regenerate color map.

Examples using matplotlib.colors.LinearSegmentedColormap

- sphx_glr_gallery_color_custom_cmap.py
- Creating Colormaps in Matplotlib

matplotlib.colors.ListedColormap

class matplotlib.colors.ListedColormap*(colors, name='from_list', N=None)*

Bases: matplotlib.colors.Colormap
Colormap object generated from a list of colors.
This may be most useful when indexing directly into a colormap, but it can also be used to generate special colormaps for ordinary mapping.

Parameters

- **colors** [list, array] List of Matplotlib color specifications, or an equivalent Nx3 or Nx4 floating point array (N rgb or rgba values).
- **name** [str, optional] String to identify the colormap.
- **N** [int, optional] Number of entries in the map. The default is `None`, in which case there is one colormap entry for each element in the list of colors. If:

  
  \[
  N < \text{len(colors)}
  \]

  
  the list will be truncated at \(N\). If:

  
  \[
  N > \text{len(colors)}
  \]

  
  the list will be extended by repetition.

```python
reversed(self, name=None)
```
Make a reversed instance of the Colormap.

Parameters

- **name** [str, optional] The name for the reversed colormap. If it’s `None` the name will be the name of the parent colormap + ”_r”.

Returns

**ListedColormap** A reversed instance of the colormap.

Examples using `matplotlib.colors.ListedColormap`

- `sphx_glr_gallery_lines_bars_and_markers_multicolored_line.py`
- `sphx_glr_gallery_specialty_plots_leftventricle_bulleye.py`
- *Customized Colorbars Tutorial*

`matplotlib.colors.LogNorm`

class `matplotlib.colors.LogNorm(vmin=None, vmax=None, clip=False)`

Bases: `matplotlib.colors.Normalize`

Normalize a given value to the 0-1 range on a log scale.

If `vmin` or `vmax` is not given, they are initialized from the minimum and maximum value respectively of the first input processed. That is, `_call_`(A) calls `autoscale_None(A)`. If `clip` is `True` and the given value falls outside the range, the returned value will be 0 or 1, whichever is closer. Returns 0 if:

\[
vmin==vmax
\]
Works with scalars or arrays, including masked arrays. If clip is True, masked values are set to 1; otherwise they remain masked. Clipping silently defeats the purpose of setting the over, under, and masked colors in the colormap, so it is likely to lead to surprises; therefore the default is clip = False.

```python
autoscale(self, A)
    Set vmin, vmax to min, max of A.

autoscale_None(self, A)
    Autoscale only None-valued vmin or vmax.

inverse(self, value)
```

Examples using `matplotlib.colors.LogNorm`

- sphx_glr_gallery_images_contours_and_fields_pcolor_demo.py
- sphx_glr_gallery_statistics_hist.py
- sphx_glr_gallery_userdemo_colormap_normalizations.py
- sphx_glr_gallery_userdemo_colormap_normalizations_lognorm.py
- Colormap Normalization

`matplotlib.colors.NoNorm`

```python
class matplotlib.colors.NoNorm(vmin=None, vmax=None, clip=False)
    Bases: matplotlib.colors.Normalize

    Dummy replacement for Normalize, for the case where we want to use indices directly in a ScalarMappable.

    If vmin or vmax is not given, they are initialized from the minimum and maximum value respectively of the first input processed. That is, __call__(A) calls autoscale_None(A). If clip is True and the given value falls outside the range, the returned value will be 0 or 1, whichever is closer. Returns 0 if:

    ```
    vmin==vmax
    ```

    Works with scalars or arrays, including masked arrays. If clip is True, masked values are set to 1; otherwise they remain masked. Clipping silently defeats the purpose of setting the over, under, and masked colors in the colormap, so it is likely to lead to surprises; therefore the default is clip = False.

    ```
    inverse(self, value)
    ```
```

`matplotlib.colors.Normalize`

```python
class matplotlib.colors.Normalize(vmin=None, vmax=None, clip=False)
    Bases: object

    A class which, when called, can normalize data into the [0.0, 1.0] interval.

    If vmin or vmax is not given, they are initialized from the minimum and maximum value respectively of the first input processed. That is, __call__(A) calls autoscale_None(A). If
clip is True and the given value falls outside the range, the returned value will be 0 or 1, whichever is closer. Returns 0 if:

\[ \text{vmin} = \text{vmax} \]

Works with scalars or arrays, including masked arrays. If clip is True, masked values are set to 1; otherwise they remain masked. Clipping silently defeats the purpose of setting the over, under, and masked colors in the colormap, so it is likely to lead to surprises; therefore the default is clip = False.

autoscale(self, A)
   Set vmin, vmax to min, max of A.
autoscale_None(self, A)
   Autoscale only None-valued vmin or vmax.

inverse(self, value)
static process_value(value)
   Homogenize the input value for easy and efficient normalization.
value can be a scalar or sequence.

   Returns result, is scalar, where result is a masked array matching value. Float
dtypes are preserved; integer types with two bytes or smaller are converted to
np.float32, and larger types are converted to np.float64. Preserving float32 when
possible, and using in-place operations, can greatly improve speed for large arrays.
   Experimental; we may want to add an option to force the use of float32.

scaled(self)
   Return whether vmin and vmax are set.

Examples using matplotlib.colors.Normalize

- sphx_glr_gallery_images_contours_and_fields_contour_image.py
- sphx_glr_gallery_images_contours_and_fields_image_masked.py
- sphx_glr_gallery_images_contours_and_fields_image_transparency_blend.py
- sphx_glr_gallery_images_contours_and_fields_multi_image.py

- sphx_glr_gallery_userdemo_colormap_normalizations_custom.py
- Constrained Layout Guide
- Customized Colorbars Tutorial
- Colormap Normalization
`matplotlib.colors.PowerNorm`

```python
class matplotlib.colors.PowerNorm(gamma, vmin=None, vmax=None, clip=False)
```

- **Bases**: `matplotlib.colors.Normalize`
- Linearly map a given value to the 0-1 range and then apply a power-law normalization over that range.

```python
inverse(self, value)
```

**Examples using `matplotlib.colors.PowerNorm`**

- `sphx_glr_gallery_showcase_mandelbrot.py`
- `sphx_glr_gallery_scales_power_norm.py`
- `sphx_glr_gallery_userdemo_colormap_normalizations.py`
- `sphx_glr_gallery_userdemo_colormap_normalizations_power.py`
- `Colormap Normalization`

`matplotlib.colors.SymLogNorm`

```python
class matplotlib.colors.SymLogNorm(linthresh, linscale=1.0, vmin=None, vmax=None, clip=False)
```

- **Bases**: `matplotlib.colors.Normalize`
- The symmetrical logarithmic scale is logarithmic in both the positive and negative directions from the origin.
- Since the values close to zero tend toward infinity, there is a need to have a range around zero that is linear. The parameter `linthresh` allows the user to specify the size of this range (`-linthresh`, `linthresh`).
- `linthresh`: The range within which the plot is linear (to avoid having the plot go to infinity around zero).
- `linscale`: This allows the linear range (`-linthresh` to `linthresh`) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when `linscale` == 1.0 (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range. Defaults to 1.

```python
autoscale(self, A)
autoscale_None(self, A)
inverse(self, value)
```

**Examples using `matplotlib.colors.SymLogNorm`**

- `sphx_glr_gallery_userdemo_colormap_normalizations.py`
- `sphx_glr_gallery_userdemo_colormap_normalizations_symlognorm.py`
17.17.2 Functions

```
from_levels_and_colors(levels, colors[, extend])
```

A helper routine to generate a cmap and a norm instance which behave similar to contour’s levels and colors arguments.

```
hsv_to_rgb(hsv)
```

Convert hsv values to rgb.

```
rgb_to_hsv(arr)
```

Convert float rgb values (in the range [0, 1]), in a numpy array to hsv values.

```
to_hex(c[, keep_alpha])
```

Convert c to a hex color.

```
to_rgb(c)
```

Convert c to an RGB color, silently dropping the alpha channel.

```
to_rgba(c[, alpha])
```

Convert c to an RGBA color.

```
to_rgba_array(c[, alpha])
```

Convert c to a (n, 4) array of RGBA colors.

```
to_rgba_array(c[, alpha])
```

Return whether c can be interpreted as an RGBA color.

```
makeMappingArray(N, data[, gamma])
```

Create an N-element 1-d lookup table.

```
get_named_colors_mapping()
```

Return the global mapping of names to named colors.

### matplotlib.colors.from_levels_and_colors

```
matplotlib.colors.from_levels_and_colors(levels, colors, extend='neither')
```

A helper routine to generate a cmap and a norm instance which behave similar to contour’s levels and colors arguments.

#### Parameters

- **levels** [sequence of numbers] The quantization levels used to construct the `BoundaryNorm`. Value v is quantized to level i if lev[i] <= v < lev[i+1].
- **colors** [sequence of colors] The fill color to use for each level. If extend is "neither" there must be n_level - 1 colors. For an extend of "min" or "max" add one extra color, and for an extend of "both" add two colors.
- **extend** [{‘neither’, ‘min’, ‘max’, ‘both’}, optional] The behaviour when a value falls out of range of the given levels. See `contourf()` for details.

#### Returns

- **(cmap, norm)** [tuple containing a `Colormap` and a `Normalize` instance]

### matplotlib.colors.hsv_to_rgb

```
matplotlib.colors.hsv_to_rgb(hsv)
```

Convert hsv values to rgb.

#### Parameters

- **hsv** [(..., 3) array-like] All values assumed to be in range [0, 1]

#### Returns

- **rgb** [(..., 3) ndarray] Colors converted to RGB values in range [0, 1]
**matplotlib.colors.rgb_to_hsv**

`matplotlib.colors.rgb_to_hsv(arr)`

Convert float rgb values (in the range [0, 1]), in a numpy array to hsv values.

**Parameters**

- `arr` ([..., 3] array-like) All values must be in the range [0, 1]

**Returns**

- `hsv` ([..., 3] ndarray) Colors converted to hsv values in range [0, 1]

**Examples using matplotlib.colors.rgb_to_hsv**

- sphx_glr_gallery_color_named_colors.py

**matplotlib.colors.to_hex**

`matplotlib.colors.to_hex(c, keep_alpha=False)`

Convert `c` to a hex color.

Uses the #rrggbb format if `keep_alpha` is False (the default), #rrggbbaa otherwise.

**matplotlib.colors.to_rgb**

`matplotlib.colors.to_rgb(c)`

Convert `c` to an RGB color, silently dropping the alpha channel.

**Examples using matplotlib.colors.to_rgb**

- sphx_glr_gallery_color_named_colors.py

**matplotlib.colors.to_rgba**

`matplotlib.colors.to_rgba(c, alpha=None)`

Convert `c` to an RGBA color.

**Parameters**

- `c` [Matplotlib color or np.ma.masked]

- `alpha` [scalar, optional] If `alpha` is not None, it forces the alpha value, except if `c` is "none" (case-insensitive), which always maps to (0, 0, 0, 0).

**Returns**

- `tuple` Tuple of (r, g, b, a) scalars.
Examples using matplotlib.colors.to_rgba

- sphx_glr_gallery_color_named_colors.py
- sphx_glr_gallery_shapes_and_collections_collections.py
- sphx_glr_gallery_shapes_and_collections_line_collection.py
- sphx_glr_gallery_event_handling_lasso_demo.py
- sphx_glr_gallery_misc_demo_ribbon_box.py
- sphx_glr_gallery_widgets_menu.py

matplotlib.colors.to_rgba_array

matplotlib.colors.to_rgba_array(c, alpha=None)
Convert c to a (n, 4) array of RGBA colors.

If alpha is not None, it forces the alpha value. If c is "none" (case-insensitive) or an empty list, an empty array is returned. If c is a masked array, an ndarray is returned with a (0, 0, 0, 0) row for each masked value or row in c.

matplotlib.colors.is_color_like

matplotlib.colors.is_color_like(c)
Return whether c can be interpreted as an RGB(A) color.

matplotlib.colors.makeMappingArray

matplotlib.colors.makeMappingArray(N, data, gamma=1.0)
Create an N-element 1-d lookup table.

This assumes a mapping \( f : [0, 1] \rightarrow [0, 1] \). The returned data is an array of N values \( y = f(x) \) where x is sampled from \([0, 1]\).

By default (\( gamma = 1 \)) x is equidistantly sampled from \([0, 1]\). The gamma correction factor \( \gamma \) distorts this equidistant sampling by \( x \rightarrow x^\gamma \).

Parameters

N [int] The number of elements of the created lookup table. This must be \( N \geq 1 \).

data [Mx3 array-like or callable] Defines the mapping \( f \).

If a Mx3 array-like, the rows define values (x, y0, y1). The x values must start with x=0, end with x=1, and all x values be in increasing order.

A value between \( x_i \) and \( x_{i+1} \) is mapped to the range \( y_{i-1} \ldots y_0 \) by linear interpolation.

For the simple case of a y-continuous mapping, y0 and y1 are identical.

The two values of y are to allow for discontinuous mapping functions. E.g. a sawtooth with a period of 0.2 and an amplitude of 1 would be:
In the special case of \( N = 1 \), by convention the returned value is \( y_0 \) for \( x = 1 \).

If \( data \) is a callable, it must accept and return numpy arrays:

\[
data(x : \text{ndarray}) \rightarrow \text{ndarray}
\]

and map values between 0 - 1 to 0 - 1.

**gamma** [float] Gamma correction factor for input distribution \( x \) of the mapping.

See also https://en.wikipedia.org/wiki/Gamma_correction.

**Returns**

- **lut** [array] The lookup table where \( \text{lut}[x \cdot (N-1)] \) gives the closest value for values of \( x \) between 0 and 1.

**Notes**

This function is internally used for LinearSegmentedColormaps.

```python
matplotlib.colors.get_named_colors_mapping
```

```python
matplotlib.colors.get_named_colors_mapping()
```

Return the global mapping of names to named colors.

### 17.18 matplotlib.container

```python
class matplotlib.container.BarContainer(patches, errorbar=None, **kwargs)
```

Bases: `matplotlib.container.Container`

Container for the artists of bar plots (e.g. created by `Axes.bar`).

The container can be treated as a tuple of the `patches` themselves. Additionally, you can access these and further parameters by the attributes.

**Attributes**

- **patches** [list of `Rectangle`] The artists of the bars.
- **errorbar** [None or `ErrorbarContainer`] A container for the error bar artists if error bars are present. `None` otherwise.

```python
class matplotlib.container.Container(kl, label=None)
```

Bases: `tuple`

Base class for containers.

Containers are classes that collect semantically related Artists such as the bars of a bar plot.
add_callback(self, func)
   Adds a callback function that will be called whenever one of the Artist’s properties changes.
   Returns an id that is useful for removing the callback with remove_callback() later.

get_children(self)
get_label(self)
   Get the label used for this artist in the legend.

pchanged(self)
   Fire an event when property changed, calling all of the registered callbacks.

remove(self)
remove_callback(self, oid)
   Remove a callback based on its id.

   See also:
   add_callback() For adding callbacks

set_label(self, s)
   Set the label to s for auto legend.

   Parameters
   s [object] Any object other than None gets converted to its str.

set_remove_method(self, f)
   [Deprecated]

   Notes
   Deprecated since version 3.0:

class matplotlib.container.ErrorbarContainer(lines, has_xerr=False, has_yerr=False, **kwargs)
   Container for the artists of error bars (e.g. created by Axes.errorbar).
The container can be treated as the lines tuple itself. Additionally, you can access these and further parameters by the attributes.

Attributes
   lines [tuple] Tuple of (data_line, caplines, barlinecols).
      - data_line : Line2D instance of x, y plot markers and/or line.
      - caplines : tuple of Line2D instances of the error bar caps.
      - barlinecols : list of LineCollection with the horizontal and vertical error ranges.

   has_xerr, has_yerr [bool] True if the errorbar has x/y errors.

class matplotlib.container.StemContainer(markerline_stemlines_baseline, **kwargs)
   Container for the artists created in a Axes.stem() plot.
The container can be treated like a namedtuple (markerline, stemlines, baseline).

**Attributes**

- **markerline** [Line2D] The artist of the markers at the stem heads.
- **stemlines** [list of Line2D] The artists of the vertical lines for all stems.
- **baseline** [Line2D] The artist of the horizontal baseline.

**Parameters**

- **markerline_stemlines_baseline** [tuple] Tuple of (markerline, stemlines, baseline). markerline contains the LineCollection of the markers, stemlines is a LineCollection of the main lines, baseline is the Line2D of the baseline.

### 17.19 matplotlib.contour

These are classes to support contour plotting and labelling for the Axes class.

```python
class matplotlib.contour.ClabelText(x=0, y=0, text='', color=None, verticalalignment='baseline', horizontalalignment='left', multialignment=None, fontproperties=None, rotation=None, linespacing=None, rotation_mode=None, usetex=None, wrap=False, **kwargs)
```

**Bases:** matplotlib.text.Text

Unlike the ordinary text, the get_rotation returns an updated angle in the pixel coordinate assuming that the input rotation is an angle in data coordinate (or whatever transform set).

Create a Text instance at x, y with string text.

Valid kwargs are

```python
def get_rotation(self):
    Return the text angle as float in degrees.

class matplotlib.contour.ContourLabeler
    Mixin to provide labelling capability to ContourSet.

    add_label(self, x, y, rotation, lev, cvalue)
    Add contour label using Text class.

    add_label_clabeltext(self, x, y, rotation, lev, cvalue)
    Add contour label using ClabelText class.

    add_label_near(self, x, y, inline=True, inline_spacing=5, transform=None)
    Add a label near the point (x, y). If transform is None (default), (x, y) is in data coordinates; if transform is False, (x, y) is in display coordinates; otherwise, the specified transform will be used to translate (x, y) into display coordinates.

    Parameters

    x, y [float] The approximate location of the label.

    inline [bool, optional, default: True] If True remove the segment of the contour beneath the label.
```
inline_spacing  [int, optional, default: 5] Space in pixels to leave on each side of label when placing inline. This spacing will be exact for labels at locations where the contour is straight, less so for labels on curved contours.

calc_label_rot_and_inline(self, slc, ind, lw, lc=None, spacing=5)
This function calculates the appropriate label rotation given the line contour coordinates in screen units, the index of the label location and the label width.

It will also break contour and calculate inlining if lc is not empty (lc defaults to the empty list if None). spacing is the space around the label in pixels to leave empty.

Do both of these tasks at once to avoid calculating path lengths multiple times, which is relatively costly.

The method used here involves calculating the path length along the contour in pixel coordinates and then looking approximately label width / 2 away from central point to determine rotation and then to break contour if desired.

c1
cl_cvalues
cl_xy
clabel(self, *args, fontsize=None, inline=True, inline_spacing=5, fmt='%1.3f', colors=None, use_clabeltext=False, manual=False, rightside_up=True)
Label a contour plot.

Call signature:

clabel(cs, [levels,] **kwargs)

Adds labels to line contours in cs, where cs is a ContourSet object returned by contour().

Parameters

  cs  [ContourSet] The ContourSet to label.

  levels [array-like, optional] A list of level values, that should be labeled. The list must be a subset of cs.levels. If not given, all levels are labeled.

  fontsize [string or float, optional] Size in points or relative size e.g., ‘smaller’, ‘x-large’. See Text.set_size for accepted string values.

  colors [color-spec, optional] The label colors:

  • If None, the color of each label matches the color of the corresponding contour.

  • If one string color, e.g., colors = ‘r’ or colors = ‘red’, all labels will be plotted in this color.

  • If a tuple of matplotlib color args (string, float, rgb, etc), different labels will be plotted in different colors in the order specified.

  inline [bool, optional] If True the underlying contour is removed where the label is placed. Default is True.

  inline_spacing [float, optional] Space in pixels to leave on each side of label when placing inline. Defaults to 5.
This spacing will be exact for labels at locations where the contour is straight, less so for labels on curved contours.

**fmt** [string or dict, optional] A format string for the label. Default is \texttt{"%.3f"}

Alternatively, this can be a dictionary matching contour levels with arbitrary strings to use for each contour level (i.e., \texttt{fmt[level]=string}), or it can be any callable, such as a \texttt{Formatter} instance, that returns a string when called with a numeric contour level.

**manual** [bool or iterable, optional] If \texttt{True}, contour labels will be placed manually using mouse clicks. Click the first button near a contour to add a label, click the second button (or potentially both mouse buttons at once) to finish adding labels. The third button can be used to remove the last label added, but only if labels are not inline. Alternatively, the keyboard can be used to select label locations (enter to end label placement, delete or backspace act like the third mouse button, and any other key will select a label location).

\textit{manual} can also be an iterable object of x,y tuples. Contour labels will be created as if mouse is clicked at each x,y positions.

**rightside_up** [bool, optional] If \texttt{True}, label rotations will always be plus or minus 90 degrees from level. Default is \texttt{True}.

**use_clabeltext** [bool, optional] If \texttt{True}, \texttt{ClabelText} class (instead of \texttt{Text}) is used to create labels. \texttt{ClabelText} recalculates rotation angles of texts during the drawing time, therefore this can be used if aspect of the axes changes. Default is \texttt{False}.

**Returns**

- **labels** A list of \texttt{Text} instances for the labels.

**get_label_coords** *(self, distances, XX, YY, ysize, lw)*

Return x, y, and the index of a label location.

Labels are plotted at a location with the smallest deviation of the contour from a straight line unless there is another label nearby, in which case the next best place on the contour is picked up. If all such candidates are rejected, the beginning of the contour is chosen.

**get_label_width** *(self, lev, fmt, fsize)*

Return the width of the label in points.

**get_text** *(self, lev, fmt)*

Get the text of the label.

**labels** *(self, inline, inline_spacing)*

Find good place to draw a label (relatively flat part of the contour).

**pop_label** *(self, index=-1)*

Defaults to removing last label, but any index can be supplied

**print_label** *(self, linecontour, labelwidth)*

Return \texttt{False} if contours are too short for a label.

**set_label_props** *(self, label, text, color)*

Set the label properties - color, fontsize, text.
too_close(self, x, y, lw)
    Return True if a label is already near this location.

class matplotlib.contour.ContourSet(ax, *args, levels=None, filled=False,
    linewidths=None, linestyles=None, alpha=None, origin=None, extent=None,
    colors=None, norm=None, vmin=None, vmax=None, extend='neither', antialiased=None,
    **kwargs)

    Bases: matplotlib.cm.ScalarMappable, matplotlib.contour.ContourLabeler

    Store a set of contour lines or filled regions.

    User-callable method: clabel

    Parameters

    ax [Axes]
    levels [[level0, level1, ..., leveln]] A list of floating point numbers indicating
    the contour levels.

    allsegs [[level0segs, level1segs, ...]] List of all the polygon segments for all
    the levels. For contour lines len(allsegs) == len(levels), and for filled
    contour regions len(allsegs) = len(levels)-1. The lists should look like:

    level0segs = [polygon0, polygon1, ...]
    polygon0 = array_like [[x0,y0], [x1,y1], ...]

    allkinds [None or [level0kinds, level1kinds, ...]] Optional list of all the poly-
    gon vertex kinds (code types), as described and used in Path. This is used
    to allow multiply- connected paths such as holes within filled polygons.
    If not None, len(allkinds) == len(allsegs). The lists should look like:

    level0kinds = [polygon0kinds, ...]
    polygon0kinds = [vertexcode0, vertexcode1, ...]

    If allkinds is not None, usually all polygons for a particular contour level
    are grouped together so that level0segs = [polygon0] and level0kinds =
    [polygon0kinds].

    **kwargs Keyword arguments are as described in the docstring of contour.

    Attributes

    ax The axes object in which the contours are drawn.
    collections A silent_list of LineCollections or PolyCollections.
    levels Contour levels.
    layers Same as levels for line contours; half-way between levels for filled
    contours. See _process_colors().

    Draw contour lines or filled regions, depending on whether keyword arg filled is False
    (default) or True.

    Call signature:

    ContourSet(ax, levels, allsegs, [allkinds], **kwargs)

    Parameters
**Axes** The Axes object to draw on.

**levels** A list of floating point numbers indicating the contour levels.

**allsegs** List of all the polygon segments for all the levels. For contour lines len(allsegs) == len(levels), and for filled contour regions len(allsegs) = len(levels)-1. The lists should look like:

```plaintext
level0segs = [polygon0, polygon1, ...]
polygon0 = array_like [[x0,y0], [x1,y1], ...]
```

**allkinds** Optional list of all the polygon vertex kinds (code types), as described and used in Path. This is used to allow multiply-connected paths such as holes within filled polygons. If not None, len(allkinds) == len(allsegs). The lists should look like:

```plaintext
level0kinds = [polygon0kinds, ...]
polygon0kinds = [vertexcode0, vertexcode1, ...]
```

If allkinds is not None, usually all polygons for a particular contour level are grouped together so that level0segs = [polygon0] and level0kinds = [polygon0kinds].

**kwargs** Keyword arguments are as described in the docstring of contour.

**changed**(self)
Call this whenever the mappable is changed to notify all the callback listeners to the 'changed' signal

**find_nearest_contour**(self, x, y, indices=None, pixel=True)
Finds contour that is closest to a point. Defaults to measuring distance in pixels (screen space - useful for manual contour labeling), but this can be controlled via a keyword argument.

Optional keyword arguments:

- **indices**: Indexes of contour levels to consider when looking for nearest point. Defaults to using all levels.
- **pixel**: If True, measure distance in pixel space, if not, measure distance in axes space. Defaults to True.

**get_alpha**(self)
returns alpha to be applied to all ContourSet artists

**get_transform**(self)
Return the Transform instance used by this ContourSet.

**legend_elements**(self, variable_name='x', str_format=<class 'str'>)
Return a list of artists and labels suitable for passing through to plt.legend() which represent this ContourSet.

The labels have the form “0 < x <= 1” stating the data ranges which the artists represent.

**Parameters**
variable_name [str] The string used inside the inequality used on the labels.

str_format [function: float -> str] Function used to format the numbers in the labels.

Returns

artists [List[Artist]] A list of the artists.

labels [List[str]] A list of the labels.

set_alpha(self, alpha)
Set the alpha blending value for all ContourSet artists. alpha must be between 0 (transparent) and 1 (opaque).

class matplotlib.contour.QuadContourSet(ax, *args, levels=None, filled=False, linewidths=None, linestyles=None, alpha=None, origin=None, extent=None, cmap=None, colors=None, norm=None, vmin=None, vmax=None, extend='neither', antialiased=None, **kwargs)

Bases: matplotlib.contour.ContourSet

Create and store a set of contour lines or filled regions.

User-callable method: clabel

Attributes

ax The axes object in which the contours are drawn.

collections A silent list of LineCollections or PolyCollections.

levels Contour levels.

layers Same as levels for line contours; half-way between levels for filled contours. See _process_colors() method.

Draw contour lines or filled regions, depending on whether keyword arg filled is False (default) or True.

Call signature:

ContourSet(ax, levels, allsegs, [allkinds], **kwargs)

Parameters

ax [Axes] The Axes object to draw on.

levels [[level0, level1, ..., leveln]] A list of floating point numbers indicating the contour levels.

allsegs [[level0segs, level1segs, ...]] List of all the polygon segments for all the levels. For contour lines len(allsegs) = len(levels), and for filled contour regions len(allsegs) = len(levels)-1. The lists should look like:

level0segs = [polygon0, polygon1, ...]
polygon0 = array_like [[x0,y0], [x1,y1], ...]

allkinds [[level0kinds, level1kinds, ...], optional] Optional list of all the polygon vertex kinds (code types), as described and used in Path. This is
used to allow multiply-connected paths such as holes within filled polygons. If not None, len(allkinds) == len(allsegs). The lists should look like:

```python
level0kinds = [polygon0kinds, ...]
polygon0kinds = [vertexcode0, vertexcode1, ...]
```

If allkinds is not None, usually all polygons for a particular contour level are grouped together so that level0segs = [polygon0] and level0kinds = [polygon0kinds].

**kwargs

Keyword arguments are as described in the docstring of `contour`.

17.20 matplotlib.dates

Matplotlib provides sophisticated date plotting capabilities, standing on the shoulders of Python `datetime` and the add-on module `dateutil`.

17.20.1 Matplotlib date format

Matplotlib represents dates using floating point numbers specifying the number of days since 0001-01-01 UTC, plus 1. For example, 0001-01-01, 06:00 is 1.25, not 0.25. Values < 1, i.e. dates before 0001-01-01 UTC are not supported.

There are a number of helper functions to convert between `datetime` objects and Matplotlib dates:
Matplotlib, Release 3.1.1

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datestr2num</td>
<td>Convert a date string to a datenum using dateutil.parser.parse().</td>
</tr>
<tr>
<td>date2num</td>
<td>Convert datetime objects to Matplotlib dates.</td>
</tr>
<tr>
<td>num2date</td>
<td>Convert Matplotlib dates to datetime objects.</td>
</tr>
<tr>
<td>num2timedelta</td>
<td>Convert number of days to a timedelta object.</td>
</tr>
<tr>
<td>epoch2num</td>
<td>Convert an epoch or sequence of epochs to the new date format, that is days since 0001.</td>
</tr>
<tr>
<td>num2epoch</td>
<td>Convert days since 0001 to epoch.</td>
</tr>
<tr>
<td>mx2num</td>
<td>Convert mx datetime instance (or sequence of mx instances) to the new date format.</td>
</tr>
<tr>
<td>drange</td>
<td>Return a sequence of equally spaced Matplotlib dates.</td>
</tr>
</tbody>
</table>

**Note:** Like Python’s datetime, mpl uses the Gregorian calendar for all conversions between dates and floating point numbers. This practice is not universal, and calendar differences can cause confusing differences between what Python and mpl give as the number of days since 0001-01-01 and what other software and databases yield. For example, the US Naval Observatory uses a calendar that switches from Julian to Gregorian in October, 1582. Hence, using their calculator, the number of days between 0001-01-01 and 2006-04-01 is 732403, whereas using the Gregorian calendar via the datetime module we find:

```python
In [1]: date(2006, 4, 1).toordinal() - date(1, 1, 1).toordinal()
Out[1]: 732401
```

All the Matplotlib date converters, tickers and formatters are timezone aware. If no explicit timezone is provided, the rcParam timezone is assumed. If you want to use a custom time zone, pass a datetime.tzinfo instance with the tz keyword argument to num2date(), plot_date(), and any custom date tickers or locators you create.

A wide range of specific and general purpose date tick locators and formatters are provided in this module. See matplotlib.ticker for general information on tick locators and formatters. These are described below.

The dateutil module provides additional code to handle date ticking, making it easy to place ticks on any kinds of dates. See examples below.

### 17.20.2 Date tickers

Most of the date tickers can locate single or multiple values. For example:

```python
# import constants for the days of the week
from matplotlib.dates import MO, TU, WE, TH, FR, SA, SU

# tick on mondays every week
loc = WeekdayLocator(byweekday=MO, tz=tz)

# tick on mondays and saturdays
loc = WeekdayLocator(byweekday=(MO, SA))
```
In addition, most of the constructors take an interval argument:

```python
# tick on mondays every second week
loc = WeekdayLocator(byweekday=MO, interval=2)
```

The rrule locator allows completely general date ticking:

```python
# tick every 5th easter
rule = IntervalRule wrapper(YEARLY, byeaster=1, interval=5)
loc = RRuleLocator(rule)
```

Here are all the date tickers:

- **MicrosecondLocator**: locate microseconds
- **SecondLocator**: locate seconds
- **MinuteLocator**: locate minutes
- **HourLocator**: locate hours
- **DayLocator**: locate specified days of the month
- **WeekdayLocator**: Locate days of the week, e.g., MO, TU
- **MonthLocator**: locate months, e.g., 7 for july
- **YearLocator**: locate years that are multiples of base
- **RRuleLocator**: locate using a `matplotlib.dates.rrulewrapper`. `rrulewrapper` is a simple wrapper around `dateutil`’s `dateutil.rrule` which allow almost arbitrary date tick specifications. See `rrule` example.
- **AutoDateLocator**: On autoscale, this class picks the best `DateLocator` (e.g., `RRuleLocator`) to set the view limits and the tick locations. If called with `interval_multiples=True` it will make ticks line up with sensible multiples of the tick intervals. E.g. if the interval is 4 hours, it will pick hours 0, 4, 8, etc as ticks. This behaviour is not guaranteed by default.

### 17.20.3 Date formatters

Here all all the date formatters:

- **AutoDateFormatter**: attempts to figure out the best format to use. This is most useful when used with the `AutoDateLocator`.
- **ConciseDateFormatter**: also attempts to figure out the best format to use, and to make the format as compact as possible while still having complete date information. This is most useful when used with the `AutoDateLocator`.
- **DateFormatter**: use `strftime()` format strings
- **IndexDateFormatter**: date plots with implicit `x` indexing.

```python
matplotlib.dates.datestr2num(d, default=None)
```

Convert a date string to a datenum using `dateutil.parser.parse()`.

**Parameters**

- **d** [string or sequence of strings] The dates to convert.
- **default** [datetime instance, optional] The default date to use when fields are missing in `d`. 

17.20. matplotlib.dates 1501
Convert datetime objects to Matplotlib dates.

Parameters

\[d\] [datetime.datetime or numpy.datetime64 or sequences of these]

Returns

float or sequence of floats Number of days (fraction part represents hours, minutes, seconds, ms) since 0001-01-01 00:00:00 UTC, plus one.

Notes

The addition of one here is a historical artifact. Also, note that the Gregorian calendar is assumed; this is not universal practice. For details see the module docstring.

Convert Matplotlib dates to datetime objects.

Parameters

\[x\] [float or sequence of floats] Number of days (fraction part represents hours, minutes, seconds) since 0001-01-01 00:00:00 UTC, plus one.

\[tz\] [string, optional] Timezone of \(x\) (defaults to rcparams timezone).

Returns

datetime or sequence of datetime Dates are returned in timezone \(tz\). If \(x\) is a sequence, a sequence of datetime objects will be returned.

Notes

The addition of one here is a historical artifact. Also, note that the Gregorian calendar is assumed; this is not universal practice. For details, see the module docstring.

Convert number of days to a timedelta object.

If \(x\) is a sequence, a sequence of timedelta objects will be returned.

Parameters

\[x\] [float, sequence of floats] Number of days. The fraction part represents hours, minutes, seconds.

Returns

datetime.timedelta or list[datetime.timedelta]

Return a sequence of equally spaced Matplotlib dates.

The dates start at \(dstart\) and reach up to, but not including \(dend\). They are spaced by \(delta\).

Parameters

\[dstart, dend\] [datetime] The date limits.

\[delta\] [datetime.timedelta] Spacing of the dates.
Returns

\textbf{drange} \quad [\texttt{numpy.array}] A list floats representing Matplotlib dates.

\texttt{matplotlib.dates.epoch2num(e)}
Convert an epoch or sequence of epochs to the new date format, that is days since 0001.

\texttt{matplotlib.dates.num2epoch(d)}
Convert days since 0001 to epoch. \texttt{d} can be a number or sequence.

\texttt{matplotlib.dates.mx2num(mxdates)}
Convert mx \texttt{datetime} instance (or sequence of mx instances) to the new date format.

\texttt{class matplotlib.dates.DateFieldFormatter(fmt, tz=\texttt{None})}
\texttt{Bases: matplotlib.ticker.Formatter}
Format a tick (in seconds since the epoch) with a \texttt{strftime} format string.

\textbf{Parameters}

- \texttt{fmt} \quad [\texttt{str}] \texttt{strftime} format string
- \texttt{tz} \quad [\texttt{tzinfo}]

\texttt{illegal_s = re.compile('((^|[^%])(%%)*%s)')}

\texttt{set_tzinfo(self, tz)}

\texttt{strftime(self, dt, fmt=None)}
[\texttt{Deprecated}] Call time.strftime for years before 1900 by rolling forward a multiple of 28 years.
\texttt{fmt} is a \texttt{datetime.datetime.strftime()} format string.

Warning: For years before 1900, depending upon the current locale it is possible that the year displayed with \texttt{%%x} might be incorrect. For years before 100, \texttt{%%y} and \texttt{%%Y} will yield zero-padded strings.

\textbf{Notes}

Deprecated since version 3.0.

\texttt{strftime_pre_1900(self, dt, fmt=None)}
[\texttt{Deprecated}] Call time.strftime for years before 1900 by rolling forward a multiple of 28 years.
\texttt{fmt} is a \texttt{strftime()} format string.

Dalke: I hope I did this math right. Every 28 years the calendar repeats, except through century leap years excepting the 400 year leap years. But only if you’re using the Gregorian calendar.

\textbf{Notes}

Deprecated since version 3.0.

\texttt{class matplotlib.dates.ConciseDateFormatter(locator, tz=\texttt{None}, formats=\texttt{None}, offset_formats=\texttt{None}, zero_formats=\texttt{None}, show_offset=True)}

\texttt{Bases: matplotlib.ticker.Formatter}
This class attempts to figure out the best format to use for the date, and to make it as compact as possible, but still be complete. This is most useful when used with the `AutoDateLocator`:

```python
>>> locator = AutoDateLocator()
>>> formatter = ConciseDateFormatter(locator)
```

**Parameters**

- **locator**  
  `[ticker.Locator]` Locator that this axis is using.

- **tz**  
  [string, optional] Passed to `dates.date2num`.

- **formats**  
  [list of 6 strings, optional] Format strings for 6 levels of tick labelling: mostly years, months, days, hours, minutes, and seconds. Strings use the same format codes as `strftime`. Default is `['%Y', '%b', '%d', '%H:%M', '%H:%M', '%S.%f']`

- **zero_formats**  
  [list of 6 strings, optional] Format strings for tick labels that are “zeros” for a given tick level. For instance, if most ticks are months, ticks around 1 Jan 2005 will be labeled “Dec”, “2005”, “Feb”. The default is `['', '%Y', '%b', '%b-%d', '%H:%M', '%H:%M']`

- **offset_formats**  
  [list of 6 strings, optional] Format strings for the 6 levels that is applied to the “offset” string found on the right side of an x-axis, or top of a y-axis. Combined with the tick labels this should completely specify the date. The default is:

  ```
  [' ', '%Y', '%Y-%m', '%Y-%m-%d', '%Y-%m-%d', '%Y-%m-%d %H:%M']
  ```

- **show_offset**  
  [bool] Whether to show the offset or not. Default is `True`.

**Examples**

See `/gallery/ticks_and_spines/date_concise_formatter`

Autoformat the date labels. The default format is used to form an initial string, and then redundant elements are removed.

```python
format_data_short(self, value)
  Return a short string version of the tick value.
  Defaults to the position-independent long value.

format_ticks(self, values)
  Return the tick labels for all the ticks at once.

get_offset(self)
```

class matplotlib.dates.IndexDateFormatter(t, fmt, tz=None)
  Bases: matplotlib.ticker.Formatter
  Use with `IndexLocator` to cycle format strings by index.
  `t` is a sequence of dates (floating point days). `fmt` is a `strftime()` format string.

class matplotlib.dates.AutoDateFormatter(locator, tz=None, defaultfmt='%Y-%m-%d')
  Bases: matplotlib.ticker.Formatter
This class attempts to figure out the best format to use. This is most useful when used with the `AutoDateLocator`.

The `AutoDateFormatter` has a scale dictionary that maps the scale of the tick (the distance in days between one major tick) and a format string. The default looks like this:

```python
self.scaled = {
    DAYS_PER_YEAR: rcParams['date.autoformat.year'],
    DAYS_PER_MONTH: rcParams['date.autoformat.month'],
    1.0: rcParams['date.autoformat.day'],
    1. / HOURS_PER_DAY: rcParams['date.autoformat.hour'],
    1. / (MINUTES_PER_DAY): rcParams['date.autoformat.minute'],
    1. / (SEC_PER_DAY): rcParams['date.autoformat.second'],
    1. / (MILLISECONDS_PER_DAY): rcParams['date.autoformat.microsecond'],
}
```

The algorithm picks the key in the dictionary that is >= the current scale and uses that format string. You can customize this dictionary by doing:

```python
>>> locator = AutoDateLocator()
>>> formatter = AutoDateFormatter(locator)
>>> formatter.scaled[1/(24.*60.)] = '%M:%S' # only show min and sec
```

A custom `FuncFormatter` can also be used. The following example shows how to use a custom format function to strip trailing zeros from decimal seconds and adds the date to the first ticklabel:
Autoformat the date labels. The default format is the one to use if none of the values in 
self.scaled are greater than the unit returned by locator._get_unit().

class matplotlib.dates.DateLocator(tz=None)
    Bases: matplotlib.ticker.Locator

    Determines the tick locations when plotting dates.
    This class is subclassed by other Locators and is not meant to be used on its own.
    tz is a tzinfo instance.

datalim_to_dt(self)
    Convert axis data interval to datetime objects.

hms0d = {'byhour': 0, 'byminute': 0, 'bysecond': 0}
nonsingular(self, vmin, vmax)
    Given the proposed upper and lower extent, adjust the range if it is too close to being 
singular (i.e. a range of ~0).

set_tzinfo(self, tz)
    Set time zone info.

viewlim_to_dt(self)
    Converts the view interval to datetime objects.

class matplotlib.dates.RRuleLocator(o, tz=None)
    Bases: matplotlib.dates.DateLocator

autoscale(self)
    Set the view limits to include the data range.

static get_unit_generic(freq)
tick_values(self, vmin, vmax)
    Return the values of the located ticks given vmin and vmax.

Note: To get tick locations with the vmin and vmax values defined automatically 
for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```
class matplotlib.dates.AutoDateLocator(tz=None, minticks=5, maxticks=None, interval_multiples=True)

Bases: matplotlib.dates.DateLocator

On autoscale, this class picks the best DateLocator to set the view limits and the tick locations.

minticks is the minimum number of ticks desired, which is used to select the type of ticking (yearly, monthly, etc.).

maxticks is the maximum number of ticks desired, which controls any interval between ticks (ticking every other, every 3, etc.). For really fine-grained control, this can be a dictionary mapping individual rrule frequency constants (YEARLY, MONTHLY, etc.) to their own maximum number of ticks. This can be used to keep the number of ticks appropriate to the format chosen in AutoDateFormatter. Any frequency not specified in this dictionary is given a default value.

tz is a tzinfo instance.

interval_multiples is a boolean that indicates whether ticks should be chosen to be multiple of the interval. This will lock ticks to ‘nicer’ locations. For example, this will force the ticks to be at hours 0,6,12,18 when hourly ticking is done at 6 hour intervals.

The AutoDateLocator has an interval dictionary that maps the frequency of the tick (a constant from dateutil.rrule) and a multiple allowed for that ticking. The default looks like this:

```python
self.intervalvald = {
    YEARLY : [1, 2, 4, 5, 10, 20, 40, 50, 100, 200, 400, 500,
               1000, 2000, 4000, 5000, 10000],
    MONTHLY : [1, 2, 3, 4, 6],
    DAILY : [1, 2, 3, 7, 14],
    HOURLY : [1, 2, 3, 4, 6, 12],
    MINUTELY: [1, 5, 10, 15, 30],
    SECONDLY: [1, 5, 10, 15, 30],
    MICROSECONDLY: [1, 2, 5, 10, 20, 50, 100, 200, 500, 1000, 2000, 5000, 10000, 20000, 50000, 100000],
    } 
```

The interval is used to specify multiples that are appropriate for the frequency of ticking. For instance, every 7 days is sensible for daily ticks, but for minutes/seconds, 15 or 30 make sense. You can customize this dictionary by doing:

```python
locator = AutoDateLocator()
locator.interval[HOURLY] = [3]  # only show every 3 hours
```

autoscale(self)

Try to choose the view limits intelligently.

get_locator(self, dmin, dmax)

Pick the best locator based on a distance.

nonsingular(self, vmin, vmax)

Given the proposed upper and lower extent, adjust the range if it is too close to being singular (i.e. a range of ~0).

refresh(self)

Refresh internal information based on current limits.
set_axis(self, axis)
tick_values(self, vmin, vmax)
    Return the values of the located ticks given vmin and vmax.

Note: To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```

class matplotlib.dates.YearLocator(base=1, month=1, day=1, tz=None)
    Bases: matplotlib.dates.DateLocator

Make ticks on a given day of each year that is a multiple of base.

Examples:

```python
# Tick every year on Jan 1st
locator = YearLocator()

# Tick every 5 years on July 4th
locator = YearLocator(5, month=7, day=4)
```

Mark years that are multiple of base on a given month and day (default jan 1).

autoscale(self)
    Set the view limits to include the data range.

tick_values(self, vmin, vmax)
    Return the values of the located ticks given vmin and vmax.

Note: To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```

class matplotlib.dates.MonthLocator(bymonth=None, bymonthday=1, interval=1, tz=None)
    Bases: matplotlib.dates.RRuleLocator

Make ticks on occurrences of each month, e.g., 1, 3, 12.

Mark every month in bymonth; bymonth can be an int or sequence. Default is range(1, 13), i.e. every month.

interval is the interval between each iteration. For example, if interval=2, mark every second occurrence.

class matplotlib.dates.WeekdayLocator(byweekday=1, interval=1, tz=None)
    Bases: matplotlib.dates.RRuleLocator
Make ticks on occurrences of each weekday.
Mark every weekday in *byweekday*; *byweekday* can be a number or sequence.
Elements of *byweekday* must be one of MO, TU, WE, TH, FR, SA, SU, the constants from *dateutil.rrule*, which have been imported into the *matplotlib.dates* namespace.

*interval* specifies the number of weeks to skip. For example, *interval*=2 plots every second week.

```python
class matplotlib.dates.DayLocator(bymonthday=None, interval=1, tz=None)
    Bases: matplotlib.dates.RRuleLocator
    Make ticks on occurrences of each day of the month. For example, 1, 15, 30.
    Mark every day in *bymonthday*; *bymonthday* can be an int or sequence.
    Default is to tick every day of the month: *bymonthday*=range(1,32)

class matplotlib.dates.HourLocator(byhour=None, interval=1, tz=None)
    Bases: matplotlib.dates.RRuleLocator
    Make ticks on occurrences of each hour.
    Mark every hour in *byhour*; *byhour* can be an int or sequence. Default is to tick every hour: *byhour*=range(24)
    *interval* is the interval between each iteration. For example, if *interval*=2, mark every second occurrence.

class matplotlib.dates.MinuteLocator(byminute=None, interval=1, tz=None)
    Bases: matplotlib.dates.RRuleLocator
    Make ticks on occurrences of each minute.
    Mark every minute in *byminute*; *byminute* can be an int or sequence. Default is to tick every minute: *byminute*=range(60)
    *interval* is the interval between each iteration. For example, if *interval*=2, mark every second occurrence.

class matplotlib.dates.SecondLocator(bysecond=None, interval=1, tz=None)
    Bases: matplotlib.dates.RRuleLocator
    Make ticks on occurrences of each second.
    Mark every second in *bysecond*; *bysecond* can be an int or sequence. Default is to tick every second: *bysecond*=range(60)
    *interval* is the interval between each iteration. For example, if *interval*=2, mark every second occurrence.

class matplotlib.dates.MicrosecondLocator(interval=1, tz=None)
    Bases: matplotlib.dates.DateLocator
    Make ticks on regular intervals of one or more microsecond(s).
```

**Note:** Due to the floating point representation of time in days since 0001-01-01 UTC (plus 1), plotting data with microsecond time resolution does not work well with current dates.

If you want microsecond resolution time plots, it is strongly recommended to use floating point seconds, not datetime-like time representation.
If you really must use `datetime.datetime()` or similar and still need microsecond precision, your only chance is to use very early years; using year 0001 is recommended.

`interval` is the interval between each iteration. For example, if `interval=2`, mark every second microsecond.

- `set_axis(self, axis)`
- `set_data_interval(self, vmin, vmax)`
- `set_view_interval(self, vmin, vmax)`
- `tick_values(self, vmin, vmax)`

  Return the values of the located ticks given `vmin` and `vmax`.

**Note:** To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```

```python
class matplotlib.dates.rrule(freq, dtstart=None, interval=1, wkst=None, count=None, until=None, bysetpos=None, bymonth=None, bymonthday=None, byyearday=None, byeaster=None, byweekno=None, byweekday=None, byhour=None, byminute=None, bysecond=None, cache=False)
```

That's the base of the `rrule` operation. It accepts all the keywords defined in the RFC as its constructor parameters (except `byday`, which was renamed to `byweekday`) and more. The constructor prototype is:

```python
rrule(freq)
```

Where freq must be one of YEARLY, MONTHLY, WEEKLY, DAILY, HOURLY, MINUTELY, or SECONDLY.

**Note:** Per RFC section 3.3.10, recurrence instances falling on invalid dates and times are ignored rather than coerced:

Recurrence rules may generate recurrence instances with an invalid date (e.g., February 30) or nonexistent local time (e.g., 1:30 AM on a day where the local time is moved forward by an hour at 1:00 AM). Such recurrence instances MUST be ignored and MUST NOT be counted as part of the recurrence set.

This can lead to possibly surprising behavior when, for example, the start date occurs at the end of the month:

```python
>>> from dateutil.rrule import rrule, MONTHLY
>>> from datetime import datetime
>>> start_date = datetime(2014, 12, 31)
>>> list(rrule(freq=MONTHLY, count=4, dtstart=start_date))
```

(continues on next page)
Additionally, it supports the following keyword arguments:

**Parameters**

- `dtstart` – The recurrence start. Besides being the base for the recurrence, missing parameters in the final recurrence instances will also be extracted from this date. If not given, datetime.now() will be used instead.

- `interval` – The interval between each freq iteration. For example, when using YEARLY, an interval of 2 means once every two years, but with HOURLY, it means once every two hours. The default interval is 1.

- `wkst` – The week start day. Must be one of the MO, TU, WE constants, or an integer, specifying the first day of the week. This will affect recurrences based on weekly periods. The default week start is got from calendar.firstweekday(), and may be modified by calendar.setfirstweekday().

- `count` – If given, this determines how many occurrences will be generated.

**Note:** As of version 2.5.0, the use of the keyword `until` in conjunction with `count` is deprecated, to make sure dateutil is fully compliant with RFC-5545 Sec. 3.3.10. Therefore, `until` and `count` must not occur in the same call to `rrule`.

- `until` – If given, this must be a datetime instance specifying the upper-bound limit of the recurrence. The last recurrence in the rule is the greatest datetime that is less than or equal to the value specified in the `until` parameter.

**Note:** As of version 2.5.0, the use of the keyword `until` in conjunction with `count` is deprecated, to make sure dateutil is fully compliant with RFC-5545 Sec. 3.3.10. Therefore, `until` and `count` must not occur in the same call to `rrule`.

- `bysetpos` – If given, it must be either an integer, or a sequence of integers, positive or negative. Each given integer will specify an occurrence number, corresponding to the nth occurrence of the rule inside the frequency period. For example, a bysetpos of -1 if combined with a MONTHLY frequency, and a byweekday of (MO, TU, WE, TH, FR), will result in the last work day of every month.

- `bymonth` – If given, it must be either an integer, or a sequence of integers, meaning the months to apply the recurrence to.
Matplotlib, Release 3.1.1

- **bymonthday** – If given, it must be either an integer, or a sequence of integers, meaning the month days to apply the recurrence to.

- **byyearday** – If given, it must be either an integer, or a sequence of integers, meaning the year days to apply the recurrence to.

- **byeaster** – If given, it must be either an integer, or a sequence of integers, positive or negative. Each integer will define an offset from the Easter Sunday. Passing the offset 0 to byeaster will yield the Easter Sunday itself. This is an extension to the RFC specification.

- **byweekno** – If given, it must be either an integer, or a sequence of integers, meaning the week numbers to apply the recurrence to. Week numbers have the meaning described in ISO8601, that is, the first week of the year is that containing at least four days of the new year.

- **byweekday** – If given, it must be either an integer (0 == MO), a sequence of integers, one of the weekday constants (MO, TU, etc), or a sequence of these constants. When given, these variables will define the weekdays where the recurrence will be applied. It’s also possible to use an argument n for the weekday instances, which will mean the nth occurrence of this weekday in the period. For example, with MONTHLY, or with YEARLY and BYMONTH, using FR(+1) in byweekday will specify the first friday of the month where the recurrence happens. Notice that in the RFC documentation, this is specified as BYDAY, but was renamed to avoid the ambiguity of that keyword.

- **byhour** – If given, it must be either an integer, or a sequence of integers, meaning the hours to apply the recurrence to.

- **byminute** – If given, it must be either an integer, or a sequence of integers, meaning the minutes to apply the recurrence to.

- **bysecond** – If given, it must be either an integer, or a sequence of integers, meaning the seconds to apply the recurrence to.

- **cache** – If given, it must be a boolean value specifying to enable or disable caching of results. If you will use the same rrule instance multiple times, enabling caching will improve the performance considerably.

```python
replace(self, **kwargs)
```

Return new rrule with same attributes except for those attributes given new values by whichever keyword arguments are specified.

```python
class matplotlib.dates.relativedelta(dt1=None, dt2=None, years=0, months=0, days=0, leapdays=0, weeks=0, hours=0, minutes=0, seconds=0, microseconds=0, year=None, month=None, day=None, weekday=None, yearday=None, nlyearday=None, hour=None, minute=None, second=None, microsecond=None)
```

Bases: object

The relativedelta type is designed to be applied to an existing datetime and can replace specific components of that datetime, or represents an interval of time.

It is based on the specification of the excellent work done by M.-A. Lemburg in his mx.DateTime extension. However, notice that this type does NOT implement the same algorithm as his work. Do NOT expect it to behave like mx.DateTime’s counterpart.
There are two different ways to build a relativedelta instance. The first one is passing it two date/datetime classes:

```
relativedelta(datetime1, datetime2)
```

The second one is passing it any number of the following keyword arguments:

```
relativedelta(arg1=x, arg2=y, arg3=z...)
```

**year, month, day, hour, minute, second, microsecond:**
- Absolute information (argument is singular); adding or subtracting a relativedelta with absolute information does not perform an arithmetic operation, but rather REPLACES the corresponding value in the original datetime with the value(s) in relativedelta.

**years, months, weeks, days, hours, minutes, seconds, microseconds:**
- Relative information, may be negative (argument is plural); adding or subtracting a relativedelta with relative information performs the corresponding arithmetic operation on the original datetime value with the information in the relativedelta.

**weekday:**
- One of the weekday instances (MO, TU, etc) available in the relativedelta module. These instances may receive a parameter N, specifying the Nth weekday, which could be positive or negative (like MO(+1) or MO(-2)). Not specifying it is the same as specifying +1. You can also use an integer, where 0=MO. This argument is always relative e.g. if the calculated date is already Monday, using MO(1) or MO(-1) won’t change the day. To effectively make it absolute, use it in combination with the day argument (e.g. day=1, MO(1) for first Monday of the month).

**leapdays:**
- Will add given days to the date found, if year is a leap year, and the date found is post 28 of February.

**yearday, nlyearday:**
- Set the yearday or the non-leap year day (jump leap days).
- These are converted to day/month/leapdays information.

There are relative and absolute forms of the keyword arguments. The plural is relative, and the singular is absolute. For each argument in the order below, the absolute form is applied first (by setting each attribute to that value) and then the relative form (by adding the value to the attribute).

The order of attributes considered when this relativedelta is added to a datetime is:

1. Year
2. Month
3. Day
4. Hours
5. Minutes
6. Seconds
7. Microseconds

Finally, weekday is applied, using the rule described above.

For example

```python
>>> from datetime import datetime
>>> from dateutil.relativedelta import relativedelta, MO
>>> dt = datetime(2018, 4, 9, 13, 37, 0)
>>> delta = relativedelta(hours=25, day=1, weekday=MO(1))
>>> dt + delta
datetime.datetime(2018, 4, 2, 14, 37)
```

First, the day is set to 1 (the first of the month), then 25 hours are added, to get to the 2nd day and 14th hour; finally the weekday is applied, but since the 2nd is already a Monday there is no effect.

`normalized(self)`

Return a version of this object represented entirely using integer values for the relative attributes.

```python
>>> relativedelta(days=1.5, hours=2).normalized()
relativedelta(days=+1, hours=+14)
```

**Returns** Returns a `dateutil.relativedelta.relativedelta` object.

`weeks`

`matplotlib.dates.seconds(s)`

[Deprecated] Return seconds as days.

**Notes**

Deprecated since version 3.1.

`matplotlib.dates.minutes(m)`

[Deprecated] Return minutes as days.

**Notes**

Deprecated since version 3.1.

`matplotlib.dates.hours(h)`

[Deprecated] Return hours as days.

**Notes**

Deprecated since version 3.1.

`matplotlib.dates.weeks(w)`

[Deprecated] Return weeks as days.
Notes

Deprecated since version 3.1.

17.21 matplotlib.dviread

A module for reading dvi files output by TeX. Several limitations make this not (currently) useful as a general-purpose dvi preprocessor, but it is currently used by the pdf backend for processing usetex text.

Interface:

```python
with Dvi(filename, 72) as dvi:
    # iterate over pages:
    for page in dvi:
        w, h, d = page.width, page.height, page.descent
        for x, y, font, glyph, width in page.text:
            fontname = font.texname
            pointsize = font.size
            ...
        for x, y, height, width in page.boxes:
            ...
```

class matplotlib.dviread.Dvi(filename, dpi)

Bases: object

A reader for a dvi (“device-independent”) file, as produced by TeX. The current implementation can only iterate through pages in order, and does not even attempt to verify the postamble.

This class can be used as a context manager to close the underlying file upon exit. Pages can be read via iteration. Here is an overly simple way to extract text without trying to detect whitespace:

```python
>>> with matplotlib.dviread.Dvi('input.dvi', 72) as dvi:
...     for page in dvi:
...         print(''.join(chr(t.glyph) for t in page.text))
```

Read the data from the file named `filename` and convert TeX's internal units to units of `dpi` per inch. `dpi` only sets the units and does not limit the resolution. Use None to return TeX's internal units.

close(self)

Close the underlying file if it is open.

class matplotlib.dviread.DviFont(scale, tfm, texname, vf)

Bases: object

Encapsulation of a font that a DVI file can refer to.

This class holds a font’s texname and size, supports comparison, and knows the widths of glyphs in the same units as the AFM file. There are also internal attributes (for use by dviread.py) that are not used for comparison.

The size is in Adobe points (converted from TeX points).

Parameters
scale [float] Factor by which the font is scaled from its natural size.

tfm [Tfm] TeX font metrics for this font

texname [bytes] Name of the font as used internally by TeX and friends, as
an ASCII bytestring. This is usually very different from any external font
names, and dviread.PsfontsMap can be used to find the external name of
the font.

vf [Vf] A TeX “virtual font” file, or None if this font is not virtual.

Attributes

texname [bytes]

size [float] Size of the font in Adobe points, converted from the slightly
smaller TeX points.

widths [list] Widths of glyphs in glyph-space units, typically 1/1000ths of
the point size.

size
texname
widths

class matplotlib.dviread.Encoding(filename)
Bases: object

Parses a *.enc file referenced from a psfonts.map style file. The format this class under-
stands is a very limited subset of PostScript.

Usage (subject to change):

```python
for name in Encoding(filename):
    whatever(name)
```

Parameters

filename [string or bytestring]

Attributes

encoding [list] List of character names

encoding

matplotlib.dviread.PsFont
alias of matplotlib.dviread.Font

class matplotlib.dviread.PsfontsMap
Bases: object

A psfonts.map formatted file, mapping TeX fonts to PS fonts.

Usage:

```python
>>> map = PsfontsMap(find_tex_file('pdftex.map'))
>>> entry = map[b'ptmbo8r']
>>> entry.texname
b'ptmbo8r'
>>> entry.pname
```
Parameters

**filename** [string or bytestring]

Notes

For historical reasons, TeX knows many Type-1 fonts by different names than the outside world. (For one thing, the names have to fit in eight characters.) Also, TeX’s native fonts are not Type-1 but Metafont, which is nontrivial to convert to PostScript except as a bitmap. While high-quality conversions to Type-1 format exist and are shipped with modern TeX distributions, we need to know which Type-1 fonts are the counterparts of which native fonts. For these reasons a mapping is needed from internal font names to font file names.

A texmf tree typically includes mapping files called e.g. psfonts.map, pdftex.map, or dvipdfm.map. The file psfonts.map is used by dvips, pdftex.map by pdfTeX, and dvipdfm.map by dvipdfm. psfonts.map might avoid embedding the 35 PostScript fonts (i.e., have no filename for them, as in the Times-Bold example above), while the pdf-related files perhaps only avoid the “Base 14” pdf fonts. But the user may have configured these files differently.

class matplotlib.dviread.Tfm(filename)

Bases: object

A TeX Font Metric file.

This implementation covers only the bare minimum needed by the Dvi class.

Parameters

**filename** [string or bytestring]

Attributes

**checksum** [int] Used for verifying against the dvi file.

**design_size** [int] Design size of the font (unknown units)

**width, height, depth** [dict] Dimensions of each character, need to be scaled by the factor specified in the dvi file. These are dicts because indexing may not start from 0.

checksum

depth

design_size

height

width

17.21. matplotlib.dviread 1517
class matplotlib.dviread.Vf(filename)
   Bases: matplotlib.dviread.Dvi

   A virtual font (*.vf file) containing subroutines for dvi files.

   Usage:

   ```python
   vf = Vf(filename)
glyph = vf[code]
glyph.text, glyph.boxes, glyph.width
   ```

   **Parameters**

   - **filename** [string or bytestring]

   **Notes**

   The virtual font format is a derivative of dvi: [http://mirrors.ctan.org/info/knuth/virtual-fonts](http://mirrors.ctan.org/info/knuth/virtual-fonts) This class reuses some of the machinery of Dvi but replaces the _read loop and dispatch mechanism.

   `matplotlib.dviread.find_tex_file(filename, format=None)`

   Find a file in the texmf tree.

   Calls kpsewhich which is an interface to the kpathsea library [?]. Most existing TeX distributions on Unix-like systems use kpathsea. It is also available as part of MikTeX, a popular distribution on Windows.

   *If the file is not found, an empty string is returned.*

   **Parameters**

   - **filename** [string or bytestring]
   - **format** [string or bytestring] Used as the value of the --format option to kpsewhich. Could be e.g. 'tfm' or 'vf' to limit the search to that type of files.

   **References**

   # 17.22 matplotlib.figure

   The figure module provides the top-level Artist, the Figure, which contains all the plot elements. The following classes are defined

   - **SubplotParams** control the default spacing of the subplots
   - **Figure** Top level container for all plot elements.

   # 17.22.1 Classes
AxesStack  Specialization of the Stack to handle all tracking of Axes in a Figure.

Figure  The top level container for all the plot elements.

SubplotParams  A class to hold the parameters for a subplot.

**matplotlib.figure.AxesStack**

```python
class matplotlib.figure.AxesStack
    Bases: matplotlib.cbook.Stack

    Specialization of the Stack to handle all tracking of Axes in a Figure. This stack stores key, (ind, axes) pairs, where:

    - **key** should be a hash of the args and kwargs used in generating the Axes.
    - **ind** is a serial number for tracking the order in which axes were added.

    The AxesStack is a callable, where `ax_stack()` returns the current axes. Alternatively the `current_key_axes()` will return the current key and associated axes.

    **add(self, key, a)**
    Add Axes `a`, with key `key`, to the stack, and return the stack.

    If `key` is unhashable, replace it by a unique, arbitrary object.

    If `a` is already on the stack, don’t add it again, but return `None`.

    **as_list(self)**
    Return a list of the Axes instances that have been added to the figure.

    **bubble(self, a)**
    Move the given axes, which must already exist in the stack, to the top.

    **current_key_axes(self)**
    Return a tuple of (key, axes) for the active axes.

    If no axes exists on the stack, then returns `(None, None)`.

    **get(self, key)**
    Return the Axes instance that was added with key. If it is not present, return `None`.

    **remove(self, a)**
    Remove the axes from the stack.
```

**matplotlib.figure.Figure**

```python
class matplotlib.figure.Figure(figsize=None, dpi=None, facecolor=None, edgecolor=None, linewidth=0.0, frameon=None, subplotpars=None, tight_layout=None, constrained_layout=None)
    Bases: matplotlib.artist.Artist

    The top level container for all the plot elements.

    The Figure instance supports callbacks through a `callbacks` attribute which is a CallbackRegistry instance. The events you can connect to are ‘dpi_changed’, and the callback will be called with `func(fig)` where `fig` is the Figure instance.

    **Attributes**
```
patch  The Rectangle instance representing the figure background patch.

suppressComposite  For multiple figure images, the figure will make com-
posite images depending on the renderer option image_nocomposite
function. If suppressComposite is a boolean, this will override the ren-
derer.

Parameters

figsize  [2-tuple of floats, default: rcParams["figure.figsize"]] Figure di-
mension (width, height) in inches.

dpi  [float, default: rcParams["figure.dpi"]] Dots per inch.

facecolor  [default: rcParams["figure.facecolor"]] The figure patch face-
color.

dedgecolor  [default: rcParams["figure.edgecolor"]] The figure patch edge
color.

linewidth  [float] The linewidth of the frame (i.e. the edge linewidth of the
figure patch).

frameon  [bool, default: rcParams["figure.frameon"]] If False, suppress
drawing the figure background patch.

subplotpars  [SubplotParams] Subplot parameters. If not given, the default
subplot parameters rcParams["figure.subplot.*"] are used.

tight_layout  [bool or dict, default: rcParams["figure.autolayout"]] If False
use subplotpars. If True adjust subplot parameters using tight_layout
with default padding. When providing a dict containing the keys pad,
w_pad, h_pad, and rect, the default tight_layout paddings will be overrid-
den.

constrained_layout  [bool] If True use constrained layout to adjust posi-
tioning of plot elements. Like tight_layout, but designed to be more
flexible. See Constrained Layout Guide for examples. (Note: does not
work with subplot() or subplot2grid().) Defaults to rcParams["figure.
constrained_layout.use"].

add_artist(self, artist, clip=False)
Add any Artist to the figure.

Usually artists are added to axes objects using matplotlib.axes.Axes.add_artist(),
but use this method in the rare cases that adding directly to the figure is necessary.

Parameters

artist  [Artist] The artist to add to the figure. If the added artist has no
transform previously set, its transform will be set to figure.transFigure.

clip  [bool, optional, default False] An optional parameter clip deter-
mines whether the added artist should be clipped by the figure patch.
Default is False, i.e. no clipping.

Returns

artist  [The added Artist]

add_axes(self, *args, **kwargs)
Add an axes to the figure.
Call signatures:

```python
add_axes(rect, projection=None, polar=False, **kwargs)
add_axes(ax)
```

**Parameters**

- `rect` [sequence of float] The dimensions [left, bottom, width, height] of the new axes. All quantities are in fractions of figure width and height.

- `projection` [{None, 'aitoff', 'hammer', 'lambert', 'mollweide', 'polar', 'rectilinear', str}, optional] The projection type of the `Axes`. `str` is the name of a custom projection, see `projections`. The default `None` results in a 'rectilinear' projection.

- `polar` [boolean, optional] If True, equivalent to `projection='polar'`.

- `sharex`, `sharey` [Axes, optional] Share the x or y axis with `sharex` and/or `sharey`. The axis will have the same limits, ticks, and scale as the axis of the shared axes.

- `label` [str] A label for the returned axes.

**Returns**

- `axes` [Axes (or a subclass of Axes)] The returned axes class depends on the projection used. It is `Axes` if rectilinear projection are used and `projections.polar.PolarAxes` if polar projection are used.

**Other Parameters**

- `**kwargs` This method also takes the keyword arguments for the returned axes class. The keyword arguments for the rectilinear axes class `Axes` can be found in the following table but there might also be other keyword arguments if another projection is used, see the actual axes class.

- pyplot.subplots

Notes

If the figure already has an axes with key (args, kwargs) then it will simply make that axes current and return it. This behavior is deprecated. Meanwhile, if you do not want this behavior (i.e., you want to force the creation of a new axes), you must use a unique set of args and kwargs. The axes label attribute has been exposed for
this purpose: if you want two axes that are otherwise identical to be added to the
figure, make sure you give them unique labels.

In rare circumstances, `add_axes` may be called with a single argument, a axes in-
stance already created in the present figure but not in the figure’s list of axes.

Examples

Some simple examples:

```python
def rect(l, b, w, h):
    fig = plt.figure()
    fig.add_axes(rect, label='label1')
    fig.add_axes(rect, label='label2')
    fig.add_axes(rect, frameon=False, facecolor='g')
    fig.add_axes(rect, polar=True)
    ax = fig.add_axes(rect, projection='polar')
    fig.delaxes(ax)
    fig.add_axes(ax)
```

add_axobserver(self, func)

Whenever the axes state change, `func(self)` will be called.

add_gridspec(self, nrows, ncols, **kwargs)

Return a `GridSpec` that has this figure as a parent. This allows complex layout of axes
in the figure.

Parameters

- `nrows` [int] Number of rows in grid.
- `ncols` [int] Number or columns in grid.

Returns

- `GridSpec` [GridSpec]

Other Parameters

- **kwargs Keyword arguments are passed to `GridSpec`.

See also:

- `matplotlib.pyplot.subplots`

Examples

Adding a subplot that spans two rows:

```python
fig = plt.figure()
gs = fig.add_gridspec(2, 2)
ax1 = fig.add_subplot(gs[0, 0])
ax2 = fig.add_subplot(gs[1, 0])
# spans two rows:
ax3 = fig.add_subplot(gs[1, 1])
```
add_subplot(self, *args, **kwargs)
    Add an Axes to the figure as part of a subplot arrangement.

    Call signatures:

    add_subplot(nrows, ncols, index, **kwargs)
    add_subplot(pos, **kwargs)
    add_subplot(ax)
    add_subplot()

Parameters

*args  Either a 3-digit integer or three separate integers describing the
    position of the subplot. If the three integers are nrows, ncols, and
    index
    in order, the subplot will take the index position on a grid with
    nrows
    rows and ncols columns. index starts at 1 in the upper left corner and
    increases to the right.

    pos is a three digit integer, where the first digit is the number of rows,
    the second the number of columns, and the third the index of the sub-
    plot. i.e. fig.add_subplot(235) is the same as fig.add_subplot(2, 3, 5).
    Note that all integers must be less than 10 for this form to work.

    If no positional arguments are passed, defaults to (1, 1, 1).

    In rare circumstances, add_subplot may be called with a single argu-
    ment, a subplot axes instance already created in the present figure but
    not in the figure’s list of axes.

    str is the name of a custom projection, see projections. The default
    None results in a ‘rectilinear’ projection.

polar [boolean, optional] If True, equivalent to projection=’polar’.

sharex, sharey [Axes, optional] Share the x or y axis with sharex and/or
    sharey. The axis will have the same limits, ticks, and scale as the axis
    of the shared axes.

label [str] A label for the returned axes.

Returns

    axes [axes.SubplotBase, or another subclass of Axes] The axes of the sub-
    plot. The returned axes base class depends on the projection used. It is
    Axes if rectilinear projection are used and projections.polar.PolarAxes if
    polar projection are used. The returned axes is then a subplot subclass
    of the base class.

Other Parameters

**kwargs This method also takes the keyword arguments for the re-
    turned axes base class. The keyword arguments for the rectilinear base
    class Axes can be found in the following table but there might also be
    other keyword arguments if another projection is used.

Figure.add_axes
pyplot.subplot
pyplot.axes
Figure.subplots
pyplot.subplots

Notes

If the figure already has a subplot with key (args, kwargs) then it will simply make that subplot current and return it. This behavior is deprecated. Meanwhile, if you do not want this behavior (i.e., you want to force the creation of a new subplot), you must use a unique set of args and kwargs. The axes label attribute has been exposed for this purpose: if you want two subplots that are otherwise identical to be added to the figure, make sure you give them unique labels.

Examples

```python
fig = plt.figure()
fig.add_subplot(221)

# equivalent but more general
ax1 = fig.add_subplot(2, 2, 1)

# add a subplot with no frame
ax2 = fig.add_subplot(222, frameon=False)

# add a polar subplot
fig.add_subplot(223, projection='polar')

# add a red subplot that share the x-axis with ax1
fig.add_subplot(224, sharex=ax1, facecolor='red')

#delete x2 from the figure
fig.delaxes(ax2)

#add x2 to the figure again
fig.add_subplot(ax2)
```

align_labels(self, axs=None)

Align the xlabels and ylabels of subplots with the same subplots row or column (respectively) if label alignment is being done automatically (i.e. the label position is not manually set).

Alignment persists for draw events after this is called.

Parameters

- **axs** [list of Axes] Optional list (or ndarray) of Axes to align the labels. Default is to align all axes on the figure.
align_xlabels(self, axs=None)
Align the labels of subplots in the same subplot column if label alignment is being done automatically (i.e. the label position is not manually set).

Alignment persists for draw events after this is called.

If a label is on the bottom, it is aligned with labels on axes that also have their label on the bottom and that have the same bottom-most subplot row. If the label is on the top, it is aligned with labels on axes with the same top-most row.

Parameters

axs [list of Axes] Optional list of (or ndarray) Axes to align the xlabels.
Default is to align all axes on the figure.

See also:

* matplotlib.figure.Figure.align_xlabels
* matplotlib.figure.Figure.align_ylabels

Notes

This assumes that axs are from the same GridSpec, so that their SubplotSpec positions correspond to figure positions.

Examples

Example with rotated xtick labels:

```python
fig, axs = plt.subplots(1, 2)
for tick in axs[0].get_xticklabels():
    tick.set_rotation(55)
axs[0].set_xlabel('XLabel 0')
axs[1].set_xlabel('XLabel 1')
fig.align_xlabels()
```

align_ylabels(self, axs=None)
Align the labels of subplots in the same subplot column if label alignment is being done automatically (i.e. the label position is not manually set).

Alignment persists for draw events after this is called.

If a label is on the left, it is aligned with labels on axes that also have their label on the left and that have the same left-most subplot column. If the label is on the right, it is aligned with labels on axes with the same right-most column.

Parameters

axs [list of Axes] Optional list (or ndarray) of Axes to align the ylabels.
Default is to align all axes on the figure.
See also:

matplotlib.figure.Figure.align_xlabels
matplotlib.figure.Figure.align_labels

Notes

This assumes that axs are from the same GridSpec, so that their SubplotSpec positions correspond to figure positions.

Examples

Example with large yticks labels:

```python
fig, axs = plt.subplots(2, 1)
axs[0].plot(np.arange(0, 1000, 50))
axs[0].set_ylabel('YLabel 0')
axs[1].set_ylabel('YLabel 1')
fig.align_ylabels()
```

autofmt_xdate(self, bottom=0.2, rotation=30, ha='right', which=None)

Date ticklabels often overlap, so it is useful to rotate them and right align them. Also, a common use case is a number of subplots with shared xaxes where the x-axis is date data. The ticklabels are often long, and it helps to rotate them on the bottom subplot and turn them off on other subplots, as well as turn off xlabels.

Parameters

- **bottom** [scalar] The bottom of the subplots for subplots_adjust().
- **rotation** [angle in degrees] The rotation of the xtick labels.
- **ha** [string] The horizontal alignment of the xticklabels.
- **which** [{None, 'major', 'minor', 'both'}] Selects which ticklabels to rotate. Default is None which works the same as major.

axes

List of axes in the Figure. You can access the axes in the Figure through this list. Do not modify the list itself. Instead, use add_axes, subplot or delaxes to add or remove an axes.

clear(self, keepObservers=False)

Clear the figure – synonym for clf().

clf(self, keepObservers=False)

Clear the figure.

Set keep_observers to True if, for example, a gui widget is tracking the axes in the figure.

colorbar(self, mappable, cax=None, ax=None, use_gridspec=True, **kw)

Create a colorbar for a ScalarMappable instance, mappable.

Documentation for the pyplot thin wrapper:

Add a colorbar to a plot.
Function signatures for the pyplot interface; all but the first are also method signatures for the colorbar() method:

```python
colorbar(**kwargs)
colorbar(mappable, **kwargs)
colorbar(mappable, cax=cax, **kwargs)
colorbar(mappable, ax=ax, **kwargs)
```

**Parameters**

- **mappable** The `matplotlib.cm.ScalarMappable` (i.e., Image, ContourSet, etc.) described by this colorbar. This argument is mandatory for the Figure. colorbar method but optional for the `pyplot.colorbar` function, which sets the default to the current image.

  Note that one can create a ScalarMappable “on-the-fly” to generate colorbars not attached to a previously drawn artist, e.g.

  ```python
  fig.colorbar(cm.ScalarMappable(norm=norm, cmap=cmap), ax=ax)
  ```

- **cax** `Axes` object, optional] Axes into which the colorbar will be drawn.

- **ax** `Axes`, list of Axes, optional] Parent axes from which space for a new colorbar axes will be stolen. If a list of axes is given they will all be resized to make room for the colorbar axes.

- **use_gridspec** [bool, optional] If `cax` is `None`, a new `cax` is created as an instance of Axes. If `ax` is an instance of Subplot and `use_gridspec` is `True`, `cax` is created as an instance of Subplot using the `gridspec` module.

**Returns**

- **colorbar** `[Colorbar]` See also its base class, `ColorbarBase`. Use `set_label` to label the colorbar.

**Notes**

Additional keyword arguments are of two kinds:

axes properties:
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orientation</td>
<td>vertical or horizontal</td>
</tr>
<tr>
<td>fraction</td>
<td>0.15; fraction of original axes to use for colorbar</td>
</tr>
<tr>
<td>pad</td>
<td>0.05 if vertical, 0.15 if horizontal; fraction of original axes between colorbar and new image axes</td>
</tr>
<tr>
<td>shrink</td>
<td>1.0; fraction by which to multiply the size of the colorbar</td>
</tr>
<tr>
<td>aspect</td>
<td>20; ratio of long to short dimensions</td>
</tr>
<tr>
<td>anchor</td>
<td>(0.0, 0.5) if vertical; (0.5, 1.0) if horizontal; the anchor point of the colorbar axes</td>
</tr>
<tr>
<td>panchor</td>
<td>(1.0, 0.5) if vertical; (0.5, 0.0) if horizontal; the anchor point of the colorbar parent axes. If False, the parent axes' anchor will be unchanged</td>
</tr>
</tbody>
</table>
### Property Description

| extend | [ ‘neither’ | ‘both’ | ‘min’ | ‘max’ ] If not ‘neither’, make pointed end(s) for out-of-range values. These are set for a given colormap using the colormap set_under and set_over methods. |
|--------|-------------------------------------------------|
| extend frac | [ None | ‘auto’ | length | lengths ] If set to None, both the minimum and maximum triangular colorbar extensions with have a length of 5% of the interior colorbar length (this is the default setting). If set to ‘auto’, makes the triangular colorbar extensions the same lengths as the interior boxes (when spacing is set to ‘uniform’) or the same lengths as the respective adjacent interior boxes (when spacing is set to ‘proportional’). If a scalar, indicates the length of both the minimum and maximum triangular colorbar extensions as a fraction of the interior colorbar length. A two-element sequence of fractions may also be given, indicating the lengths of the minimum and maximum colorbar extensions respectively as a fraction of the interior colorbar length. |
| extend direct | bool If False the minimum and maximum colorbar extensions will be triangular (the default). If True the extensions will be rectangular. |
| spacing | [ ‘uniform’ | ‘proportional’ ] Uniform spacing gives each discrete color the same space; proportional makes the space proportional to the data interval. |
| ticks | [ None | list of ticks | Locator object ] If None, ticks are determined automatically from the input. |
| format | [ None | format string | Formatter object ] If None, the ScalarFormatter is used. If a format string is given, e.g., ‘%.3f’, that is used. An alternative Formatter object may be given instead. |
| drawedges | Whether to draw lines at color boundaries. |

The following will probably be useful only in the context of indexed colors (that is, when the mappable has norm=NoNorm()), or other unusual circumstances.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boundaries</td>
<td>None or a sequence</td>
</tr>
<tr>
<td>values</td>
<td>None or a sequence which must be of length 1 less than the sequence of boundaries. For each region delimited by adjacent entries in boundaries, the color mapped to the corresponding value in values will be used.</td>
</tr>
</tbody>
</table>

If `mappable` is a `ContourSet`, its `extend` kwarg is included automatically.

The `shrink` kwarg provides a simple way to scale the colorbar with respect to the axes. Note that if `cax` is specified, it determines the size of the colorbar and `shrink` and `aspect` kwargs are ignored.

For more precise control, you can manually specify the positions of the axes objects. 
in which the mappable and the colorbar are drawn. In this case, do not use any of the axes properties kwargs.

It is known that some vector graphics viewers (svg and pdf) renders white gaps between segments of the colorbar. This is due to bugs in the viewers, not Matplotlib. As a workaround, the colorbar can be rendered with overlapping segments:

```python
cbar = colorbar()
cbar.solids.set_edgecolor("face")
draw()
```

However this has negative consequences in other circumstances, e.g. with semi-transparent images (alpha < 1) and colorbar extensions; therefore, this workaround is not used by default (see issue #1188).

`contains(self, mouseevent)`
Test whether the mouse event occurred on the figure.

**Returns**

- `bool, {}`

`delaxes(self, ax)`
Remove the `Axes ax` from the figure and update the current axes.

`dpi`
The resolution in dots per inch.

`draw(self, renderer)`
Render the figure using `matplotlib.backend_bases.RendererBase` instance `renderer`.

`draw_artist(self, a)`
Draw `matplotlib.artist.Artist` instance `a` only. This is available only after the figure is drawn.

`execute_constrained_layout(self, renderer=None)`
Use `layoutbox` to determine pos positions within axes.

See also `set_constrained_layout_pads`.

`figimage(self, X, xo=0, yo=0, alpha=None, norm=None, cmap=None, vmin=None, vmax=None, origin=None, resize=False, **kwargs)`
Add a non-resampled image to the figure.

The image is attached to the lower or upper left corner depending on `origin`.

**Parameters**

- `X` The image data. This is an array of one of the following shapes:
  - MxN: luminance (grayscale) values
  - MxNx3: RGB values
  - MxNx4: RGBA values

- `xo, yo` [int] The x/y image offset in pixels.

- `alpha` [None or float] The alpha blending value.

- `norm` [`matplotlib.colors.Normalize`] A `Normalize` instance to map the luminance to the interval [0, 1].

**vmin, vmax** [scalar] If norm is not given, these values set the data limits for the colormap.

**origin** ['upper', 'lower']) Indicates where the [0, 0] index of the array is in the upper left or lower left corner of the axes. Defaults to rcParams['image.origin'].

**resize** [bool] If True, resize the figure to match the given image size.

**Returns**

matplotlib.image.FigureImage

**Other Parameters**

**kwargs** Additional kwargs are Artist kwargs passed on to FigureImage.

**Notes**

figimage complements the axes image (imshow()) which will be resampled to fit the current axes. If you want a resampled image to fill the entire figure, you can define an Axes with extent [0,0,1,1].

**Examples:**

```python
f = plt.figure()
nx = int(f.get_figwidth() * f.dpi)
ny = int(f.get_figheight() * f.dpi)
data = np.random.random((ny, nx))
f.figimage(data)
plt.show()
```

frameon

Return the figure’s background patch visibility, i.e. whether the figure background will be drawn. Equivalent to Figure.patch.get_visible().

gca(self, **kwargs)

Get the current axes, creating one if necessary.

The following kwargs are supported for ensuring the returned axes adheres to the given projection etc., and for axes creation if the active axes does not exist:

<table>
<thead>

</tbody>
</table>

`get_axes(self)`
Return a list of axes in the Figure. You can access and modify the axes in the Figure through this list.

Do not modify the list itself. Instead, use `add_axes`, `subplot` or `delaxes` to add or remove an axes.

Note: This is equivalent to the property `axes`.

`get_children(self)`
Get a list of artists contained in the figure.

`get_constrained_layout(self)`
Return a boolean: True means constrained layout is being used.

See *Constrained Layout Guide*.

`get_constrained_layout_pads(self, relative=False)`
Get padding for constrained_layout.

Returns a list of \( w_{pad}, h_{pad} \) in inches and \( w_{space} \) and \( h_{space} \) as fractions of the subplot.

See *Constrained Layout Guide*.

**Parameters**

- **relative** [boolean] If True, then convert from inches to figure relative.

**get_default_bbox_extra_artists(self)**

**get_dpi(self)**
Return the resolution in dots per inch as a float.

**get_edgecolor(self)**
Get the edge color of the Figure rectangle.

**get_facecolor(self)**
Get the face color of the Figure rectangle.

**get_figheight(self)**
Return the figure height as a float.

**get_figwidth(self)**
Return the figure width as a float.

**get_frameon(self)**
Return the figure’s background patch visibility, i.e. whether the figure background will be drawn. Equivalent to `Figure.patch.get_visible()`.

**get_size_inches(self)**
Returns the current size of the figure in inches.

**Returns**

- **size** [ndarray] The size (width, height) of the figure in inches.

See also:

- `matplotlib.Figure.set_size_inches`

**get_tight_layout(self)**
Return whether `tight_layout` is called when drawing.

**get_tightbbox(self, renderer, bbox_extra_artists=None)**
Return a (tight) bounding box of the figure in inches.

Artists that have `artist.set_in_layout(False)` are not included in the bbox.

**Parameters**

- **renderer** `[RendererBase instance]` renderer that will be used to draw the figures (i.e. `fig.canvas.get_renderer()`)

- **bbox_extra_artists** [list of `Artist` or `None`] List of artists to include in the tight bounding box. If `None` (default), then all artist children of each axes are included in the tight bounding box.
Returns

bbox [BboxBase] containing the bounding box (in figure inches).

get_window_extent(self, *args, **kwargs)

Return the figure bounding box in display space. Arguments are ignored.

ginput(self, n=1, timeout=30, show_clicks=True, mouse_add=1, mouse_pop=3, mouse_stop=2)

Blocking call to interact with a figure.

Wait until the user clicks n times on the figure, and return the coordinates of each click in a list.

There are three possible interactions:

• Add a point.
• Remove the most recently added point.
• Stop the interaction and return the points added so far.

The actions are assigned to mouse buttons via the arguments mouse_add, mouse_pop and mouse_stop. Mouse buttons are defined by the numbers:

• 1: left mouse button
• 2: middle mouse button
• 3: right mouse button
• None: no mouse button

Parameters

n [int, optional, default: 1] Number of mouse clicks to accumulate. If negative, accumulate clicks until the input is terminated manually.

timeout [scalar, optional, default: 30] Number of seconds to wait before timing out. If zero or negative will never timeout.

show_clicks [bool, optional, default: True] If True, show a red cross at the location of each click.

mouse_add [{1, 2, 3, None}, optional, default: 1 (left click)] Mouse button used to add points.

mouse_pop [{1, 2, 3, None}, optional, default: 3 (right click)] Mouse button used to remove the most recently added point.

mouse_stop [{1, 2, 3, None}, optional, default: 2 (middle click)] Mouse button used to stop input.

Returns

points [list of tuples] A list of the clicked (x, y) coordinates.

Notes

The keyboard can also be used to select points in case your mouse does not have one or more of the buttons. The delete and backspace keys act like right clicking (i.e., remove last point), the enter key terminates input and any other key (not already used by the window manager) selects a point.
init_layoutbox(self)
Initialize the layoutbox for use in constrained_layout.

legend(self, *args, **kwargs)
Place a legend on the figure.

To make a legend from existing artists on every axes:

```
legend()
```

To make a legend for a list of lines and labels:

```
legend(
    (line1, line2, line3),
    ('label1', 'label2', 'label3'),
    loc='upper right')
```

These can also be specified by keyword:

```
legend(
    handles=(line1, line2, line3),
    labels=('label1', 'label2', 'label3'),
    loc='upper right')
```

**Parameters**

- **handles** [sequence of Artist, optional] A list of Artists (lines, patches) to be added to the legend. Use this together with labels, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.

  The length of handles and labels should be the same in this case. If they are not, they are truncated to the smaller length.

- **labels** [sequence of strings, optional] A list of labels to show next to the artists. Use this together with handles, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.

**Returns**

- matplotlib.legend.Legend instance

**Other Parameters**

- **loc** [str or pair of floats, default: rcParams["legend.loc"] ("best" for axes, "upper right" for figures)] The location of the legend.

  The strings 'upper left', 'upper right', 'lower left', 'lower right' place the legend at the corresponding corner of the axes/figure.

  The strings 'upper center', 'lower center', 'center left', 'center right' place the legend at the center of the corresponding edge of the axes/figure.

  The string 'center' places the legend at the center of the axes/figure.

  The string 'best' places the legend at the location, among the nine locations defined so far, with the minimum overlap with other drawn artists. This option can be quite slow for plots with large amounts of data; your plotting speed may benefit from providing a specific location.
The location can also be a 2-tuple giving the coordinates of the lower-left corner of the legend in axes coordinates (in which case `bbox_to_anchor` will be ignored).

For back-compatibility, 'center right' (but no other location) can also be spelled 'right', and each "string" locations can also be given as a numeric value:

<table>
<thead>
<tr>
<th>Location String</th>
<th>Location Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>'best'</td>
<td>0</td>
</tr>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>

`bbox_to_anchor` [BboxBase, 2-tuple, or 4-tuple of floats] Box that is used to position the legend in conjunction with `loc`. Defaults to `axes.bbox` (if called as a method to `Axes.legend`) or `figure.bbox` (if `Figure.legend`). This argument allows arbitrary placement of the legend.

Bbox coordinates are interpreted in the coordinate system given by `bbox_transform`, with the default transform Axes or Figure coordinates, depending on which `legend` is called.

If a 4-tuple or `BboxBase` is given, then it specifies the bbox $(x, y, width, height)$ that the legend is placed in. To put the legend in the best location in the bottom right quadrant of the axes (or figure):

```
loc='best', bbox_to_anchor=(0.5, 0.5, 0.5, 0.5)
```

A 2-tuple $(x, y)$ places the corner of the legend specified by `loc` at $x, y$. For example, to put the legend’s upper right-hand corner in the center of the axes (or figure) the following keywords can be used:

```
loc='upper right', bbox_to_anchor=(0.5, 0.5)
```

`ncol` [integer] The number of columns that the legend has. Default is 1.

`prop` [None or `matplotlib.font_manager.FontProperties` or dict] The font properties of the legend. If None (default), the current `matplotlib.rcParams` will be used.

`fontsize` [int or float or {'xx-small', 'x-small', 'small', 'medium', 'large', 'x-large', 'xx-large'}] Controls the font size of the legend. If the value is numeric the size will be the absolute font size in points. String values are relative to the current default font size. This argument is only used if `prop` is not specified.

`numpoints` [None or int] The number of marker points in the legend when creating a legend entry for a `Line2D` (line). Default is None, which will take the value from `rcParams["legend.numpoints"]`. 
**scatterpoints** [None or int] The number of marker points in the legend when creating a legend entry for a `PathCollection` (scatter plot). Default is `None`, which will take the value from `rcParams["legend.scatterpoints"]`.

**scatteryoffsets** [iterable of floats] The vertical offset (relative to the font size) for the markers created for a scatter plot legend entry. 0.0 is at the base the legend text, and 1.0 is at the top. To draw all markers at the same height, set to [0.5]. Default is [0.375, 0.5, 0.3125].

**markerscale** [None or int or float] The relative size of legend markers compared with the originally drawn ones. Default is `None`, which will take the value from `rcParams["legend.markerscale"]`.

**markerfirst** [bool] If `True`, legend marker is placed to the left of the legend label. If `False`, legend marker is placed to the right of the legend label. Default is `True`.

**frameon** [None or bool] Control whether the legend should be drawn on a patch (frame). Default is `None`, which will take the value from `rcParams["legend.frameon"]`.

**fancybox** [None or bool] Control whether round edges should be enabled around the `FancyBboxPatch` which makes up the legend’s background. Default is `None`, which will take the value from `rcParams["legend.fancybox"]`.

**shadow** [None or bool] Control whether to draw a shadow behind the legend. Default is `None`, which will take the value from `rcParams["legend.shadow"]`.

**framealpha** [None or float] Control the alpha transparency of the legend’s background. Default is `None`, which will take the value from `rcParams["legend.framealpha"]`. If shadow is activated and `framealpha` is `None`, the default value is ignored.

**facecolor** [None or “inherit” or a color spec] Control the legend’s background color. Default is `None`, which will take the value from `rcParams["legend.facecolor"]`. If "inherit", it will take `rcParams["axes.facecolor"]`.

**edgcolor** [None or “inherit” or a color spec] Control the legend’s background patch edge color. Default is `None`, which will take the value from `rcParams["legend.edgecolor"]`. If "inherit", it will take `rcParams["axes.edgecolor"]`.

**mode** ["expand", None)] If `mode` is set to "expand" the legend will be horizontally expanded to fill the axes area (or `bbox_to_anchor` if defines the legend’s size).

**bbox_transform** [None or `matplotlib.transforms.Transform`] The transform for the bounding box (`bbox_to_anchor`). For a value of `None` (default) the Axes’ `transAxes` transform will be used.

**title** [str or None] The legend’s title. Default is no title (`None`).

**title_fontsize**: str or None The fontsize of the legend’s title. Default is the default fontsize.

**borderpad** [float or None] The fractional whitespace inside the legend border. Measured in font-size units. Default is `None`, which will take the
value from `rcParams["legend.borderpad"]`.

**labelspsacing** [float or None] The vertical space between the legend entries. Measured in font-size units. Default is `None`, which will take the value from `rcParams["legend.labelspacing"]`.

**handlelength** [float or None] The length of the legend handles. Measured in font-size units. Default is `None`, which will take the value from `rcParams["legend.handlelength"]`.

**handletextpad** [float or None] The pad between the legend handle and text. Measured in font-size units. Default is `None`, which will take the value from `rcParams["legend.handletextpad"]`.

**borderaxespad** [float or None] The pad between the axes and legend border. Measured in font-size units. Default is `None`, which will take the value from `rcParams["legend.borderaxespad"]`.

**columnspacing** [float or None] The spacing between columns. Measured in font-size units. Default is `None`, which will take the value from `rcParams["legend.columnspacing"]`.

**handler_map** [dict or None] The custom dictionary mapping instances or types to a legend handler. This handler_map updates the default handler map found at `matplotlib.legend.Legend.get_legend_handler_map()`.

**Notes**

Not all kinds of artist are supported by the legend command. See Legend guide for details.

```python
savefig(self, fname, *, transparent=None, **kwargs)
```

Save the current figure.

Call signature:

```python
savefig(fname, dpi=None, facecolor='w', edgecolor='w',
orientation='portrait', papertype=None, format=None,
transparent=False, bbox_inches=None, pad_inches=0.1,
frameon=None, metadata=None)
```

The output formats available depend on the backend being used.

**Parameters**

- **fname** [str or PathLike or file-like object] A path, or a Python file-like object, or possibly some backend-dependent object such as `matplotlib.backends.backend_pdf.PdfPages`.

  If `format` is not set, then the output format is inferred from the extension of `fname`, if any, and from `rcParams["savefig.format"]` otherwise. If `format` is set, it determines the output format.

  Hence, if `fname` is not a path or has no extension, remember to specify `format` to ensure that the correct backend is used.

**Other Parameters**
dpi [[None | scalar > 0 | ‘figure’]] The resolution in dots per inch. If None, defaults to rcParams[“savefig.dpi”]. If ‘figure’, uses the figure’s dpi value.

quality [[None | 1 <= scalar <= 100 ]] The image quality, on a scale from 1 (worst) to 95 (best). Applicable only if format is jpg or jpeg, ignored otherwise. If None, defaults to rcParams[“savefig.jpeg_quality”] (95 by default). Values above 95 should be avoided; 100 completely disables the JPEG quantization stage.

optimize [bool] If True, indicates that the JPEG encoder should make an extra pass over the image in order to select optimal encoder settings. Applicable only if format is jpg or jpeg, ignored otherwise. Is False by default.

progressive [bool] If True, indicates that this image should be stored as a progressive JPEG file. Applicable only if format is jpg or jpeg, ignored otherwise. Is False by default.

facecolor [color spec or None, optional] The facecolor of the figure; if None, defaults to rcParams[“savefig.facecolor”].

decoration [color spec or None, optional] The edgecolor of the figure; if None, defaults to rcParams[“savefig.edgecolor”].

orientation [{‘landscape’, ‘portrait’}] Currently only supported by the postscript backend.

deprecated

bbox_inches [str or Bbox, optional] Bbox in inches. Only the given portion of the figure is saved. If ‘tight’, try to figure out the tight bbox of the figure. If None, use savefig.bbox

pad_inches [scalar, optional] Amount of padding around the figure when bbox_inches is ‘tight’. If None, use savefig.pad_inches

bbox_extra_artists [list of Artist, optional] A list of extra artists that will be considered when the tight bbox is calculated.

metadata [dict, optional] Key/value pairs to store in the image metadata. The supported keys and defaults depend on the image format and backend:

- ‘png’ with Agg backend: See the parameter metadata of print_png.
- ‘pdf’ with pdf backend: See the parameter metadata of PdfPages.
- ‘eps’ and ‘ps’ with PS backend: Only ‘Creator’ is supported.
**pil_kwargs** [dict, optional] Additional keyword arguments that are passed to `PIL.Image.save` when saving the figure. Only applicable for formats that are saved using Pillow, i.e. JPEG, TIFF, and (if the keyword is set to a non-None value) PNG.

```python
sca(self, a)
    Set the current axes to be a and return a.
```

```python
set_canvas(self, canvas)
    Set the canvas that contains the figure
```

**Parameters**

```python
canvas [FigureCanvas]
```

```python
set_constrained_layout(self, constrained)
    Set whether `constrained_layout` is used upon drawing. If None, the rc-Params[‘figure.constrained_layout.use’] value will be used.
```

When providing a dict containing the keys `w_pad`, `h_pad` the default `constrained_layout` paddings will be overridden. These pads are in inches and default to 3.0/72.0. `w_pad` is the width padding and `h_pad` is the height padding.

See *Constrained Layout Guide*.

**Parameters**

```python
constrained [bool or dict or None]
```

```python
set_constrained_layout_pads(self, **kwargs)
    Set padding for `constrained_layout`. Note the `kwargs` can be passed as a dictionary
    `fig.set_constrained_layout(**paddict)`. See *Constrained Layout Guide*.
```

**Parameters**

```python
w_pad [scalar] Width padding in inches. This is the pad around axes and
        is meant to make sure there is enough room for fonts to look good.
        Defaults to 3 pts = 0.04167 inches
```

```python
h_pad [scalar] Height padding in inches. Defaults to 3 pts.
```

```python
wspace [scalar] Width padding between subplots, expressed as a fraction
        of the subplot width. The total padding ends up being w_pad +
```

```python
hspace [scalar] Height padding between subplots, expressed as a fraction
        of the subplot width. The total padding ends up being h_pad +
```

```python
set_dpi(self, val)
    Set the resolution of the figure in dots-per-inch.
```

**Parameters**

```python
val [float]
```

```python
set_edgecolor(self, color)
    Set the edge color of the Figure rectangle.
```

**Parameters**

```python
color [color]
```
set_facecolor(self, color)
    Set the face color of the Figure rectangle.

    Parameters
    color [color]

set_figheight(self, val, forward=True)
    Set the height of the figure in inches.

    Parameters
    val [float]
    forward [bool]

set_figwidth(self, val, forward=True)
    Set the width of the figure in inches.

    Parameters
    val [float]
    forward [bool]

set_frameon(self, b)
    Set the figure's background patch visibility, i.e. whether the figure background will
    be drawn. Equivalent to Figure.patch.set_visible().

    Parameters
    b [bool]

set_size_inches(self, w, h=None, forward=True)
    Set the figure size in inches.

    Call signatures:

    fig.set_size_inches(w, h)  # OR
    fig.set_size_inches((w, h))

    optional kwarg forward=True will cause the canvas size to be automatically updated;
    e.g., you can resize the figure window from the shell

    ACCEPTS: a (w, h) tuple with w, h in inches

    See also:

    matplotlib.Figure.get_size_inches

set_tight_layout(self, tight)
    Set whether and how tight_layout is called when drawing.

    Parameters
    tight [bool or dict with keys "pad", "w_pad", "h_pad", "rect" or None]
    If a bool, sets whether to call tight_layout upon drawing. If None, use
    the figure.autolayout rcparam instead. If a dict, pass it as kwargs to
tight_layout, overriding the default paddings.

show(self, warn=True)
    If using a GUI backend with pyplot, display the figure window.

    If the figure was not created using figure(), it will lack a FigureManagerBase, and will
    raise an AttributeError.
**Warning:** This does not manage an GUI event loop. Consequently, the figure may only be shown briefly or not shown at all if you or your environment are not managing an event loop.

Proper use cases for `Figure.show` include running this from a GUI application or an IPython shell.

If you’re running a pure python shell or executing a non-GUI python script, you should use `matplotlib.pyplot.show` instead, which takes care of managing the event loop for you.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>warn</strong></td>
<td>[bool] If True and we are not running headless (i.e. on Linux with an unset DISPLAY), issue warning when called on a non-GUI backend.</td>
</tr>
</tbody>
</table>

```python
def subplots(self, nrows=1, ncols=1, sharex=False, sharey=False, squeeze=True, subplot_kw=None, gridspec_kw=None)
```

Add a set of subplots to this figure.

This utility wrapper makes it convenient to create common layouts of subplots in a single call.

### Parameters

- **nrows, ncols** [int, optional, default: 1] Number of rows/columns of the subplot grid.
- **sharex, sharey** [bool or {'none', 'all', 'row', 'col'}, default: False] Controls sharing of properties among x (sharex) or y (sharey) axes:
  - True or ‘all’: x- or y-axis will be shared among all subplots.
  - False or ‘none’: each subplot x- or y-axis will be independent.
  - ‘row’: each subplot row will share an x- or y-axis.
  - ‘col’: each subplot column will share an x- or y-axis.

When subplots have a shared x-axis along a column, only the x tick labels of the bottom subplot are created. Similarly, when subplots have a shared y-axis along a row, only the y tick labels of the first column subplot are created. To later turn other subplots’ ticklabels on, use `tick_params`.

- **squeeze** [bool, optional, default: True]
  - If True, extra dimensions are squeezed out from the returned array of Axes:
    - if only one subplot is constructed (nrows=ncols=1), the resulting single Axes object is returned as a scalar.
    - for Nx1 or 1xM subplots, the returned object is a 1D numpy object array of Axes objects.
    - for NxM, subplots with N>1 and M>1 are returned as a 2D array.
  - If False, no squeezing at all is done: the returned Axes object is always a 2D array containing Axes instances, even if it ends up being 1x1.
**subplot_kw** [dict, optional] Dict with keywords passed to the *add_subplot()* call used to create each subplot.

**gridspec_kw** [dict, optional] Dict with keywords passed to the *GridSpec* constructor used to create the grid the subplots are placed on.

**Returns**

*ax* [Axes object or array of Axes objects.] *ax* can be either a single *Axes* object or an array of *Axes* objects if more than one subplot was created. The dimensions of the resulting array can be controlled with the *squeeze* keyword, see above.

**Examples**

```python
# First create some toy data:
x = np.linspace(0, 2*np.pi, 400)
y = np.sin(x**2)

# Create a figure
plt.figure()

# Creates a subplot
ax = fig.subplots()
ax.plot(x, y)
ax.set_title('Simple plot')

# Creates two subplots and unpacks the output array immediately
ax1, ax2 = fig.subplots(1, 2, sharey=True)
ax1.plot(x, y)
ax1.set_title('Sharing Y axis')
ax2.scatter(x, y)

# Creates four polar axes, and accesses them through the # returned array
axes = fig.subplots(2, 2, subplot_kw=dict(polar=True))
axes[0, 0].plot(x, y)
axes[1, 1].scatter(x, y)

# Share a X axis with each column of subplots
fig.subplots(2, 2, sharex='col')

# Share a Y axis with each row of subplots
fig.subplots(2, 2, sharey='row')

# Share both X and Y axes with all subplots
fig.subplots(2, 2, sharex='all', sharey='all')

# Note that this is the same as
fig.subplots(2, 2, sharex=True, sharey=True)
```

**subplots_adjust** *(self, left=None, bottom=None, right=None, top=None, wspace=None, hspace=None)*

Update the *SubplotParams* with *kwargs* (defaulting to *rc* when *None*) and update the
subplot locations.

tsuptitle(self, t, **kwargs)
Add a centered title to the figure.

**Parameters**

- **t** [str] The title text.
- **x** [float, default 0.5] The x location of the text in figure coordinates.
- **y** [float, default 0.98] The y location of the text in figure coordinates.
- **horizontalalignment**, **ha** [{'center', 'left', 'right'}, default: 'center']
  The horizontal alignment of the text relative to (x, y).
- **verticalalignment**, **va** [{'top', 'center', 'bottom', 'baseline'}, default: 'top']
  The vertical alignment of the text relative to (x, y).
- **fontsize**, **size** [default: \texttt{rcParams["figure.titlesize"]}] The font size of the text. See \texttt{Text.set_size} for possible values.
- **fontweight**, **weight** [default: \texttt{rcParams["figure.titleweight"]}] The font weight of the text. See \texttt{Text.set_weight} for possible values.

**Returns**

text The \texttt{Text} instance of the title.

**Other Parameters**

- **fontproperties** [None or dict, optional] A dict of font properties. If \texttt{fontproperties} is given the default values for font size and weight are taken from the \texttt{FontProperties} defaults. \texttt{rcParams["figure.titlesize"]} and \texttt{rcParams["figure.titleweight"]} are ignored in this case.
- **** **kwargs** Additional kwargs are \texttt{matplotlib.text.Text} properties.

**Examples**

```python
>>> fig.suptitle('This is the figure title', fontsize=12)
```

text(self, x, y, s, fontdict=None, withdash=<deprecated parameter>, **kwargs)
Add text to figure.

**Parameters**

- **x, y** [float] The position to place the text. By default, this is in figure coordinates, floats in [0, 1]. The coordinate system can be changed using the \texttt{transform} keyword.
- **s** [str] The text string.
- **fontdict** [dictionary, optional, default: None] A dictionary to override the default text properties. If fontdict is None, the defaults are determined by your rc parameters. A property in \texttt{kwargs} override the same property in fontdict.
- **withdash** [boolean, optional, default: False] Creates a \texttt{TextWithDash} instance instead of a \texttt{Text} instance.

**Returns**
**text** [Text]

**Other Parameters**

**kwargs [Text properties] Other miscellaneous text parameters.

**See also:**

`Axes.text`
**tight_layout**

```python
tight_layout(self, renderer=None, pad=1.08, h_pad=None, w_pad=None, rect=None)
```

Automatically adjust subplot parameters to give specified padding.

To exclude an artist on the axes from the bounding box calculation that determines the subplot parameters (i.e. legend, or annotation), then set `a.set_in_layout(False)` for that artist.

**Parameters**

- `renderer` [subclass of `RendererBase`, optional] Defaults to the renderer for the figure.
- `pad` [float, optional] Padding between the figure edge and the edges of subplots, as a fraction of the font size.
- `h_pad, w_pad` [float, optional] Padding (height/width) between edges of adjacent subplots, as a fraction of the font size. Defaults to `pad`.
- `rect` [tuple (left, bottom, right, top), optional] A rectangle (left, bottom, right, top) in the normalized figure coordinate that the whole subplots area (including labels) will fit into. Default is (0, 0, 1, 1).

**See also:**

- `Figure.set_tight_layout`
- `pyplot.tight_layout`

**waitforbuttonpress**

```python
waitforbuttonpress(self, timeout=-1)
```

Blocking call to interact with the figure.

This will return True if a key was pressed, False if a mouse button was pressed and None if `timeout` was reached without either being pressed.

If `timeout` is negative, does not timeout.

- sphx_glr_gallery_user_interfaces_embedding_in_wx4_sgskip.py
matplotlib.figure.SubplotParams

class matplotlib.figure.SubplotParams(
    left=None,    bottom=None,    right=None,    top=None,    wspace=None,    hspace=None)

Bases: object

A class to hold the parameters for a subplot.

All dimensions are fractions of the figure width or height. Defaults are given by rcParams["figure.subplot.[name]"].

Parameters

left [float] The left side of the subplots of the figure.
right [float] The right side of the subplots of the figure.
bottom [float] The bottom of the subplots of the figure.
top [float] The top of the subplots of the figure.
wspace [float] The amount of width reserved for space between subplots, expressed as a fraction of the average axis width.
hspace [float] The amount of height reserved for space between subplots, expressed as a fraction of the average axis height.

update(self, left=None, bottom=None, right=None, top=None, wspace=None, hspace=None)

Update the dimensions of the passed parameters. None means unchanged.

Examples using matplotlib.figure.SubplotParams

• sphx_glr_gallery_pyplots_auto_subplots_adjust.py

17.22.2 Functions
figaspect

Calculate the width and height for a figure with a specified aspect ratio.

matplotlib.figure.figaspect

matplotlib.figure.figaspect(arg)

Calculate the width and height for a figure with a specified aspect ratio.

While the height is taken from rcParams["figure.figsize"], the width is adjusted to match the desired aspect ratio. Additionally, it is ensured that the width is in the range [4., 16.] and the height is in the range [2., 16.]. If necessary, the default height is adjusted to ensure this.

Parameters

arg [scalar or 2d array] If a scalar, this defines the aspect ratio (i.e. the ratio height / width). In case of an array the aspect ratio is number of rows / number of columns, so that the array could be fitted in the figure undistorted.

Returns

width, height The figure size in inches.

Notes

If you want to create an axes within the figure, that still preserves the aspect ratio, be sure to create it with equal width and height. See examples below.

Thanks to Fernando Perez for this function.

Examples

Make a figure twice as tall as it is wide:

```python
w, h = figaspect(2.)
fig = Figure(figsize=(w, h))
ax = fig.add_axes([0.1, 0.1, 0.8, 0.8])
ax.imshow(A, **kwargs)
```

Make a figure with the proper aspect for an array:

```python
A = rand(5,3)
w, h = figaspect(A)
fig = Figure(figsize=(w, h))
ax = fig.add_axes([0.1, 0.1, 0.8, 0.8])
ax.imshow(A, **kwargs)
```

17.23 matplotlib.font_manager

A module for finding, managing, and using fonts across platforms.
This module provides a single `FontManager` instance that can be shared across backends and platforms. The `findfont()` function returns the best TrueType (TTF) font file in the local or system font path that matches the specified `FontProperties` instance. The `FontManager` also handles Adobe Font Metrics (AFM) font files for use by the PostScript backend.

The design is based on the W3C Cascading Style Sheet, Level 1 (CSS1) font specification. Future versions may implement the Level 2 or 2.1 specifications.

class matplotlib.font_manager.FontEntry(fname='', name='', style='normal', variant='normal', weight='normal', stretch='normal', size='medium')

Bases: object

A class for storing Font properties. It is used when populating the font lookup dictionary.

class matplotlib.font_manager.FontManager(size=None, weight='normal')

Bases: object

On import, the `FontManager` singleton instance creates a list of TrueType fonts based on the font properties: name, style, variant, weight, stretch, and size. The `findfont()` method does a nearest neighbor search to find the font that most closely matches the specification. If no good enough match is found, a default font is returned.

afmfiles
defaultFont

findfont(self, prop, fontext='ttf', directory=None, fallback_to_default=True, rebuild_if_missing=True)

Find a font that most closely matches the given font properties.

Parameters

prop [str or `FontProperties`] The font properties to search for. This can be either a `FontProperties` object or a string defining a `fontconfig` patterns.

fontext [{'ttf', 'afm'}, optional, default: 'ttf'] The extension of the font file:

- `ttf`: TrueType and OpenType fonts (.ttf, .ttc, .otf)
- `afm`: Adobe Font Metrics (.afm)

directory [str, optional] If given, only search this directory and its sub-directories.

fallback_to_default [bool] If True, will fallback to the default font family (usually "DejaVu Sans" or "Helvetica") if the first lookup hard-fails.

rebuild_if_missing [bool] Whether to rebuild the font cache and search again if no match is found.

Returns

Notes

This performs a nearest neighbor search. Each font is given a similarity score to the target font properties. The first font with the highest score is returned. If no
matches below a certain threshold are found, the default font (usually DejaVu Sans) is returned.

The result is cached, so subsequent lookups don’t have to perform the O(n) nearest neighbor search.

See the W3C Cascading Style Sheet, Level 1 documentation for a description of the font finding algorithm.

```python
static get_default_size()
    Return the default font size.

get_default_weight(self)
    Return the default font weight.

score_family(self, families, family2)
    Returns a match score between the list of font families in families and the font family name family2.
    An exact match at the head of the list returns 0.0.
    A match further down the list will return between 0 and 1.
    No match will return 1.0.

score_size(self, size1, size2)
    Returns a match score between size1 and size2.
    If size2 (the size specified in the font file) is ‘scalable’, this function always returns 0.0, since any font size can be generated.
    Otherwise, the result is the absolute distance between size1 and size2, normalized so that the usual range of font sizes (6pt - 72pt) will lie between 0.0 and 1.0.

score_stretch(self, stretch1, stretch2)
    Returns a match score between stretch1 and stretch2.
    The result is the absolute value of the difference between the CSS numeric values of stretch1 and stretch2, normalized between 0.0 and 1.0.

score_style(self, style1, style2)
    Returns a match score between style1 and style2.
    An exact match returns 0.0.
    A match between ‘italic’ and ‘oblique’ returns 0.1.
    No match returns 1.0.

score_variant(self, variant1, variant2)
    Returns a match score between variant1 and variant2.
    An exact match returns 0.0, otherwise 1.0.

score_weight(self, weight1, weight2)
    Returns a match score between weight1 and weight2.
    The result is 0.0 if both weight1 and weight 2 are given as strings and have the same value.
    Otherwise, the result is the absolute value of the difference between the CSS numeric values of weight1 and weight2, normalized between 0.05 and 1.0.

set_default_weight(self, weight)
    Set the default font weight. The initial value is ‘normal’.
```
ttffiles
class matplotlib.font_manager.FontProperties(family=None, style=None, variant=None, weight=None, stretch=None, size=None, fname=None)

Bases: object

A class for storing and manipulating font properties.

The font properties are those described in the W3C Cascading Style Sheet, Level 1 font specification. The six properties are:

- **family**: A list of font names in decreasing order of priority. The items may include a generic font family name, either ‘serif’, ‘sans-serif’, ‘cursive’, ‘fantasy’, or ‘monospace’. In that case, the actual font to be used will be looked up from the associated rcParam.

- **style**: Either ‘normal’, ‘italic’ or ‘oblique’.

- **variant**: Either ‘normal’ or ‘small-caps’.

The default font property for TrueType fonts (as specified in the default rcParams) is:

```
sans-serif, normal, normal, normal, normal, scalable.
```

Alternatively, a font may be specified using an absolute path to a .ttf file, by using the `fname` kwarg.

The preferred usage of font sizes is to use the relative values, e.g., ‘large’, instead of absolute font sizes, e.g., 12. This approach allows all text sizes to be made larger or smaller based on the font manager’s default font size.

This class will also accept a **fontconfig pattern**, if it is the only argument provided. This support does not require fontconfig to be installed. We are merely borrowing its pattern syntax for use here.

Note that Matplotlib’s internal font manager and fontconfig use a different algorithm to lookup fonts, so the results of the same pattern may be different in Matplotlib than in other applications that use fontconfig.

`copy(self)`
Return a copy of self.

`get_family(self)`
Return a list of font names that comprise the font family.

`get_file(self)`
Return the filename of the associated font.

`get_fontconfig_pattern(self)`
Get a **fontconfig pattern** suitable for looking up the font as specified with fontconfig’s `fc-match` utility.
This support does not require fontconfig to be installed or support for it to be enabled. We are merely borrowing its pattern syntax for use here.

**get_name(self)**
Return the name of the font that best matches the font properties.

**get_size(self)**
Return the font size.

**get_size_in_points(self)**

**get_slant(self)**
Return the font style. Values are: ‘normal’, ‘italic’ or ‘oblique’.

**get_stretch(self)**

**get_style(self)**
Return the font style. Values are: ‘normal’, ‘italic’ or ‘oblique’.

**get_variant(self)**
Return the font variant. Values are: ‘normal’ or ‘small-caps’.

**get_weight(self)**

**set_family(self, family)**
Change the font family. May be either an alias (generic name is CSS parlance), such as: ‘serif’, ‘sans-serif’, ‘cursive’, ‘fantasy’, or ‘monospace’, a real font name or a list of real font names. Real font names are not supported when text.usetex is True.

**set_file(self, file)**
Set the filename of the fontfile to use. In this case, all other properties will be ignored.

**set_fontconfig_pattern(self, pattern)**
Set the properties by parsing a fontconfig pattern.

This support does not require fontconfig to be installed or support for it to be enabled. We are merely borrowing its pattern syntax for use here.

**set_name(self, family)**
Change the font family. May be either an alias (generic name is CSS parlance), such as: ‘serif’, ‘sans-serif’, ‘cursive’, ‘fantasy’, or ‘monospace’, a real font name or a list of real font names. Real font names are not supported when text.usetex is True.

**set_size(self, size)**

**set_slant(self, style)**
Set the font style. Values are: ‘normal’, ‘italic’ or ‘oblique’.

**set_stretch(self, stretch)**
```python
set_style(self, style)
    Set the font style. Values are: 'normal', 'italic' or 'oblique'.

set_variant(self, variant)
    Set the font variant. Values are: 'normal' or 'small-caps'.

set_weight(self, weight)
    Set the font weight. May be either a numeric value in the range 0-1000 or one of
    'ultralight', 'light', 'normal', 'regular', 'book', 'medium', 'roman', 'semibold', 'demibold', 'demi', 'bold', 'heavy', 'extra bold', 'black'
```

```python
class matplotlib.font_manager.JSONEncoder(*, skipkeys=False, ensure_ascii=True,
                                check_circular=True, allow_nan=True,
                                sort_keys=False, indent=None, separators=None, default=None)
```
else:
    return list(iterable)
# Let the base class default method raise the TypeError
return JSONEncoder.default(self, o)

matplotlib.font_manager.OSXInstalledFonts(directories=None, fontext='ttf')

[Deprecated] Get list of font files on OS X.

Notes

Deprecated since version 3.1.

class matplotlib.font_manager.TempCache(**kwargs)
    Bases: object

[Deprecated] A class to store temporary caches that are (a) not saved to disk and (b) invalidated whenever certain font-related rcParams—namely the family lookup lists—are changed or the font cache is reloaded. This avoids the expensive linear search through all fonts every time a font is looked up.

Notes

Deprecated since version 3.0.

get(self, prop)

invalidating_rcparams = ('font.serif', 'font.sans-serif', 'font.cursive', 'font.fantasy', 'font.monospace')
make_rcparams_key(self)
set(self, prop, value)

matplotlib.font_manager.afmFontProperty(fontpath, font)

Extract information from an AFM font file.

Parameters

font [AFM] The AFM font file from which information will be extracted.

Returns

FontEntry The extracted font properties.

matplotlib.font_manager.createFontList(fontfiles, fontext='ttf')

A function to create a font lookup list. The default is to create a list of TrueType fonts. An AFM font list can optionally be created.

matplotlib.font_manager.findSystemFonts(fontpaths=None, fontext='ttf')

Search for fonts in the specified font paths. If no paths are given, will use a standard set of system paths, as well as the list of fonts tracked by fontconfig if fontconfig is installed and available. A list of TrueType fonts are returned by default with AFM fonts as an option.

matplotlib.font_manager.get_font(filename, hinting_factor=None)

matplotlib.font_manager.get_fontconfig_fonts(fontext='ttf')

List the font filenames known to fc-list having the given extension.
matplotlib.font_manager.get_fontext_synonyms(fontext)
Return a list of file extensions extensions that are synonyms for the given file extension fileext.

matplotlib.font_manager.is_opentype_cff_font(filename)
Return whether the given font is a Postscript Compact Font Format Font embedded in an OpenType wrapper. Used by the PostScript and PDF backends that can not subset these fonts.

matplotlib.font_manager.json_dump(data, filename)
Dumps a data structure as JSON in the named file.
Handles FontManager and its fields. File paths that are children of the Matplotlib data path (typically, fonts shipped with Matplotlib) are stored relative to that data path (to remain valid across virtualenvs).

matplotlib.font_manager.json_load(filename)
Loads a data structure as JSON from the named file.
Handles FontManager and its fields. Relative file paths are interpreted as being relative to the Matplotlib data path, and transformed into absolute paths.

matplotlib.font_manager.list_fonts(directory, extensions)
Return a list of all fonts matching any of the extensions, found recursively under the directory.

matplotlib.font_manager.ttfFontProperty(font)
Extract information from a TrueType font file.

Parameters
- font [FT2Font] The TrueType font file from which information will be extracted.

Returns
- FontEntry The extracted font properties.

matplotlib.font_manager.win32FontDirectory()
Return the user-specified font directory for Win32. This is looked up from the registry key:
```plaintext
\HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Shell\Folders\Fonts
```
If the key is not found, %WINDIR%\Fonts will be returned.

matplotlib.font_manager.win32InstalledFonts(directory=None, fontext='ttf')
Search for fonts in the specified font directory, or use the system directories if none given. Additionally, it is searched for user fonts installed. A list of TrueType font filenames are returned by default, or AFM fonts if fontext == ‘afm’.

17.24 matplotlib.fontconfig_pattern

A module for parsing and generating fontconfig patterns.

class matplotlib.fontconfig_pattern.FontconfigPatternParser
Bases: object

A simple pyparsing-based parser for fontconfig patterns.
parse(self, pattern)
    Parse the given fontconfig pattern and return a dictionary of key/value pairs useful for initializing a font_manager.FontProperties object.

matplotlib.fontconfig_pattern.family_escape(repl, string, count=0)
    Return the string obtained by replacing the leftmost non-overlapping occurrences of pattern in string by the replacement repl.

matplotlib.fontconfig_pattern.family_unescape(repl, string, count=0)
    Return the string obtained by replacing the leftmost non-overlapping occurrences of pattern in string by the replacement repl.

matplotlib.fontconfig_pattern.generate_fontconfig_pattern(d)
    Given a dictionary of key/value pairs, generates a fontconfig pattern string.

matplotlib.fontconfig_pattern.parse_fontconfig_pattern(pattern)
    Parse the given fontconfig pattern and return a dictionary of key/value pairs useful for initializing a font_manager.FontProperties object.

matplotlib.fontconfig_pattern.value_escape(repl, string, count=0)
    Return the string obtained by replacing the leftmost non-overlapping occurrences of pattern in string by the replacement repl.

matplotlib.fontconfig_pattern.value_unescape(repl, string, count=0)
    Return the string obtained by replacing the leftmost non-overlapping occurrences of pattern in string by the replacement repl.

17.25 matplotlib.gridspec

gridspec contains classes that help to layout multiple Axes in a grid-like pattern within a figure. The GridSpec specifies the overall grid structure. Individual cells within the grid are referenced by SubplotSpecs.

See the tutorial Customizing Figure Layouts Using GridSpec and Other Functions for a comprehensive usage guide.

17.25.1 Classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GridSpec(nrows, ncols[, figure, left, ...])</td>
<td>Specifies the geometry of the grid that a subplot can be placed in.</td>
</tr>
<tr>
<td>SubplotSpec(gridspec, num1[, num2])</td>
<td>Specifies the location of a subplot in a GridSpec.</td>
</tr>
<tr>
<td>GridSpecBase(nrows, ncols[, height_ratios, ...])</td>
<td>A base class of GridSpec that specifies the geometry of the grid that a subplot will be placed.</td>
</tr>
<tr>
<td>GridSpecFromSubplotSpec(nrows, ncols, ...[, ...])</td>
<td>GridSpec whose subplot layout parameters are inherited from the location specified by a given SubplotSpec.</td>
</tr>
</tbody>
</table>
matplotlib.gridspec.GridSpec

class matplotlib.gridspec.GridSpec(nrows, ncols, figure=None, left=None, bottom=None, right=None, top=None, wspace=None, hspace=None, width_ratios=None, height_ratios=None)

Bases: matplotlib.gridspec.GridSpecBase

Specifies the geometry of the grid that a subplot can be placed in.

The location of grid is determined by similar way as the SubplotParams.

The number of rows and number of columns of the grid need to be set. Optionally, the subplot layout parameters (e.g., left, right, etc.) can be tuned.

Parameters

nrows [int] Number of rows in grid.
ncols [int] Number or columns in grid.
figure [Figure, optional]
left, right, top, bottom [float, optional] Extent of the subplots as a fraction of figure width or height. Left cannot be larger than right, and bottom cannot be larger than top.
wspace [float, optional] The amount of width reserved for space between subplots, expressed as a fraction of the average axis width.
hspace [float, optional] The amount of height reserved for space between subplots, expressed as a fraction of the average axis height.
height_ratios [length nrows iterable, optional] Height ratios of the rows.

Notes

See SubplotParams for descriptions of the layout parameters.

get_subplot_params(self, figure=None)
Return a dictionary of subplot layout parameters. The default parameters are from rcParams unless a figure attribute is set.

locally_modified_subplot_params(self)
tight_layout(self, figure, renderer=None, pad=1.08, h_pad=None, w_pad=None, rect=None)
Adjust subplot parameters to give specified padding.

Parameters

pad [float] Padding between the figure edge and the edges of subplots, as a fraction of the font-size.

h_pad, w_pad [float, optional] Padding (height/width) between edges of adjacent subplots. Defaults to pad.
rect [tuple of 4 floats, optional] (left, bottom, right, top) rectangle in normalized figure coordinates that the whole subplots area (including labels) will fit into. Default is (0, 0, 1, 1).
update(self, **kwargs)
    Update the current values.
    Values set to None use the rcParams value.

Examples using matplotlib.gridspec.GridSpec

- sphx_glr_gallery_lines_bars_and_markers_psd_demo.py
- sphx_glr_gallery_images_contours_and_fields_plot_streamplot.py
- sphx_glr_gallery_subplots_axes_and_figures_align_labels_demo.py
- sphx_glr_gallery_subplots_axes_and_figures_demo_constrained_layout.py
- sphx_glr_gallery_subplots_axes_and_figures_gridspec_multicolumn.py
- sphx_glr_gallery_subplots_axes_and_figures_gridspec_nested.py

- sphx_glr_gallery_userdemo_demo_gridspec06.py
- Customizing Figure Layouts Using GridSpec and Other Functions
- Constrained Layout Guide
- Tight Layout guide
- origin and extent in imshow

matplotlib.gridspec.SubplotSpec
class matplotlib.gridspec.SubplotSpec(gridspec, num1, num2=None)
    Bases: object
    Specifies the location of a subplot in a GridSpec.

    **Note:** Likely, you’ll never instantiate a SubplotSpec yourself. Instead you will typically obtain one from a GridSpec using item-access.

    **Parameters**
    - gridspec [GridSpec] The GridSpec, which the subplot is referencing.
    - num1, num2 [int] The subplot will occupy the num1-th cell of the given gridspec. If num2 is provided, the subplot will span between num1-th cell and num2-th cell. The index starts from 0.

    get_geometry(self)
    Return the subplot geometry as tuple (n_rows, n_cols, start, stop).
    The indices start and stop define the range of the subplot within the GridSpec. stop is inclusive (i.e. for a single cell start == stop).

    get_gridspec(self)
get_position(self, figure, return_all=False)
    Update the subplot position from figure.subplotpars.

get_rows_columns(self)
    Return the subplot row and column numbers as a tuple (n_rows, n_cols, row_start, row_stop, col_start, col_stop).

get_topmost_subplotspec(self)
    Return the topmost SubplotSpec instance associated with the subplot.

subgridspec(self, nrows, ncols, **kwargs)
    Create a GridSpec within this subplot.
    The created GridSpecFromSubplotSpec will have this SubplotSpec as a parent.

Parameters
    nrows [int] Number of rows in grid.
    ncols [int] Number or columns in grid.

Returns
    gridspec [GridSpecFromSubplotSpec]

Other Parameters
    **kwargs All other parameters are passed to GridSpecFromSubplotSpec.

See also:

matplotlib.pyplot.subplots

Examples

Adding three subplots in the space occupied by a single subplot:

```python
fig = plt.figure()
gs0 = fig.add_gridspec(3, 1)
ax1 = fig.add_subplot(gs0[0])
ax2 = fig.add_subplot(gs0[1])
gssub = gs0[2].subgridspec(1, 3)
for i in range(3):
    fig.add_subplot(gssub[0, i])
```

matplotlib.gridspec.GridSpecBase

class matplotlib.gridspec.GridSpecBase(nrows, ncols, height_ratios=None, width_ratios=None)
Bases: object
    A base class of GridSpec that specifies the geometry of the grid that a subplot will be placed.
    The number of rows and number of columns of the grid need to be set. Optionally, the ratio of heights and widths of rows and columns can be specified.

get_geometry(self)
    Return a tuple containing the number of rows and columns in the grid.
get_grid_positions(self, fig, raw=False)
    Return lists of bottom and top position of rows, left and right positions of columns.
    If raw=True, then these are all in units relative to the container with no margins. (used for constrained_layout).

get_height_ratios(self)

get_subplot_params(self, figure=None, fig=None)

get_width_ratios(self)

new_subplotspec(self, loc, rowspan=1, colspan=1)
    Create and return a SubplotSpec instance.

set_height_ratios(self, height_ratios)

set_width_ratios(self, width_ratios)

matplotlib.gridspec.GridSpecFromSubplotSpec

class matplotlib.gridspec.GridSpecFromSubplotSpec(nrows, ncols, subplot_spec, wspace=None, hspace=None, height_ratios=None, width_ratios=None)

    Bases: matplotlib.gridspec.GridSpecBase

    GridSpec whose subplot layout parameters are inherited from the location specified by
    a given SubplotSpec.

    The number of rows and number of columns of the grid need to be set. An instance of
    SubplotSpec is also needed to be set from which the layout parameters will be inherited.
    The wspace and hspace of the layout can be optionally specified or the default values
    (from the figure or rcParams) will be used.

    get_subplot_params(self, figure=None)
        Return a dictionary of subplot layout parameters.

    get_topmost_subplotspec(self)
        Return the topmost SubplotSpec instance associated with the subplot.

Examples using matplotlib.gridspec.GridSpecFromSubplotSpec

- sphx_glr_gallery_subplots_axes_and_figures_demo_constrained_layout.py
- sphx_glr_gallery_subplots_axes_and_figures_gridspec_nested.py
- sphx_glr_gallery_userdemo_demo_gridspec06.py
- Customizing Figure Layouts Using GridSpec and Other Functions

17.26 matplotlib.image

The image module supports basic image loading, rescaling and display operations.
class matplotlib.image.AxesImage(ax, cmap=None, norm=None, interpolation=None, origin=None, extent=None, filternorm=1, filterrad=4.0, resample=False, **kwargs)

Bases: matplotlib.image._ImageBase

interpolation and cmap default to their rc settings
cmap is a colors.Colormap instance norm is a colors.Normalize instance to map luminance to 0-1
extent is data axes (left, right, bottom, top) for making image plots registered with data plots. Default is to label the pixel centers with the zero-based row and column indices.
Additional kwargs are matplotlib.artist properties

format_cursor_data(self, data)
Return a string representation of data.

Note: This method is intended to be overridden by artist subclasses. As an end-user of Matplotlib you will most likely not call this method yourself.

The default implementation converts ints and floats and arrays of ints and floats into a comma-separated string enclosed in square brackets.

See also:

get_cursor_data

get_cursor_data(self, event)
Return the image value at the event position or None if the event is outside the image.

See also:

matplotlib.artist.Artist.get_cursor_data

get_extent(self)
Get the image extent: left, right, bottom, top

get_window_extent(self, renderer=None)
Get the axes bounding box in display space.
The bounding box' width and height are nonnegative.
Subclasses should override for inclusion in the bounding box "tight" calculation. Default is to return an empty bounding box at 0, 0.
Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

make_image(self, renderer, magnification=1.0, unsampled=False)
Normalize, rescale, and colormap this image’s data for rendering using renderer, with the given magnification.
If unsampled is True, the image will not be scaled, but an appropriate affine transformation will be returned instead.
Returns

**image** [(M, N, 4) uint8 array] The RGBA image, resampled unless unsampled is True.

**x, y** [float] The upper left corner where the image should be drawn, in pixel space.

**trans** [Affine2D] The affine transformation from image to pixel space.

```python
def set_extent(self, extent)
    extent is data axes (left, right, bottom, top) for making image plots
    This updates ax.dataLim, and, if autoscaling, sets viewLim to tightly fit the image, regardless of dataLim. Autoscaling state is not changed, so following this with ax.autoscale_view will redo the autoscaling in accord with dataLim.
```

```python
class matplotlib.image.BboxImage(bbox, cmap=None, norm=None, interpolation=None, origin=None, filternorm=1, filterrad=4.0, unsampled=False, interp_at_native=<deprecated parameter>, **kwargs)
    Bases: matplotlib.image._ImageBase
    The Image class whose size is determined by the given bbox.
    cmap is a colors.Colormap instance norm is a colors.Normalize instance to map luminance to 0-1
    kwargs are an optional list of Artist keyword args
    ```

```python
def contains(self, mouseevent)
    Test whether the mouse event occurred within the image.
```

```python
def get_transform(self)
    Return the Transform instance used by this artist.
```

```python
def get_window_extent(self, renderer=None)
    Get the axes bounding box in display space.
    The bounding box' width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box “tight” calculation. Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.
```

```python
def interp_at_native
```

```python
def make_image(self, renderer, magnification=1.0, unsampled=False)
    Normalize, rescale, and colormap this image’s data for rendering using renderer, with the given magnification.
    If unsampled is True, the image will not be scaled, but an appropriate affine transformation will be returned instead.

Returns

**image** [(M, N, 4) uint8 array] The RGBA image, resampled unless unsampled is True.
x, y [float] The upper left corner where the image should be drawn, in pixel space.

trans [Affine2D] The affine transformation from image to pixel space.

class matplotlib.image.FigureImage(fig, cmap=None, norm=None, offsetx=0, offsety=0, origin=None, **kwargs)

Bases: matplotlib.image._ImageBase

cmap is a colors.Colormap instance norm is a colors.Normalize instance to map luminance to 0-1

dkwarg is an optional list of Artist keyword args

def get_extent(self)
    Get the image extent: left, right, bottom, top

def make_image(self, renderer, magnification=1.0, unsampled=False)
    Normalize, rescale, and colormap this image’s data for rendering using renderer, with the given magnification.

    If unsampled is True, the image will not be scaled, but an appropriate affine transformation will be returned instead.

Returns

image [(M, N, 4) uint8 array] The RGBA image, resampled unless unsampled is True.

x, y [float] The upper left corner where the image should be drawn, in pixel space.

def set_data(self, A)
    Set the image array.

zorder = 0

class matplotlib.image.NonUniformImage(ax, *, interpolation=’nearest’, **kwargs)

Bases: matplotlib.image.AxesImage

dkwarg is identical to those for AxesImage, except that ’nearest’ and ’bilinear’ are the only supported ’interpolation’ options.

def get_extent(self)
    Get the image extent: left, right, bottom, top

def make_image(self, renderer, magnification=1.0, unsampled=False)
    Normalize, rescale, and colormap this image’s data for rendering using renderer, with the given magnification.

    If unsampled is True, the image will not be scaled, but an appropriate affine transformation will be returned instead.

Returns

image [(M, N, 4) uint8 array] The RGBA image, resampled unless unsampled is True.

x, y [float] The upper left corner where the image should be drawn, in pixel space.

def trans [Affine2D] The affine transformation from image to pixel space.
set_array(self, *args)
Retained for backwards compatibility - use set_data instead.

Parameters
A [array-like]

set_cmap(self, cmap)
set the colormap for luminance data

Parameters
cmap [colormap or registered colormap name]

set_data(self, x, y, A)
Set the grid for the pixel centers, and the pixel values.

x and y are monotonic 1-D ndarrays of lengths N and M, respectively, specifying pixel centers

A is an (M,N) ndarray or masked array of values to be colormapped, or a (M,N,3) RGB array, or a (M,N,4) RGBA array.

set_filternorm(self, s)
Set whether the resize filter normalizes the weights.
See help for imshow.

Parameters
filternorm [bool]

set_filterrad(self, s)
Set the resize filter radius only applicable to some interpolation schemes – see help for imshow

Parameters
filterrad [positive float]

set_interpolation(self, s)
Parameters
s [str, None] Either ‘nearest’, ‘bilinear’, or None.

set_norm(self, norm)
Set the normalization instance.

Parameters
norm [Normalize]

Notes
If there are any colorbars using the mappable for this norm, setting the norm of the mappable will reset the norm, locator, and formatters on the colorbar to default.

class matplotlib.image.PcolorImage(ax, x=None, y=None, A=None, cmap=None, norm=None, **kwargs)
Bases: matplotlib.image.AxesImage
Make a pcolor-style plot with an irregular rectangular grid.
This uses a variation of the original irregular image code, and it is used by pcolorfast for
the corresponding grid type.

cmap defaults to its rc setting

cmap is a colors.Colormap instance norm is a colors.Normalize instance to map lumi-
nance to 0-1

Additional kwargs are matplotlib.artist properties

```
get_cursor_data(self, event)
    Return the image value at the event position or None if the event is outside the
    image.
```

See also:

```
matplotlib.artist.Artist.get_cursor_data
```

```
make_image(self, renderer, magnification=1.0, unsampled=False)
    Normalize, rescale, and colormap this image’s data for rendering using renderer,
    with the given magnification.

    If unsampled is True, the image will not be scaled, but an appropriate affine trans-
    formation will be returned instead.

    Returns

    image [(M, N, 4) uint8 array] The RGBA image, resampled unless unsam-
           pled is True.
    x, y [float] The upper left corner where the image should be drawn, in
           pixel space.
    trans [Affine2D] The affine transformation from image to pixel space.
```

```
set_array(self, *args)
    Retained for backwards compatibility - use set_data instead.
```

Parameters

```
A [array-like]
```

```
set_data(self, x, y, A)
    Set the grid for the rectangle boundaries, and the data values.

    x and y are monotonic 1-D ndarrays of lengths N+1 and M+1,
    respectively, specifying rectangle boundaries. If None, they will
    be created as uniform arrays from 0 through N and 0 through M,
    respectively.

    A is an (M,N) ndarray or masked array of values to be colored,
    or a (M,N,3) RGB array, or a (M,N,4) RGBA array.
```

```
matplotlib.image.composite_images(images, renderer, magnification=1.0)
    Composite a number of RGBA images into one. The images are composited in the order
    in which they appear in the images list.
```

Parameters

```
images [list of Images] Each must have a make_image method. For each
    image, can_composite should return True, though this is not enforced
    by this function. Each image must have a purely affine transformation
    with no shear.
```
renderer [RendererBase instance]
magnification [float] The additional magnification to apply for the ren-
derer in use.

Returns
tuple [image, offset_x, offset_y] Returns the tuple:
• image: A numpy array of the same type as the input images.
• offset_x, offset_y: The offset of the image (left, bottom) in the output
figure.

matplotlib.image.imread(fname, format=None)
Read an image from a file into an array.

Parameters
fname [str or file-like] The image file to read. This can be a filename, a
URL or a Python file-like object opened in read-binary mode.
format [str, optional] The image file format assumed for reading the data.
If not given, the format is deduced from the filename. If nothing can
be deduced, PNG is tried.

Returns
imagedata [numpy.array] The image data. The returned array has shape
• (M, N) for grayscale images.
• (M, N, 3) for RGB images.
• (M, N, 4) for RGBA images.

Notes
Matplotlib can only read PNGs natively. Further image formats are supported via the
optional dependency on Pillow. Note, URL strings are not compatible with Pillow. Check
the Pillow documentation for more information.

matplotlib.image.imsave(fname, arr, vmin=None, vmax=None, cmap=None, for-
mat=None, origin=None, dpi=100)
Save an array as an image file.

Parameters
fname [str or PathLike file-like] A path or a Python file-like object to
store the image in. If format is not set, then the output format is in-
ferrred from the extension of filename, if any, and from rcParams["savefig.
format"] otherwise. If format is set, it determines the output format.
arr [array-like] The image data. The shape can be one of MxN (lumi-
nance), MxN3 (RGB) or MxN4 (RGBA).

vmin, vmax [scalar, optional] vmin and vmax set the color scaling for the
image by fixing the values that map to the colormap color limits. If
either vmin or vmax is None, that limit is determined from the arr
min/max value.
cmap [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps scalar data to colors. It is ignored for RGB(A) data. Defaults to rcParams["image.cmap"] (‘viridis’).

format [str, optional] The file format, e.g. ‘png’, ‘pdf’, ‘svg’, ... The behavior when this is unset is documented under fname.

origin [{‘upper’, ‘lower’}, optional] Indicates whether the (0, 0) index of the array is in the upper left or lower left corner of the axes. Defaults to rcParams["image.origin"] (‘upper’).

dpi [int] The DPI to store in the metadata of the file. This does not affect the resolution of the output image.

matplotlib.image.pil_to_array(pilImage)
Load a PIL image and return it as a numpy array.

Returns

numpy.array The array shape depends on the image type:

- (M, N) for grayscale images.
- (M, N, 3) for RGB images.
- (M, N, 4) for RGBA images.

matplotlib.image.thumbnail(infile, thumbfile, scale=0.1, interpolation=’bilinear’, preview=False)
Make a thumbnail of image in infile with output filename thumbfile.
See /gallery/misc/image_thumbnail_sgskip.

Parameters

infile [str or file-like] The image file – must be PNG, or Pillow-readable if you have Pillow installed.

thumbfile [str or file-like] The thumbnail filename.

scale [float, optional] The scale factor for the thumbnail.

interpolation [str, optional] The interpolation scheme used in the resampling. See the interpolation parameter of imshow for possible values.

preview [bool, optional] If True, the default backend (presumably a user interface backend) will be used which will cause a figure to be raised if show is called. If it is False, the figure is created using FigureCanvasBase and the drawing backend is selected as savefig would normally do.

Returns

figure [Figure] The figure instance containing the thumbnail.

17.27 matplotlib.legend

The legend module defines the Legend class, which is responsible for drawing legends associated with axes and/or figures.
**Important:** It is unlikely that you would ever create a Legend instance manually. Most users would normally create a legend via the `legend()` function. For more details on legends there is also a legend guide.

The Legend class can be considered as a container of legend handles and legend texts. Creation of corresponding legend handles from the plot elements in the axes or figures (e.g., lines, patches, etc.) are specified by the handler map, which defines the mapping between the plot elements and the legend handlers to be used (the default legend handlers are defined in the `legend_handler` module). Note that not all kinds of artist are supported by the legend yet by default but it is possible to extend the legend handler’s capabilities to support arbitrary objects. See the legend guide for more information.

```python
class matplotlib.legend.DraggableLegend(legend, use_blit=False, update='loc')
```

Wrapper around a Legend to support mouse dragging.

**Parameters**

- `legend` ([Legend][legend]) The Legend instance to wrap.
- `use_blit` (bool, optional) Use blitting for faster image composition. For details see `FuncAnimation`.
- `update` ({‘loc’, ‘bbox’}, optional) If “loc”, update the `loc` parameter of the legend upon finalizing. If “bbox”, update the `bbox_to_anchor` parameter.

```python
artist_picker(self, legend, evt)
```

```python
finalize_offset(self)
```

```python
class matplotlib.legend.Legend(parent, handles, labels, loc=None, numpoints=None, markerscale=None, markerfirst=True, scatterpoints=None, scatteryoffsets=None, prop=None, fontsize=None, borderpad=None, labelspacing=None, handlelength=None, handleheight=None, handletextpad=None, borderaxespad=None, columnspacing=None, ncol=1, mode=None, fancybox=None, shadow=None, title=None, title_fontsize=None, framealpha=None, edgecolor=None, facecolor=None, bbox_to_anchor=None, bbox_transform=None, frameon=None, handler_map=None)
```

Bases: matplotlib.artist.Artist

Place a legend on the axes at location `loc`.

**Parameters**

- `parent` ([Axes or Figure][parent]) The artist that contains the legend.
- `handles` (sequence of Artist) A list of Artists (lines, patches) to be added to the legend.
- `labels` (sequence of strings) A list of labels to show next to the artists. The length of handles and labels should be the same. If they are not, they are truncated to the smaller of both lengths.

**Other Parameters**
loc [str or pair of floats, default: `rcParams['legend.loc']` ('best' for axes, 'upper right' for figures)] The location of the legend.

The strings 'upper left', 'upper right', 'lower left', 'lower right' place the legend at the corresponding corner of the axes/figure.

The strings 'upper center', 'lower center', 'center left', 'center right' place the legend at the center of the corresponding edge of the axes/figure.

The string 'center' places the legend at the center of the axes/figure.

The string 'best' places the legend at the location, among the nine locations defined so far, with the minimum overlap with other drawn artists. This option can be quite slow for plots with large amounts of data; your plotting speed may benefit from providing a specific location.

The location can also be a 2-tuple giving the coordinates of the lower-left corner of the legend in axes coordinates (in which case `bbox_to_anchor` will be ignored).

For back-compatibility, 'center right' (but no other location) can also be spelled 'right', and each "string" locations can also be given as a numeric value:

<table>
<thead>
<tr>
<th>Location String</th>
<th>Location Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>'best'</td>
<td>0</td>
</tr>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>

bbox_to_anchor [BboxBase, 2-tuple, or 4-tuple of floats] Box that is used to position the legend in conjunction with `loc`. Defaults to axes.bbox (if called as a method to `Axes.legend`) or figure.bbox (if `Figure.legend`). This argument allows arbitrary placement of the legend.

Bbox coordinates are interpreted in the coordinate system given by `bbox_transform`, with the default transform Axes or Figure coordinates, depending on which `legend` is called.

If a 4-tuple or BboxBase is given, then it specifies the bbox (x, y, width, height) that the legend is placed in. To put the legend in the best location in the bottom right quadrant of the axes (or figure):

```python
loc='best', bbox_to_anchor=(0.5, 0., 0.5, 0.5)
```

A 2-tuple (x, y) places the corner of the legend specified by `loc` at x, y. For example, to put the legend's upper right-hand corner in the center of the axes (or figure) the following keywords can be used:
ncol [integer] The number of columns that the legend has. Default is 1.

prop [None or matplotlib.font_manager.FontProperties or dict] The font properties of the legend. If None (default), the current matplotlib.rcParams will be used.

fontsize [int or float or {'xx-small', 'x-small', 'small', 'medium', 'large', 'x-large', 'xx-large'}] Controls the font size of the legend. If the value is numeric the size will be the absolute font size in points. String values are relative to the current default font size. This argument is only used if prop is not specified.

numpoints [None or int] The number of marker points in the legend when creating a legend entry for a Line2D (line). Default is None, which will take the value from rcParams["legend.numpoints"].

scatterpoints [None or int] The number of marker points in the legend when creating a legend entry for a PathCollection (scatter plot). Default is None, which will take the value from rcParams["legend.scatterpoints"].

scatteryoffsets [iterable of floats] The vertical offset (relative to the font size) for the markers created for a scatter plot legend entry. 0.0 is at the base the legend text, and 1.0 is at the top. To draw all markers at the same height, set to [0.5]. Default is [0.375, 0.5, 0.3125].

markerscale [None or int or float] The relative size of legend markers compared with the originally drawn ones. Default is None, which will take the value from rcParams["legend.markerscale"].

markerfirst [bool] If True, legend marker is placed to the left of the legend label. If False, legend marker is placed to the right of the legend label. Default is True.

frameon [None or bool] Control whether the legend should be drawn on a patch (frame). Default is None, which will take the value from rcParams["legend.frameon"].

fancybox [None or bool] Control whether round edges should be enabled around the FancyBboxPatch which makes up the legend's background. Default is None, which will take the value from rcParams["legend.fancybox"].

shadow [None or bool] Control whether to draw a shadow behind the legend. Default is None, which will take the value from rcParams["legend.shadow"].

framealpha [None or float] Control the alpha transparency of the legend's background. Default is None, which will take the value from rcParams["legend.framealpha"]. If shadow is activated and framealpha is None, the default value is ignored.

facecolor [None or "inherit" or a color spec] Control the legend's background color. Default is None, which will take the value from rcParams["legend.facecolor"]. If "inherit", it will take rcParams["axes.facecolor"].
**edgcolor** [None or “inherit” or a color spec] Control the legend’s background patch edge color. Default is None, which will take the value from rcParams["legend.edgecolor"] If “inherit”, it will take rcParams["axes.edgcolor"].

**mode** [{"expand", None}] If mode is set to "expand" the legend will be horizontally expanded to fill the axes area (or bbox_to_anchor if defines the legend’s size).

**bbox_transform** [None or matplotlib.transforms.Transform] The transform for the bounding box (bbox_to_anchor). For a value of None (default) the Axes’ transAxes transform will be used.

**title** [str or None] The legend’s title. Default is no title (None).

**title_fontsize**: str or None The fontsize of the legend’s title. Default is the default fontsize.

**borderpad** [float or None] The fractional whitespace inside the legend border. Measured in font-size units. Default is None, which will take the value from rcParams["legend.borderpad"].

**labelspsacing** [float or None] The vertical space between the legend entries. Measured in font-size units. Default is None, which will take the value from rcParams["legend.labelspsacing"].

**handlelength** [float or None] The length of the legend handles. Measured in font-size units. Default is None, which will take the value from rcParams["legend.handlelength"].

**handletextpad** [float or None] The pad between the legend handle and text. Measured in font-size units. Default is None, which will take the value from rcParams["legend.handletextpad"].

**borderaxespad** [float or None] The pad between the axes and legend border. Measured in font-size units. Default is None, which will take the value from rcParams["legend.borderaxespad"].

**columnspacing** [float or None] The spacing between columns. Measured in font-size units. Default is None, which will take the value from rcParams["legend.columnspacing"].

**handler_map** [dict or None] The custom dictionary mapping instances or types to a legend handler. This handler_map updates the default handler map found at matplotlib.legend.Legend.get_legend_handler_map().

### Notes

Users can specify any arbitrary location for the legend using the bbox_to_anchor keyword argument. bbox_to_anchor can be an instance of BboxBase(or its derivatives) or a tuple of 2 or 4 floats. See set_bbox_to_anchor() for more detail.

The legend location can be specified by setting loc with a tuple of 2 floats, which is interpreted as the lower-left corner of the legend in the normalized axes coordinate.

```python
codes = {'best': 0, 'center': 10, 'center left': 6, 'center right': 7, 'lower center': 8, 'lower contains(self, event)
    Test whether the artist contains the mouse event.
```
Parameters

mouseevent [matplotlib.backend_bases.MouseEvent]

Returns

contains [bool] Whether any values are within the radius.

details [dict] An artist-specific dictionary of details of the event context, such as which points are contained in the pick radius. See the individual Artist subclasses for details.

See also:

set.contains, get.contains

draw(self, renderer)

Draw everything that belongs to the legend.

draw_frame(self, b)

Set draw frame to b.

Parameters

b [bool]

get_bbox_to_anchor(self)

Return the bbox that the legend will be anchored to.

get_children(self)

Return a list of child artists.

classmethod get_default_handler_map()

A class method that returns the default handler map.

get_draggable(self)

Return True if the legend is draggable, False otherwise.

get_frame(self)

Return the Rectangle instances used to frame the legend.

get_frame_on(self)

Get whether the legend box patch is drawn.

static get_legend_handler(legend_handler_map, orig_handle)

Return a legend handler from legend_handler_map that corresponds to orig_handler.

legend_handler_map should be a dictionary object (that is returned by the get_legend_handler_map method).

It first checks if the orig.handle itself is a key in the legend_handler_map and return the associated value. Otherwise, it checks for each of the classes in its method-resolution-order. If no matching key is found, it returns None.

get_legend_handler_map(self)

Return the handler map.

get_lines(self)

Return a list of Line2D instances in the legend.

get_patches(self)

Return a list of Patch instances in the legend.
get_texts(self)
Return a list of Text instances in the legend.

get_tightbbox(self, renderer)
Like Legend.get_window_extent, but uses the box for the legend.

Parameters
renderer [RendererBase instance] renderer that will be used to draw
the figures (i.e. fig.canvas.get_renderer())

Returns
'.BboxBase' [containing the bounding box in figure pixel co-
ordinates.]

get_title(self)
Return the Text instance for the legend title.

get_window_extent(self, renderer=None)
Return extent of the legend.

set_bbox_to_anchor(self, bbox, transform=None)
Set the bbox that the legend will be anchored to.

bbox can be

• A BboxBase instance
• A tuple of (left, bottom, width, height) in the given transform (normalized
axes coordinate if None)
• A tuple of (left, bottom) where the width and height will be assumed to be
zero.

classmethod set_default_handler_map(handler_map)
A class method to set the default handler map.

set_draggable(self, state, use_blit=False, update='loc')
Enable or disable mouse dragging support of the legend.

Parameters
state [bool] Whether mouse dragging is enabled.
use_blit [bool, optional] Use blitting for faster image composition. For
details see FuncAnimation.
update [{‘loc’, ‘bbox’}, optional] The legend parameter to be changed
when dragged:
• ‘loc’: update the loc parameter of the legend
• ‘bbox’: update the bbox_to_anchor parameter of the legend

Returns
If state is True this returns the DraggableLegend helper
instance. Otherwise this returns None.

set_frame_on(self, b)
Set whether the legend box patch is drawn.

Parameters
b [bool]
Matplotlib, Release 3.1.1

```python
set_title(self, title, prop=None)
   Set the legend title. Fontproperties can be optionally set with prop parameter.

classmethod update_default_handler_map(handler_map)
   A class method to update the default handler map.
```

```
zorder = 5
```

## 17.28 `matplotlib.legend_handler`

This module defines default legend handlers.

It is strongly encouraged to have read the legend guide before this documentation.

Legend handlers are expected to be a callable object with a following signature.

```python
legend_handler(legend, orig_handle, fontsize, handlebox)
```

Where `legend` is the legend itself, `orig_handle` is the original plot, `fontsize` is the fontsize in pixels, and `handlebox` is a OffsetBox instance. Within the call, you should create relevant artists (using relevant properties from the `legend` and/or `orig_handle`) and add them into the handlebox. The artists needs to be scaled according to the fontsize (note that the size is in pixel, i.e., this is dpi-scaled value).

This module includes definition of several legend handler classes derived from the base class (HandlerBase) with the following method:

```python
def legend_artist(self, legend, orig_handle, fontsize, handlebox)
```

```python
class matplotlib.legend_handler.HandlerBase(xpad=0.0, ypad=0.0, update_func=None)
   A Base class for default legend handlers.
   The derived classes are meant to override create_artists method, which has a following signature:

   ```python
def create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans):
```

The overridden method needs to create artists of the given transform that fits in the given dimension (xdescent, ydescent, width, height) that are scaled by fontsize if necessary.

```python
adjust_drawing_area(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize)
create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
legend_artist(self, legend, orig_handle, fontsize, handlebox)
```

Return the artist that this HandlerBase generates for the given original artist/handle.

### Parameters

- **legend** ([`matplotlib.legend.Legend` instance]) The legend for which these legend artists are being created.
- **orig_handle** ([`matplotlib.artist.Artist` or similar]) The object for which these legend artists are being created.
**fontsize** [float or int] The fontsize in pixels. The artists being created should be scaled according to the given fontsize.

**handlebox** [matplotlib.offsetbox.OffsetBox instance] The box which has been created to hold this legend entry’s artists. Artists created in the `legend_artist` method must be added to this handlebox inside this method.

```python
def update_prop(self, legend_handle, orig_handle, legend)
```

```python
class matplotlib.legend_handler.HandlerCircleCollection(yoffs=None, sizes=None, **kw)
```

Handler for CircleCollections.

```python
def create_collection(self, orig_handle, sizes, offsets, transOffset)
```

```python
class matplotlib.legend_handler.HandlerErrorbar(xerr_size=0.5, yerr_size=None, marker_pad=0.3, numpoints=None, **kw)
```

Handler for Errorbars.

```python
def create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
```

```python
def get_err_size(self, legend, xdescent, ydescent, width, height, fontsize)
```

```python
class matplotlib.legend_handler.HandlerLine2D(marker_pad=0.3, numpoints=None, **kw)
```

Handler for `Line2D` instances.

**Parameters**

- **marker_pad** [float] Padding between points in legend entry.
- **numpoints** [int] Number of points to show in legend entry.

**Notes**

Any other keyword arguments are given to `HandlerNpoints`.

```python
def create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
```

```python
class matplotlib.legend_handler.HandlerLineCollection(marker_pad=0.3, numpoints=None, **kw)
```

Handler for `LineCollection` instances.

**Parameters**

- **marker_pad** [float] Padding between points in legend entry.
- **numpoints** [int] Number of points to show in legend entry.

**Notes**

Any other keyword arguments are given to `HandlerNpoints`.

```python
def create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
```

```python
def get_numpoints(self, legend)
```

17.28. matplotlib.legend_handler 1577
class matplotlib.legend_handler.HandlerNpoints(marker_pad=0.3, numpoints=None, **kw)

A legend handler that shows numpoints points in the legend entry.

**Parameters**

- **marker_pad** [float] Padding between points in legend entry.
- **numpoints** [int] Number of points to show in legend entry.

**Notes**

Any other keyword arguments are given to HandlerBase.

get_numpoints(self, legend)

get_xdata(self, legend, xdescent, ydescent, width, height, fontsize)

class matplotlib.legend_handler.HandlerNpointsYoffsets(numpoints=None, yoffsets=None, **kw)

A legend handler that shows numpoints in the legend, and allows them to be individually offset in the y-direction.

**Parameters**

- **numpoints** [int] Number of points to show in legend entry.
- **yoffsets** [array of floats] Length numpoints list of y offsets for each point in legend entry.

**Notes**

Any other keyword arguments are given to HandlerNpoints.

get_ydata(self, legend, xdescent, ydescent, width, height, fontsize)

class matplotlib.legend_handler.HandlerPatch(patch_func=None, **kw)

Handler for Patch instances.

**Parameters**

- **patch_func** [callable, optional] The function that creates the legend key artist. patch_func should have the signature:

```python
def patch_func(legend=legend, orig_handle=orig_handle, xdescent=xdescent, ydescent=ydescent, width=width, height=height, fontsize=fontsize)
```

Subsequently the created artist will have its update_prop method called and the appropriate transform will be applied.

**Notes**

Any other keyword arguments are given to HandlerBase.

create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
class matplotlib.legend_handler.HandlerPathCollection(yoffsets=None, sizes=None, **kw)
    Handler for PathCollections, which are used by scatter.
    create_collection(self, orig_handle, sizes, offsets, transOffset)

class matplotlib.legend_handler.HandlerPolyCollection(xpad=0.0, ypad=0.0, update_func=None)
    Handler for PolyCollection used in fill_between and stackplot.
    create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)

class matplotlib.legend_handler.HandlerRegularPolyCollection(yoffsets=None, sizes=None, **kw)
    Handler for RegularPolyCollections.
    create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
    create_collection(self, orig_handle, sizes, offsets, transOffset)
    get_numpoints(self, legend)
    get_sizes(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize)
    update_prop(self, legend_handle, orig_handle, legend)

class matplotlib.legend_handler.HandlerTuple(ndivide=1, pad=None, **kw)
    Handler for Tuple.
    create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
    get_ydata(self, legend, xdescent, ydescent, width, height, fontsize)

class matplotlib.legend_handler.HandlerStem(marker_pad=0.3, numpoints=None, bottom=None, yoffsets=None, **kw)
    Handler for plots produced by stem.

    Parameters
    marker_pad [float] Padding between points in legend entry. Default is 0.3.
    numpoints [int, optional] Number of points to show in legend entry.
    bottom [float, optional]
    yoffsets [array of floats, optional] Length numpoints list of y offsets for each point in legend entry.

    Notes

    Any other keyword arguments are given to HandlerNpointsYoffsets.
    create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
    get_ydata(self, legend, xdescent, ydescent, width, height, fontsize)

class matplotlib.legend_handler.HandlerTuple(ndivide=1, pad=None, **kw)
    Handler for Tuple.

    Parameters
    ndivide [int, optional] The number of sections to divide the legend area into. If None, use the length of the input tuple. Default is 1.
    pad [float, optional] If None, fall back to legend.borderpad as the default. In units of fraction of font size. Default is None.
Matplotlib, Release 3.1.1

```python
create_artists(self, legend, orig_handle, xdescent, ydescent, width, height, fontsize, trans)
```

```python
matplotlib.legend_handler.update_from_first_child(tgt, src)
```

## 17.29 `matplotlib.lines`

This module contains all the 2D line class which can draw with a variety of line styles, markers and colors.

### 17.29.1 Classes

`Line2D(xdata, ydata[, linewidth, linestyle, ...])`  
A line - the line can have both a solid linestyle connecting all the vertices, and a marker at each vertex.

`VertexSelector(line)`  
Manage the callbacks to maintain a list of selected vertices for `matplotlib.lines.Line2D`.

```
matplotlib.lines.Line2D

class matplotlib.lines.Line2D(xdata, ydata, linewidth=None, linestyle=None, color=None, marker=None, markersize=None, markeredgewidth=None, markeredgecolor=None, markerfacecolor=None, markerfacecoloralt='none', fillstyle=None, antialiased=None, dash_capstyle=None, solid_capstyle=None, dash_joinstyle=None, solid_joinstyle=None, pickradius=5, drawstyle=None, markevery=None, **kwargs)
```

Bases: `matplotlib.artist.Artist`

A line - the line can have both a solid linestyle connecting all the vertices, and a marker at each vertex. Additionally, the drawing of the solid line is influenced by the drawstyle, e.g., one can create “stepped” lines in various styles.

Create a `Line2D` instance with x and y data in sequences `xdata, ydata`.

The kwARGS are `Line2D` properties:

See `set_linestyle()` for a description of the line styles, `set_marker()` for a description of the markers, and `set_drawstyle()` for a description of the draw styles.

**axes**

The `Axes` instance the artist resides in, or `None`.

**contains(self, mouseevent)**

Test whether the mouse event occurred on the line. The pick radius determines the precision of the location test (usually within five points of the value). Use `get_pickradius()` or `set_pickradius()` to view or modify it.

**Parameters**

- `mouseevent` [`matplotlib.backend_bases.MouseEvent`]

**Returns**

- `contains` [bool] Whether any values are within the radius.
- `details` [dict] A dictionary {'ind': pointlist}, where `pointlist` is a list of points of the line that are within the pickradius around the event position.
TODO: sort returned indices by distance

draw(self, renderer)

Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented
to not have any effect if the Artist is not visible (Artist.get_visible is False).

Parameters

renderer [RendererBase subclass.]

drawStyleKeys = ['default', 'steps-mid', 'steps-pre', 'steps-post', 'steps']
drawStyles = {'default': '_draw_lines', 'steps': '_draw_steps_pre', 'steps-mid': '_draw_steps_mid'
fillStyles = ('full', 'left', 'right', 'bottom', 'top', 'none')
filled_markers = ('o', 'v', '^', '<', '>', '8', 's', 'p', '*', 'h', 'H', 'D', 'd', 'P', 'X')

get_aa(self)

Alias for get_antialiased.

get_antialiased(self)

Return whether antialiased rendering is used.

get_c(self)

Alias for get_color.

get_color(self)

Return the line color.

See also set_color.

get_dash_capstyle(self)

Return the cap style for dashed lines.

See also set_dash_capstyle.

get_dash_joinstyle(self)

Return the join style for dashed lines.

See also set_dash_joinstyle.

get_data(self, orig=True)

Return the xdata, ydata.

If orig is True, return the original data.

get_drawstyle(self)

Return the drawstyle.

See also set_drawstyle.

gets(self)

Alias for get_drawstyle.

get_fillstyle(self)

Return the marker fill style.

See also set_fillstyle.

get_linestyle(self)

Return the linestyle.

See also set_linestyle.
get_linewidth(self)
    Return the linewidth in points.
    See also set_linewidth.

get_ls(self)
    Alias for get_linestyle.

get_lw(self)
    Alias for get_linewidth.

get_marker(self)
    Return the line marker.
    See also set_marker.

get_markeredgecolor(self)
    Return the marker edge color.
    See also set_markeredgecolor.

get_markeredgewidth(self)
    Return the marker edge width in points.
    See also set_markeredgewidth.

get_markerfacecolor(self)
    Return the marker face color.
    See also set_markerfacecolor.

get_markerfacecoloralt(self)
    Return the alternate marker face color.
    See also set_markerfacecoloralt.

get_markersize(self)
    Return the marker size in points.
    See also set_markersize.

get_markevery(self)
    Return the markevery setting for marker subsampling.
    See also set_markevery.

get_mec(self)
    Alias for get_markeredgecolor.

get_mew(self)
    Alias for get_markeredgewidth.

get_mfc(self)
    Alias for get_markerfacecolor.

get_mfcalt(self)
    Alias for get_markerfacecoloralt.

get_ms(self)
    Alias for get_markersize.

get_path(self)
    Return the Path object associated with this line.
get_pickradius(self)
    Return the pick radius used for containment tests.
    See contains for more details.

get_solid_capstyle(self)
    Return the cap style for solid lines.
    See also set_solid_capstyle.

get_solid_joinstyle(self)
    Return the join style for solid lines.
    See also set_solid_joinstyle.

get_window_extent(self, renderer)
    Get the axes bounding box in display space.
    The bounding box' width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box "tight" calculation.
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window extent of the artist changes. The extent can change due to any changes in the transform stack, such as changing the axes limits, the figure size, or the canvas used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

get_xdata(self, orig=True)
    Return the xdata.
    If orig is True, return the original data, else the processed data.

get_ydata(self, orig=True)
    Return the ydata.
    If orig is True, return the original data, else the processed data.

is_dashed(self)
    Return whether line has a dashed linestyle.
    See also set_linestyle.

lineStyles = {'': '_draw_nothing', ' ': '_draw_nothing', '-': '_draw_solid', '--': '_draw_dashed', '-.': '_draw_dash_dot', ':': '_draw_dotted', 'None': '_draw_nothing'}
markers = {'.': 'point', ',': 'pixel', 'o': 'circle', 'v': 'triangle_down', '^': 'triangle_up', '<': 'triangle_left', 'r': 'caretupbase', 'R': 'caretupbase', '1': 'caretupbase', '2': 'caretdownbase', '3': 'caretdownbase', '4': 'caretupbase', 10: 'caretupbase', 11: 'caretdownbase', 'None': 'nothing', None: 'nothing', ' ': 'nothing', '': 'nothing'}

recache(self, always=False)
    recache_always(self)

def set_aa(self, b)
    Alias for set_antialiased.

set_antialiased(self, b)
    Set whether to use antialiased rendering.

Parameters
    b [bool]
```python
set_c(self, color)
    Alias for set_color.

set_color(self, color)
    Set the color of the line.

    Parameters
    color [color]

set_dash_capstyle(self, s)
    Set the cap style for dashed lines.

    Parameters
    s [{'butt', 'round', 'projecting'}]

set_dash_joinstyle(self, s)
    Set the join style for dashed lines.

    Parameters
    s [{'miter', 'round', 'bevel'}] For examples see
    /gallery/lines_bars_and_markers/joinstyle.

set_dashes(self, seq)
    Set the dash sequence.
    The dash sequence is a sequence of floats of even length describing the length of
    dashes and spaces in points.
    For example, (5, 2, 1, 2) describes a sequence of 5 point and 1 point dashes sepa-
    rated by 2 point spaces.

    Parameters
    seq [sequence of floats (on/off ink in points) or (None, None)] If seq is
    empty or (None, None), the linestyle will be set to solid.

set_data(self, *args)
    Set the x and y data.

    Parameters
    *args [(2, N) array or two 1D arrays]

set_drawstyle(self, drawstyle)
    Set the drawstyle of the plot.
    The drawstyle determines how the points are connected.

    Parameters
    drawstyle [{'default', 'steps', 'steps-pre', 'steps-mid', 'steps-post'},
                default: 'default'] For 'default', the points are connected with
                straight lines.
                The steps variants connect the points with step-like lines, i.e. hor-
                zontal lines with vertical steps. They differ in the location of the
                step:
                • 'steps-pre': The step is at the beginning of the line segment, i.e.
                  the line will be at the y-value of point to the right.
                • 'steps-mid': The step is halfway between the points.
• ‘steps-post’: The step is at the end of the line segment, i.e. the line will be at the y-value of the point to the left.

• ‘steps’ is equal to ‘steps-pre’ and is maintained for backward-compatibility.

```
set_ds(self, drawstyle)
```

Alias for `set_drawstyle`.

```
set_fillstyle(self, fs)
```

Set the marker fill style.

**Parameters**

`fs` [{‘full’, ‘left’, ‘right’, ‘bottom’, ‘top’, ‘none’}] Possible values:

• ‘full’: Fill the whole marker with the `markerfacecolor`.

• ‘left’, ‘right’, ‘bottom’, ‘top’: Fill the marker half at the given side with the `markerfacecolor`. The other half of the marker is filled with `markerfacecoloralt`.

• ‘none’: No filling.

For examples see `/gallery/lines_bars_and_markers/marker_fillstyle_reference`.

```
set_linestyle(self, ls)
```

Set the linestyle of the line.

**Parameters**

`ls` [{‘-‘, ‘–’, ‘-.’, ‘:’, ”, (offset, on-off-seq), ...}] Possible values:

• A string:

<table>
<thead>
<tr>
<th>Linestyle</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘-’ or ‘solid’</td>
<td>solid line</td>
</tr>
<tr>
<td>‘--’ or ‘dashed’</td>
<td>dashed line</td>
</tr>
<tr>
<td>‘-.’ or ‘dashdot’</td>
<td>dash-dotted line</td>
</tr>
<tr>
<td>‘:’ or ‘dotted’</td>
<td>dotted line</td>
</tr>
<tr>
<td>‘None’ or ‘ ’</td>
<td>draw nothing</td>
</tr>
</tbody>
</table>

Optionally, the string may be preceded by a drawstyle, e.g. ‘steps--’. See `set_drawstyle()` for details.

• Alternatively a dash tuple of the following form can be provided:

```
(offset, onoffseq)
```

where `onoffseq` is an even length tuple of on and off ink in points. See also `set_dashes()`.

```
set_linewidth(self, w)
```

Set the line width in points.

**Parameters**

`w` [float]

```
set_ls(self, ls)
```

Alias for `set_linestyle`.
set_lw(self, w)
    Alias for set_linewidth.

set_marker(self, marker)
    Set the line marker.

    Parameters
    marker [marker style] See markers for full description of possible arguments.

set_markeredgecolor(self, ec)
    Set the marker edge color.

    Parameters
    ec [color]

set_markeredgewidth(self, ew)
    Set the marker edge width in points.

    Parameters
    ew [float]

set_markerfacecolor(self, fc)
    Set the marker face color.

    Parameters
    fc [color]

set_markerfacecoloralt(self, fc)
    Set the alternate marker face color.

    Parameters
    fc [color]

set_markersize(self, sz)
    Set the marker size in points.

    Parameters
    sz [float]

set_markevery(self, every)
    Set the markevery property to subsample the plot when using markers.
    e.g., if every=5, every 5-th marker will be plotted.

    Parameters
    every [None or int or (int, int) or slice or List[int] or float or (float, float)] Which markers to plot.
    • every=None, every point will be plotted.
    • every=N, every N-th marker will be plotted starting with marker 0.
    • every=(start, N), every N-th marker, starting at point start, will be plotted.
    • every=slice(start, end, N), every N-th marker, starting at point start, up to but not including point end, will be plotted.
• every=[i, j, m, n], only markers at points i, j, m, and n will be plotted.
• every=0.1, (i.e. a float) then markers will be spaced at approximately equal distances along the line; the distance along the line between markers is determined by multiplying the display-coordinate distance of the axes bounding-box diagonal by the value of every.
• every=(0.5, 0.1) (i.e. a length-2 tuple of float), the same functionality as every=0.1 is exhibited but the first marker will be 0.5 multiplied by the display-coordinate-diagonal-distance along the line.

Notes

Setting the markevery property will only show markers at actual data points. When using float arguments to set the markevery property on irregularly spaced data, the markers will likely not appear evenly spaced because the actual data points do not coincide with the theoretical spacing between markers.

When using a start offset to specify the first marker, the offset will be from the first data point which may be different from the first the visible data point if the plot is zoomed in.

If zooming in on a plot when using float arguments then the actual data points that have markers will change because the distance between markers is always determined from the display-coordinates axes-bounding-box-diagonal regardless of the actual axes data limits.

set_mec(self, ec)
   Alias for set_markeredgecolor.

set_mew(self, ew)
   Alias for set_markeredgewidth.

set_mfc(self, fc)
   Alias for set_markerfacecolor.

set_mfcalt(self, fc)
   Alias for set_markerfacecoloralt.

set_ms(self, sz)
   Alias for set_markersize.

set_picker(self, p)
   Sets the event picker details for the line.

   Parameters
   p [float or callable[[Artist, Event], Tuple[bool, dict]]] If a float, it is used as the pick radius in points.

set_pickradius(self, d)
   Set the pick radius used for containment tests.

   See contains for more details.

   Parameters
   d [float] Pick radius, in points.
set_solid_capstyle(self, s)
    Set the cap style for solid lines.

    Parameters
    s [{’butt’, ’round’, ’projecting’}]

set_solid_joinstyle(self, s)
    Set the join style for solid lines.

    Parameters
    s [{’miter’, ’round’, ’bevel’}]  For examples see
    /gallery/lines_bars_and_markers/joinstyle.

set_transform(self, t)
    Set the Transformation instance used by this artist.

    Parameters
    t [matplotlib.transforms.Transform]

set_xdata(self, x)
    Set the data array for x.

    Parameters
    x [1D array]

set_ydata(self, y)
    Set the data array for y.

    Parameters
    y [1D array]

update_from(self, other)
    Copy properties from other to self.

validCap = (’butt’, ’round’, ’projecting’)
validJoin = (’miter’, ’round’, ’bevel’)
verticalOffset
zorder = 2

Examples using matplotlib.lines.Line2D

• sphx_glr_gallery_text_labels_and_annotations_custom_legends.py
• sphx_glr_gallery_text_labels_and_annotations_legend_demo.py
• sphx_glr_gallery_text_labels_and_annotations_line_with_text.py
• sphx_glr_gallery_pyplots_fig_axes_customize_simple.py
• sphx_glr_gallery_pyplots_fig_x.py
• sphx_glr_gallery_shapes_and_collections_artist_reference.py
• Oscilloscope
• sphx_glr_gallery_event_handling_pick_event_demo.py
• sphx_glr_gallery_event_handling_poly_editor.py
matplotlib.lines.VertexSelector

class matplotlib.lines.VertexSelector(line):
    Bases: object
    Manage the callbacks to maintain a list of selected vertices for `matplotlib.lines.Line2D`.
    Derived classes should override `process_selected()` to do something with the picks.
    Here is an example which highlights the selected verts with red circles:

    ```python
    import numpy as np
    import matplotlib.pyplot as plt
    import matplotlib.lines as lines

    class HighlightSelected(lines.VertexSelector):
        def __init__(self, line, fmt='ro', **kwargs):
            lines.VertexSelector.__init__(self, line)
            self.markers, = self.axes.plot([], [], fmt, **kwargs)

        def process_selected(self, ind, xs, ys):
            self.markers.set_data(xs, ys)
            self.canvas.draw()

    fig, ax = plt.subplots()
    x, y = np.random.rand(2, 30)
    line, = ax.plot(x, y, 'bs-', picker=5)

    selector = HighlightSelected(line)
    plt.show()
    ```

    Initialize the class with a `matplotlib.lines.Line2D` instance. The line should already be added to some `matplotlib.axes.Axes` instance and should have the picker property set.

    `onpick(self, event)`
    When the line is picked, update the set of selected indices.

    `process_selected(self, ind, xs, ys)`
    Default “do nothing” implementation of the `process_selected()` method.

    `ind` are the indices of the selected vertices. `xs` and `ys` are the coordinates of the selected vertices.

17.29.2 Functions
segment_hits(cx, cy, x, y, radius)

Return the indices of the segments in the polyline with coordinates (cx, cy) that are within a distance radius of the point (x, y).

matplotlib.lines.segment_hits

matplotlib.lines.segment_hits(cx, cy, x, y, radius)

Return the indices of the segments in the polyline with coordinates (cx, cy) that are within a distance radius of the point (x, y).

17.30 matplotlib.markers

This module contains functions to handle markers. Used by both the marker functionality of plot and scatter.

All possible markers are defined here:

<table>
<thead>
<tr>
<th>marker</th>
<th>symbol</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>⋄</td>
<td>point</td>
</tr>

Table 145 – continued from previous page

<table>
<thead>
<tr>
<th>marker</th>
<th>symbol</th>
<th>description</th>
</tr>
</thead>
</table>
| (numsides, style, angle)|        | The marker can also be a tuple (numsides, style, angle), which will create a custom, regular symbol.
|                         |        | numsides: the number of sides
|                         |        | style: the style of the regular symbol:
|                         |        | • 0: a regular polygon
|                         |        | • 1: a star-like symbol
|                         |        | • 2: an asterisk
|                         |        | • 3: a circle (numsides and angle is ignored); deprecated.
|                         |        | angle: the angle of rotation of the symbol  

For backward compatibility, the form (verts, 0) is also accepted, but it is deprecated and equivalent to just verts for giving a raw set of vertices that define the shape.

None is the default which means ‘nothing’, however this table is referred to from other docs for the valid inputs from marker inputs and in those cases None still means ‘default’.

Note that special symbols can be defined via the STIX math font, e.g. "$\$". For an overview over the STIX font symbols refer to the STIX font table. Also see the /gallery/text_labels_and_annotations/stix_fonts_demo.

Integer numbers from 0 to 11 create lines and triangles. Those are equally accessible via capitalized variables, like CARETDOWNBASE. Hence the following are equivalent:

```
plt.plot([1,2,3], marker=11)
plt.plot([1,2,3], marker=matplotlib.markers.CARETDOWNBASE)
```

Examples showing the use of markers:

- /gallery/lines_bars_and_markers/marker_reference
- /gallery/lines_bars_and_markers/marker_fillstyle_reference
- /gallery/shapes_and_collections/marker_path

17.30.1 Classes
MarkerStyle([marker, fillstyle])

Parameters

matplotlib.markers.MarkerStyle

class matplotlib.markers.MarkerStyle(marker=None, fillstyle=None)
   Bases: object

   Parameters
   marker [string or array_like, optional, default: None] See the descriptions of possible markers in the module docstring.

   fillstyle [string, optional, default: 'full', 'left', 'right', 'bottom', 'top', 'none']

   Attributes
   markers [list of known marks]
   fillstyles [list of known fillstyles]
   filled_markers [list of known filled markers.]

   get_alt_path(self)
   get_alt_transform(self)
   get_capstyle(self)
   get_fillstyle(self)
   get_joinstyle(self)
   get_marker(self)
   get_path(self)
   get_snap_threshold(self)
   get_transform(self)
   is_filled(self)

   markers = {'.': 'point', ',': 'pixel', 'o': 'circle', 'v': 'triangle_down', '^': 'triangle_up', '<': 'triangle_left', '>': 'triangle_right', '8': 'eight', 's': 'square', 'p': 'pentagon', '*': 'asterisk', 'h': 'hexagon', 'H': 'regular_hexagon', 'd': 'diamond', 'D': 'regular_diamond', 'P': 'pentagram', 'X': 'cross', 'None': 'nothing', None: 'nothing', ' ': 'nothing'}

   set_fillstyle(self, fillstyle)
      Sets fillstyle

   Parameters
   fillstyle [string amongst known fillstyles]

   set_marker(self, marker)
17.31 matplotlib.mathtext

is a module for parsing a subset of the TeX math syntax and drawing them to a matplotlib backend.

For a tutorial of its usage see Writing mathematical expressions. This document is primarily concerned with implementation details.

The module uses pyparsing to parse the TeX expression.

The Bakoma distribution of the TeX Computer Modern fonts, and STIX fonts are supported. There is experimental support for using arbitrary fonts, but results may vary without proper
tweaking and metrics for those fonts.

class matplotlib.mathtext.Accent(c, state, math=True)
    Bases: matplotlib.mathtext.Char

    The font metrics need to be dealt with differently for accents, since they are already
    offset correctly from the baseline in TrueType fonts.

grow(self)
    Grows one level larger. There is no limit to how big something can get.

render(self, x, y)
    Render the character to the canvas.

shrink(self)
    Shrinks one level smaller. There are only three levels of sizes, after which things
    will no longer get smaller.

class matplotlib.mathtext.AutoHeightChar(c, height, depth, state, always=False, factor=None)
    Bases: matplotlib.mathtext.Hlist

    AutoHeightChar will create a character as close to the given height and depth as possible.
    When using a font with multiple height versions of some characters (such as the BaKoMa
    fonts), the correct glyph will be selected, otherwise this will always just return a scaled
    version of the glyph.

class matplotlib.mathtext.AutoWidthChar(c, width, state, always=False, char_class=<class 'mat-
   plotlib.mathtext.Char'>)
    Bases: matplotlib.mathtext.Hlist

    AutoWidthChar will create a character as close to the given width as possible. When using
    a font with multiple width versions of some characters (such as the BaKoMa fonts), the
    correct glyph will be selected, otherwise this will always just return a scaled version of
    the glyph.

class matplotlib.mathtext.BakomaFonts(*args, **kwargs)
    Bases: matplotlib.mathtext.TruetypeFonts

    Use the Bakoma TrueType fonts for rendering.

    Symbols are strewn about a number of font files, each of which has its own proprietary
    8-bit encoding.

    alias = '\[\]

    get Sized alternatives for symbol(self, fontname, sym)
        Override if your font provides multiple sizes of the same symbol. Should return a
        list of symbols matching sym in various sizes. The expression renderer will select
        the most appropriate size for a given situation from this list.

    target = ']'}

class matplotlib.mathtext.Box(width, height, depth)
    Bases: matplotlib.mathtext.Node

    Represents any node with a physical location.

grow(self)
    Grows one level larger. There is no limit to how big something can get.

render(self, x1, y1, x2, y2)
**Matplotlib, Release 3.1.1**

```
shrink(self)
    Shrinks one level smaller. There are only three levels of sizes, after which things
    will no longer get smaller.

class matplotlib.mathtext.Char(c, state, math=True)
    Bases: matplotlib.mathtext.Node

    Represents a single character. Unlike TeX, the font information and metrics are stored
    with each Char to make it easier to lookup the font metrics when needed. Note that
    TeX boxes have a width, height, and depth, unlike Type1 and TrueType which use a full
    bounding box and an advance in the x-direction. The metrics must be converted to the
    TeX way, and the advance (if different from width) must be converted into a Kern node
    when the Char is added to its parent Hlist.

get_kerning(self, next)
    Return the amount of kerning between this and the given character. Called when
    characters are strung together into Hlist to create Kern nodes.

grow(self)
    Grows one level larger. There is no limit to how big something can get.

is_slanted(self)

render(self, x, y)
    Render the character to the canvas

shrink(self)
    Shrinks one level smaller. There are only three levels of sizes, after which things
    will no longer get smaller.

class matplotlib.mathtext.ComputerModernFontConstants
    Bases: matplotlib.mathtext.FontConstantsBase

delta = 0.075

delta_integral = 0.3

delta_slanted = 0.3

script_space = 0.075

sub1 = 0.2

sub2 = 0.3

subdrop = 0.2

sup1 = 0.45

class matplotlib.mathtext.DejaVuFonts(*args, **kwargs)
    Bases: matplotlib.mathtext.UnicodeFonts

    use_cmex = False

class matplotlib.mathtext.DejaVuSansFontConstants
    Bases: matplotlib.mathtext.FontConstantsBase

class matplotlib.mathtext.DejaVuSansFonts(*args, **kwargs)
    Bases: matplotlib.mathtext.DejaVuFonts

    A font handling class for the DejaVu Sans fonts
    If a glyph is not found it will fallback to Stix Sans
```
class matplotlib.mathtext.DejaVuSerifFontConstants
   Bases: matplotlib.mathtext.FontConstantsBase

class matplotlib.mathtext.DejaVuSerifFonts(*args, **kwargs)
   Bases: matplotlib.mathtext.DejaVuFonts
      A font handling class for the DejaVu Serif fonts
      If a glyph is not found it will fallback to Stix Serif

matplotlib.mathtext.Error(msg)
   Helper class to raise parser errors.

class matplotlib.mathtext.Fill
   Bases: matplotlib.mathtext.Glue

class matplotlib.mathtext.Fill1
   Bases: matplotlib.mathtext.Glue

class matplotlib.mathtext.FontConstantsBase
   Bases: object
      A set of constants that controls how certain things, such as sub- and superscripts are laid out. These are all metrics that can't be reliably retrieved from the font itself.
      delta = 0.025
      delta_integral = 0.1
      delta_slanted = 0.2
      script_space = 0.05
      sub1 = 0.3
      sub2 = 0.5
      subdrop = 0.4
      sup1 = 0.7

class matplotlib.mathtext.Fonts(default_font_prop, mathtext_backend)
   Bases: object
      An abstract base class for a system of fonts to use for mathtext.
      The class must be able to take symbol keys and font file names and return the character metrics. It also delegates to a backend class to do the actual drawing.
      default_font_prop: A FontProperties object to use for the default non-math font, or the base font for Unicode (generic) font rendering.
      mathtext_backend: A subclass of MathTextBackend used to delegate the actual rendering.

   destroy(self)
      Fix any cyclical references before the object is about to be destroyed.

   get_kern(self, font1, fontclass1, sym1, fontsize1, font2, fontclass2, sym2, fontsize2, dpi)
      Get the kerning distance for font between sym1 and sym2.
fontX: one of the TeX font names:

- tt, it, rm, cal, sf, bf or default/regular (non-math)

fontclassX: TODO

symX: a symbol in raw TeX form. e.g., '1', 'x' or 'sigma'

fontsizeX: the fontsize in points

dpi: the current dots-per-inch

get_metrics(self, font, font_class, sym, fontsize, dpi, math=True)

font: one of the TeX font names:

- tt, it, rm, cal, sf, bf or default/regular (non-math)

font_class: TODO

sym: a symbol in raw TeX form. e.g., '1', 'x' or 'sigma'

fontsize: font size in points

dpi: current dots-per-inch

math: whether sym is a math character

Returns an object with the following attributes:

- advance: The advance distance (in points) of the glyph.
- height: The height of the glyph in points.
- width: The width of the glyph in points.
- xmin, xmax, ymin, ymax - the ink rectangle of the glyph
- iceberg - the distance from the baseline to the top of the glyph. This corresponds to TeX's definition of "height".

get_results(self, box)

Get the data needed by the backend to render the math expression. The return value is backend-specific.

get_sized_alternatives_for_symbol(self, fontname, sym)

Override if your font provides multiple sizes of the same symbol. Should return a list of symbols matching sym in various sizes. The expression renderer will select the most appropriate size for a given situation from this list.

get_underline_thickness(self, font, fontsize, dpi)

Get the line thickness that matches the given font. Used as a base unit for drawing lines such as in a fraction or radical.

get_used_characters(self)

Get the set of characters that were used in the math expression. Used by backends that need to subset fonts so they know which glyphs to include.

get_xheight(self, font, fontsize, dpi)

Get the xheight for the given font and fontsize.

render_glyph(self, ox, oy, facename, font_class, sym, fontsize, dpi)

Draw a glyph at

- ox, oy: position
• facename: One of the TeX face names
• font_class:
• sym: TeX symbol name or single character
• fontsize: font size in points
• dpi: The dpi to draw at.

render_rect_filled(self, x1, y1, x2, y2)
  Draw a filled rectangle from (x1, y1) to (x2, y2).

set_canvas_size(self, w, h, d)
  Set the size of the buffer used to render the math expression. Only really necessary for the bitmap backends.

class matplotlib.mathtext.Glue(glue_type, copy=False)
  Bases: matplotlib.mathtext.Node
  Most of the information in this object is stored in the underlying GlueSpec class, which is shared between multiple glue objects. (This is a memory optimization which probably doesn’t matter anymore, but it’s easier to stick to what TeX does.)

grow(self)
  Grows one level larger. There is no limit to how big something can get.

shrink(self)
  Shrinks one level smaller. There are only three levels of sizes, after which things will no longer get smaller.

class matplotlib.mathtext.GlueSpec(width=0.0, stretch=0.0, stretch_order=0, shrink=0.0, shrink_order=0)
  Bases: object
  See Glue.

copy(self)
  classmethod factory(glue_type)

class matplotlib.mathtext.HCentered(elements)
  Bases: matplotlib.mathtext.Hlist
  A convenience class to create an Hlist whose contents are centered within its enclosing box.

class matplotlib.mathtext.Hbox(width)
  Bases: matplotlib.mathtext.Box
  A box with only width (zero height and depth).

class matplotlib.mathtext.Hlist(elements, w=0.0, m='additional', do_kern=True)
  Bases: matplotlib.mathtext.List
  A horizontal list of boxes.

hpack(self, w=0.0, m='additional')
  The main duty of hpack() is to compute the dimensions of the resulting boxes, and to adjust the glue if one of those dimensions is pre-specified. The computed sizes normally enclose all of the material inside the new box; but some items may stick out if negative glue is used, if the box is overfull, or if a \vbox includes other boxes that have been shifted left.

• w: specifies a width
• $m$: is either ‘exactly’ or ‘additional’.

Thus, $hpack(w, 'exactly')$ produces a box whose width is exactly $w$, while $hpack(w, 'additional')$ yields a box whose width is the natural width plus $w$. The default values produce a box with the natural width.

```python
def kern(self):
    """Insert Kern nodes between Char nodes to set kerning. The Char nodes themselves determine the amount of kerning they need (in get_kerning()), and this function just creates the linked list in the correct way."""
```

```python
class matplotlib.mathtext.Hrule(state, thickness=None)
    Bases: matplotlib.mathtext.Rule

    Convenience class to create a horizontal rule.
```

```python
class matplotlib.mathtext.Kern(width)
    Bases: matplotlib.mathtext.Node

    A Kern node has a width field to specify a (normally negative) amount of spacing. This spacing correction appears in horizontal lists between letters like A and V when the font designer said that it looks better to move them closer together or further apart. A kern node can also appear in a vertical list, when its width denotes additional spacing in the vertical direction.
```

```python
def depth = 0

def grow(self):
    """Grows one level larger. There is no limit to how big something can get."""

def height = 0

def shrink(self):
    """Shrinks one level smaller. There are only three levels of sizes, after which things will no longer get smaller."""
```

```python
class matplotlib.mathtext.List(elements)
    Bases: matplotlib.mathtext.Box

    A list of nodes (either horizontal or vertical).
```

```python
def grow(self):
    """Grows one level larger. There is no limit to how big something can get."""

def shrink(self):
    """Shrinks one level smaller. There are only three levels of sizes, after which things will no longer get smaller."""
```

```python
class matplotlib.mathtext.MathTextParser(output)
    Bases: object

    Create a MathTextParser for the given backend output.
```

```python
def get_depth(self, texstr, dpi=120, fontsize=14)
    """Parameters"
    
    texstr [str] A valid mathtext string, e.g., r’IQ: $sigma_i=15$’.

    dpi [float] The dots-per-inch setting used to render the text.

    Returns"
    
    depth [int] Offset of the baseline from the bottom of the image, in pixels.
```

17.31. matplotlib.mathtext 1601
parse(self, s, dpi=72, prop=None)
    Parse the given math expression s at the given dpi. If prop is provided, it is a
    FontProperties object specifying the "default" font to use in the math expression,
    used for all non-math text.
    The results are cached, so multiple calls to parse() with the same expression should
    be fast.

to_mask(self, texstr, dpi=120, fontsize=14)
    Parameters
    texstr [str] A valid mathtext string, e.g., r'IQ: $\sigma_i=15$'.
    dpi [float] The dots-per-inch setting used to render the text.
    fontsize [int] The font size in points
    Returns
    depth [int] Offset of the baseline from the bottom of the image, in pixels.

to_png(self, filename, texstr, color='black', dpi=120, fontsize=14)
    Render a tex expression to a PNG file.
    Parameters
    filename A writable filename or fileobject.
    texstr [str] A valid mathtext string, e.g., r'IQ: $\sigma_i=15$'.
    color [color] The text color.
    dpi [float] The dots-per-inch setting used to render the text.
    fontsize [int] The font size in points.
    Returns
    depth [int] Offset of the baseline from the bottom of the image, in pixels.

to_rgba(self, texstr, color='black', dpi=120, fontsize=14)
    Parameters
    texstr [str] A valid mathtext string, e.g., r'IQ: $\sigma_i=15$'.
    color [color] The text color.
    dpi [float] The dots-per-inch setting used to render the text.
    fontsize [int] The font size in points.
    Returns
    array [(M, N, 4) array] RGBA color values of rasterized tex, colorized
    with color.
    depth [int] Offset of the baseline from the bottom of the image, in pixels.
class matplotlib.mathtext.MathtextBackend
    Bases: object

    The base class for the mathtext backend-specific code. The purpose of MathtextBackend subclasses is to interface between mathtext and a specific matplotlib graphics backend.

    Subclasses need to override the following:
        • render_glyph()
        • render_rect_filled()
        • get_results()

    And optionally, if you need to use a FreeType hinting style:
        • get_hinting_type()

get_hinting_type(self)
    Get the FreeType hinting type to use with this particular backend.

get_results(self, box)
    Return a backend-specific tuple to return to the backend after all processing is done.

render_glyph(self, ox, oy, info)
    Draw a glyph described by info to the reference point (ox, oy).

render_rect_filled(self, x1, y1, x2, y2)
    Draw a filled black rectangle from (x1, y1) to (x2, y2).

set_canvas_size(self, w, h, d)
    Dimension the drawing canvas

class matplotlib.mathtext.MathtextBackendAgg
    Bases: matplotlib.mathtext.MathtextBackend

    Render glyphs and rectangles to an FTImage buffer, which is later transferred to the Agg image by the Agg backend.

get_hinting_type(self)
    Get the FreeType hinting type to use with this particular backend.

get_results(self, box, used_characters)
    Return a backend-specific tuple to return to the backend after all processing is done.

render_glyph(self, ox, oy, info)
    Draw a glyph described by info to the reference point (ox, oy).

render_rect_filled(self, x1, y1, x2, y2)
    Draw a filled black rectangle from (x1, y1) to (x2, y2).

set_canvas_size(self, w, h, d)
    Dimension the drawing canvas

class matplotlib.mathtext.MathtextBackendBitmap
    Bases: matplotlib.mathtext.MathtextBackendAgg

    get_results(self, box, used_characters)
        Return a backend-specific tuple to return to the backend after all processing is done.

class matplotlib.mathtext.MathtextBackendCairo
    Bases: matplotlib.mathtext.MathtextBackend

    Store information to write a mathtext rendering to the Cairo backend.
get_results(self, box, used_characters)
    Return a backend-specific tuple to return to the backend after all processing is done.

render_glyph(self, ox, oy, info)
    Draw a glyph described by info to the reference point (ox, oy).

render_rect_filled(self, x1, y1, x2, y2)
    Draw a filled black rectangle from (x1, y1) to (x2, y2).

class matplotlib.mathtext.MathtextBackendPath
    Bases: matplotlib.mathtext.MathtextBackend
    Store information to write a mathtext rendering to the text path machinery.

get_results(self, box, used_characters)
    Return a backend-specific tuple to return to the backend after all processing is done.

render_glyph(self, ox, oy, info)
    Draw a glyph described by info to the reference point (ox, oy).

render_rect_filled(self, x1, y1, x2, y2)
    Draw a filled black rectangle from (x1, y1) to (x2, y2).

class matplotlib.mathtext.MathtextBackendPdf
    Bases: matplotlib.mathtext.MathtextBackend
    Store information to write a mathtext rendering to the PDF backend.

get_results(self, box, used_characters)
    Return a backend-specific tuple to return to the backend after all processing is done.

render_glyph(self, ox, oy, info)
    Draw a glyph described by info to the reference point (ox, oy).

render_rect_filled(self, x1, y1, x2, y2)
    Draw a filled black rectangle from (x1, y1) to (x2, y2).

class matplotlib.mathtext.MathtextBackendPs
    Bases: matplotlib.mathtext.MathtextBackend
    Store information to write a mathtext rendering to the PostScript backend.

get_results(self, box, used_characters)
    Return a backend-specific tuple to return to the backend after all processing is done.

render_glyph(self, ox, oy, info)
    Draw a glyph described by info to the reference point (ox, oy).

render_rect_filled(self, x1, y1, x2, y2)
    Draw a filled black rectangle from (x1, y1) to (x2, y2).

class matplotlib.mathtext.MathtextBackendSvg
    Bases: matplotlib.mathtext.MathtextBackend
    Store information to write a mathtext rendering to the SVG backend.

get_results(self, box, used_characters)
    Return a backend-specific tuple to return to the backend after all processing is done.

render_glyph(self, ox, oy, info)
    Draw a glyph described by info to the reference point (ox, oy).

render_rect_filled(self, x1, y1, x2, y2)
    Draw a filled black rectangle from (x1, y1) to (x2, y2).
class matplotlib.mathtext.NegFil
    Bases: matplotlib.mathtext.Glue

class matplotlib.mathtext.NegFill
    Bases: matplotlib.mathtext.Glue

class matplotlib.mathtext.NegFilll
    Bases: matplotlib.mathtext.Glue

class matplotlib.mathtext.Node
    Bases: object
    A node in the TeX box model
    get_kerning(self, next)
    grow(self)
        Grows one level larger. There is no limit to how big something can get.
    render(self, x, y)
    shrink(self)
        Shrinks one level smaller. There are only three levels of sizes, after which things will no longer get smaller.

class matplotlib.mathtext.Parser
    Bases: object
    This is the pyparsing-based parser for math expressions. It actually parses full strings containing math expressions, in that raw text may also appear outside of pairs of $.$
    The grammar is based directly on that in TeX, though it cuts a few corners.

class State(font_output, font, font_class, fontsize, dpi)
    Bases: object
    Stores the state of the parser.
    States are pushed and popped from a stack as necessary, and the “current” state is always at the top of the stack.
    copy(self)
    font
    accent(self, s, loc, toks)
    auto_delim(self, s, loc, toks)
    binom(self, s, loc, toks)
    c_over_c(self, s, loc, toks)
    customspace(self, s, loc, toks)
    dfrac(self, s, loc, toks)
    end_group(self, s, loc, toks)
    font(self, s, loc, toks)
    frac(self, s, loc, toks)
    function(self, s, loc, toks)
    genfrac(self, s, loc, toks)
get_state(self)
    Get the current State of the parser.

group(self, s, loc, toks)
is_between_brackets(self, s, loc)
is_dropsub(self, nucleus)
is_overunder(self, nucleus)
is_slanted(self, nucleus)
main(self, s, loc, toks)
math(self, s, loc, toks)
math_string(self, s, loc, toks)
non_math(self, s, loc, toks)
operatorname(self, s, loc, toks)
overline(self, s, loc, toks)
parse(self, s, fonts_object, fontsize, dpi)
    Parse expression s using the given fonts_object for output, at the given fontsize and dpi.
    Returns the parse tree of Node instances.

pop_state(self)
    Pop a State off of the stack.
push_state(self)
    Push a new State onto the stack which is just a copy of the current state.

required_group(self, s, loc, toks)
simple_group(self, s, loc, toks)
snowflake(self, s, loc, toks)
space(self, s, loc, toks)
sqrt(self, s, loc, toks)
stackrel1(self, s, loc, toks)
    [Deprecated]

Notes

Deprecated since version 3.1:

start_group(self, s, loc, toks)
subsuper(self, s, loc, toks)
symbol(self, s, loc, toks)
unknown_symbol(self, s, loc, toks)

class matplotlib.mathtext.Rule(width, height, depth, state)
    Bases: matplotlib.mathtext.Box
A `Rule` node stands for a solid black rectangle; it has width, depth, and height fields just as in an `Hlist`. However, if any of these dimensions is inf, the actual value will be determined by running the rule up to the boundary of the innermost enclosing box. This is called a “running dimension.” The width is never running in an `Hlist`; the height and depth are never running in a `Vlist`.

```python
def render(self, x, y, w, h):
```

```python
class matplotlib.mathtext.STIXFontConstants
    Bases: matplotlib.mathtext.FontConstantsBase

delta = 0.05
    delta_integral = 0.3
    delta_slanted = 0.3
    script_space = 0.1
    sub2 = 0.6
    sup1 = 0.8
```

```python
class matplotlib.mathtext.STIXSansFontConstants
    Bases: matplotlib.mathtext.FontConstantsBase

delta_integral = 0.3
    delta_slanted = 0.6
    script_space = 0.05
    sup1 = 0.8
```

```python
class matplotlib.mathtext.Ship
    Bases: object

    Once the boxes have been set up, this sends them to output. Since boxes can be inside of boxes inside of boxes, the main work of `Ship` is done by two mutually recursive routines, `hlist_out()` and `vlist_out()`, which traverse the `Hlist` nodes and `Vlist` nodes inside of horizontal and vertical boxes. The global variables used in TeX to store state as it processes have become member variables here.

    static clamp(value)
```

```python
        hlist_out(self, box)
        vlist_out(self, box)
```

```python
class matplotlib.mathtext.SsGlue
    Bases: matplotlib.mathtext.Glue
```

```python
class matplotlib.mathtext.StandardPsFonts(default_font_prop)
    Bases: matplotlib.mathtext.Fonts

    Use the standard postscript fonts for rendering to backend_ps

    Unlike the other font classes, BakomaFont and UnicodeFont, this one requires the Ps backend.
```

```python
    basepath = '/home/pi/.virtualenvs/mpl311-doc/lib/python3.7/site-packages/matplotlib/mpl-data/fonts/afm'
    fontmap = {'cal': 'pzcmi8a', 'rm': 'pncr8a', 'tt': 'pcrr8a', 'it': 'pncri8a', 'sf': 'phvr8a', 'bf':
```
get_kern(self, font1, fontclass1, sym1, fontsize1, font2, fontclass2, sym2, fontsize2, dpi)
Get the kerning distance for font between sym1 and sym2.

fontX: one of the TeX font names:

| tt, it, rm, cal, sf, bf | default/regular (non-math) |

fontclassX: TODO

symX: a symbol in raw TeX form. e.g., '1', 'x' or 'sigma'

fontsizeX: the fontsize in points

dpi: the current dots-per-inch

get_underline_thickness(self, font, fontsize, dpi)
Get the line thickness that matches the given font. Used as a base unit for drawing lines such as in a fraction or radical.

get_xheight(self, font, fontsize, dpi)
Get the xheight for the given font and fontsize.

class matplotlib.mathtext.StixFonts(*args, **kwargs)
Bases: matplotlib.mathtext.UnicodeFonts
A font handling class for the STIX fonts.

In addition to what UnicodeFonts provides, this class:

- supports "virtual fonts" which are complete alpha numeric character sets with different font styles at special Unicode code points, such as "Blackboard".
- handles sized alternative characters for the STIXSizeX fonts.

cmfallback = False

get_sized_alternatives_for_symbol(self, fontname, sym)
Override if your font provides multiple sizes of the same symbol. Should return a list of symbols matching sym in various sizes. The expression renderer will select the most appropriate size for a given situation from this list.

use_cmem = False

class matplotlib.mathtext.StixSansFonts(*args, **kwargs)
Bases: matplotlib.mathtext.StixFonts
A font handling class for the STIX fonts (that uses sans-serif characters by default).

class matplotlib.mathtext.SubSuperCluster
Bases: matplotlib.mathtext.Hlist

SubSuperCluster is a sort of hack to get around that fact that this code do a two-pass parse like TeX. This lets us store enough information in the hlist itself, namely the nucleus, sub- and super-script, such that if another script follows that needs to be attached, it can be reconfigured on the fly.

class matplotlib.mathtext.TruetypeFonts(default_font_prop, mathtext_backend)
Bases: matplotlib.mathtext.Fonts
A generic base class for all font setups that use TrueType fonts (through FT2Font).

destroy(self)
Fix any cyclic references before the object is about to be destroyed.
get_kern(self, font1, fontclass1, sym1, fontsize1, font2, fontclass2, sym2, fontsize2, dpi)
Get the kerning distance for font between sym1 and sym2.

fontX: one of the TeX font names:

| tt, it, rm, cal, sf, bf | default/regular (non-math) |

fontclassX: TODO

symX: a symbol in raw TeX form. e.g., '1', 'x' or 'sigma'

fontsizeX: the fontsize in points

dpi: the current dots-per-inch

get_underline_thickness(self, font, fontsize, dpi)
Get the line thickness that matches the given font. Used as a base unit for drawing lines such as in a fraction or radical.

get_xheight(self, fontname, fontsize, dpi)
Get the xheight for the given font and fontsize.

class matplotlib.mathtext.UnicodeFonts(*args, **kwargs)
Bases: matplotlib.mathtext.TruetypeFonts
An abstract base class for handling Unicode fonts.

While some reasonably complete Unicode fonts (such as DejaVu) may work in some situations, the only Unicode font I’m aware of with a complete set of math symbols is STIX. This class will “fallback” on the Bakoma fonts when a required symbol can not be found in the font.

get_sized_alternatives_for_symbol(self, fontname, sym)
Override if your font provides multiple sizes of the same symbol. Should return a list of symbols matching sym in various sizes. The expression renderer will select the most appropriate size for a given situation from this list.

use_cmex = True

class matplotlib.mathtext.VCentered(elements)
Bases: matplotlib.mathtext.Hlist
A convenience class to create a Vlist whose contents are centered within its enclosing box.

class matplotlib.mathtext.Vbox(height, depth)
Bases: matplotlib.mathtext.Box
A box with only height (zero width).

class matplotlib.mathtext.Vlist(elements, h=0.0, m='additional')
Bases: matplotlib.mathtext.List
A vertical list of boxes.

vpack(self, h=0.0, m='additional', l=inf)
The main duty of vpack() is to compute the dimensions of the resulting boxes, and to adjust the glue if one of those dimensions is pre-specified.

• h: specifies a height

• m: is either ‘exactly’ or ‘additional’.
• \( h \): a maximum height

Thus, `vpack(h, 'exactly')` produces a box whose height is exactly \( h \), while `vpack(h, 'additional')` yields a box whose height is the natural height plus \( h \). The default values produce a box with the natural width.

class matplotlib.mathtext.Vrule
    Bases: matplotlib.mathtext.Rule

Convenience class to create a vertical rule.

matplotlib.mathtext.get_unicode_index(symbol, math=True)
    Return the integer index (from the Unicode table) of `symbol`.

    Parameters

    symbol [str] A single unicode character, a TeX command (e.g. r'pi') or a
    Type1 symbol name (e.g. 'phi').

    math [bool, default is True] If False, always treat as a single unicode char-
    acter.

matplotlib.mathtext.math_to_image(s, filename_or_obj, prop=None, dpi=None, for-
mat=None)
    Given a math expression, renders it in a closely-clipped bounding box to an image file.

    s A math expression. The math portion should be enclosed in dollar signs.

    filename_or_obj A filepath or writable file-like object to write the image data to.

    prop If provided, a FontProperties() object describing the size and style of the text.

    dpi Override the output dpi, otherwise use the default associated with the output format.

    format The output format, e.g., ‘svg’, ‘pdf’, ‘ps’ or ‘png’. If not provided, will be deduced
    from the filename.

17.32 matplotlib.mlab

Numerical python functions written for compatibility with MATLAB commands with the same
names. Most numerical python functions can be found in the numpy and scipy libraries. What
remains here is code for performing spectral computations.

17.32.1 Spectral functions

cohere Coherence (normalized cross spectral density)

csd Cross spectral density using Welch’s average periodogram

detrend Remove the mean or best fit line from an array

psd Power spectral density using Welch’s average periodogram

specgram Spectrogram (spectrum over segments of time)

complex_spectrum Return the complex-valued frequency spectrum of a signal

magnitude_spectrum Return the magnitude of the frequency spectrum of a signal

angle_spectrum Return the angle (wrapped phase) of the frequency spectrum of a signal
**phase_spectrum**  Return the phase (unwrapped angle) of the frequency spectrum of a signal

**detrend_mean**  Remove the mean from a line.

**detrend_linear**  Remove the best fit line from a line.

**detrend_none**  Return the original line.

**stride_windows**  Get all windows in an array in a memory-efficient manner

**stride_repeat**  Repeat an array in a memory-efficient manner

**apply_window**  Apply a window along a given axis

class `matplotlib.mlab.GaussianKDE(dataset, bw_method=None)`

    Bases: `object`

    Representation of a kernel-density estimate using Gaussian kernels.

    **Parameters**

    - **dataset**  [array_like] Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).

    - **bw_method**  [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `GaussianKDE` instance as only parameter and return a scalar. If None (default), ‘scott’ is used.

    **Attributes**

    - **dataset**  [ndarray] The dataset with which `gaussian_kde` was initialized.

    - **dim**  [int] Number of dimensions.

    - **num_dp**  [int] Number of datapoints.

    - **factor**  [float] The bandwidth factor, obtained from `kde.covariance_factor`, with which the covariance matrix is multiplied.

    - **covariance**  [ndarray] The covariance matrix of `dataset`, scaled by the calculated bandwidth (`kde.factor`).

    - **inv_cov**  [ndarray] The inverse of `covariance`.

    **Methods**

    - **kde.evaluate(points)**  (ndarray) Evaluate the estimated pdf on a provided set of points.

    - **kde(points)**  (ndarray) Same as `kde.evaluate(points)`

    - **covariance_factor(self)**

    - **evaluate(self, points)**

        Evaluate the estimated pdf on a set of points.

        **Parameters**

        - **points**  [(# of dimensions, # of points)-array] Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.
Returns

values [(# of points,-)array] The values at each point.

Raises

ValueError [if the dimensionality of the input points is different] than the dimensionality of the KDE.

scotts_factor(self)

silverman_factor(self)

matplotlib.mlab.angle_spectrum(x, Fs=None, window=None, pad_to=None, sides=None)

Compute the angle of the frequency spectrum (wrapped phase spectrum) of x. Data is padded to a length of pad_to and the windowing function window is applied to the signal.

Parameters

x [1-D array or sequence] Array or sequence containing the data

Fs [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

window [callable or ndarray] A function or a vector of length NFFT. To create window vectors see window_hanning, window_none, numpy.blackman, numpy.hamming, numpy.bartlett, scipy.signal, scipy.signal.get_window, etc. The default is window_hanning. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

sides [{'default', 'onesided', 'twosided'}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

pad_to [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the n parameter in the call to fft(). The default is None, which sets pad_to equal to the length of the input signal (i.e. no padding).

Returns

spectrum [1-D array] The values for the angle spectrum in radians (real valued)

freqs [1-D array] The frequencies corresponding to the elements in spectrum

See also:

complex_spectrum This function returns the angle value of complex_spectrum.
magnitude_spectrum Returns the magnitudes of the corresponding frequencies.
phase_spectrum Returns the phase (unwrapped angle) of the corresponding frequencies.
specgram Can return the complex spectrum of segments within the signal.
matplotlib.mlab.apply_window(x, window, axis=0, return_window=None)
    Apply the given window to the given 1D or 2D array along the given axis.

    Parameters
    x [1D or 2D array or sequence] Array or sequence containing the data.
    window [function or array.] Either a function to generate a window or an
    array with length x.shape[axis]
    axis [integer] The axis over which to do the repetition. Must be 0 or 1.
    The default is 0
    return_window [bool] If true, also return the 1D values of the window
    that was applied

matplotlib.mlab.cohere(x, y, NFFT=256, Fs=2, detrend=<function detrend_none
    at 0x7f69881a1378>, window=<function window_hanning at
    0x7f6988216bf8>, noverlap=0, pad_to=None, sides='default',
    scale_by_freq=None)
    The coherence between x and y. Coherence is the normalized cross spectral density:

    \[ C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}} \]

    Parameters
    x, y Array or sequence containing the data
    Fs [scalar] The sampling frequency (samples per time unit). It is used to
    calculate the Fourier frequencies, freqs, in cycles per time unit. The
    default value is 2.
    window [callable or ndarray] A function or a vector of length NFFT. To
    create window vectors see window_hanning, window_none, numpy.blackman,
    numpy.hamming, numpy.bartlett, scipy.signal, scipy.signal.get_window,
    etc. The default is window_hanning. If a function is passed as the arg-
    ument, it must take a data segment as an argument and return the
    windowed version of the segment.
    sides [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the
    spectrum to return. Default gives the default behavior, which returns
    one-sided for real data and both for complex data. ‘onesided’ forces
    the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
    pad_to [int] The number of points to which the data segment is padded
    when performing the FFT. This can be different from NFFT, which
    specifies the number of data points used. While not increasing the
    actual resolution of the spectrum (the minimum distance between re-
    solvable peaks), this can give more points in the plot, allowing for more
    detail. This corresponds to the n parameter in the call to fft(). The de-
    fault is None, which sets pad_to equal to NFFT
    NFFT [int] The number of data points used in each block for the FFT. A
    power 2 is most efficient. The default value is 256. This should NOT be
    used to get zero padding, or the scaling of the result will be incorrect.
    Use pad_to for this instead.
    detrend [{‘none’, ‘mean’, ‘linear’} or callable, default ‘none’] The func-
    tion applied to each segment before fft-ing, designed to remove the
mean or linear trend. Unlike in MATLAB, where the\textit{detrend} parameter is a vector, in Matplotlib it is a function. The\textit{mlab} module defines\textit{detrend\_none}, \textit{detrend\_mean}, and \textit{detrend\_linear}, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls \textit{detrend\_none}. ‘mean’ calls \textit{detrend\_mean}. ‘linear’ calls \textit{detrend\_linear}.

\textbf{scale\_by\_freq} [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz\(^{-1}\). This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

\textbf{noverlap} [integer] The number of points of overlap between blocks. The default value is 0 (no overlap).

\textbf{Returns}

The return value is the tuple \((C_{xy}, f)\), where \(f\) are the frequencies of the coherence vector. For\textit{cohere}, scaling the individual densities by the sampling frequency has no effect, since the factors cancel out.

See also:

- \textit{psd()}, \textit{csd()} For information about the methods used to compute \(P_{xy}, P_{xx}\) and \(P_{yy}\).

\texttt{matplotlib.mlab.complex\_spectrum}(x, Fs=None, window=None, pad\_to=None, sides=None)

Compute the complex-valued frequency spectrum of \(x\). Data is padded to a length of \(pad\_to\) and the windowing function \(window\) is applied to the signal.

\textbf{Parameters}

- \(x\) [1-D array or sequence] Array or sequence containing the data
- \(Fs\) [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.
- \textit{window} [callable or ndarray] A function or a vector of length \(NFFT\). To create window vectors see \textit{window\_hanning}, \textit{window\_none}, \textit{numpy\_blackman}, \textit{numpy\_hamming}, \textit{numpy\_bartlett}, \textit{scipy\_signal}, \textit{scipy\_signal\_get\_window}, etc. The default is \textit{window\_hanning}. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- \textit{sides} [{'default', ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- \textit{pad\_to} [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the \(n\) parameter in the call to \textit{fft()}. The default is None, which sets \textit{pad\_to} equal to the length of the input signal (i.e. no padding).

\textbf{Returns}
spectrum [1-D array] The values for the complex spectrum (complex valued)

freqs [1-D array] The frequencies corresponding to the elements in spectrum

See also:
magnitude_spectrum Returns the absolute value of this function.
angle_spectrum Returns the angle of this function.
phase_spectrum Returns the phase (unwrapped angle) of this function.
specgram Can return the complex spectrum of segments within the signal.

matplotlib.mlab.csd(x, y, NFFT=None, Fs=None, detrend=None, window=None, noverlap=None, pad_to=None, sides=None, scale_by_freq=None)
Compute the cross-spectral density.
The cross spectral density $P_{xy}$ by Welch’s average periodogram method. The vectors $x$ and $y$ are divided into $NFFT$ length segments. Each segment is detrended by function detrend and windowed by function window. noverlap gives the length of the overlap between segments. The product of the direct FFTs of $x$ and $y$ are averaged over each segment to compute $P_{xy}$, with a scaling to correct for power loss due to windowing.

If len(x) < NFFT or len(y) < NFFT, they will be zero padded to NFFT.

Parameters

- **x, y** [1-D arrays or sequences] Arrays or sequences containing the data
- **Fs** [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.
- **window** [callable or ndarray] A function or a vector of length $NFFT$. To create window vectors see window_hanning, window_none, numpy.blackman, numpy.hamming, numpy.bartlett, scipy.signal, scipy.signal.get_window, etc. The default is window_hanning. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- **sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- **noverlap** [int] The number of points to which the data segment is padded when performing the FFT. This can be different from $NFFT$, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the $n$ parameter in the call to fft(). The default is None, which sets noverlap to None.
- **noverlap** [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use pad_to for this instead.
**detrend** ['none', 'mean', 'linear'] or callable, default 'none' The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the detrend parameter is a vector, in Matplotlib it is a function. The mlab module defines detrend_none, detrend_mean, and detrend_linear, but you can use a custom function as well. You can also use a string to choose one of the functions: 'none' calls detrend_none. 'mean' calls detrend_mean. 'linear' calls detrend_linear.

**scale_by_freq** [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz ^ -1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

**noverlap** [integer] The number of points of overlap between segments. The default value is 0 (no overlap).

**Returns**

- **Pxy** [1-D array] The values for the cross spectrum \( P_{xy} \) before scaling (real valued)
- **freqs** [1-D array] The frequencies corresponding to the elements in Pxy

**See also:**

- `psd` equivalent to setting \( y = x \).

**References**

matplotlib.mlab.demean(x, axis=0)

[Deprecated] Return x minus its mean along the specified axis.

**Parameters**

- **x** [array or sequence] Array or sequence containing the data Can have any dimensionality
- **axis** [integer] The axis along which to take the mean. See numpy.mean for a description of this argument.

**See also:**

- `detrend_mean` Same as `demean` except for the default axis.

**Notes**

Deprecated since version 3.1.

matplotlib.mlab.detrend(x, key=None, axis=None)

Return x with its trend removed.

**Parameters**

- **x** [array or sequence] Array or sequence containing the data.
key  [[ 'default' | 'constant' | 'mean' | 'linear' | 'none'] or function] Specifies the detrend algorithm to use. 'default' is 'mean', which is the same as detrend_mean. 'constant' is the same. 'linear' is the same as detrend_linear. 'none' is the same as detrend_none. The default is 'mean'. See the corresponding functions for more details regarding the algorithms. Can also be a function that carries out the detrend operation.

axis  [integer] The axis along which to do the detrending.

See also:

detrend_mean  Implementation of the 'mean' algorithm.
detrend_linear  Implementation of the 'linear' algorithm.
detrend_none  Implementation of the 'none' algorithm.

matplotlib.mlab.detrend_linear(y)
Return x minus best fit line; 'linear' detrending.

Parameters

y  [0-D or 1-D array or sequence] Array or sequence containing the data
axis  [integer] The axis along which to take the mean. See numpy.mean for a description of this argument.

See also:

detrend_mean  Another detrend algorithm.
detrend_none  Another detrend algorithm.
detrend  A wrapper around all the detrend algorithms.

matplotlib.mlab.detrend_mean(x, axis=None)
Return x minus the mean(x).

Parameters

x  [array or sequence] Array or sequence containing the data Can have any dimensionality
axis  [integer] The axis along which to take the mean. See numpy.mean for a description of this argument.

See also:

detrend_linear  Another detrend algorithm.
detrend_none  Another detrend algorithm.
detrend  A wrapper around all the detrend algorithms.

matplotlib.mlab.detrend_none(x, axis=None)
Return x: no detrending.

Parameters

x  [any object] An object containing the data
**axis** [integer] This parameter is ignored. It is included for compatibility with `detrend_mean`

**See also:**

- `detrend_mean` Another detrend algorithm.
- `detrend_linear` Another detrend algorithm.
- `detrend` A wrapper around all the detrend algorithms.

```python
matplotlib.mlab.magnitude_spectrum(x, Fs=None, window=None, pad_to=None, sides=None)
```

Compute the magnitude (absolute value) of the frequency spectrum of `x`. Data is padded to a length of `pad_to` and the windowing function `window` is applied to the signal.

**Parameters**

- `x` [1-D array or sequence] Array or sequence containing the data
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.
- `window` [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- `sides` [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- `pad_to` [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to the length of the input signal (i.e. no padding).

**Returns**

- `spectrum` [1-D array] The values for the magnitude spectrum (real valued)
- `freqs` [1-D array] The frequencies corresponding to the elements in `spectrum`

**See also:**

- `psd` Returns the power spectral density.
- `complex_spectrum` This function returns the absolute value of `complex_spectrum`.
- `angle_spectrum` Returns the angles of the corresponding frequencies.
- `phase_spectrum` Returns the phase (unwrapped angle) of the corresponding frequencies.
- `specgram` Can return the complex spectrum of segments within the signal.
Compute the phase of the frequency spectrum (unwrapped angle spectrum) of x. Data is padded to a length of `pad_to` and the windowing function `window` is applied to the signal.

**Parameters**

- `x` [1-D array or sequence] Array or sequence containing the data
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.
- `window` [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- `sides` [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- `pad_to` [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to the length of the input signal (i.e. no padding).

**Returns**

- `spectrum` [1-D array] The values for the phase spectrum in radians (real valued)
- `freqs` [1-D array] The frequencies corresponding to the elements in `spectrum`

See also:

- `complex_spectrum` This function returns the phase value of `complex_spectrum`
- `magnitude_spectrum` Returns the magnitudes of the corresponding frequencies.
- `angle_spectrum` Returns the angle (wrapped phase) of the corresponding frequencies.
- `specgram` Can return the complex spectrum of segments within the signal.

Compute the power spectral density.

The power spectral density $P_{xx}$ by Welch’s average periodogram method. The vector `x` is divided into `NFFT` length segments. Each segment is detrended by function `detrend` and windowed by function `window`. `noverlap` gives the length of the overlap between segments. The $|\text{fft}(i)|^2$ of each segment $i$ are averaged to compute $P_{xx}$.

If `len(x) < NFFT`, it will be zero padded to `NFFT`.

**Parameters**

- `x` [1-D array or sequence] Array or sequence containing the data
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.
- `window` [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- `sides` [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- `pad_to` [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to the length of the input signal (i.e. no padding).

**Returns**

- `spectrum` [1-D array] The values for the phase spectrum in radians (real valued)
- `freqs` [1-D array] The frequencies corresponding to the elements in `spectrum`

See also:

- `complex_spectrum` This function returns the phase value of `complex_spectrum`
- `magnitude_spectrum` Returns the magnitudes of the corresponding frequencies.
- `angle_spectrum` Returns the angle (wrapped phase) of the corresponding frequencies.
- `specgram` Can return the complex spectrum of segments within the signal.

Compute the power spectral density.

The power spectral density $P_{xx}$ by Welch’s average periodogram method. The vector `x` is divided into `NFFT` length segments. Each segment is detrended by function `detrend` and windowed by function `window`. `noverlap` gives the length of the overlap between segments. The $|\text{fft}(i)|^2$ of each segment $i$ are averaged to compute $P_{xx}$.

If `len(x) < NFFT`, it will be zero padded to `NFFT`. 
x  [1-D array or sequence] Array or sequence containing the data

Fs [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

window [ callable or ndarray] A function or a vector of length NFFT. To create window vectors see window_hanning, window_none, numpy.blackman, numpy.hamming, numpy.bartlett, scipy.signal, scipy.signal.get_window, etc. The default is window_hanning. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

sides [ {'default', 'onesided', 'twosided'}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

pad_to [ int] The number of points to which the data segment is padded when performing the FFT. This can be different from NFFT, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the n parameter in the call to fft(). The default is None, which sets pad_to equal to NFFT

NFFT [ int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use pad_to for this instead.

detrend [ {'none', 'mean', 'linear'} or callable, default 'none'] The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the detrend parameter is a vector, in Matplotlib is it a function. The mlab module defines detrend_none, detrend_mean, and detrend_linear, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls detrend_none. ‘mean’ calls detrend_mean. ‘linear’ calls detrend_linear.

scale_by_freq [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

noverlap [ integer] The number of points of overlap between segments. The default value is 0 (no overlap).

Returns

Pxx [1-D array] The values for the power spectrum $P_{xx}$ (real valued)

freqs [1-D array] The frequencies corresponding to the elements in Pxx

See also:

specgram specgram differs in the default overlap; in not returning the mean of the segment periodograms; and in returning the times of the segments.
magnitude_spectrum returns the magnitude spectrum.
csd returns the spectral density between two signals.

References

matplotlib.mlab.specgram(x, NFFT=None, Fs=None, detrend=None, window=None, noverlap=None, pad_to=None, sides=None, scale_by_freq=None, mode=None)

Compute a spectrogram.

Compute and plot a spectrogram of data in x. Data are split into NFFT length segments and the spectrum of each section is computed. The windowing function window is applied to each segment, and the amount of overlap of each segment is specified with noverlap.

Parameters

x [array_like] 1-D array or sequence.

Fs [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

window [callable or ndarray] A function or a vector of length NFFT. To create window vectors see window_hanning, window_none, numpy.blackman, numpy.hamming, numpy.bartlett, scipy.signal, scipy.signal.get_window, etc. The default is window_hanning. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

sides [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

pad_to [int] The number of points to which the data segment is padded when performing the FFT. This can be different from NFFT, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the n parameter in the call to fft(). The default is None, which sets pad_to equal to NFFT

NFFT [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use pad_to for this instead.

detrend [{‘none’, ‘mean’, ‘linear’} or callable, default ‘none’] The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the detrend parameter is a vector, in Matplotlib is it a function. The mlab module defines detrend_none, detrend_mean, and detrend_linear, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls detrend_none. ‘mean’ calls detrend_mean. ‘linear’ calls detrend_linear.
scale_by_freq [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

noverlap [int, optional] The number of points of overlap between blocks. The default value is 128.

mode [str, optional]

What sort of spectrum to use, default is ‘psd’.

‘psd’ Returns the power spectral density.
‘complex’ Returns the complex-valued frequency spectrum.
‘magnitude’ Returns the magnitude spectrum.
‘angle’ Returns the phase spectrum without unwrapping.
‘phase’ Returns the phase spectrum with unwrapping.

Returns

spectrum [array_like] 2-D array, columns are the periodograms of successive segments.
freqs [array_like] 1-D array, frequencies corresponding to the rows in spectrum.
t [array_like] 1-D array, the times corresponding to midpoints of segments (i.e the columns in spectrum).

See also:

psd differs in the overlap and in the return values.
complex_spectrum similar, but with complex valued frequencies.
magnitude_spectrum similar single segment when mode is ‘magnitude’.
angle_spectrum similar to single segment when mode is ‘angle’.
phase_spectrum similar to single segment when mode is ‘phase’.

Notes

detrend and scale_by_freq only apply when mode is set to ‘psd’.

matplotlib.mlab.stride_repeat(x, n, axis=0)
Repeat the values in an array in a memory-efficient manner. Array x is stacked vertically n times.

Warning: It is not safe to write to the output array. Multiple elements may point to the same piece of memory, so modifying one value may change others.

Parameters

x [1D array or sequence] Array or sequence containing the data.
n [integer] The number of time to repeat the array.
axis [integer] The axis along which the data will run.

References

stackoverflow: Repeat NumPy array without replicating data?

matplotlib.mlab.stride_windows(x, n, noverlap=None, axis=0)
Get all windows of x with length n as a single array, using strides to avoid data duplication.

**Warning:** It is not safe to write to the output array. Multiple elements may point to the same piece of memory, so modifying one value may change others.

Parameters

x [1D array or sequence] Array or sequence containing the data.

n [integer] The number of data points in each window.

noverlap [integer] The overlap between adjacent windows. Default is 0 (no overlap)

axis [integer] The axis along which the windows will run.

References

stackoverflow: Rolling window for 1D arrays in Numpy? stackoverflow: Using strides for an efficient moving average filter

matplotlib.mlab.window_hanning(x)
Return x times the hanning window of len(x).

See also:

window_none Another window algorithm.

matplotlib.mlab.window_none(x)
No window function; simply return x.

See also:

window_hanning Another window algorithm.

17.33 matplotlib.offsetbox

The OffsetBox is a simple container artist. The child artist are meant to be drawn at a relative position to its parent. The [VH]Packer, DrawingArea and TextArea are derived from the OffsetBox.

The [VH]Packer automatically adjust the relative positions of their children, which should be instances of the OffsetBox. This is used to align similar artists together, e.g., in legend.
The DrawingArea can contain any Artist as a child. The DrawingArea has a fixed width and height. The position of children relative to the parent is fixed. The TextArea is contains a single Text instance. The width and height of the TextArea instance is the width and height of the its child text.

class matplotlib.offsetbox.AnchoredOffsetbox(loc, pad=0.4, borderpad=0.5, child=None, prop=None, frameon=True, bbox_to_anchor=None, bbox_transform=None, **kwargs)

Bases: matplotlib.offsetbox.OffsetBox

An offset box placed according to the legend location loc. AnchoredOffsetbox has a single child. When multiple children is needed, use other OffsetBox class to enclose them. By default, the offset box is anchored against its parent axes. You may explicitly specify the bbox_to_anchor.

loc is a string or an integer specifying the legend location. The valid location codes are:

<table>
<thead>
<tr>
<th>Location</th>
<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>upper right</td>
<td>1</td>
</tr>
<tr>
<td>upper left</td>
<td>2</td>
</tr>
<tr>
<td>lower left</td>
<td>3</td>
</tr>
<tr>
<td>lower right</td>
<td>4</td>
</tr>
<tr>
<td>right</td>
<td>5</td>
</tr>
<tr>
<td>center left</td>
<td>6</td>
</tr>
<tr>
<td>center right</td>
<td>7</td>
</tr>
<tr>
<td>lower center</td>
<td>8</td>
</tr>
<tr>
<td>upper center</td>
<td>9</td>
</tr>
<tr>
<td>center</td>
<td>10</td>
</tr>
</tbody>
</table>

pad [pad around the child for drawing a frame. given in] fraction of fontsize.

borderpad : pad between offsetbox frame and the bbox_to_anchor,

child : OffsetBox instance that will be anchored.

prop : font property. This is only used as a reference for paddings.

frameon : draw a frame box if True.

bbox_to_anchor : bbox to anchor. Use self.axes.bbox if None.

bbox_transform : with which the bbox_to_anchor will be transformed.

codes = {'center': 10, 'center left': 6, 'center right': 7, 'lower center': 8, 'lower left': 3, 'lower right': 4, 'right': 5, 'right': 5, (same as 'center right', for back-compatibility), 'upper center': 9, 'center': 10, 'upper left': 2, 'upper right': 1}

draw(self, renderer)

draw the artist

going_to_anchor(self)

draw the artist

going_to_anchor(self)

draw the artist

going_to_anchor(self)

draw the artist

going_to_anchor(self)

draw the artist

going_to_anchor(self)

draw the artist

going_to_anchor(self)

draw the artist

going_to_anchor(self)

draw the artist
get_window_extent(self, renderer)
get the bounding box in display space.

set_bbox_to_anchor(self, bbox, transform=None)
set the bbox that the child will be anchored.

bbox can be a Bbox instance, a list of [left, bottom, width, height], or a list of [left, bottom] where the width and height will be assumed to be zero. The bbox will be transformed to display coordinate by the given transform.

set_child(self, child)
set the child to be anchored

update_frame(self, bbox, fontsize=None)

zorder = 5

class matplotlib.offsetbox.AnchoredText(s, loc, pad=0.4, borderpad=0.5, prop=None, **kwargs)

Bases: matplotlib.offsetbox.AnchoredOffsetbox

AnchoredOffsetbox with Text.

Parameters

s [string] Text.
loc [str] Location code.

pad [float, optional] Pad between the text and the frame as fraction of the font size.

borderpad [float, optional] Pad between the frame and the axes (or bbox_to_anchor).

prop [dictionary, optional, default: None] Dictionary of keyword parameters to be passed to the Text instance contained inside AnchoredText.

Notes

Other keyword parameters of AnchoredOffsetbox are also allowed.

class matplotlib.offsetbox.AnnotationBbox(offsetbox, xy, xybox=None, xycoords='data', boxcoords=None, frameon=True, pad=0.4, annotation_clip=None, box_alignment=(0.5, 0.5), bboxprops=None, arrowprops=None, fontsize=None, **kwargs)

Bases: matplotlib.artist.Artist, matplotlib.text._AnnotationBase

Annotation-like class, but with offsetbox instead of Text.

offsetbox : OffsetBox instance

xycoords [same as Annotation but can be a tuple of two] strings which are interpreted as x and y coordinates.

boxcoords [similar to textcoords as Annotation but can be a] tuple of two strings which are interpreted as x and y coordinates.

box_alignment [a tuple of two floats for a vertical and] horizontal alignment of the offset box w.r.t. the boxcoords. The lower-left corner is (0.0) and upper-right corner is (1.1).
other parameters are identical to that of Annotation.

`contains(self, event)`
Test whether the artist contains the mouse event.

**Parameters**

- `mouseevent` ([`matplotlib.backend_bases.MouseEvent`])

**Returns**

- `contains` ([bool]) Whether any values are within the radius.
- `details` ([dict]) An artist-specific dictionary of details of the event context, such as which points are contained in the pick radius. See the individual Artist subclasses for details.

**See also:**

- `set_contains`, `get_contains`

`draw(self, renderer)`
Draw the `Annotation` object to the given `renderer`.

`get_children(self)`
Return a list of the child `Artists` of this `Artist`.

`get_fontsize(self, s=None)`
return fontsize in points

`set_fontsize(self, s=None)`
set fontsize in points

`update_positions(self, renderer)`
Update the pixel positions of the annotated point and the text.

`xyann`

`zorder = 3`

**class** `matplotlib.offsetbox.AuxTransformBox(aux_transform)`

**Bases:** `matplotlib.offsetbox.OffsetBox`

Offset Box with the `aux_transform`. Its children will be transformed with the aux_transform first then will be offseted. The absolute coordinate of the aux_transform is meaning as it will be automatically adjust so that the left-lower corner of the bounding box of children will be set to (0,0) before the offset transform.

It is similar to drawing area, except that the extent of the box is not predetermined but calculated from the window extent of its children. Furthermore, the extent of the children will be calculated in the transformed coordinate.

`add_artist(self, a)`
Add any `Artist` to the container box
```python
draw(self, renderer)
    Draw the children
get_extent(self, renderer)
    Return with, height, xdescent, ydescent of box
get_offset(self)
    return offset of the container.
get_transform(self)
    Return the Transform applied to the children
get_window_extent(self, renderer)
    get the bounding box in display space.
set_offset(self, xy)
    Set the offset of the container.

Parameters

    xy [(float, float)] The (x,y) coordinates of the offset in display units.

set_transform(self, t)
    set_transform is ignored.
```

class matplotlib.offsetbox.DraggableAnnotation(annotation, use_blit=False)
    Bases: matplotlib.offsetbox.DraggableBase

    save_offset(self)

    update_offset(self, dx, dy)

class matplotlib.offsetbox.DraggableBase(ref_artist, use_blit=False)
    Bases: object

    Helper base class for a draggable artist (legend, offsetbox).

    Derived classes must override the following methods:

```python
def save_offset(self):
    '''
    Called when the object is picked for dragging; should save the
    reference position of the artist.
    '''

def update_offset(self, dx, dy):
    '''
    Called during the dragging; (*dx*, *dy*) is the pixel offset from
    the point where the mouse drag started.
    '''
```

Optionally, you may override the following methods:

```python
def artist_picker(self, artist, evt):
    '''The picker method that will be used.'''
    return self.ref_artist.contains(evt)

def finalize_offset(self):
    '''Called when the mouse is released.''
```
In the current implementation of DraggableLegend and DraggableAnnotation, update_offset places the artists in display coordinates, and finalize_offset recalculates their position in axes coordinate and set a relevant attribute.

```python
artist_picker(self, artist, evt)
disconnect(self)
    Disconnect the callbacks.
finalize_offset(self)
on_motion(self, evt)
on_motion_blit(self, evt)
on_pick(self, evt)
on_release(self, event)
save_offset(self)
update_offset(self, dx, dy)
```

```python
class matplotlib.offsetbox.DraggableOffsetBox(ref_artist, offsetbox, use_blit=False)
    Bases: matplotlib.offsetbox.DraggableBase
get_loc_in_canvas(self)
save_offset(self)
update_offset(self, dx, dy)
```

```python
class matplotlib.offsetbox.DrawingArea(width, height, xdescent=0.0, ydescent=0.0, clip=False)
    Bases: matplotlib.offsetbox.OffsetBox
The DrawingArea can contain any Artist as a child. The DrawingArea has a fixed width and height. The position of children relative to the parent is fixed. The children can be clipped at the boundaries of the parent.

width, height : width and height of the container box. xdescent, ydescent : descent of the box in x- and y-direction. clip : Whether to clip the children

add_artist(self, a)
    Add any Artist to the container box
clip_children
    If the children of this DrawingArea should be clipped by DrawingArea bounding box.

draw(self, renderer)
    Draw the children

get_extent(self, renderer)
    Return with, height, xdescent, ydescent of box

get_offset(self)
    return offset of the container.

get_transform(self)
    Return the Transform applied to the children

get_window_extent(self, renderer)
    get the bounding box in display space.
```
set_offset(self, xy)
    Set the offset of the container.

    Parameters
    xy [(float, float)] The (x,y) coordinates of the offset in display units.

    set_transform(self, t)
    set_transform is ignored.

class matplotlib.offsetbox.HPacker(pad=None, sep=None, width=None, height=None, align='baseline', mode='fixed', children=None)
    Bases: matplotlib.offsetbox.PackerBase

    The HPacker has its children packed horizontally. It automatically adjusts the relative positions of children at draw time.

    Parameters
    pad [float, optional] Boundary pad.
    sep [float, optional] Spacing between items.
    width [float, optional]
    height [float, optional] Width and height of the container box, calculated if None.
    align [str] Alignment of boxes.
    mode [str] Packing mode.

    Notes

    pad and sep need to given in points and will be scale with the renderer dpi, while width and height need to be in pixels.

    get_extentOffsets(self, renderer)
    update offset of children and return the extents of the box

class matplotlib.offsetbox.OffsetBox(*args, **kwargs)
    Bases: matplotlib.artist.Artist

    The OffsetBox is a simple container artist. The child artist are meant to be drawn at a relative position to its parent.

    axes
    The Axes instance the artist resides in, or None.

    contains(self, mouseevent)
    Test whether the artist contains the mouse event.

    Parameters
    mouseevent [matplotlib.backend_bases.MouseEvent]

    Returns

    contains [bool] Whether any values are within the radius.

details [dict] An artist-specific dictionary of details of the event context, such as which points are contained in the pick radius. See the individual Artist subclasses for details.
See also:

set_contains, get_contains

draw(self, renderer)
    Update the location of children if necessary and draw them to the given renderer.

get_children(self)
    Return a list of artists it contains.

get_extent(self, renderer)
    Return with, height, xdescent, ydescent of box

get_extent_offsets(self, renderer)

get_offset(self, width, height, xdescent, ydescent, renderer)
    Get the offset

    accepts extent of the box

get_visible_children(self)
    Return a list of visible artists it contains.

get_window_extent(self, renderer)
    get the bounding box in display space.

set_figure(self, fig)
    Set the figure

    accepts a class:Figure instance

set_height(self, height)
    Set the height

    accepts float

set_offset(self, xy)
    Set the offset.

Parameters

xy [(float, float) or callable] The (x,y) coordinates of the offset in display units. A callable must have the signature:

```python
def offset(width, height, xdescent, ydescent, renderer) -> (float, float)
```

set_width(self, width)
    Set the width

    accepts float

class matplotlib.offsetbox.OffsetImage(arr, zoom=1, cmap=None, norm=None, interpolation=None, origin=None, filternorm=1, filterrad=4.0, resample=False, dpi_cor=True, **kwargs)

    Bases: matplotlib.offsetbox.OffsetBox
draw(self, renderer)
    Draw the children

get_children(self)
    Return a list of artists it contains.
get_data(self)
get_extent(self, renderer)
    Return with, height, xdescent, ydescent of box
get_offset(self)
    return offset of the container.
get_window_extent(self, renderer)
    get the bounding box in display space.
get_zoom(self)
set_data(self, arr)
set_zoom(self, zoom)

class matplotlib.offsetbox.PackerBase(pad=None, sep=None, width=None, height=None, align=None, mode=None, children=None)
Bases: matplotlib.offsetbox.OffsetBox

Parameters

    pad [float, optional] Boundary pad.
    sep [float, optional] Spacing between items.
    width [float, optional]
    height [float, optional] Width and height of the container box, calculated if None.
    align [str, optional] Alignment of boxes. Can be one of top, bottom, left, right, center and baseline
    mode [str, optional] Packing mode.

Notes

    pad and sep need to given in points and will be scale with the renderer dpi, while width and height need to be in pixels.

class matplotlib.offsetbox.PaddedBox(child, pad=None, draw_frame=False, patch_attrs=None)
Bases: matplotlib.offsetbox.OffsetBox

    pad : boundary pad

    Note: pad need to given in points and will be scale with the renderer dpi, while width and height need to be in pixels.

draw(self, renderer)
    Update the location of children if necessary and draw them to the given renderer.
draw_frame(self, renderer)
get_extent_offsets(self, renderer)
    update offset of childrens and return the extents of the box
update_frame(self, bbox, fontsize=None)
class matplotlib.offsetbox.TextArea(s, textprops=None, multilinelinebaseline=None, minimumdescent=True)
Bases: matplotlib.offsetbox.OffsetBox

The TextArea is contains a single Text instance. The text is placed at (0,0) with baseline+left alignment. The width and height of the TextArea instance is the width and height of the its child text.

**Parameters**

- **s** [str] a string to be displayed.
  - **textprops** [dictionary, optional, default: None] Dictionary of keyword parameters to be passed to the Text instance contained inside TextArea.
  - **multilinelinebaseline** [bool, optional] If True, baseline for multiline text is adjusted so that it is (approximately) center-aligned with singleline text.
  - **minimumdescent** [bool, optional] If True, the box has a minimum descent of “p”.

draw(self, renderer)
  Draw the children

get_extent(self, renderer)
  Return with, height, xdescent, ydescent of box

get_minimumdescent(self)
  Get minimumdescent.

get_multilinebaseline(self)
  Multilinebaseline

get_offset(self)
  Return offset of the container.

get_text(self)
  Returns the string representation of this area’s text

get_window_extent(self, renderer)
  Get the bounding box in display space.

set_minimumdescent(self, t)
  Set minimumdescent.
  - If True, extent of the single line text is adjusted so that it has minimum descent of “p”

set_multilinebaseline(self, t)
  Set multilinebaseline.
  - If True, baseline for multiline text is adjusted so that it is (approximately) center-aligned with single-line text.

set_offset(self, xy)
  Set the offset of the container.

**Parameters**

  - **xy** [(float, float)] The (x,y) coordinates of the offset in display units.

set_text(self, s)
  Set the text of this area as a string.
set_transform(self, t)
    set_transform is ignored.

class matplotlib.offsetbox.VPacker(pad=None, sep=None, width=None, height=None, align='baseline', mode='fixed', children=None)
    Bases: matplotlib.offsetbox.PackerBase

    The VPacker has its children packed vertically. It automatically adjust the relative positions of children in the drawing time.

    Parameters
    
    pad [float, optional] Boundary pad.
    sep [float, optional] Spacing between items.
    width [float, optional]
    height [float, optional] width and height of the container box, calculated if None.
    mode [str, optional] Packing mode.

    Notes

    pad and sep need to given in points and will be scale with the renderer dpi, while width and height need to be in pixels.

    get_extent_offsets(self, renderer)
    update offset of childrens and return the extents of the box

    matplotlib.offsetbox.bbox_artist(*args, **kwargs)

17.34 matplotlib.patches

17.34.1 Classes

    Arc(xy, width, height[, angle, theta1, theta2]) An elliptical arc, i.e.
    Arrow(x, y, dx, dy[, width]) An arrow patch.
    ArrowStyle
        ArrowStyle is a container class which defines several arrowstyle classes, which is used to create an arrow path along a given path.
    BoxStyle
        BoxStyle is a container class which defines several boxstyle classes, which are used for FancyBboxPatch.
    Circle(xy[, radius]) A circle patch.
    CirclePolygon(xy[, radius, resolution]) A polygon-approximation of a circle patch.
    ConnectionPatch(xyA, xyB, coordsA[, ...]) A ConnectionPatch class is to make connecting lines between two points (possibly in different axes).

</tbody>
</table>

**matplotlib.patches.Arc**

class matplotlib.patches.Arc(xy, width, height, angle=0.0, theta1=0.0, theta2=360.0, **kwargs)

Bases: matplotlib.patches.Ellipse

An elliptical arc, i.e. a segment of an ellipse.

Due to internal optimizations, there are certain restrictions on using Arc:

- The arc cannot be filled.
- The arc must be used in an Axes instance—it can not be added directly to a Figure—because it is optimized to only render the segments that are inside the axes bounding box with high resolution.

**Parameters**

- **xy** [(float, float)] The center of the ellipse.
- **width** [float] The length of the horizontal axis.
- **height** [float] The length of the vertical axis.
- **angle** [float] Rotation of the ellipse in degrees (counterclockwise).
- **theta1, theta2** [float, optional] Starting and ending angles of the arc in degrees. These values are relative to angle, e.g. if angle = 45 and theta1 = 90 the absolute starting angle is 135. Default theta1 = 0, theta2 = 360, i.e. a complete ellipse. The arc is drawn in the counterclockwise direction. Angles greater than or equal to 360, or smaller than 0, are represented by an equivalent angle in the range [0, 360), by taking the input value mod 360.
Other Parameters

**kwargs [Patch properties] Most Patch properties are supported as keyword arguments, with the exception of fill and facecolor because filling is not supported.

</tr>
</tbody>
</table>

draw(self, renderer)

Draw the arc to the given renderer.

Notes

Ellipses are normally drawn using an approximation that uses eight cubic Bezier splines. The error of this approximation is 1.89818e-6, according to this unverified source:

Lancaster, Don. *Approximating a Circle or an Ellipse Using Four Bezier Cubic Splines.*

There is a use case where very large ellipses must be drawn with very high accuracy,
and it is too expensive to render the entire ellipse with enough segments (either splines or line segments). Therefore, in the case where either radius of the ellipse is large enough that the error of the spline approximation will be visible (greater than one pixel offset from the ideal), a different technique is used.

In that case, only the visible parts of the ellipse are drawn, with each visible arc using a fixed number of spline segments (8). The algorithm proceeds as follows:

1. The points where the ellipse intersects the axes bounding box are located. (This is done by performing an inverse transformation on the axes bbox such that it is relative to the unit circle – this makes the intersection calculation much easier than doing rotated ellipse intersection directly).

This uses the “line intersecting a circle” algorithm from:

2. The angles of each of the intersection points are calculated.

3. Proceeding counterclockwise starting in the positive x-direction, each of the visible arc-segments between the pairs of vertices are drawn using the Bezier arc approximation technique implemented in `matplotlib.path.Path.arc()`.

Examples using `matplotlib.patches.Arc`

- sphx_glr_gallery_units_ellipse_with_units.py

`matplotlib.patches.Arrow`

class matplotlib.patches.Arrow(x, y, dx, dy, width=1.0, **kwargs)
Bases: matplotlib.patches.Patch

An arrow patch.

Draws an arrow from (x, y) to (x + dx, y + dy). The width of the arrow is scaled by width.

**Parameters**

- x [scalar] x coordinate of the arrow tail
- y [scalar] y coordinate of the arrow tail
- dx [scalar] Arrow length in the x direction
- dy [scalar] Arrow length in the y direction
- width [scalar, optional (default: 1)] Scale factor for the width of the arrow.
  With a default value of 1, the tail width is 0.2 and head width is 0.6.

**kwargs Keyword arguments control the Patch properties:

FancyArrow Patch that allows independent control of the head and tail properties

```python
def get_patch_transform(self)
    Return the Transform instance which takes patch coordinates to data coordinates.
    For example, one may define a patch of a circle which represents a radius of 5 by
    providing coordinates for a unit circle, and a transform which scales the coordinates
    (the patch coordinate) by 5.

def get_path(self)
    Return the path of this patch
```

- sphx_glr_gallery_shapes_and_collections_artist_reference.py

matplotlib.patches.ArrowStyle

```python
class matplotlib.patches.ArrowStyle
    Bases: matplotlib.patches._Style
```

17.34. matplotlib.patches 1637
ArrowStyle is a container class which defines several arrowstyle classes, which is used to create an arrow path along a given path. These are mainly used with FancyArrowPatch.

A arrowstyle object can be either created as:

```python
ArrowStyle.Fancy(head_length=.4, head_width=.4, tail_width=.4)
```

or:

```python
ArrowStyle("Fancy", head_length=.4, head_width=.4, tail_width=.4)
```

or:

```python
ArrowStyle("Fancy, head_length=.4, head_width=.4, tail_width=.4")
```

The following classes are defined

<table>
<thead>
<tr>

<td>widthA=1.0, angleA=None, widthB=1.0, angleB=None</td>
</tr>
</tbody>
</table>

An instance of any arrow style class is a callable object, whose call signature is:

```python
__call__(self, path, mutation_size, linewidth, aspect_ratio=1.)
```

and it returns a tuple of a Path instance and a boolean value. path is a Path instance along which the arrow will be drawn. mutation_size and aspect_ratio have the same meaning as in BoxStyle. linewidth is a line width to be stroked. This is meant to be used to correct the location of the head so that it does not overshoot the destination point, but not all classes support it.

return the instance of the subclass with the given style name.

```python
class BarAB(widthA=1.0, angleA=None, widthB=1.0, angleB=None)
```

Bases: matplotlib.patches._Bracket

An arrow with a bar(|) at both ends.

**Parameters**

- **widthA** [float, optional, default] Width of the bracket
angleA [float, optional, default] Angle between the bracket and the line
widthB [float, optional, default] Width of the bracket
angleB [float, optional, default] Angle between the bracket and the line

class BracketA(widthA=1.0, lengthA=0.2, angleA=None)
Bases: matplotlib.patches._Bracket

An arrow with a bracket(]) at its end.

Parameters

widthA [float, optional, default] Width of the bracket
lengthA [float, optional, default] Length of the bracket
angleA [float, optional, default] Angle between the bracket and the line

class BracketAB(widthA=1.0, lengthA=0.2, angleA=None, widthB=1.0, lengthB=0.2, angleB=None)
Bases: matplotlib.patches._Bracket

An arrow with a bracket(]) at both ends.

Parameters

widthA [float, optional, default] Width of the bracket
lengthA [float, optional, default] Length of the bracket
angleA [float, optional, default] Angle between the bracket and the line
widthB [float, optional, default] Width of the bracket
lengthB [float, optional, default] Length of the bracket
angleB [float, optional, default] Angle between the bracket and the line

class BracketB(widthB=1.0, lengthB=0.2, angleB=None)
Bases: matplotlib.patches._Bracket

An arrow with a bracket([) at its end.

Parameters

widthB [float, optional, default] Width of the bracket
lengthB [float, optional, default] Length of the bracket
angleB [float, optional, default] Angle between the bracket and the line

class Curve
Bases: matplotlib.patches._Curve

A simple curve without any arrow head.

class CurveA(head_length=0.4, head_width=0.2)
Bases: matplotlib.patches._Curve

An arrow with a head at its begin point.
Parameters

**head_length** [float, optional, default] Length of the arrow head

**head_width** [float, optional, default] Width of the arrow head

class CurveAB(head_length=0.4, head_width=0.2)
Bases: matplotlib.patches._Curve

An arrow with heads both at the begin and the end point.

Parameters

**head_length** [float, optional, default] Length of the arrow head

**head_width** [float, optional, default] Width of the arrow head

class CurveB(head_length=0.4, head_width=0.2)
Bases: matplotlib.patches._Curve

An arrow with a head at its end point.

Parameters

**head_length** [float, optional, default] Length of the arrow head

**head_width** [float, optional, default] Width of the arrow head

class CurveFilledA(head_length=0.4, head_width=0.2)
Bases: matplotlib.patches._Curve

An arrow with filled triangle head at the begin.

Parameters

**head_length** [float, optional, default] Length of the arrow head

**head_width** [float, optional, default] Width of the arrow head

class CurveFilledAB(head_length=0.4, head_width=0.2)
Bases: matplotlib.patches._Curve

An arrow with filled triangle heads at both ends.

Parameters

**head_length** [float, optional, default] Length of the arrow head

**head_width** [float, optional, default] Width of the arrow head

class CurveFilledB(head_length=0.4, head_width=0.2)
Bases: matplotlib.patches._Curve

An arrow with filled triangle head at the end.

Parameters

**head_length** [float, optional, default] Length of the arrow head

**head_width** [float, optional, default] Width of the arrow head

class Fancy(head_length=0.4, head_width=0.4, tail_width=0.4)
Bases: matplotlib.patches._Base

A fancy arrow. Only works with a quadratic Bezier curve.
**head_width** [float, optional, default] Width of the arrow head

**tail_width** [float, optional, default] Width of the arrow tail

transmute(self, path, mutation_size, linewidth)

The transmute method is the very core of the ArrowStyle class and must be overridden in the subclasses. It receives the path object along which the arrow will be drawn, and the mutation_size, with which the arrow head etc. will be scaled. The linewidth may be used to adjust the path so that it does not pass beyond the given points. It returns a tuple of a Path instance and a boolean. The boolean value indicate whether the path can be filled or not. The return value can also be a list of paths and list of booleans of a same length.

class Simple(head_length=0.5, head_width=0.5, tail_width=0.2)

Bases: matplotlib.patches._Base

A simple arrow. Only works with a quadratic Bezier curve.

**Parameters**

**head_length** [float, optional, default] Length of the arrow head

**head_width** [float, optional, default] Width of the arrow head

**tail_width** [float, optional, default] Width of the arrow tail

transmute(self, path, mutation_size, linewidth)

The transmute method is the very core of the ArrowStyle class and must be overridden in the subclasses. It receives the path object along which the arrow will be drawn, and the mutation_size, with which the arrow head etc. will be scaled. The linewidth may be used to adjust the path so that it does not pass beyond the given points. It returns a tuple of a Path instance and a boolean. The boolean value indicate whether the path can be filled or not. The return value can also be a list of paths and list of booleans of a same length.

class Wedge(tail_width=0.3, shrink_factor=0.5)

Bases: matplotlib.patches._Base

Wedge(?) shape. Only works with a quadratic Bezier curve. The begin point has a width of the tail_width and the end point has a width of 0. At the middle, the width is shrink_factor*tail_width.

**Parameters**

**tail_width** [float, optional, default] Width of the tail

**shrink_factor** [float, optional, default] Fraction of the arrow width at the middle point

transmute(self, path, mutation_size, linewidth)

The transmute method is the very core of the ArrowStyle class and must be overridden in the subclasses. It receives the path object along which the arrow will be drawn, and the mutation_size, with which the arrow head etc. will be scaled. The linewidth may be used to adjust the path so that it does not pass beyond the given points. It returns a tuple of a Path instance and a boolean. The boolean value indicate whether the path can be filled or not. The return value can also be a list of paths and list of booleans of a same length.
Examples using *matplotlib.patches.ArrowStyle*

- sphx_glr_gallery_pyplots_whats_new_98_4_fancy.py

### *matplotlib.patches.BoxStyle*

**class** `matplotlib.patches.BoxStyle`

**Bases:** `matplotlib.patches._Style`

*BoxStyle* is a container class which defines several boxstyle classes, which are used for `FancyBboxPatch`.

A style object can be created as:

```python
BoxStyle.Round(pad=0.2)
```

or:

```python
BoxStyle("Round", pad=0.2)
```

or:

```python
BoxStyle("Round, pad=0.2")
```

Following boxstyle classes are defined.

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circle</td>
<td>circle</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>DArrow</td>
<td>darrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>LArrow</td>
<td>larrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>RArrow</td>
<td>rarrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>Round</td>
<td>round</td>
<td>pad=0.3, rounding_size=None</td>
</tr>
<tr>
<td>Round4</td>
<td>round4</td>
<td>pad=0.3, rounding_size=None</td>
</tr>
<tr>
<td>Roundtooth</td>
<td>roundtooth</td>
<td>pad=0.3, tooth_size=None</td>
</tr>
<tr>
<td>Sawtooth</td>
<td>sawtooth</td>
<td>pad=0.3, tooth_size=None</td>
</tr>
<tr>
<td>Square</td>
<td>square</td>
<td>pad=0.3</td>
</tr>
</tbody>
</table>

An instance of any boxstyle class is a callable object, whose call signature is:

```python
__call__(self, x0, y0, width, height, mutation_size, aspect_ratio=1.)
```

and returns a `Path` instance. `x0, y0, width` and `height` specify the location and size of the box to be drawn. `mutation_size` determines the overall size of the mutation (by which I mean the transformation of the rectangle to the fancy box). `mutation_aspect` determines the aspect-ratio of the mutation.

return the instance of the subclass with the given style name.

**class** `Circle(pad=0.3)`

**Bases:** `matplotlib.patches._Base`

A simple circle box.

**Parameters**

- **pad** [float] The amount of padding around the original box.
The transmute method is a very core of the BboxTransmuter class and must be overridden in the subclasses. It receives the location and size of the rectangle, and the mutation_size, with which the amount of padding and etc. will be scaled. It returns a Path instance.

class DArrow(pad=0.3)
    Bases: matplotlib.patches._Base
    (Double) Arrow Box
    transmute(self, x0, y0, width, height, mutation_size)
    The transmute method is a very core of the BboxTransmuter class and must be overridden in the subclasses. It receives the location and size of the rectangle, and the mutation_size, with which the amount of padding and etc. will be scaled. It returns a Path instance.

class LArrow(pad=0.3)
    Bases: matplotlib.patches._Base
    (left) Arrow Box
    transmute(self, x0, y0, width, height, mutation_size)
    The transmute method is a very core of the BboxTransmuter class and must be overridden in the subclasses. It receives the location and size of the rectangle, and the mutation_size, with which the amount of padding and etc. will be scaled. It returns a Path instance.

class RArrow(pad=0.3)
    Bases: matplotlib.patches.LArrow
    (right) Arrow Box
    transmute(self, x0, y0, width, height, mutation_size)
    The transmute method is a very core of the BboxTransmuter class and must be overridden in the subclasses. It receives the location and size of the rectangle, and the mutation_size, with which the amount of padding and etc. will be scaled. It returns a Path instance.

class Round(pad=0.3, rounding_size=None)
    Bases: matplotlib.patches._Base
    A box with round corners.

    pad  amount of padding

    rounding_size  rounding radius of corners. pad if None
    transmute(self, x0, y0, width, height, mutation_size)
    The transmute method is a very core of the BboxTransmuter class and must be overridden in the subclasses. It receives the location and size of the rectangle, and the mutation_size, with which the amount of padding and etc. will be scaled. It returns a Path instance.

class Round4(pad=0.3, rounding_size=None)
    Bases: matplotlib.patches._Base
    Another box with round edges.

    pad  amount of padding

    rounding_size  rounding size of edges. pad if None
The transmute method is a very core of the BboxTransmuter class and must be overridden in the subclasses. It receives the location and size of the rectangle, and the mutation_size, with which the amount of padding and etc. will be scaled. It returns a Path instance.

class Roundtooth(
    pad=0.3, tooth_size=None
):
    Bases: matplotlib.patches.Sawtooth
    A rounded tooth box.

    pad  amount of padding

    tooth_size  size of the sawtooth. pad* if None

class Sawtooth(
    pad=0.3, tooth_size=None
):
    Bases: matplotlib.patches._Base
    A sawtooth box.

    pad  amount of padding

    tooth_size  size of the sawtooth. pad* if None

class Square(
    pad=0.3
):
    Bases: matplotlib.patches._Base
    A simple square box.

    pad  amount of padding

Examples using matplotlib.patches.BoxStyle

- sphx_glr_gallery_pyplots_whats_new_98_4_fancy.py
- sphx_glr_gallery_shapes_and_collections_artist_reference.py
- sphx_glr_gallery_shapes_and_collections_fancybox_demo.py
**Matplotlib, Release 3.1.1**

`matplotlib.patches.Circle`

```python
class matplotlib.patches.Circle(xy, radius=5, **kwargs)
    Bases: matplotlib.patches.Ellipse

A circle patch.

Create true circle at center \( xy = (x, y) \) with given \( radius \). Unlike `CirclePolygon` which is a polygonal approximation, this uses Bezier splines and is much closer to a scale-free circle.

Valid kwargs are:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg_filter</td>
<td>a filter function, which takes a ((m, n, 3)) float array and a dpi value, and returns a ((m, n, 3)) array</td>

Transformations Tutorial

matplotlib.patches.CirclePolygon

class matplotlib.patches.CirclePolygon(xy, radius=5, resolution=20, **kwargs)
    Bases: matplotlib.patches.RegularPolygon

    A polygon-approximation of a circle patch.

    Create a circle at \(xy = (x, y)\) with given \(radius\). This circle is approximated by a regular
    polygon with \(resolution\) sides. For a smoother circle drawn with splines, see Circle.

    Valid kwarg are:

    Property | Description
    --------------------
    agg_filter | a filter function, which takes a \((m, n, 3)\) float array and a dpi value, and returns a \((m, n, 3)\) array
    alpha | float or None
    animated | bool
    antialiased or aa | unknown
    capstyle | {'butt', 'round', 'projecting'}
    clip_box | Bbox

**matplotlib.patches.ConnectionPatch**

class matplotlib.patches.ConnectionPatch(xyA, xyB, coordsA, coordsB=None, axesA=None, axesB=None, arrowstyle='-', arrow_transmuter=None, connectionstyle='arc3', connector=None, patchA=None, patchB=None, shrinkA=0.0, shrinkB=0.0, mutation_scale=10.0, mutation_aspect=None, clip_on=False, dpi_cor=1.0, **kwargs)

Bases: matplotlib.patches.FancyArrowPatch

A ConnectionPatch class is to make connecting lines between two points (possibly in different axes).

Connect point xyA in coordsA with point xyB in coordsB

Valid keys are
<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arrowstyle</td>
<td>the arrow style</td>
</tr>
<tr>
<td>connectionstyle</td>
<td>the connection style</td>
</tr>
<tr>
<td>relpos</td>
<td>default is (0.5, 0.5)</td>
</tr>
<tr>
<td>patchA</td>
<td>default is bounding box of the text</td>
</tr>
<tr>
<td>patchB</td>
<td>default is None</td>
</tr>
<tr>
<td>shrinkA</td>
<td>default is 2 points</td>
</tr>
<tr>
<td>shrinkB</td>
<td>default is 2 points</td>
</tr>
<tr>
<td>mutation_scale</td>
<td>default is text size (in points)</td>
</tr>
<tr>
<td>mutation_aspect</td>
<td>default is 1.</td>
</tr>
<tr>
<td>?</td>
<td>any key for matplotlib.patches.PathPatch</td>
</tr>
</tbody>
</table>

coordsA and coordsB are strings that indicate the coordinates of xyA and xyB.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>’figure points’</td>
<td>points from the lower left corner of the figure</td>
</tr>
<tr>
<td>’figure pixels’</td>
<td>pixels from the lower left corner of the figure</td>
</tr>
<tr>
<td>’figure fraction’</td>
<td>0,0 is lower left of figure and 1,1 is upper, right</td>
</tr>
<tr>
<td>’axes points’</td>
<td>points from lower left corner of axes</td>
</tr>
<tr>
<td>’axes pixels’</td>
<td>pixels from lower left corner of axes</td>
</tr>
<tr>
<td>’axes fraction’</td>
<td>0,1 is lower left of axes and 1,1 is upper right</td>
</tr>
<tr>
<td>’data’</td>
<td>use the coordinate system of the object being annotated (default)</td>
</tr>
<tr>
<td>’offset points’</td>
<td>Specify an offset (in points) from the xy value</td>
</tr>
<tr>
<td>’polar’</td>
<td>you can specify theta, r for the annotation, even in cartesian plots. Note that if you are using a polar axes, you do not need to specify polar for the coordinate system since that is the native “data” coordinate system.</td>
</tr>
</tbody>
</table>

Alternatively they can be set to any valid Transform.

draw(self, renderer)
    Draw the Patch to the given renderer.

get_annotation_clip(self)
    Return annotation_clip attribute. See set_annotation_clip() for the meaning of return values.

get_path_in_displaycoord(self)
    Return the mutated path of the arrow in the display coord
set_annotation_clip(self, b)
set annotation clip attribute.

- **True**: the annotation will only be drawn when self.xy is inside the axes.
- **False**: the annotation will always be drawn regardless of its position.
- None: the self.xy will be checked only if xycoords is “data”

**Examples using matplotlib.patches.ConnectionPatch**

- sphx_glr_gallery_pie_and_polar_charts_bar_of_pie.py
- sphx_glr_gallery_userdemo_connect_simple01.py

**matplotlib.patches.ConnectionStyle**

class matplotlib.patches.ConnectionStyle
Bases: matplotlib.patches._Style

*ConnectionStyle* is a container class which defines several connectionstyle classes, which is used to create a path between two points. These are mainly used with *FancyArrowPatch*.

A connectionstyle object can be either created as:

```
ConnectionStyle.Arc3(rad=0.2)
```

or:

```
ConnectionStyle("Arc3", rad=0.2)
```

or:

```
ConnectionStyle("Arc3, rad=0.2")
```

The following classes are defined:

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Angle</td>
<td>angle</td>
<td>angleA=90, angleB=0, rad=0.0</td>
</tr>
<tr>
<td>Angle3</td>
<td>angle3</td>
<td>angleA=90, angleB=0</td>
</tr>
<tr>
<td>Arc</td>
<td>arc</td>
<td>angleA=0, angleB=0, armA=None, armB=None, rad=0.0</td>
</tr>
<tr>
<td>Arc3</td>
<td>arc3</td>
<td>rad=0.0</td>
</tr>
<tr>
<td>Bar</td>
<td>bar</td>
<td>armA=0.0, armB=0.0, fraction=0.3, angle=None</td>
</tr>
</tbody>
</table>

An instance of any connection style class is an callable object, whose call signature is:

```
__call__(self, posA, posB,
        patchA=None, patchB=None,
        shrinkA=2., shrinkB=2.)
```

and it returns a *Path* instance. *posA* and *posB* are tuples of x,y coordinates of the two points to be connected. *patchA* (or *patchB*) is given, the returned path is clipped so that it start (or end) from the boundary of the patch. The path is further shrunk by *shrinkA* (or *shrinkB*) which is given in points.
return the instance of the subclass with the given style name.

```python
class Angle(angleA=90, angleB=0, rad=0.0):
    Bases: matplotlib.patches._Base

    Creates a piecewise continuous quadratic Bezier path between two points. The path
    has a one passing-through point placed at the intersecting point of two lines which
    cross the start and end point, and have a slope of angleA and angleB, respectively.
    The connecting edges are rounded with rad.

    angleA  starting angle of the path
    angleB  ending angle of the path
    rad    rounding radius of the edge
```

```python
class Angle3(angleA=90, angleB=0):
    Bases: matplotlib.patches._Base

    Creates a simple quadratic Bezier curve between two points. The middle control
    points is placed at the intersecting point of two lines which cross the start and end
    point, and have a slope of angleA and angleB, respectively.

    angleA  starting angle of the path
    angleB  ending angle of the path
```

```python
class Arc(angleA=0, angleB=0, armA=None, armB=None, rad=0.0):
    Bases: matplotlib.patches._Base

    Creates a piecewise continuous quadratic Bezier path between two points. The path
    can have two passing-through points, a point placed at the distance of armA and
    angle of angleA from point A, another point with respect to point B. The edges are
    rounded with rad.

    angleA  : starting angle of the path
    angleB  : ending angle of the path
    armA    : length of the starting arm
    armB    : length of the ending arm
    rad     : rounding radius of the edges
```

```python
class Arc3(rad=0.0):
    Bases: matplotlib.patches._Base

    Creates a simple quadratic Bezier curve between two points. The curve is created
    so that the middle control point (C1) is located at the same distance from the start
    (C0) and end points(C2) and the distance of the C1 to the line connecting C0-C2 is
    rad times the distance of C0-C2.

    rad   curvature of the curve.
```

```python
class Bar(armA=0.0, armB=0.0, fraction=0.3, angle=None):
    Bases: matplotlib.patches._Base
A line with angle between A and B with armA and armB. One of the arms is extended so that they are connected in a right angle. The length of armA is determined by (armA + fraction x AB distance). Same for armB.

**Parameters**
- **armA** [float] minimum length of armA
- **armB** [float] minimum length of armB
- **fraction** [float] a fraction of the distance between two points that will be added to armA and armB.
- **angle** [float or None] angle of the connecting line (if None, parallel to A and B)

```python
class matplotlib.patches.Ellipse

matplotlib.patches.Ellipse(xy, width, height, angle=0, **kwargs)
Bases: matplotlib.patches.Patch

A scale-free ellipse.

**Parameters**
- **xy** [(float, float)] xy coordinates of ellipse centre.
- **width** [float] Total length (diameter) of horizontal axis.
- **height** [float] Total length (diameter) of vertical axis.
- **angle** [scalar, optional] Rotation in degrees anti-clockwise.

**Notes**

Valid keyword arguments are

<table>

</tbody>
</table>

center
Return the center of the ellipse

get_center(self)
Return the center of the ellipse

get_patch_transform(self)
Return the Transform instance which takes patch coordinates to data coordinates.
For example, one may define a patch of a circle which represents a radius of 5 by providing coordinates for a unit circle, and a transform which scales the coordinates (the patch coordinate) by 5.

get_path(self)
Return the vertices of the rectangle

set_center(self, xy)
Set the center of the ellipse.

Parameters

xy [(float, float)]

Examples using matplotlib.patches.Ellipse

- sphx_glr_gallery_statistics_confidence_ellipse.py
- sphx_glr_gallery_text_labels_and_annotations_annotation_demo.py
- sphx_glr_gallery_shapes_and_collections_artist_reference.py

- sphx_glr_gallery_userdemo_anchored_box03.py
matplotlib.patches.FancyArrow

class matplotlib.patches.FancyArrow(x, y, dx, dy, width=0.001, length_includes_head=False, head_width=None, head_length=None, shape='full', overhang=0, head_starts_at_zero=False, **kwargs)

Bases: matplotlib.patches.Polygon

Like Arrow, but lets you set head width and head height independently.

Constructor arguments

**width**: float (default: 0.001) width of full arrow tail

**length_includes_head**: bool (default: False) True if head is to be counted in calculating the length.

**head_width**: float or None (default: 3*width) total width of the full arrow head

**head_length**: float or None (default: 1.5 * head_width) length of arrow head

**shape**: ['full', 'left', 'right'] (default: 'full') draw the left-half, right-half, or full arrow

**overhang**: float (default: 0) fraction that the arrow is swept back (0 overhang means triangular shape). Can be negative or greater than one.

**head_starts_at_zero**: bool (default: False) if True, the head starts being drawn at coordinate 0 instead of ending at coordinate 0.

Other valid kwargs (inherited from Patch) are:

<table>

matplotlib.patches.FancyArrowPatch

class matplotlib.patches.FancyArrowPatch(posA=None, posB=None, path=None, arrowstyle='simple', arrow_transmuter=None, connectionstyle='arc3', connector=None, patchA=None, patchB=None, shrinkA=2, shrinkB=2, mutation_scale=1, mutation_aspect=None, dpi_cor=1, **kwargs)

Bases: matplotlib.patches.Patch

A fancy arrow patch. It draws an arrow using the ArrowStyle.

The head and tail positions are fixed at the specified start and end points of the arrow, but the size and shape (in display coordinates) of the arrow does not change when the axis is moved or zoomed.

If posA and posB are given, a path connecting two points is created according to connectionstyle. The path will be clipped with patchA and patchB and further shrunken by shrinkA and shrinkB. An arrow is drawn along this resulting path using the arrowstyle parameter.

Alternatively if path is provided, an arrow is drawn along this path and patchA, patchB, shrinkA, and shrinkB are ignored.

**Parameters**

- **posA, posB** [None, tuple, optional (default: None)] (x,y) coordinates of arrow tail and arrow head respectively.

- **path** [None, Path (default: None)] matplotlib.path.Path instance. If provided, an arrow is drawn along this path and patchA, patchB, shrinkA, and shrinkB are ignored.

- **arrowstyle** [str or ArrowStyle, optional (default: ‘simple’)]

  Describes how the fancy arrow will be drawn. It can be string of the available arrowstyle names, with optional comma-separated
attributes, or an \texttt{ArrowStyle} instance. The optional attributes are meant to be scaled with the \textit{mutation_scale}. The following arrow styles are available:

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Curve</td>
<td>-</td>

</tr>
</tbody>
</table>

\textbf{arrow\_transmuter} Ignored

\textbf{connectionstyle} \texttt{[str, ConnectionStyle, or None, optional]}

\textbf{(default: ‘arc3’)}

Describes how \textit{posA} and \textit{posB} are connected. It can be an instance of the \texttt{ConnectionStyle} class or a string of the connectionstyle name, with optional comma-separated attributes. The following connection styles are available:

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Angle</td>
<td>angle</td>
<td>angleA=90, angleB=0, rad=0.0</td>
</tr>
<tr>
<td>Angle3</td>
<td>angle3</td>
<td>angleA=90, angleB=0</td>
</tr>
<tr>
<td>Arc</td>
<td>arc</td>
<td>angleA=0, angleB=0, armA=None, armB=None, rad=0.0</td>
</tr>
<tr>
<td>Arc3</td>
<td>arc3</td>
<td>rad=0.0</td>
</tr>
<tr>
<td>Bar</td>
<td>bar</td>
<td>armA=0.0, armB=0.0, fraction=0.3, angle=None</td>
</tr>
</tbody>
</table>

\textbf{connector} Ignored

\textbf{patchA, patchB} \texttt{[None, Patch, optional (default: None)]} Head and tail patch respectively. \texttt{matplotlib\_patch.Patch} instance.
shrinkA, shrinkB [scalar, optional (default: 2)] Shrink factor of the tail and head of the arrow respectively

mutation_scale [scalar, optional (default: 1)] Value with which attributes of arrowstyle (e.g., head_length) will be scaled.

mutation_aspect [None, scalar, optional (default: None)] The height of the rectangle will be squeezed by this value before the mutation and the mutated box will be stretched by the inverse of it.

dpi.cor [scalar, optional (default: 1)] dpi.cor is currently used for linewidth-related things and shrink factor. Mutation scale is affected by this.

Notes

Valid kwargs are:

draw(self, renderer)
Draw the Patch to the given renderer.

get_arrowstyle(self)
Return the arrowstyle object.

get_connectionstyle(self)
Return the ConnectionStyle instance.

get_dpi_cor(self)

dpi_cor is currently used for linewidth-related things and shrink factor. Mutation scale is affected by this.

Returns

dpi_cor [scalar]

get_mutation_aspect(self)
Return the aspect ratio of the bbox mutation.

get_mutation_scale(self)
Return the mutation scale.

Returns

scale [scalar]

get_path(self)
Return the path of the arrow in the data coordinates. Use get_path_in_displaycoord() method to retrieve the arrow path in display coordinates.

get_path_in_displaycoord(self)
Return the mutated path of the arrow in display coordinates.

set_arrowstyle(self, arrowstyle=None, **kw)
Set the arrow style. Old attributes are forgotten. Without arguments (or with arrowstyle=None) returns available box styles as a list of strings.

Parameters

arrowstyle [None, ArrowStyle, str, optional (default: None)] Can be a string with arrowstyle name with optional comma-separated attributes, e.g.:

```python
set_arrowstyle("Fancy,head_length=0.2")
```

Alternatively attributes can be provided as keywords, e.g.:

```python
set_arrowstyle("fancy", head_length=0.2)
```

set_connectionstyle(self, connectionstyle, **kw)
Set the connection style. Old attributes are forgotten.

Parameters

connectionstyle [None, ConnectionStyle instance, or string] Can be a string with connectionstyle name with optional comma-separated attributes, e.g.:

```python
set_connectionstyle("arc,angleA=0,armA=30,rad=10")
```

Alternatively, the attributes can be provided as keywords, e.g.:
```python
set_connectionstyle("arc", angleA=0, armA=30, rad=10)
```

Without any arguments (or with `connectionstyle=None`), return available styles as a list of strings.

```python
set_dpi_cor(self, dpi_cor)

dpi_cor is currently used for linewidth-related things and shrink factor. Mutation scale is affected by this.

Parameters

dpi_cor [scalar]
```

```python
set_mutation_aspect(self, aspect)

Set the aspect ratio of the bbox mutation.

Parameters

aspect [scalar]
```

```python
set_mutation_scale(self, scale)

Set the mutation scale.

Parameters

scale [scalar]
```

```python
set_patchA(self, patchA)

Set the tail patch.

Parameters

```

```python
set_patchB(self, patchB)

Set the head patch.

Parameters

```

```python
set_positions(self, posA, posB)

Set the begin and end positions of the connecting path.

Parameters

posA, posB [None, tuple] (x,y) coordinates of arrow tail and arrow head respectively. If None use current value.
```

Examples using `matplotlib.patches.FancyArrowPatch`

- sphx_glr_gallery_shapes_and_collections_arrow_guide.py
- sphx_glr_gallery_userdemo_connectionstyle_demo.py

```python
matplotlib.patches.FancyBboxPatch
class matplotlib.patches.FancyBboxPatch(xy, width, height, boxstyle='round',
bbox_transmuter=None, mutation_scale=1.0,
mutation_aspect=None, **kwargs)

Bases: matplotlib.patches.Patch
```
A fancy box around a rectangle with lower left at \( xy = (x, y) \) with specified width and height.

`FancyBboxPatch` is similar to `Rectangle`, but it draws a fancy box around the rectangle. The transformation of the rectangle box to the fancy box is delegated to the `BoxTransmuterBase` and its derived classes.

**Parameters**

- `xy` [float, float] The lower left corner of the box.
- `width` [float] The width of the box.
- `height` [float] The height of the box.
- `boxstyle` [str or `matplotlib.patches.BoxStyle`]
  
  The style of the fancy box. This can either be a `BoxStyle` instance or a string of the style name and optionally comma separated attributes (e.g. “Round, pad=0.2”). This string is passed to `BoxStyle` to construct a `BoxStyle` object. See there for a full documentation.

The following box styles are available:

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circle</td>
<td>circle</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>DArrow</td>
<td>darrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>LArrow</td>
<td>larrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>RArrow</td>
<td>rarrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>Round</td>
<td>round</td>
<td>pad=0.3, rounding_size=None</td>
</tr>
<tr>
<td>Round4</td>
<td>round4</td>
<td>pad=0.3, rounding_size=None</td>
</tr>
<tr>
<td>Roundtooth</td>
<td>roundtooth</td>
<td>pad=0.3, tooth_size=None</td>
</tr>
<tr>
<td>Sawtooth</td>
<td>sawtooth</td>
<td>pad=0.3, tooth_size=None</td>
</tr>
<tr>
<td>Square</td>
<td>square</td>
<td>pad=0.3</td>
</tr>
</tbody>
</table>

- `mutation_scale` [float, optional, default: 1] Scaling factor applied to the attributes of the box style (e.g. pad or rounding_size).

- `mutation_aspect` [float, optional] The height of the rectangle will be squeezed by this value before the mutation and the mutated box will be stretched by the inverse of it. For example, this allows different horizontal and vertical padding.

**Other Parameters**

- `**kwargs` [Patch properties]

<table>

</tbody>
</table>

get_bbox(self)
Return the Bbox of the rectangle.

get_boxstyle(self)
Return the boxstyle object.

get_height(self)
Return the height of the rectangle.

get_mutation_aspect(self)
Return the aspect ratio of the bbox mutation.

get_mutation_scale(self)
Return the mutation scale.

get_path(self)
Return the mutated path of the rectangle.

get_width(self)
Return the width of the rectangle.

g_x(self)
Return the left coord of the rectangle.

g_y(self)
Return the bottom coord of the rectangle.

set_bounds(self, *args)
Set the bounds of the rectangle.
Call signatures:
**set_bounds** *(left, bottom, width, height)*

**Parameters**

- **left, bottom** [float] The coordinates of the bottom left corner of the rectangle.
- **width, height** [float] The width/height of the rectangle.

**set_boxstyle** *(self, boxstyle=None, **kw)*

Set the box style.

*boxstyle* can be a string with boxstyle name with optional comma-separated attributes. Alternatively, the attrs can be provided as keywords:

```python
set_boxstyle("round, pad=0.2")
set_boxstyle("round", pad=0.2)
```

Old attrs simply are forgotten.

Without argument (or with *boxstyle* = None), it returns available box styles.

The following boxstyles are available:

<table>
<thead>
<tr>
<th>Class</th>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Circle</td>
<td>circle</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>DArrow</td>
<td>darrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>LArrow</td>
<td>larrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>RArrow</td>
<td>rarrow</td>
<td>pad=0.3</td>
</tr>
<tr>
<td>Round</td>
<td>round</td>
<td>pad=0.3, rounding_size=None</td>
</tr>
<tr>
<td>Round4</td>
<td>round4</td>
<td>pad=0.3, rounding_size=None</td>
</tr>
<tr>
<td>Roundtooth</td>
<td>roundtooth</td>
<td>pad=0.3, tooth_size=None</td>
</tr>
<tr>
<td>Sawtooth</td>
<td>sawtooth</td>
<td>pad=0.3, tooth_size=None</td>
</tr>
<tr>
<td>Square</td>
<td>square</td>
<td>pad=0.3</td>
</tr>
</tbody>
</table>

**set_height** *(self, h)*

Set the rectangle height.

**Parameters**

- **h** [float]

**set_mutation_aspect** *(self, aspect)*

Set the aspect ratio of the bbox mutation.

**Parameters**

- **aspect** [float]

**set_mutation_scale** *(self, scale)*

Set the mutation scale.

**Parameters**

- **scale** [float]
set_width(self, w)
    Set the rectangle width.

    Parameters
    w [float]

set_x(self, x)
    Set the left coord of the rectangle.

    Parameters
    x [float]

set_y(self, y)
    Set the bottom coord of the rectangle.

    Parameters
    y [float]

Examples using matplotlib.patches.FancyBboxPatch

- sphx_glr_gallery_shapes_and_collections_artist_reference.py
- sphx_glr_gallery_shapes_and_collections_fancybox_demo.py

matplotlib.patches.Patch

class matplotlib.patches.Patch
    Description
    agg_filter a filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array
    alpha float or None
    animated bool
    antialiased or aa unknown
    capstyle {'butt', 'round', 'projecting'}
    clip_box Bbox

</tbody>
</table>

contains(self, mouseevent, radius=None)
Test whether the mouse event occurred in the patch.

Returns

(bool, empty dict)

contains_point(self, point, radius=None)
Returns True if the given point is inside the path (transformed with its transform attribute).

radius allows the path to be made slightly larger or smaller.

contains_points(self, points, radius=None)
Returns a bool array which is True if the (closed) path contains the corresponding point. (transformed with its transform attribute).

points must be Nx2 array. radius allows the path to be made slightly larger or smaller.

draw(self, renderer)
Draw the Patch to the given renderer.

fill
return whether fill is set

g_get_aas(self)
Alias for get_antialiased.

g_get_antialiased(self)
Returns True if the Patch is to be drawn with antialiasing.

g_get_capstyle(self)
Return the current capstyle.

g_get_data_transform(self)
Return the Transform instance which maps data coordinates to physical coordinates.

g_get_ec(self)
Alias for get_edgecolor.
get_edgecolor(self)
    Return the edge color of the Patch.

get_extents(self)
    Return a Bbox object defining the axis-aligned extents of the Patch.

get_facecolor(self)
    Return the face color of the Patch.

gf(self)
    Alias for get_facecolor.

gffill(self)
    return whether fill is set

gf_hatch(self)
    Return the current hatching pattern

gf_joinstyle(self)
    Return the current joinstyle

gf_linestyle(self)
    Return the linestyle.

gf linewidth(self)
    Return the line width in points.

gf ls(self)
    Alias for get_linestyle.

gf lw(self)
    Alias for get_linewidth.

gf patch_transform(self)
    Return the Transform instance which takes patch coordinates to data coordinates.
    For example, one may define a patch of a circle which represents a radius of 5 by
    providing coordinates for a unit circle, and a transform which scales the coordinates
    (the patch coordinate) by 5.

gf path(self)
    Return the path of this patch

gf transform(self)
    Return the Transform applied to the Patch.

gf verts(self)
    Return a copy of the vertices used in this patch
    If the patch contains Bezier curves, the curves will be interpolated by line segments.
    To access the curves as curves, use get_path().

gf window_extent(self, renderer=None)
    Get the axes bounding box in display space.
    The bounding box' width and height are nonnegative.
    Subclasses should override for inclusion in the bounding box “tight” calculation.
    Default is to return an empty bounding box at 0, 0.
    Be careful when using this function, the results will not update if the artist window
    extent of the artist changes. The extent can change due to any changes in the
    transform stack, such as changing the axes limits, the figure size, or the canvas.
used (as is done when saving a figure). This can lead to unexpected behavior where interactive figures will look fine on the screen, but will save incorrectly.

```python
set_aa(self, aa)
    Alias for set_antialiased.
```

```python
set_alpha(self, alpha)
    Set the alpha transparency of the patch.
```

**Parameters**

- **alpha** [float or None]

```python
set_antialiased(self, aa)
    Set whether to use antialiased rendering.
```

**Parameters**

- **b** [bool or None]

```python
set_capstyle(self, s)
    Set the patch capstyle
```

**Parameters**

- **s** [{'butt', 'round', 'projecting'}]

```python
set_color(self, c)
    Set both the edgecolor and the facecolor.
```

**Parameters**

- **c** [color]

**See also:**

- `Patch.set_facecolor`, `Patch.set_edgecolor` For setting the edge or face color individually.

```python
set_ec(self, color)
    Alias for set_edgecolor.
```

```python
set_edgecolor(self, color)
    Set the patch edge color.
```

**Parameters**

- **color** [color or None or ‘auto’]

```python
set_facecolor(self, color)
    Set the patch face color.
```

**Parameters**

- **color** [color or None]

```python
set_fc(self, color)
    Alias for set_facecolor.
```

```python
set_fill(self, b)
    Set whether to fill the patch.
```

**Parameters**

- **b** [bool]
set_hatch(self, hatch)
    Set the hatching pattern

    hatch can be one of:

    / - diagonal hatching
    \ - back diagonal
    | - vertical
    - - horizontal
    + - crossed
    x - crossed diagonal
    o - small circle
    O - large circle
    . - dots
    * - stars

    Letters can be combined, in which case all the specified hatchings are done. If same letter repeats, it increases the density of hatching of that pattern.

    Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

    Parameters

    hatch ["/{', '\\', '|', '+', 'x', 'o', 'O', '.', '*', '*'}"]

set_joinstyle(self, s)
    Set the patch joinstyle

    Parameters

    s ["miter", "round", "bevel"]

set_linestyle(self, ls)
    Set the patch linestyle.

    linestyle description
    "-" or 'solid' solid line
    "--" or 'dashed' dashed line
    "-.." or 'dashdot' dash-dotted line
    ':' or 'dotted' dotted line

    Alternatively a dash tuple of the following form can be provided:

    (offset, onoffseq),

    where onoffseq is an even length tuple of on and off ink in points.

    Parameters

    ls ["-', '+', ';', ';', ';', '.', (offset, on-off-seq), ...] The line style.

set_linewidth(self, w)
    Set the patch linewidth in points.

    Parameters

    w [float or None]

set_ls(self, ls)
    Alias for set_linestyle.
set_lw(self, w)
    Alias for set_linewidth.

update_from(self, other)
    Updates this Patch from the properties of other.

validCap = ('butt', 'round', 'projecting')
validJoin = ('miter', 'round', 'bevel')
zorder = 1

Examples using matplotlib.patches.Patch

* sphx_glr_gallery_text_labels_and_annotations_custom_legends.py
* Legend guide

matplotlib.patches.PathPatch

class matplotlib.patches.PathPatch(path, **kwargs)
    Bases: matplotlib.patches.Patch
    
    A general polycurve path patch.
    
    path is a matplotlib.path.Path object.

    Valid kwargs are:

    +-------------------------------------------------+-
    | Property        | Description                        |
    +-------------------------------------------------+-
    | agg_filter      | a filter function, which takes a  |
    |                 | (m, n, 3) float array and a dpi    |
    |                 | value, and returns a (m, n, 3)      |
    |                 | float array                         |
    | alpha           | float or None                       |
    | animated        | bool                                |
    | antialiased or  | unknown                            |
    | aa              |                                    |
    | capstyle        | {'butt', 'round', 'projecting'}    |
    | clip_box        | Bbox                               |
    | clip_on         | bool                               |
    | clip_path       | [(Path, Transform) | Patch | None]               |
    | color           | color                              |
    | contains        | callable                            |
    | edgecolor or ec | color or None or 'auto'            |
    | facecolor or fc | color or None                       |
    | figure          | Figure                             |
    | fill            | bool                               |
    | gid             | str                                |
    | hatch           | {'/', '\', '|', '-', '+', 'x', 'o', 'O', '.', '*'} |

matplotlib.patches.Polygon

```python
class matplotlib.patches.Polygon(xy, closed=True, **kwargs)
    Bases: matplotlib.patches.Patch
    A general polygon patch.
    xy is a numpy array with shape Nx2.
    If closed is True, the polygon will be closed so the starting and ending points are the same.
    Valid kwargs are:
```
<table>

</table>

get_closed(self)
Returns if the polygon is closed

Returns
closed [bool] If the path is closed

get_path(self)
Get the path of the polygon

Returns
path [Path] The Path object for the polygon

get_xy(self)
Get the vertices of the path.

Returns
vertices [(N, 2) numpy array] The coordinates of the vertices.

set_closed(self, closed)
Set if the polygon is closed
Parameters

closed [bool] True if the polygon is closed

**set_xy**(self, xy)
Set the vertices of the polygon.

Parameters

xy [(N, 2) array-like] The coordinates of the vertices.

xy The vertices of the path as (N, 2) numpy array.

Examples using matplotlib.patches.Polygon

- sphx_glr_gallery_statistics_boxplot_demo.py
- sphx_glr_gallery_shapes_and_collections_hatch_demo.py

- sphx_glr_gallery_event_handling_trifinder_event_demo.py

Annotations

matplotlib.patches.Rectangle

class matplotlib.patches.Rectangle(xy, width, height, angle=0.0, **kwargs)
    Bases: matplotlib.patches.Patch

    A rectangle with lower left at xy = (x, y) with specified width, height and rotation angle.

Parameters

xy [(float, float)] The bottom and left rectangle coordinates

width [float] Rectangle width

height [float] Rectangle height

angle [float, optional] rotation in degrees anti-clockwise about xy (default is 0.0)

fill [bool, optional] Whether to fill the rectangle (default is True)

</table>

get_bbox(self)
Return the height of the rectangle.

get_height(self)
Return the height of the rectangle.

get_patch_transform(self)
Return the Transform instance which takes patch coordinates to data coordinates.

For example, one may define a patch of a circle which represents a radius of 5 by providing coordinates for a unit circle, and a transform which scales the coordinates (the patch coordinate) by 5.

get_path(self)
Return the vertices of the rectangle.

get_width(self)
Return the width of the rectangle.

get_x(self)
Return the left coord of the rectangle.

get_xy(self)
Return the left and bottom coords of the rectangle.
get_y(self)
    Return the bottom coord of the rectangle.

set_bounds(self, *args)
    Set the bounds of the rectangle: l,b,w,h
    ACCEPTS: (left, bottom, width, height)

set_height(self, h)
    Set the height of the rectangle.

set_width(self, w)
    Set the width of the rectangle.

set_x(self, x)
    Set the left coord of the rectangle.

set_xy(self, xy)
    Set the left and bottom coords of the rectangle.

    Parameters
    
    xy (float, float)

set_y(self, y)
    Set the bottom coord of the rectangle.

xy
    Return the left and bottom coords of the rectangle.

matplotlib.patches.RegularPolygon

class matplotlib.patches.RegularPolygon(xy, numVertices, radius=5, orientation=0, **kwargs)
    Bases: matplotlib.patches.Patch
A regular polygon patch.
Constructor arguments:

**xy** A length 2 tuple \((x, y)\) of the center.

**numVertices** the number of vertices.

**radius** The distance from the center to each of the vertices.

**orientation** rotates the polygon (in radians).

Valid kwargs are:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg_filter</td>
<td>a filter function, which takes a ((m, n, 3)) float array and a dpi value, and returns a ((m, n, 3)) float array</td>

</tbody>
</table>

**get_patch_transform(self)**
Return the `Transform` instance which takes patch coordinates to data coordinates.

For example, one may define a patch of a circle which represents a radius of 5 by providing coordinates for a unit circle, and a transform which scales the coordinates (the patch coordinate) by 5.

**get_path(self)**
Return the path of this patch
Examples using `matplotlib.patches.RegularPolygon`

- sphx_glr_gallery_shapes_and_collections_artist_reference.py
- sphx_glr_gallery_specialty_plots_radar_chart.py

`matplotlib.patches.Shadow`

class `matplotlib.patches.Shadow(patch, ox, oy, props=None, **kwargs)`

Bases: `matplotlib.patches.Patch`

Create a shadow of the given `patch` offset by `ox, oy`. `props`, if not `None`, is a patch property update dictionary. If `None`, the shadow will have the same color as the face, but darkened.

`kwargs` are

<table>
<thead>
<tr>

</tbody>
</table>

```python
draw(self, renderer)
Draw the Patch to the given renderer.
```

```python
def get_patch_transform(self):
    Return the Transform instance which takes patch coordinates to data coordinates.
    For example, one may define a patch of a circle which represents a radius of 5 by
    providing coordinates for a unit circle, and a transform which scales the coordinates
    (the patch coordinate) by 5.
```

```python
def get_path(self):
    Return the path of this patch
```

Examples using `matplotlib.patches.Shadow`

- sphx_glr_gallery_text_labels_and_annotations_demo_text_path.py
- sphx_glr_gallery_misc_svg_filter_pie.py

`matplotlib.patches.Wedge`

```python
class matplotlib.patches.Wedge(center, r, theta1, theta2, width=None, **kwargs)
    Bases: matplotlib.patches.Patch
```

Wedge shaped patch.

A wedge centered at x, y center with radius r that sweeps theta1 to theta2 (in degrees). If width is given, then a partial wedge is drawn from inner radius r - width to outer radius r.

Valid kwargs are:

<table>
<thead>
<tr>
<th>Property</th>

- sphx_glr_gallery_shapes_and_collections_patch_collection.py

**matplotlib.patches.YAArrow**

class matplotlib.patches.YAArrow(**kwargs)
    Bases: matplotlib.patches.Patch

    [Deprecated] Yet another arrow class.

This is an arrow that is defined in display space and has a tip at x1, y1 and a base at x2, y2.
Notes

Deprecated since version 3.0.

get_patch_transform(self)
   Return the Transform instance which takes patch coordinates to data coordinates.
   For example, one may define a patch of a circle which represents a radius of 5 by
   providing coordinates for a unit circle, and a transform which scales the coordinates
   (the patch coordinate) by 5.

get_path(self)
   Return the path of this patch

getpoints(self, x1, y1, x2, y2, k)
   For line segment defined by (x1, y1) and (x2, y2) return the points on the line that
   is perpendicular to the line and intersects (x2, y2) and the distance from (x2, y2) of
   the returned points is k.

17.34.2 Functions

bbox_artist(artist, renderer[, props, fill])
   This is a debug function to draw a rectangle around the bounding box returned
   by get_window_extent() of an artist, to test whether the artist is returning the correct
   bbox.

   props is a dict of rectangle props with the additional property 'pad' that sets the padding
   around the bbox in points.

draw_bbox(bbox, renderer[, color, trans])
   This is a debug function to draw a rectangle around the bounding box returned
   by get_window_extent() of an artist, to test whether the artist is returning the correct
   bbox.

matplotlib.patches.bbox_artist

matplotlib.patches.bbox_artist(artist, renderer, props=None, fill=True)
   This is a debug function to draw a rectangle around the bounding box returned by
   get_window_extent() of an artist, to test whether the artist is returning the correct bbox.

   props is a dict of rectangle props with the additional property ‘pad’ that sets the padding
   around the bbox in points.

matplotlib.patches.draw_bbox

matplotlib.patches.draw_bbox(bbox, renderer, color='k', trans=None)
   This is a debug function to draw a rectangle around the bounding box returned by
   get_window_extent() of an artist, to test whether the artist is returning the correct bbox.

17.35 matplotlib.path

A module for dealing with the polylines used throughout Matplotlib.
The primary class for polyline handling in Matplotlib is Path. Almost all vector drawing makes use of Paths somewhere in the drawing pipeline.

Whilst a Path instance itself cannot be drawn, some Artist subclasses, such as PathPatch and PathCollection, can be used for convenient Path visualisation.

class matplotlib.path.Path(vertices, codes=None, interpolation_steps=1, closed=False, readonly=False)

Bases: object

Path represents a series of possibly disconnected, possibly closed, line and curve segments.

The underlying storage is made up of two parallel numpy arrays:

- vertices: an Nx2 float array of vertices
- codes: an N-length uint8 array of vertex types

These two arrays always have the same length in the first dimension. For example, to represent a cubic curve, you must provide three vertices as well as three codes CURVE3.

The code types are:

- STOP [1 vertex (ignored)] A marker for the end of the entire path (currently not required and ignored)
- MOVETO [1 vertex] Pick up the pen and move to the given vertex.
- LINETO [1 vertex] Draw a line from the current position to the given vertex.
- CURVE3 [1 control point, 1 endpoint] Draw a quadratic Bezier curve from the current position, with the given control point, to the given end point.
- CURVE4 [2 control points, 1 endpoint] Draw a cubic Bezier curve from the current position, with the given control points, to the given end point.
- CLOSEPOLY [1 vertex (ignored)] Draw a line segment to the start point of the current polyline.

Users of Path objects should not access the vertices and codes arrays directly. Instead, they should use iter_segments() or cleaned() to get the vertex/code pairs. This is important, since many Path objects, as an optimization, do not store a codes at all, but have a default one provided for them by iter_segments().

Some behavior of Path objects can be controlled by rcParams. See the rcParams whose keys contain 'path.'.

Note: The vertices and codes arrays should be treated as immutable - there are a number of optimizations and assumptions made up front in the constructor that will not change when the data changes.

Create a new path with the given vertices and codes.

Parameters

vertices [array_like] The (n, 2) float array, masked array or sequence of pairs representing the vertices of the path.

If vertices contains masked values, they will be converted to NaNs which are then handled correctly by the Agg PathIterator and other consumers of path data, such as iter_segments().
codes [{None, array_like}, optional] n-length array integers representing the codes of the path. If not None, codes must be the same length as vertices. If None, vertices will be treated as a series of line segments.

_interpolation_steps [int, optional] Used as a hint to certain projections, such as Polar, that this path should be linearly interpolated immediately before drawing. This attribute is primarily an implementation detail and is not intended for public use.

closed [bool, optional] If codes is None and closed is True, vertices will be treated as line segments of a closed polygon.

readonly [bool, optional] Makes the path behave in an immutable way and sets the vertices and codes as read-only arrays.

CLOSEPOLY = 79
CURVE3 = 3
CURVE4 = 4
LINETO = 2
MOVETO = 1

NUM_VERTICES_FOR_CODE = {0: 1, 1: 1, 2: 1, 3: 2, 4: 3, 79: 1}
A dictionary mapping Path codes to the number of vertices that the code expects.

STOP = 0

classmethod arc(theta1, theta2, n=None, is_wedge=False)
Return the unit circle arc from angles theta1 to theta2 (in degrees).

theta2 is unwrapped to produce the shortest arc within 360 degrees. That is, if theta2 > theta1 + 360, the arc will be from theta1 to theta2 - 360 and not a full circle plus some extra overlap.

If n is provided, it is the number of spline segments to make. If n is not provided, the number of spline segments is determined based on the delta between theta1 and theta2.

Masionobe, L. 2003. Drawing an elliptical arc using polylines, quadratic or cubic Bezier curves.

classmethod circle(center=(0.0, 0.0), radius=1.0, readonly=False)
Return a Path representing a circle of a given radius and center.

Parameters

center [pair of floats] The center of the circle. Default (0, 0).

radius [float] The radius of the circle. Default is 1.

readonly [bool] Whether the created path should have the “readonly” argument set when creating the Path instance.

Notes

The circle is approximated using 8 cubic Bezier curves, as described in

Lancaster, Don. Approximating a Circle or an Ellipse Using Four Bezier Cubic Splines.
cleaned(self, transform=None, remove_nans=False, clip=None, quantize=False, simplify=False, curves=False, stroke_width=1.0, snap=False, sketch=None)
Return a new Path with vertices and codes cleaned according to the parameters.

See also:
Path.iter_segments for details of the keyword arguments.

clip_to_bbox(self, bbox, inside=True)
Clip the path to the given bounding box.
The path must be made up of one or more closed polygons. This algorithm will not
behave correctly for unclosed paths.
If inside is True, clip to the inside of the box, otherwise to the outside of the box.

code_type
alias of numpy.uint8
codes
The list of codes in the Path as a 1-D numpy array. Each code is one of STOP, MOVETO,
LINETO, CURVE3, CURVE4 or CLOSEPOLY. For codes that correspond to more than one
vertex (CURVE3 and CURVE4), that code will be repeated so that the length of self.
vertices and self.codes is always the same.

contains_path(self, path, transform=None)
Returns whether this (closed) path completely contains the given path.
If transform is not None, the path will be transformed before performing the test.

contains_point(self, point, transform=None, radius=0.0)
Returns whether the (closed) path contains the given point.
If transform is not None, the path will be transformed before performing the test.
radius allows the path to be made slightly larger or smaller.

contains_points(self, points, transform=None, radius=0.0)
Returns a bool array which is True if the (closed) path contains the corresponding
point.
If transform is not None, the path will be transformed before performing the test.
radius allows the path to be made slightly larger or smaller.

copy(self)
Returns a shallow copy of the Path, which will share the vertices and codes with the
source Path.

deprecated(self, memo=None)
Returns a deep copy of the Path. The Path will not be readonly, even if the source
Path is.

get_extents(self, transform=None)
Returns the extents (xmin, ymin, xmax, ymax) of the path.
Unlike computing the extents on the vertices alone, this algorithm will take into
account the curves and deal with control points appropriately.

has_nonfinite
hatch(hatchpattern, density=6)

Given a hatch specifier, hatchpattern, generates a Path that can be used in a repeated hatching pattern. density is the number of lines per unit square.

interpolated(self, steps)

Returns a new path resampled to length N x steps. Does not currently handle interpolating curves.

intersects_bbox(self, bbox, filled=True)

Returns True if this path intersects a given Bbox.

density, when True, treats the path as if it was filled. That is, if the path completely encloses the bounding box, intersects_bbox() will return True.

The bounding box is always considered filled.

intersects_path(self, other, filled=True)

Returns True if this path intersects another given path.

filled = True, when True, treats the paths as if they were filled. That is, if one path completely encloses the other, intersects_path() will return True.

inter_segments(self, transform=None, remove_nans=True, clip=None, snap=False, stroke_width=1.0, simplify=None, curves=True, sketch=None)

Iterates over all of the curve segments in the path. Each iteration returns a 2-tuple (vertices, code), where vertices is a sequence of 1-3 coordinate pairs, and code is a Path code.

Additionally, this method can provide a number of standard cleanups and conversions to the path.

Parameters

transform [None or Transform] If not None, the given affine transformation will be applied to the path.

remove_nans [bool, optional] Whether to remove all NaNs from the path and skip over them using MOVETO commands.

clip [None or (float, float, float, float), optional] If not None, must be a four-tuple (x1, y1, x2, y2) defining a rectangle in which to clip the path.

snap [None or bool, optional] If True, snap all nodes to pixels; if False, don't snap them. If None, perform snapping if the path contains only segments parallel to the x or y axes, and no more than 1024 of them.

stroke_width [float, optional] The width of the stroke being drawn (used for path snapping).

simplify [None or bool, optional] Whether to simplify the path by removing vertices that do not affect its appearance. If None, use the should_simplify attribute. See also rcParams["path.simplify"] and rcParams["path.simplify_threshold"].

curves [bool, optional] If True, curve segments will be returned as curve segments. If False, all curves will be converted to line segments.

sketch [None or sequence, optional] If not None, must be a 3-tuple of the form (scale, length, randomness), representing the sketch...
class method make_compound_path(*args)
    Make a compound path from a list of Path objects.

class method make_compound_path_from_polys(XY)
    Make a compound path object to draw a number of polygons with equal numbers
    of sides XY is a (numpolys x numsides x 2) numpy array of vertices. Return object
    is a Path

readonly
    True if the Path is read-only.

should_simplify
    True if the vertices array should be simplified.

simplify_threshold
    The fraction of a pixel difference below which vertices will be simplified out.

to_polygons(self, transform=None, width=0, height=0, closed_only=True)
    Convert this path to a list of polygons or polylines. Each polygon/polyline is an
    N x 2 array of vertices. In other words, each polygon has no MOVETO instructions or
curves. This is useful for displaying in backends that do not support compound
paths or Bezier curves.

    If width and height are both non-zero then the lines will be simplified so that vertices
    outside of (0, 0), (width, height) will be clipped.

    If closed_only is True (default), only closed polygons, with the last point being the
    same as the first point, will be returned. Any unclosed polylines in the path will be
explicitly closed. If `closed_only` is `False`, any unclosed polygons in the path will be returned as unclosed polygons, and the closed polygons will be returned explicitly closed by setting the last point to the same as the first point.

```python
transformed(self, transform)

Return a transformed copy of the path.
```

See also:

- `matplotlib.transforms.TransformedPath` A specialized path class that will cache the transformed result and automatically update when the transform changes.

```python
classmethod unit_circle()

Return the readonly `Path` of the unit circle.

For most cases, `Path.circle()` will be what you want.
```

```python
classmethod unit_circle_righthalf()

Return a `Path` of the right half of a unit circle.

See `Path.circle` for the reference on the approximation used.
```

```python
classmethod unit_rectangle()

Return a `Path` instance of the unit rectangle from (0, 0) to (1, 1).
```

```python
classmethod unit_regular_asterisk(numVertices)

Return a `Path` for a unit regular asterisk with the given numVertices and radius of 1.0, centered at (0, 0).
```

```python
classmethod unit_regular_polygon(numVertices)

Return a `Path` instance for a unit regular polygon with the given `numVertices` and radius of 1.0, centered at (0, 0).
```

```python
classmethod unit_regular_star(numVertices, innerCircle=0.5)

Return a `Path` for a unit regular star with the given numVertices and radius of 1.0, centered at (0, 0).
```

`vertices`

The list of vertices in the `Path` as an Nx2 numpy array.

```python
classmethod wedge(theta1, theta2, n=None)

Return the unit circle wedge from angles `theta1` to `theta2` (in degrees).

`theta2` is unwrapped to produce the shortest wedge within 360 degrees. That is, if `theta2 > theta1 + 360`, the wedge will be from `theta1` to `theta2 - 360` and not a full circle plus some extra overlap.

If `n` is provided, it is the number of spline segments to make. If `n` is not provided, the number of spline segments is determined based on the delta between `theta1` and `theta2`.

See `Path.arc` for the reference on the approximation used.
```

```python
matplotlib.path.get_path_collection_extents(master_transform, paths, transforms, offsets, offset_transform)

Given a sequence of `Paths`, `Transforms` objects, and offsets, as found in a `PathCollection`, returns the bounding box that encapsulates all of them.
```

Parameters

paths [list of Path]
transform [list of Affine2D]
offsets [(N, 2) array-like]
offset_transform [Affine2D] Transform applied to the offsets before offsetting the path.

Notes
The way that paths, transforms and offsets are combined follows the same method as for collections: Each is iterated over independently, so if you have 3 paths, 2 transforms and 1 offset, their combinations are as follows:

(A, A, A), (B, B, A), (C, A, A)

matplotlib.path.get_paths_extents(paths, transforms=[])

[Deprecated] Given a sequence of Path objects and optional Transform objects, returns the bounding box that encapsulates all of them.
paths is a sequence of Path instances.
transforms is an optional sequence of Affine2D instances to apply to each path.

Notes
Deprecated since version 3.1.

17.36 matplotlib.path_effects
Defines classes for path effects. The path effects are supported in Text, Line2D and Patch.
class matplotlib.path_effects.AbstractPathEffect(offset=(0.0, 0.0))
    Bases: object
    A base class for path effects.
    Subclasses should override the draw_path method to add effect functionality.
    Parameters
    offset [pair of floats] The offset to apply to the path, measured in points.

draw_path(self, renderer, gc, tpath, affine, rgbFace=None)
    Derived should override this method. The arguments are the same as matplotlib.backend_bases.RendererBase.draw_path() except the first argument is a renderer.
class matplotlib.path_effects.Normal(offset=(0.0, 0.0))
    Bases: matplotlib.path_effects.AbstractPathEffect
    The “identity” PathEffect.
    The Normal PathEffect’s sole purpose is to draw the original artist with no special path effect.
    Parameters
    offset [pair of floats] The offset to apply to the path, measured in points.
class matplotlib.path_effects.PathEffectRenderer(path_effects, renderer)
    Bases: matplotlib.backend_bases.RendererBase

    Implements a Renderer which contains another renderer. This proxy then
    intercepts draw calls, calling the appropriate AbstractPathEffect draw
    method.

    **Note:** Not all methods have been overridden on this RendererBase subclass. It may be
    necessary to add further methods to extend the PathEffects capabilities further.

    **Parameters**

    - `path_effects` [iterable of AbstractPathEffect] The path effects which this
      renderer represents.
    - `renderer` [matplotlib.backend_bases.RendererBase instance]

    `copy_with_path_effect(self, path_effects)`

    `draw_markers(self, gc, marker_path, marker_trans, path, *args, **kwargs)`
    Draws a marker at each of the vertices in path. This includes all vertices, including
    control points on curves. To avoid that behavior, those vertices should be removed
    before calling this function.
    This provides a fallback implementation of `draw_markers` that makes multiple calls
    to `draw_path()`. Some backends may want to override this method in order to draw
    the marker only once and reuse it multiple times.

    **Parameters**

    - `gc` [GraphicsContextBase] The graphics context
    - `marker_trans` [matplotlib.transforms.Transform] An affine transform
      applied to the marker.
    - `trans` [matplotlib.transforms.Transform] An affine transform applied to
      the path.

    `draw_path(self, gc, tpath, affine, rgbFace=None)`
    Draws a `Path` instance using the given affine transform.

    `draw_path_collection(self, gc, master_transform, paths, *args, **kwargs)`
    Draws a collection of paths selecting drawing properties from the lists `facecolors`,
    `edgecolors`, `linewidths`, `linestyles` and `antialiaseds`. `offsets` is a list of offsets to apply
to each of the paths. The offsets in `offsets` are first transformed by `offsetTrans`
before being applied. `offset_position` may be either “screen” or “data” depending
on the space that the offsets are in.
    This provides a fallback implementation of `draw_path_collection()` that makes multi-
ple calls to `draw_path()`. Some backends may want to override this in order
to render each set of path data only once, and then reference that path multiple
times with the different offsets, colors, styles etc. The generator methods
`_iter_collection_raw_paths()` and `_iter_collection()` are provided to help with (and
standardize) the implementation across backends. It is highly recommended to use
those generators, so that changes to the behavior of `draw_path_collection()` can be
made globally.
new_gc(self)
    Return an instance of a GraphicsContextBase.

points_to_pixels(self, points)
    Convert points to display units.

    You need to override this function (unless your backend doesn’t have a dpi, e.g.,
    postscript or svg). Some imaging systems assume some value for pixels per inch:
    \[
    \text{points to pixels = points} \times \frac{\text{pixels per inch}}{72.0} \times \frac{\text{dpi}}{72.0}
    \]

    Parameters
      points [scalar or array_like] a float or a numpy array of float
    Returns
      Points converted to pixels

class matplotlib.path_effects.PathPatchEffect(offset=(0, 0), **kwargs)
    Bases: matplotlib.path_effects.AbstractPathEffect

    Draws a PathPatch instance whose Path comes from the original PathEffect artist.

    Parameters
      offset [pair of floats] The offset to apply to the path, in points.
      **kwargs All keyword arguments are passed through to the PathPatch
               constructor. The properties which cannot be overridden are “path”,
               “clip_box” “transform” and “clip_path”.

draw_path(self, renderer, gc, tpath, affine, rgbFace)
    Derived should override this method. The arguments are the same as matplotlib.
    backend_bases.RendererBase.draw_path() except the first argument is a renderer.

class matplotlib.path_effects.SimpleLineShadow(offset=(2, -2), shadow_color='k',
                                              alpha=0.3, rho=0.3, **kwargs)
    Bases: matplotlib.path_effects.AbstractPathEffect

    A simple shadow via a line.

    Parameters
      offset [pair of floats] The offset to apply to the path, in points.
      shadow_color [color] The shadow color. Default is black. A value of None
                       takes the original artist’s color with a scale factor of rho.
      alpha [float] The alpha transparency of the created shadow patch. De-
                   fault is 0.3.
      rho [float] A scale factor to apply to the rgbFace color if shadow_rgbFace is
                   None. Default is 0.3.
      **kwargs Extra keywords are stored and passed through to
               AbstractPathEffect._update_gc().

draw_path(self, renderer, gc, tpath, affine, rgbFace)
    Overrides the standard draw_path to add the shadow offset and necessary color
    changes for the shadow.
class matplotlib.patheffects.SimplePatchShadow(offset=(2, -2), shadow_rgbFace=None, alpha=None, rho=0.3, **kwargs)
Bases: matplotlib.patheffects(AbstractPathEffect

A simple shadow via a filled patch.

Parameters

offset [pair of floats] The offset of the shadow in points.

shadow_rgbFace [color] The shadow color.

alpha [float] The alpha transparency of the created shadow patch. Default is 0.3. http://matplotlib.1069221.n5.nabble.com/path-effects-question-td27630.html

rho [float] A scale factor to apply to the rgbFace color if shadow_rgbFace is not specified. Default is 0.3.

**kwargs Extra keywords are stored and passed through to AbstractPathEffect._update_gc().

draw_path(self, renderer, gc, tpath, affine, rgbFace)

Overrides the standard draw_path to add the shadow offset and necessary color changes for the shadow.

class matplotlib.patheffects.Stroke(offset=(0, 0), **kwargs)
Bases: matplotlib.patheffects.AbstractPathEffect

A line based PathEffect which re-draws a stroke.

The path will be stroked with its gc updated with the given keyword arguments, i.e., the keyword arguments should be valid gc parameter values.

draw_path(self, renderer, gc, tpath, affine, rgbFace)

draw the path with updated gc.

class matplotlib.patheffects.withSimplePatchShadow(offset=(2, -2), shadow_rgbFace=None, alpha=None, rho=0.3, **kwargs)
Bases: matplotlib.patheffects.SimplePatchShadow

Adds a simple SimplePatchShadow and then draws the original Artist to avoid needing to call Normal.

Parameters

offset [pair of floats] The offset of the shadow in points.

shadow_rgbFace [color] The shadow color.

alpha [float] The alpha transparency of the created shadow patch. Default is 0.3. http://matplotlib.1069221.n5.nabble.com/path-effects-question-td27630.html

rho [float] A scale factor to apply to the rgbFace color if shadow_rgbFace is not specified. Default is 0.3.

**kwargs Extra keywords are stored and passed through to AbstractPathEffect._update_gc().

draw_path(self, renderer, gc, tpath, affine, rgbFace)

Overrides the standard draw_path to add the shadow offset and necessary color changes for the shadow.
class matplotlib.pathEffects.withStroke(offset=(0, 0), **kwargs)

Bases: matplotlib.pathEffects.Stroke

Adds a simple Stroke and then draws the original Artist to avoid needing to call Normal. The path will be stroked with its gc updated with the given keyword arguments, i.e., the keyword arguments should be valid gc parameter values.

draw_path(self, renderer, gc, tpath, affine, rgbFace)
  draw the path with updated gc.

17.37 matplotlib.pyplot

17.37.1 Pyplot function overview

matplotlib.pyplot is a state-based interface to matplotlib.

matplotlib.pyplot is a state-based interface to matplotlib. It provides a MATLAB-like way of plotting.

pyplot is mainly intended for interactive plots and simple cases of programmatic plot generation:

```python
import numpy as np
import matplotlib.pyplot as plt

x = np.arange(0, 5, 0.1)
y = np.sin(x)
plt.plot(x, y)
```

The object-oriented API is recommended for more complex plots.

Functions

<table>
<thead>
<tr>
<th>matplotlib.pyplot function</th>

<tr>
<td><code>jet()</code></td>
<td>Set the colormap to “jet”.</td>
</tr>
<tr>
<td><code>legend(\*args, \*\*kwargs)</code></td>
<td>Place a legend on the axes.</td>
</tr>
<tr>
<td><code>locator_params([axis, tight])</code></td>
<td>Control behavior of major tick locators.</td>
</tr>
<tr>
<td><code>loglog(\*args, \*\*kwargs)</code></td>
<td>Make a plot with log scaling on both the x and y axis.</td>
</tr>
<tr>
<td><code>magma()</code></td>
<td>Set the colormap to “magma”.</td>
</tr>
<tr>
<td><code>magnitude_spectrum(x[, Fs, Fc, window, ...])</code></td>
<td>Plot the magnitude spectrum.</td>
</tr>
<tr>
<td><code>margins([margins[, x, y, tight]])</code></td>
<td>Set or retrieve autoscaling margins.</td>
</tr>
<tr>
<td><code>matshow(A[, fignum])</code></td>
<td>Display an array as a matrix in a new figure window.</td>
</tr>
<tr>
<td><code>minorticks_off()</code></td>
<td>Remove minor ticks from the axes.</td>
</tr>
<tr>
<td><code>minorticks_on()</code></td>
<td>Display minor ticks on the axes.</td>
</tr>
<tr>
<td><code>nipy_spectral()</code></td>
<td>Set the colormap to “nipy_spectral”.</td>
</tr>
<tr>
<td><code>pause(interval)</code></td>
<td>Pause for interval seconds.</td>
</tr>
<tr>
<td><code>pcolor(\*args[, alpha, norm, cmap, vmin, ...])</code></td>
<td>Create a pseudocolor plot with a non-regular rectangular grid.</td>
</tr>
<tr>
<td><code>pcolormesh(\*args[, alpha, norm, cmap, ...])</code></td>
<td>Create a pseudocolor plot with a non-regular rectangular grid.</td>
</tr>
<tr>
<td><code>phase_spectrum(x[, Fs, Fc, window, pad_to, ...])</code></td>
<td>Plot the phase spectrum.</td>
</tr>
<tr>
<td><code>pie(x[, explode, labels, colors, autopct, ...])</code></td>
<td>Plot a pie chart.</td>
</tr>
<tr>
<td><code>pink()</code></td>
<td>Set the colormap to “pink”.</td>
</tr>
<tr>
<td><code> plasma()</code></td>
<td>Set the colormap to “plasma”.</td>
</tr>
<tr>
<td><code>plot(\*args[, scalex, scaley, data])</code></td>

</tbody>
</table>

17.37. matplotlib.pyplot 1691
tight_layout([pad, h_pad, w_pad, rect])  Automatically adjust subplot parameters to
give specified padding.

title(label[, fontdict, loc, pad])  Set a title for the axes.

tricontour(*args, **kwargs)  Draw contours on an unstructured triangular grid.

tricontourf(*args, **kwargs)  Draw contours on an unstructured triangular grid.

tripcolor(*args[, alpha, norm, cmap, vmin, ...])  Create a pseudocolor plot of an unstructured triangular grid.

triplet(*args, **kwargs)  Draw a unstructured triangular grid as lines
and/or markers.

twinx([ax])  Make and return a second axes that shares
the x-axis.

twiny([ax])  Make and return a second axes that shares
the y-axis.

uninstall_repl_displayhook()  Uninstall the matplotlib display hook.

violinplot(dataset[, positions, vert, ...])  Make a violin plot.

viridis()  Set the colormap to “viridis”.

vlines(x, ymin, ymax[, colors, linestyles, ...])  Plot vertical lines.

waitforbuttonpress(*args, **kwargs)  Blocking call to interact with the figure.

winter()  Set the colormap to “winter”.

xcorr(x, y[, normed, detrend, usevlines, ...])  Plot the cross correlation between x and y.

xkcd([scale, length, randomness])  Turn on xkcd sketch-style drawing
mode. This will only have effect on things
drawn after this function is called.

xlabel(xlabel[, fontdict, labelpad])  Set the label for the x-axis.

xlim(*args, **kwargs)  Get or set the x limits of the current axes.

xscale(value, **kwargs)  Set the x-axis scale.

xticks([ticks, labels])  Get or set the current tick locations and labels
of the x-axis.

ylabel(ylabel[, fontdict, labelpad])  Set the label for the y-axis.

ylim(*args, **kwargs)  Get or set the y-limits of the current axes.

yscale(value, **kwargs)  Set the y-axis scale.

yticks([ticks, labels])  Get or set the current tick locations and labels
of the y-axis.

```
matplotlib.pyplot.acorr

matplotlib.pyplot.acorr(x, *, data=None, **kwargs)
Plot the autocorrelation of x.

Parameters

x [array-like]

detrend [callable, optional, default: mlab.detrend_none] x is detrended by
the detrend callable. This must be a function x = detrend(x) accepting
and returning an numpy.array. Default is no normalization.

normed [bool, optional, default: True] If True, input vectors are normal-
ised to unit length.

usevlines [bool, optional, default: True] Determines the plot style.
```
If True, vertical lines are plotted from 0 to the acorr value using Axes.vlines. Additionally, a horizontal line is plotted at y=0 using Axes.axhline.

If False, markers are plotted at the acorr values using Axes.plot.

**maxlags** [int, optional, default: 10] Number of lags to show. If None, will return all \(2 \times \text{len}(x) - 1\) lags.

**Returns**

- **lags** [array (length \(2 \times \text{maxlags} + 1\))] The lag vector.
- **c** [array (length \(2 \times \text{maxlags} + 1\))] The auto correlation vector.
- **line** [LineCollection or Line2D] *Artist* added to the axes of the correlation:
  - LineCollection if usevlines is True.
  - Line2D if usevlines is False.
- **b** [Line2D or None] Horizontal line at 0 if usevlines is True None usevlines is False.

**Other Parameters**

- **linestyle** [Line2D property, optional] The linestyle for plotting the data points. Only used if usevlines is False.
- **marker** [str, optional, default: ‘o’] The marker for plotting the data points. Only used if usevlines is False.

**Notes**

The cross correlation is performed with numpy.correlate() with mode = "full".

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

**Examples using matplotlib.pyplot.acorr**

- sphx_glr_gallery_lines_bars_and_markers_xcorr_acorr_demo.py

**matplotlib.pyplot.angle_spectrum**

**matplotlib.pyplot.angle_spectrum**(x, Fs=None, Fc=None, window=None, pad_to=None, sides=None, *, data=None, **kwargs)

Plot the angle spectrum.

Compute the angle spectrum (wrapped phase spectrum) of x. Data is padded to a length of pad_to and the windowing function window is applied to the signal.
Parameters

**x** [1-D array or sequence] Array or sequence containing the data.

**Fs** [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, *freqs*, in cycles per time unit. The default value is 2.

**window** [callable or ndarray] A function or a vector of length *NFFT*. To create window vectors see :func:`window_hanning`, :func:`window_none`, :func:`numpy.blackman`, :func:`numpy.hamming`, :func:`numpy.bartlett`, :func:`scipy.signal`, :func:`scipy.signal.get_window`, etc. The default is :func:`window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

**sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

**pad_to** [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the *n* parameter in the call to *fft()* The default is None, which sets *pad_to* equal to the length of the input signal (i.e. no padding).

**Fc** [int] The center frequency of *x* (defaults to 0), which offsets the *x* extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

Returns

**spectrum** [1-D array] The values for the angle spectrum in radians (real valued).

**freqs** [1-D array] The frequencies corresponding to the elements in *spectrum*.

**line** [a Line2D instance] The line created by this function.

Other Parameters

****kwargs** Keyword arguments control the Line2D properties:

See also:

magnitude_spectrum() angle_spectrum() plots the magnitudes of the corresponding frequencies.

phase_spectrum() phase_spectrum() plots the unwrapped version of this function.

specgram() specgram() can plot the angle spectrum of segments within the signal in a colormap.

Notes

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).
matplotlib.pyplot.annotate

Annotate the point \texttt{xy} with text \texttt{text}. In the simplest form, the text is placed at \texttt{xy}.

Optionally, the text can be displayed in another position \texttt{xytext}. An arrow pointing from the text to the annotated point \texttt{xy} can then be added by defining \texttt{arrowprops}.

**Parameters**

- \textbf{text} [str] The text of the annotation. \texttt{s} is a deprecated synonym for this parameter.
- \textbf{xy} [(float, float)] The point (x,y) to annotate.
- \textbf{xytext} [(float, float), optional] The position (x,y) to place the text at. If \texttt{None}, defaults to \texttt{xy}.
- \textbf{xycoords} [str, \textit{Artist}, \textit{Transform}, callable or tuple, optional] The coordinate system that \texttt{xy} is given in. The following types of values are supported:
  - One of the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'figure points'</td>
<td>Points from the lower left of the figure</td>
</tr>
<tr>
<td>'figure pixels'</td>
<td>Points from the lower left of the figure</td>
</tr>
<tr>
<td>'figure fraction'</td>
<td>Fraction of figure from lower left</td>
</tr>
<tr>
<td>'axes points'</td>
<td>Points from lower left corner of axes</td>
</tr>
<tr>
<td>'axes pixels'</td>
<td>Points from lower left corner of axes</td>
</tr>
<tr>
<td>'axes fraction'</td>
<td>Fraction of axes from lower left</td>
</tr>
<tr>
<td>'data'</td>
<td>Use the coordinate system of the object being annotated (default)</td>
</tr>
<tr>
<td>'polar'</td>
<td>(theta,r) if not native 'data' coordinates</td>
</tr>
</tbody>
</table>

- An \textit{Artist}: \texttt{xy} is interpreted as a fraction of the artists \textit{Bbox}. E.g. (0, 0) would be the lower left corner of the bounding box and (0.5, 1) would be the center top of the bounding box.
- A \textit{Transform} to transform \texttt{xy} to screen coordinates.
- A function with one of the following signatures:

```python
def transform(renderer) -> Bbox
def transform(renderer) -> Transform
```

where \textit{renderer} is a \textit{RendererBase} subclass.

The result of the function is interpreted like the \textit{Artist} and \textit{Transform} cases above.
- A tuple \((xcoords, ycoords)\) specifying separate coordinate systems for \(x\) and \(y\). \(xcoords\) and \(ycoords\) must each be of one of the above described types.

See Advanced Annotation for more details.

Defaults to ‘data’.

textcoords [str, Artist, Transform, callable or tuple, optional] The coordinate system that \(xytext\) is given in.

All \(xycoords\) values are valid as well as the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'offset points'</td>
<td>Offset (in points) from the (xy) value</td>
</tr>
<tr>
<td>'offset pixels'</td>
<td>Offset (in pixels) from the (xy) value</td>
</tr>
</tbody>
</table>

Defaults to the value of \(xycoords\), i.e. use the same coordinate system for annotation point and text position.

arrowprops [dict, optional] The properties used to draw a FancyArrowPatch arrow between the positions \(xy\) and \(xytext\).

If \(arrowprops\) does not contain the key ‘arrowstyle’ the allowed keys are:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>The width of the arrow in points</td>
</tr>
<tr>
<td>headwidth</td>
<td>The width of the base of the arrow head in points</td>
</tr>
<tr>
<td>headlength</td>
<td>The length of the arrow head in points</td>
</tr>
<tr>
<td>shrink</td>
<td>Fraction of total length to shrink from both ends</td>
</tr>
<tr>
<td>?</td>
<td>Any key to matplotlib.patches.FancyArrowPatch</td>
</tr>
</tbody>
</table>

If \(arrowprops\) contains the key ‘arrowstyle’ the above keys are forbidden. The allowed values of ‘arrowstyle’ are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-'</td>
<td>None</td>
</tr>
<tr>
<td>'-&gt;'</td>
<td>head_length=0.4,head_width=0.2</td>
</tr>
<tr>
<td>'-[]'</td>
<td>widthB=1.0,lengthB=0.2,angleB=None</td>
</tr>
<tr>
<td>'</td>
<td>-'</td>
</tr>
<tr>
<td>'-</td>
<td>&gt;'</td>
</tr>
<tr>
<td>'&lt;-'</td>
<td>head_length=0.4,head_width=0.2</td>
</tr>
<tr>
<td>'&lt;</td>
<td>-'</td>
</tr>
<tr>
<td>'&lt;</td>
<td>&gt;'</td>
</tr>
<tr>
<td>'fancy'</td>
<td>head_length=0.4,head_width=0.4,tail_width=0.4</td>
</tr>
<tr>
<td>'simple'</td>
<td>head_length=0.5,head_width=0.5,tail_width=0.2</td>
</tr>
<tr>
<td>'wedge'</td>
<td>tail_width=0.3,shrink_factor=0.5</td>
</tr>
</tbody>
</table>

Valid keys for FancyArrowPatch are:
<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arrowstyle</td>
<td>the arrow style</td>
</tr>
<tr>
<td>connectionstyle</td>
<td>the connection style</td>
</tr>
<tr>
<td>relpos</td>
<td>default is (0.5, 0.5)</td>
</tr>
<tr>
<td>patchA</td>
<td>default is bounding box of the text</td>
</tr>
<tr>
<td>patchB</td>
<td>default is None</td>
</tr>
<tr>
<td>shrinkA</td>
<td>default is 2 points</td>
</tr>
<tr>
<td>shrinkB</td>
<td>default is 2 points</td>
</tr>
<tr>
<td>mutation_scale</td>
<td>default is text size (in points)</td>
</tr>
<tr>
<td>mutation_aspect</td>
<td>default is 1.</td>
</tr>
<tr>
<td>?</td>
<td>any key for matplotlib.patches.PathPatch</td>
</tr>
</tbody>
</table>

Defaults to None, i.e. no arrow is drawn.

**annotation_clip** [bool or None, optional] Whether to draw the annotation when the annotation point xy is outside the axes area.

- If *True*, the annotation will only be drawn when xy is within the axes.
- If *False*, the annotation will always be drawn.
- If *None*, the annotation will only be drawn when xy is within the axes and xycoords is ‘data’.

Defaults to *None*.

**kwargs** Additional kwargs are passed to *Text*.

**Returns**

- **annotation** [*Annotation*]

**See also:**

*Advanced Annotation*

- *Pyplot tutorial*
matplotlib.pyplot.arrow

matplotlib.pyplot.arrow(x, y, dx, dy, **kwargs)
Add an arrow to the axes.
This draws an arrow from \((x, y)\) to \((x+dx, y+dy)\).

Parameters
\(x, y \ [\text{float}]\) The x and y coordinates of the arrow base.
\(dx, dy \ [\text{float}]\) The length of the arrow along x and y direction.

Returns
\(arrow \ [\text{FancyArrow}]\) The created \texttt{FancyArrow} object.

Other Parameters
**kwargs Optional kwargs (inherited from \texttt{FancyArrow} patch) control the arrow construction and properties:

Constructor arguments
\(width: \text{float (default: 0.001)}\) width of full arrow tail
\(\text{length includes head: bool (default: False)}\) True if head is to be counted in calculating the length.

\(\text{head width: float or None (default: 3*width)}\) total width of the full arrow head

\(\text{head length: float or None (default: 1.5 * head width)}\) length of arrow head

\(\text{shape: [‘full’, ‘left’, ‘right’] (default: ‘full’)}\) draw the left-half, right-half, or full arrow

\(\text{overhang: float (default: 0)}\) fraction that the arrow is swept back (0 overhang means triangular shape). Can be negative or greater than one.

\(\text{head starts at zero: bool (default: False)}\) if True, the head starts being drawn at coordinate 0 instead of ending at coordinate 0.

Other valid kwargs (inherited from \texttt{Patch}) are:

<table>

Notes

The resulting arrow is affected by the axes aspect ratio and limits. This may produce an arrow whose head is not square with its stem. To create an arrow whose head is square with its stem, use `annotate()` for example:

```python
>>> ax.annotate("", xy=(0.5, 0.5), xytext=(0, 0),
...     arrowprops=dict(arrowstyle="-"))
```

Examples using `matplotlib.pyplot.arrow`

- sphx_glr_gallery_text_labels_and_annotations_arrow_demo.py

`matplotlib.pyplot.autoscale`

`matplotlib.pyplot.autoscale(enable=True, axis='both', tight=None)`

Autoscale the axis view to the data (toggle).

Convenience method for simple axis view autoscaling. It turns autoscaling on or off, and then, if autoscaling for either axis is on, it performs the autoscaling on the specified axis or axes.

Parameters

- **enable** [bool or None, optional] True (default) turns autoscaling on, False turns it off. None leaves the autoscaling state unchanged.
- **axis** [\{‘both’, ‘x’, ‘y’\}, optional] which axis to operate on; default is ‘both’
- **tight** [bool or None, optional] If True, set view limits to data limits; if False, let the locator and margins expand the view limits; if None, use...
tight scaling if the only artist is an image, otherwise treat `tight` as False. The `tight` setting is retained for future autoscaling until it is explicitly changed.

```python
matplotlib.pyplot.autumn
```

Set the colormap to “autumn”.

This changes the default colormap as well as the colormap of the current image if there is one. See `help(colormaps)` for more information.

```python
matplotlib.pyplot.axes
```

Add an axes to the current figure and make it the current axes.

Call signatures:

```python
plt.axes()
plt.axes(rect, projection=None, polar=False, **kwargs)
plt.axes(ax)
```

**Parameters**

- `arg [{None, 4-tuple, Axes}]` The exact behavior of this function depends on the type:
  - `None`: A new full window axes is added using `subplot(111, **kwargs)`
  - 4-tuple of floats `rect = [left, bottom, width, height]`. A new axes is added with dimensions `rect` in normalized (0, 1) units using `add_axes` on the current figure.
  - `Axes`: This is equivalent to `pyplot.sca`. It sets the current axes to `arg`. Note: This implicitly changes the current figure to the parent of `arg`.

**Note:** The use of an `axes.Axes` as an argument is deprecated and will be removed in v3.0. Please use `pyplot.sca` instead.

- `projection [{None, 'aitoff', 'hammer', 'lambert', 'mollweide', 'polar', 'rectilinear', str}, optional]` The projection type of the `Axes`. `str` is the name of a costum projection, see `projections`. The default None results in a ‘rectilinear’ projection.

- `polar [boolean, optional]` If True, equivalent to `projection='polar'`.

- `sharex, sharey [Axes, optional]` Share the x or y axis with sharex and/or sharey. The axis will have the same limits, ticks, and scale as the axis of the shared axes.

- `label [str]` A label for the returned axes.
Returns

**axes** [Axes (or a subclass of Axes)] The returned axes class depends on the projection used. It is Axes if rectilinear projection are used and projections.polar.PolarAxes if polar projection are used.

Other Parameters

**kwargs** This method also takes the keyword arguments for the returned axes class. The keyword arguments for the rectilinear axes class Axes can be found in the following table but there might also be other keyword arguments if another projection is used, see the actual axes class.

- `Figure.add_subplot`
- `Figure.subplots`
- `pyplot.subplots`

Notes

If the figure already has a axes with key `(args, kwargs)` then it will simply make that axes current and return it. This behavior is deprecated. Meanwhile, if you do not want this behavior (i.e., you want to force the creation of a new axes), you must use a unique set of args and kwargs. The axes `label` attribute has been exposed for this purpose: if you want two axes that are otherwise identical to be added to the figure, make sure you give them unique labels.

Examples

```python
# Creating a new full window axes
plt.axes()

# Creating a new axes with specified dimensions and some kwargs
plt.axes((left, bottom, width, height), facecolor='w')
```

matplotlib.pyplot.axhline

matplotlib.pyplot.axhline(y=0, xmin=0, xmax=1, **kwargs)

Add a horizontal line across the axis.

**Parameters**

- **y** [scalar, optional, default: 0] y position in data coordinates of the horizontal line.
- **xmin** [scalar, optional, default: 0] Should be between 0 and 1, 0 being the far left of the plot, 1 the far right of the plot.
- **xmax** [scalar, optional, default: 1] Should be between 0 and 1, 0 being the far left of the plot, 1 the far right of the plot.

**Returns**

- **line** [Line2D]

**Other Parameters**

- ****kwargs** Valid kwargs are Line2D properties, with the exception of 'transform':

**See also:**

- `hlines` Add horizontal lines in data coordinates.
- `axhspan` Add a horizontal span (rectangle) across the axis.

**Examples**

- draw a thick red hline at `y` = 0 that spans the xrange:

  ```python
  >>> axhline(linewidth=4, color='r')
  ```

- draw a default hline at `y` = 1 that spans the xrange:

  ```python
  >>> axhline(y=1)
  ```

- draw a default hline at `y` = .5 that spans the middle half of the xrange:

  ```python
  >>> axhline(y=.5, xmin=0.25, xmax=0.75)
  ```

**Examples using matplotlib.pyplot.axhline**

- sphx_glr_gallery_subplots_axes_and_figures_axhspan_demo.py
matplotlib.pyplot.axhspan

matplotlib.pyplot.axhspan(ymin, ymax, xmin=0, xmax=1, **kwargs)

Add a horizontal span (rectangle) across the axis.

Draw a horizontal span (rectangle) from $y_{min}$ to $y_{max}$. With the default values of $x_{min}$ = 0 and $x_{max}$ = 1, this always spans the xrange, regardless of the xlim settings, even if you change them, e.g., with the set_xlim() command. That is, the horizontal extent is in axes coords: 0=left, 0.5=middle, 1.0=right but the $y$ location is in data coordinates.

Parameters

- **ymin** [float] Lower limit of the horizontal span in data units.
- **ymax** [float] Upper limit of the horizontal span in data units.
- **xmin** [float, optional, default: 0] Lower limit of the vertical span in axes (relative 0-1) units.
- **xmax** [float, optional, default: 1] Upper limit of the vertical span in axes (relative 0-1) units.

Returns

- **Polygon** [Polygon]

Other Parameters

- ****kwargs [Polygon properties.]

**See also:**

`axvspan` Add a vertical span across the axes.

**Examples using** matplotlib.pyplot.axhspan

- sphx_glur_gallery_subplots_axes_and_figures_axhspan_demo.py

**matplotlib.pyplot.axis**

`matplotlib.pyplot.axis(*args, **kwargs)`

Convenience method to get or set some axis properties.

Call signatures:

```
xmin, xmax, ymin, ymax = axis()
xmin, xmax, ymin, ymax = axis([xmin, xmax, ymin, ymax])
xmin, xmax, ymin, ymax = axis(option)
xmin, xmax, ymin, ymax = axis(**kwargs)
```

**Parameters**

- `xmin, xmax, ymin, ymax` [float, optional] The axis limits to be set. Either none or all of the limits must be given. This can also be achieved using

```
ax.set(xlim=(xmin, xmax), ylim=(ymin, ymax))
```

- `option` [bool or str] If a bool, turns axis lines and labels on or off. If a string, possible values are:
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'on'</td>
<td>Turn on axis lines and labels. Same as True.</td>
</tr>
<tr>
<td>'off'</td>
<td>Turn off axis lines and labels. Same as False.</td>
</tr>
<tr>
<td>'equal'</td>
<td>Set equal scaling (i.e., make circles circular) by changing axis limits.</td>
</tr>
<tr>
<td>'scaled'</td>
<td>Set equal scaling (i.e., make circles circular) by changing dimensions of the plot box.</td>
</tr>
<tr>
<td>'tight'</td>
<td>Set limits just large enough to show all data.</td>
</tr>
<tr>
<td>'auto'</td>
<td>Automatic scaling (fill plot box with data).</td>
</tr>
<tr>
<td>'normal'</td>
<td>Same as 'auto'; deprecated.</td>
</tr>
<tr>
<td>'image'</td>
<td>'scaled' with axis limits equal to data limits.</td>
</tr>
<tr>
<td>'square'</td>
<td>Square plot; similar to 'scaled', but initially forcing xmax-xmin = ymax-ymin.</td>
</tr>
</tbody>
</table>

**emit** [bool, optional, default True] Whether observers are notified of the axis limit change. This option is passed on to `set_xlim` and `set_ylim`.

**Returns**

- **xmin, xmax, ymin, ymax** [float] The axis limits.

**See also:**

- `matplotlib.axes.Axes.set_xlim`
- `matplotlib.axes.Axes.set_ylim`

**Examples using matplotlib.pyplot.axis**

- sphx_glr_gallery_lines_bars_and_markers_fill.py
- sphx_glr_gallery_text_labels_and_annotations_autowrap.py
- sphx_glr_gallery_text_labels_and_annotations_text_alignment.py
- sphx_glr_gallery_shapes_and_collections_artist_reference.py
- Pyplot tutorial

**matplotlib.pyplot.axvline**

- `matplotlib.pyplot.axvline(x=0, ymin=0, ymax=1, **kwargs)`
  Add a vertical line across the axes.

**Parameters**

- **x** [scalar, optional, default: 0] x position in data coordinates of the vertical line.
- **ymin** [scalar, optional, default: 0] Should be between 0 and 1, 0 being the bottom of the plot, 1 the top of the plot.
- **ymax** [scalar, optional, default: 1] Should be between 0 and 1, 0 being the bottom of the plot, 1 the top of the plot.
**Returns**

`line` [Line2D]

**Other Parameters**

**kwargs  **Valid kwargs are `Line2D` properties, with the exception of ‘transform’:

**See also:**
vlines Add vertical lines in data coordinates.
axvspan Add a vertical span (rectangle) across the axis.

Examples

• draw a thick red vline at $x = 0$ that spans the yrange:

```python
>>> axvline(linewidth=4, color='r')
```

• draw a default vline at $x = 1$ that spans the yrange:

```python
>>> axvline(x=1)
```

• draw a default vline at $x = .5$ that spans the middle half of the yrange:

```python
>>> axvline(x=.5, ymin=0.25, ymax=0.75)
```

Examples using matplotlib.pyplot.axvline

• sphx_glr_gallery_subplots_axes_and_figures_axhspan_demo.py
• sphx_glr_gallery_color_color_cycle_default.py

matplotlib.pyplot.axvspan

```python
matplotlib.pyplot.axvspan(xmin, xmax, ymin=0, ymax=1, **kwargs)
```

Add a vertical span (rectangle) across the axes.

Draw a vertical span (rectangle) from $x_{\text{min}}$ to $x_{\text{max}}$. With the default values of $y_{\text{min}} = 0$ and $y_{\text{max}} = 1$. This always spans the yrange, regardless of the ylim settings, even if you change them, e.g., with the `set_ylim()` command. That is, the vertical extent is in axes coords: 0=bottom, 0.5=middle, 1.0=top but the x location is in data coordinates.

Parameters

- `xmin` [scalar] Number indicating the first X-axis coordinate of the vertical span rectangle in data units.
- `xmax` [scalar] Number indicating the second X-axis coordinate of the vertical span rectangle in data units.
- `ymin` [scalar, optional] Number indicating the first Y-axis coordinate of the vertical span rectangle in relative Y-axis units (0-1). Default to 0.
- `ymax` [scalar, optional] Number indicating the second Y-axis coordinate of the vertical span rectangle in relative Y-axis units (0-1). Default to 1.

Returns

- `rectangle` [matplotlib.patches.Polygon] Vertical span (rectangle) from $(x_{\text{min}}, y_{\text{min}})$ to $(x_{\text{max}}, y_{\text{max}})$.

Other Parameters
**kwargs Optional parameters are properties of the class matplotlib.patches.Polygon.

See also:

axhspan Add a horizontal span across the axes.

Examples

Draw a vertical, green, translucent rectangle from x = 1.25 to x = 1.55 that spans the yrange of the axes.

```python
>>> axvspan(1.25, 1.55, facecolor='g', alpha=0.5)
```

Examples using matplotlib.pyplot.axvspan

- sphx_glr_gallery_subplots_axes_and_figures_axhspan_demo.py

matplotlib.pyplot.bar

```python
matplotlib.pyplot.bar(x, height, width=0.8, bottom=None, *, align='center', data=None, **kwargs)
```

Make a bar plot.

The bars are positioned at x with the given alignment. Their dimensions are given by width and height. The vertical baseline is bottom (default 0).

Each of x, height, width, and bottom may either be a scalar applying to all bars, or it may be a sequence of length N providing a separate value for each bar.

Parameters

- x [sequence of scalars] The x coordinates of the bars. See also align for the alignment of the bars to the coordinates.
- height [scalar or sequence of scalars] The height(s) of the bars.
- width [scalar or array-like, optional] The width(s) of the bars (default: 0.8).
- bottom [scalar or array-like, optional] The y coordinate(s) of the bars bases (default: 0).
- align [{’center’, ’edge’}, optional, default: ’center’] Alignment of the bars to the x coordinates:
  - ’center’: Center the base on the x positions.
  - ’edge’: Align the left edges of the bars with the x positions.

To align the bars on the right edge pass a negative width and align=’edge’.

Returns

- container [BarContainer] Container with all the bars and optionally error-bars.
Other Parameters

**color** [scalar or array-like, optional] The colors of the bar faces.

**edgecolor** [scalar or array-like, optional] The colors of the bar edges.

**linewidth** [scalar or array-like, optional] Width of the bar edge(s). If 0, don’t draw edges.

**tick_label** [string or array-like, optional] The tick labels of the bars. Default: None (Use default numeric labels.)

**xerr, yerr** [scalar or array-like of shape(N,) or shape(2,N), optional] If not None, add horizontal / vertical errorbars to the bar tips. The values are +/- sizes relative to the data:

- scalar: symmetric +/- values for all bars
- shape(N,): symmetric +/- values for each bar
- shape(2,N): Separate - and + values for each bar. First row contains the lower errors, the second row contains the upper errors.
- None: No errorbar. (Default)

See /gallery/statistics/errorbar_features for an example on the usage of xerr and yerr.

**ecolor** [scalar or array-like, optional, default: ‘black’] The line color of the errorbars.

**capsize** [scalar, optional] The length of the error bar caps in points. Default: None, which will take the value from rcParams["errorbar.capsize"].

**error_kw** [dict, optional] Dictionary of kwargs to be passed to the errorbar method. Values of ecolor or capsize defined here take precedence over the independent kwargs.

**log** [bool, optional, default: False] If True, set the y-axis to be log scale.

**orientation** [{‘vertical’, ‘horizontal’}, optional] This is for internal use only. Please use barh for horizontal bar plots. Default: ‘vertical’.

See also:

barh Plot a horizontal bar plot.

Notes

The optional arguments color, edgecolor, linewidth, xerr, and yerr can be either scalars or sequences of length equal to the number of bars. This enables you to use bar as the basis for stacked bar charts, or candlestick plots. Detail: xerr and yerr are passed directly to errorbar(), so they can also have shape 2xN for independent specification of lower and upper errors.

Other optional kwargs:

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

**Examples using matplotlib.pyplot.bar**

- sphx_glr_gallery_lines_bars_and_markers_bar_stacked.py
- sphx_glr_gallery_lines_bars_and_markers_barchart.py
- sphx_glr_gallery_statistics_barchart_demo.py
- sphx_glr_gallery_pie_and_polar_charts_nested_pie.py
matplotlib.pyplot.barbs

matplotlib.pyplot.barbs(*args, data=None, **kw)
Plot a 2D field of barbs.

Call signature:

```python
barbs([X, Y], U, V, [C], **kw)
```

Where X, Y define the barb locations, U, V define the barb directions, and C optionally sets the color.

All arguments may be 1D or 2D. U, V, C may be masked arrays, but masked X, Y are not supported at present.

Barbs are traditionally used in meteorology as a way to plot the speed and direction of wind observations, but can technically be used to plot any two dimensional vector quantity. As opposed to arrows, which give vector magnitude by the length of the arrow, the barbs give more quantitative information about the vector magnitude by putting slanted lines or a triangle for various increments in magnitude, as show schematically below:

```
\/:    /\    / \   /  \  /    \       \
`/:   `/:  `/: `/:  `/: `/: `/: `/: `/: `:  
```

The largest increment is given by a triangle (or “flag”). After those come full lines (barbs). The smallest increment is a half line. There is only, of course, ever at most 1 half line. If the magnitude is small and only needs a single half-line and no full lines or triangles, the half-line is offset from the end of the barb so that it can be easily distinguished from barbs with a single full line. The magnitude for the barb shown above would nominally be 65, using the standard increments of 50, 10, and 5.

See also https://en.wikipedia.org/wiki/Wind_barb.

**Parameters**

- **X, Y** [1D or 2D array-like, optional] The x and y coordinates of the barb locations. See pivot for how the barbs are drawn to the x, y positions.
  
  If not given, they will be generated as a uniform integer meshgrid based on the dimensions of U and V.

  If X and Y are 1D but U, V are 2D, X, Y are expanded to 2D using x, y = np.meshgrid(X, Y). In this case len(X) and len(Y) must match the column and row dimensions of U and V.

- **U, V** [1D or 2D array-like] The x and y components of the barb shaft.
C [1D or 2D array-like, optional] Numeric data that defines the barb colors by colormapping via \texttt{norm} and \texttt{cmap}.

This does not support explicit colors. If you want to set colors directly, use \texttt{barbcolor} instead.

length [float, default: 7] Length of the barb in points; the other parts of the barb are scaled against this.

pivot [{‘tip’, ‘middle’} or float, default: ‘tip’] The part of the arrow that is anchored to the X, Y grid. The barb rotates about this point. This can also be a number, which shifts the start of the barb that many points away from grid point.

barbcolor [color or color sequence] Specifies the color of all parts of the barb except for the flags. This parameter is analogous to the \texttt{edgecolor} parameter for polygons, which can be used instead. However this parameter will override facecolor.

flagcolor [color or color sequence] Specifies the color of any flags on the barb. This parameter is analogous to the \texttt{facecolor} parameter for polygons, which can be used instead. However, this parameter will override facecolor. If this is not set (and C has not either) then \texttt{flagcolor} will be set to match \texttt{barbcolor} so that the barb has a uniform color. If \texttt{C} has been set, \texttt{flagcolor} has no effect.

sizes [dict, optional] A dictionary of coefficients specifying the ratio of a given feature to the length of the barb. Only those values one wishes to override need to be included. These features include:

- ‘spacing’ - space between features (flags, full/half barbs)
- ‘height’ - height (distance from shaft to top) of a flag or full barb
- ‘width’ - width of a flag, twice the width of a full barb
- ‘emptybarb’ - radius of the circle used for low magnitudes

fill_empty [bool, default: False] Whether the empty bars (circles) that are drawn should be filled with the flag color. If they are not filled, the center is transparent.

rounding [bool, default: True] Whether the vector magnitude should be rounded when allocating barb components. If True, the magnitude is rounded to the nearest multiple of the half-barb increment. If False, the magnitude is simply truncated to the next lowest multiple.

barb_increments [dict, optional] A dictionary of increments specifying values to associate with different parts of the barb. Only those values one wishes to override need to be included.

- ‘half’ - half barbs (Default is 5)
- ‘full’ - full barbs (Default is 10)
- ‘flag’ - flags (default is 50)

flip_barb [bool or array-like of bool, default: False] Whether the lines and flags should point opposite to normal. Normal behavior is for the barbs and lines to point right (comes from wind barbs having these features point towards low pressure in the Northern Hemisphere).
A single value is applied to all barbs. Individual barbs can be flipped by passing a bool array of the same size as $U$ and $V$.

**Returns**

barbs [Barbs]

**Other Parameters**

**kwargs The barbs can further be customized using `PolyCollection` keyword arguments:

</table>

**Notes**
Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.pyplot.barbs

- sphx_glr_gallery_images_contours_and_fields_barb Demo of barbs

matplotlib.pyplot.barh

matplotlib.pyplot.barh(y, width, height=0.8, left=None, *, align='center', **kwargs)

Make a horizontal bar plot.

The bars are positioned at y with the given alignment. Their dimensions are given by width and height. The horizontal baseline is left (default 0).

Each of y, width, height, and left may either be a scalar applying to all bars, or it may be a sequence of length N providing a separate value for each bar.

Parameters

- y [scalar or array-like] The y coordinates of the bars. See also align for the alignment of the bars to the coordinates.
- width [scalar or array-like] The width(s) of the bars.
- height [sequence of scalars, optional, default: 0.8] The heights of the bars.
- left [sequence of scalars] The x coordinates of the left sides of the bars (default: 0).
- align [{‘center’, ‘edge’}, optional, default: ‘center’] Alignment of the base to the y coordinates:
  - ‘center’: Center the bars on the y positions.
  - ‘edge’: Align the bottom edges of the bars with the y positions.

To align the bars on the top edge pass a negative height and align='edge'.

Returns

- container [BarContainer] Container with all the bars and optionally error-bars.

Other Parameters

- color [scalar or array-like, optional] The colors of the bar faces.
- edgecolor [scalar or array-like, optional] The colors of the bar edges.
**linewidth** [scalar or array-like, optional] Width of the bar edge(s). If 0, don’t draw edges.

**tick_label** [string or array-like, optional] The tick labels of the bars. Default: None (Use default numeric labels.)

**xerr, yerr** [scalar or array-like of shape(N,) or shape(2,N), optional] If not None, add horizontal / vertical errorbars to the bar tips. The values are +/- sizes relative to the data:

- scalar: symmetric +/- values for all bars
- shape(N,): symmetric +/- values for each bar

- **shape(2,N): Separate - and + values for each bar. First row** contains the lower errors, the second row contains the upper errors.
- **None**: No errorbar. (default)

See /gallery/statistics/errorbar_features for an example on the usage of xerr and yerr.

**ecolor** [scalar or array-like, optional, default: ‘black’] The line color of the errorbars.

**capsize** [scalar, optional] The length of the error bar caps in points. Default: None, which will take the value from rcParams["errorbar.capsize"].

**error_kw** [dict, optional] Dictionary of kwargs to be passed to the errorbar method. Values of ecolor or capsize defined here take precedence over the independent kwargs.

**log** [bool, optional, default: False] If True, set the x-axis to be log scale.

See also:

- **bar** Plot a vertical bar plot.

Notes

The optional arguments color, edgecolor, linewidth, xerr, and yerr can be either scalars or sequences of length equal to the number of bars. This enables you to use bar as the basis for stacked bar charts, or candlestick plots. Detail: xerr and yerr are passed directly to errorbar(), so they can also have shape 2xN for independent specification of lower and upper errors.

Examples using matplotlib.pyplot.barh

• sphx_glr_gallery_lines_bars_and_markers_horizontal_barchart_distribution.py

matplotlib.pyplot.bone

matplotlib.pyplot.bone()

Set the colormap to "bone".

This changes the default colormap as well as the colormap of the current image if there is one. See help(colormaps) for more information.

matplotlib.pyplot.box

matplotlib.pyplot.box(on=None)

Turn the axes box on or off on the current axes.

Parameters

on [bool or None] The new Axes box state. If None, toggle the state.

See also:
matplotlib.axes.Axes.set_frame_on()
matplotlib.axes.Axes.get_frame_on()

matplotlib.pyplot.boxplot

```python
matplotlib.pyplot.boxplot(x, notch=None, sym=None, vert=None, whis=None, positions=None, widths=None, patch_artist=None, bootstrap=None, usermedians=None, conf_intervals=None, meanline=None, showmeans=None, showmedians=None, showbox=None, showfliers=None, boxprops=None, labels=None, flierprops=None, medianprops=None, meanprops=None, capprops=None, whiskerprops=None, manage_ticks=True, autorange=False, zorder=None, *, data=None)
```

Make a box and whisker plot.

Make a box and whisker plot for each column of x or each vector in sequence x. The box extends from the lower to upper quartile values of the data, with a line at the median. The whiskers extend from the box to show the range of the data. Flier points are those past the end of the whiskers.

**Parameters**

- **x** [Array or a sequence of vectors.] The input data.
- **notch** [bool, optional (False)] If True, will produce a notched box plot. Otherwise, a rectangular boxplot is produced. The notches represent the confidence interval (CI) around the median. See the entry for the bootstrap parameter for information regarding how the locations of the notches are computed.

**Note:** In cases where the values of the CI are less than the lower quartile or greater than the upper quartile, the notches will extend beyond the box, giving it a distinctive “flipped” appearance. This is expected behavior and consistent with other statistical visualization packages.

- **sym** [str, optional] The default symbol for flier points. Enter an empty string (") if you don’t want to show fliers. If None, then the fliers default to ‘b+’ If you want more control use the flierprops kwarg.
- **vert** [bool, optional (True)] If True (default), makes the boxes vertical. If False, everything is drawn horizontally.
- **whis** [float, sequence, or string (default = 1.5)] As a float, determines the reach of the whiskers to the beyond the first and third quartiles. In other words, where IQR is the interquartile range (Q3-Q1), the upper whisker will extend to last datum less than Q3 + whis*IQR. Similarly, the lower whisker will extend to the first datum greater than Q1 - whis*IQR. Beyond the whiskers, data are considered outliers and are plotted as individual points. Set this to an unreasonably high value to force the whiskers to show the min and max values. Alternatively, set this to an ascending sequence of percentile (e.g., [5, 95]) to set the
whiskers at specific percentiles of the data. Finally, whis can be the string 'range' to force the whiskers to the min and max of the data.

**bootstrap** [int, optional] Specifies whether to bootstrap the confidence intervals around the median for notched boxplots. If bootstrap is None, no bootstrapping is performed, and notches are calculated using a Gaussian-based asymptotic approximation (see McGill, R., Tukey, J.W., and Larsen, W.A., 1978, and Kendall and Stuart, 1967). Otherwise, bootstrap specifies the number of times to bootstrap the median to determine its 95% confidence intervals. Values between 1000 and 10000 are recommended.

**usermedians** [array-like, optional] An array or sequence whose first dimension (or length) is compatible with x. This overrides the medians computed by matplotlib for each element of usermedians that is not None. When an element of usermedians is None, the median will be computed by matplotlib as normal.

**conf_intervals** [array-like, optional] Array or sequence whose first dimension (or length) is compatible with x and whose second dimension is 2. When the an element of conf_intervals is not None, the notch locations computed by matplotlib are overridden (provided notch is True). When an element of conf_intervals is None, the notches are computed by the method specified by the other kwargs (e.g., bootstrap).

**positions** [array-like, optional] Sets the positions of the boxes. The ticks and limits are automatically set to match the positions. Defaults to range(1, N+1) where N is the number of boxes to be drawn.

**widths** [scalar or array-like] Sets the width of each box either with a scalar or a sequence. The default is 0.5, or 0.15*(distance between extreme positions), if that is smaller.

**patch_artist** [bool, optional (False)] If False produces boxes with the Line2D artist. Otherwise, boxes and drawn with Patch artists.

**labels** [sequence, optional] Labels for each dataset. Length must be compatible with dimensions of x.

**manage_ticks** [bool, optional (True)] If True, the tick locations and labels will be adjusted to match the boxplot positions.

**autorange** [bool, optional (False)] When True and the data are distributed such that the 25th and 75th percentiles are equal, whis is set to 'range' such that the whisker ends are at the minimum and maximum of the data.

**meanline** [bool, optional (False)] If True (and showmeans is True), will try to render the mean as a line spanning the full width of the box according to meanprops (see below). Not recommended if shownotches is also True. Otherwise, means will be shown as points.

**zorder** [scalar, optional (None)] Sets the zorder of the boxplot.

**Returns**

**result** [dict] A dictionary mapping each component of the boxplot to a list of the matplotlib.lines.Line2D instances created. That dictionary has the following keys (assuming vertical boxplots):
- **boxes**: the main body of the boxplot showing the quartiles and the median's confidence intervals if enabled.
- **medians**: horizontal lines at the median of each box.
- **whiskers**: the vertical lines extending to the most extreme, non-outlier data points.
- **caps**: the horizontal lines at the ends of the whiskers.
- **fliers**: points representing data that extend beyond the whiskers (fliers).
- **means**: points or lines representing the means.

**Other Parameters**

- **showcaps** [bool, optional (True)] Show the caps on the ends of whiskers.
- **showbox** [bool, optional (True)] Show the central box.
- **showfliers** [bool, optional (True)] Show the outliers beyond the caps.
- **showmeans** [bool, optional (False)] Show the arithmetic means.
- **capprops** [dict, optional (None)] Specifies the style of the caps.
- **boxprops** [dict, optional (None)] Specifies the style of the box.
- **whiskerprops** [dict, optional (None)] Specifies the style of the whiskers.
- **flierprops** [dict, optional (None)] Specifies the style of the fliers.
- **medianprops** [dict, optional (None)] Specifies the style of the median.
- **meanprops** [dict, optional (None)] Specifies the style of the mean.

**Notes**

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

**Examples using matplotlib.pyplot.boxplot**

- sphx_glr_gallery_pyplots_boxplot_demo_pyplot.py

**matplotlib.pyplot.broken_barh**

- matplotlib.pyplot.broken_barh(xranges, yrange, *, data=None, **kwargs)
  Plot a horizontal sequence of rectangles.
A rectangle is drawn for each element of \( \text{xranges} \). All rectangles have the same vertical position and size defined by \( \text{yrange} \).

This is a convenience function for instantiating a \(\text{BrokenBarHCollection}\), adding it to the axes and autoscaling the view.

**Parameters**

- **xranges** [sequence of tuples \((\text{xmin}, \text{xwidth})\)] The x-positions and extends of the rectangles. For each tuple \((\text{xmin}, \text{xwidth})\) a rectangle is drawn from \(\text{xmin}\) to \(\text{xmin} + \text{xwidth}\).
- **yranges** [(\(\text{ymin}, \text{ymax}\))] The y-position and extend for all the rectangles.

**Returns**

- **collection** [A \(\text{BrokenBarHCollection}\)]

**Other Parameters**

- ****kwarg**s** [\(\text{BrokenBarHCollection}\) properties] Each kwarg can be either a single argument applying to all rectangles, e.g.:

  ```
  facecolors='black'
  ```

  or a sequence of arguments over which is cycled, e.g.:

  ```
  facecolors=('black', 'blue')
  ```

  would create interleaving black and blue rectangles.

Notes

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All positional and all keyword arguments.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

`matplotlib.pyplot.cla`

`matplotlib.pyplot.cla()`  
Clear the current axes.

`matplotlib.pyplot.clabel`

`matplotlib.pyplot.clabel(CS, *args, **kwargs)`  
Label a contour plot.  
Call signature:  
```python  
clabel(cs, [levels,] **kwargs)  
```  
Adds labels to line contours in `cs`, where `cs` is a `ContourSet` object returned by `contour()`.

**Parameters**

- **cs** [ContourSet] The ContourSet to label.
- **levels** [array-like, optional] A list of level values, that should be labeled. The list must be a subset of `cs.levels`. If not given, all levels are labeled.
**fontsize** [string or float, optional] Size in points or relative size e.g., ‘smaller’, ‘x-large’. See `Text.set_size` for accepted string values.

**colors** [color-spec, optional] The label colors:

- If *None*, the color of each label matches the color of the corresponding contour.
- If one string color, e.g., `colors = 'r'` or `colors = 'red'`, all labels will be plotted in this color.
- If a tuple of matplotlib color args (string, float, rgb, etc), different labels will be plotted in different colors in the order specified.

**inline** [bool, optional] If True the underlying contour is removed where the label is placed. Default is True.

**inline_spacing** [float, optional] Space in pixels to leave on each side of label when placing inline. Defaults to 5.

This spacing will be exact for labels at locations where the contour is straight, less so for labels on curved contours.

**fmt** [string or dict, optional] A format string for the label. Default is ‘%1.3f’

Alternatively, this can be a dictionary matching contour levels with arbitrary strings to use for each contour level (i.e., `fmt[level]=string`), or it can be any callable, such as a Formatter instance, that returns a string when called with a numeric contour level.

**manual** [bool or iterable, optional] If True, contour labels will be placed manually using mouse clicks. Click the first button near a contour to add a label, click the second button (or potentially both mouse buttons at once) to finish adding labels. The third button can be used to remove the last label added, but only if labels are not inline. Alternatively, the keyboard can be used to select label locations (enter to end label placement, delete or backspace act like the third mouse button, and any other key will select a label location).

`manual` can also be an iterable object of x,y tuples. Contour labels will be created as if mouse is clicked at each x,y positions.

**rightside_up** [bool, optional] If True, label rotations will always be plus or minus 90 degrees from level. Default is True.

**use_clabeltext** [bool, optional] If True, ClabelText class (instead of Text) is used to create labels. ClabelText recalculates rotation angles of texts during the drawing time, therefore this can be used if aspect of the axes changes. Default is False.

**Returns**

**labels** A list of Text instances for the labels.

**Examples using matplotlib.pyplot.clabel**

- sphx_glr_gallery_images_contours_and_fields_contour_demo.py
- sphx_glr_gallery_images_contours_and_fields_contour_label_demo.py
matplotlib.pyplot.clf

```python
matplotlib.pyplot.clf()
```
Clear the current figure.

**Examples using `matplotlib.pyplot.clf`**

- `sphx_glr_gallery_images_contours_and_fields_contourf_demo.py`
- `sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py`

matplotlib.pyplot.clim

```python
matplotlib.pyplot.clim(vmin=None, vmax=None)
```
Set the color limits of the current image.

If either `vmin` or `vmax` is `None`, the image min/max respectively will be used for color scaling.

If you want to set the clim of multiple images, use `set_clim` on every image, for example:

```python
for im in gca().get_images():
    im.set_clim(0, 0.5)
```

matplotlib.pyplot.close

```python
matplotlib.pyplot.close(fig=None)
```
Close a figure window.

**Parameters**

- `fig` [None or int or str or `Figure`] The figure to close. There are a number of ways to specify this:
  - `None`: the current figure
  - `Figure`: the given `Figure` instance
  - `int`: a figure number
  - `str`: a figure name
  - `'all'`: all figures

**Examples using `matplotlib.pyplot.close`**

- `sphx_glr_gallery_event_handling_pipong.py`
- `sphx_glr_gallery_misc_multipage_pdf.py`
matplotlib.pyplot.cohere

Plot the coherence between $x$ and $y$. Coherence is the normalized cross spectral density:

$$C_{xy} = \frac{|P_{xy}|^2}{P_{xx}P_{yy}}$$

**Parameters**

- **Fs** [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.
- **window** [callable or ndarray] A function or a vector of length $NFFT$. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- **sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- **pad_to** [int] The number of points to which the data segment is padded when performing the FFT. This can be different from $NFFT$, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the $n$ parameter in the call to fft(). The default is None, which sets pad_to equal to $NFFT$.
- **NFFT** [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use pad_to for this instead.
- **detrend** [{‘none’, ‘mean’, ‘linear’} or callable, default ‘none’] The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the detrend parameter is a vector, in Matplotlib it is a function. The mlab module defines `detrend_none`, `detrend_mean`, and `detrend_linear`, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls `detrend_none`, ‘mean’ calls `detrend_mean`, ‘linear’ calls `detrend_linear`. 

Plot the coherence between $x$ and $y$. Coherence is the normalized cross spectral density:
scale_by_freq [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

nooverlap [int] The number of points of overlap between blocks. The default value is 0 (no overlap).

Fc [int] The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

Returns

Cxy [1-D array] The coherence vector.

freqs [1-D array] The frequencies for the elements in Cxy.

Other Parameters

**kwargs Keyword arguments control the Line2D properties:

**Notes**

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’, ‘y’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

**References**

```python
matplotlib.pyplot.colorbar
```

```
matplotlib.pyplot.colorbar(mappable=None, cax=None, ax=None, **kw)
```

Add a colorbar to a plot.

Function signatures for the `pyplot` interface; all but the first are also method signatures for the `colorbar()` method:

```python
colorbar(**kwargs)
colorbar(mappable, **kwargs)
colorbar(mappable, cax=cax, **kwargs)
colorbar(mappable, ax=ax, **kwargs)
```

**Parameters**

- mappable The `matplotlib.cm.ScalarMappable` (i.e., `Image`, `ContourSet`, etc.) described by this colorbar. This argument is mandatory for the `Figure` `colorbar` method but optional for the `pyplot.colorbar` function, which sets the default to the current image.

Note that one can create a `ScalarMappable` “on-the-fly” to generate colorbars not attached to a previously drawn artist, e.g.
```python
fig.colorbar(cm.ScalarMappable(norm=norm, cmap=cmap), ax=ax)
```

**cax** [Axes object, optional] Axes into which the colorbar will be drawn.

**ax** [Axes, list of Axes, optional] Parent axes from which space for a new colorbar axes will be stolen. If a list of axes is given they will all be resized to make room for the colorbar axes.

**use_gridspec** [bool, optional] If `cax` is `None`, a new `cax` is created as an instance of Axes. If `ax` is an instance of Subplot and `use_gridspec` is `True`, `cax` is created as an instance of Subplot using the `gridspec` module.

**Returns**

**colorbar** [Colorbar] See also its base class, ColorbarBase. Use `set_label` to label the colorbar.

**Notes**

Additional keyword arguments are of two kinds:

**axes properties:**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orientation</td>
<td>vertical or horizontal</td>
</tr>
<tr>
<td>fraction</td>
<td>0.15; fraction of original axes to use for colorbar</td>
</tr>
<tr>
<td>pad</td>
<td>0.05 if vertical, 0.15 if horizontal; fraction of original axes between colorbar and new image axes</td>
</tr>
<tr>
<td>shrink</td>
<td>1.0; fraction by which to multiply the size of the colorbar</td>
</tr>
<tr>
<td>aspect</td>
<td>20; ratio of long to short dimensions</td>
</tr>
<tr>
<td>anchor</td>
<td>(0.0, 0.5) if vertical; (0.5, 1.0) if horizontal; the anchor point of the colorbar axes</td>
</tr>
<tr>
<td>panchor</td>
<td>(1.0, 0.5) if vertical; (0.5, 0.0) if horizontal; the anchor point of the colorbar parent axes. If False, the parent axes' anchor will be unchanged</td>
</tr>
</tbody>
</table>

**colorbar properties:**
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>extend</code></td>
<td>[ 'neither'</td>
</tr>
<tr>
<td><code>extendfrac</code></td>
<td>[ None</td>
</tr>
<tr>
<td><code>extendrect</code></td>
<td>bool If False the minimum and maximum colorbar extensions will be triangular (the default). If True the extensions will be rectangular.</td>
</tr>
<tr>
<td><code>spacing</code></td>
<td>[ 'uniform'</td>
</tr>
<tr>
<td><code>ticks</code></td>
<td>[ None</td>
</tr>
<tr>
<td><code>format</code></td>
<td>[ None</td>
</tr>
<tr>
<td><code>drawedges</code></td>
<td>Whether to draw lines at color boundaries.</td>
</tr>
</tbody>
</table>

The following will probably be useful only in the context of indexed colors (that is, when the mappable has norm=NoNorm()), or other unusual circumstances.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>boundaries</code></td>
<td>None or a sequence</td>
</tr>
<tr>
<td><code>values</code></td>
<td>None or a sequence which must be of length 1 less than the sequence of <code>boundaries</code>. For each region delimited by adjacent entries in <code>boundaries</code>, the color mapped to the corresponding value in <code>values</code> will be used.</td>
</tr>
</tbody>
</table>

If `mappable` is a `ContourSet`, its `extend` kwarg is included automatically.

The `shrink` kwarg provides a simple way to scale the colorbar with respect to the axes. Note that if `cax` is specified, it determines the size of the colorbar and `shrink` and `aspect` kwargs are ignored.

For more precise control, you can manually specify the positions of the axes objects in
which the mappable and the colorbar are drawn. In this case, do not use any of the axes properties kwargs.

It is known that some vector graphics viewers (svg and pdf) renders white gaps between segments of the colorbar. This is due to bugs in the viewers, not Matplotlib. As a workaround, the colorbar can be rendered with overlapping segments:

```python
cbar = colorbar()
cbar.solids.set_edgecolor("face")
draw()
```

However this has negative consequences in other circumstances, e.g. with semi-transparent images (alpha < 1) and colorbar extensions; therefore, this workaround is not used by default (see issue #1188).

**Examples using** matplotlib.pyplot.colorbar

- `sphx_glr_gallery_images_contours_and_fields_contour_demo.py`
- `sphx_glr_gallery_images_contours_and_fields_contour_image.py`
- `sphx_glr_gallery_images_contours_and_fields_contourf_demo.py`
- `sphx_glr_gallery_images_contours_and_fields_contourf_hatching.py`
- `sphx_glr_gallery_images_contours_and_fields_contourf_log.py`
- `sphx_glr_gallery_images_contours_and_fields_image_annotated_heatmap.py`
- `sphx_glr_gallery_images_contours_and_fields_image_masked.py`

- `Image tutorial`
- `Tight Layout guide`

**matplotlib.pyplot.connect**

`matplotlib.pyplot.connect(s, func)`

Connect event with string `s` to `func`. The signature of `func` is:
```python
def func(event)
```

where event is a `matplotlib.backend_bases.Event`. The following events are recognized:

- 'button_press_event'
- 'button_release_event'
- 'draw_event'
- 'key_press_event'
- 'key_release_event'
- 'motion_notify_event'
- 'pick_event'
- 'resize_event'
- 'scroll_event'
- 'figure_enter_event',
- 'figure_leave_event',
- 'axes_enter_event',
- 'axes_leave_event'
- 'close_event'

For the location events (button and key press/release), if the mouse is over the axes, the variable `event.inaxes` will be set to the `Axes` the event occurs is over, and additionally, the variables `event.xdata` and `event.ydata` will be defined. This is the mouse location in data coords. See `KeyEvent` and `MouseEvent` for more info.

Return value is a connection id that can be used with `mpl_disconnect()`.

**Examples**

**Usage:**

```python
def on_press(event):
    print('you pressed', event.button, event.xdata, event.ydata)

cid = canvas.mpl_connect('button_press_event', on_press)
```

**Examples using matplotlib.pyplot.connect**

- sphx_glr_gallery_event_handling_coords_demo.py
- sphx_glr_gallery_widgets_rectangle_selector.py
Contouring in Matplotlib

**Contouring**

- **Plot contours**
  - Call signature:
    ```python
    contour([X, Y], Z, [levels], **kwargs)
    ```

  - The `contour` and `contourf` functions draw contour lines and filled contours, respectively. They support the same parameters and return values.

**Parameters**

- `X, Y` (array-like, optional)
  - The coordinates of the values in `Z`.
  - `X` and `Y` must both be 2-D with the same shape as `Z` (e.g., created via `numpy.meshgrid`), or they must both be 1-D such that `len(X) == M` is the number of columns in `Z` and `len(Y) == N` is the number of rows in `Z`.
  - If not given, they are assumed to be integer indices, i.e., `X = range(M)` and `Y = range(N)`.

- `Z` (array-like(N, M))
  - The height values over which the contour is drawn.

- `levels` (int or array-like, optional)
  - Determines the number and positions of the contour lines / regions.
  - If an int `n`, use `n` data intervals; i.e., draw `n+1` contour lines. The level heights are automatically chosen.
  - If array-like, draw contour lines at the specified levels. The values must be in increasing order.

**Returns**

- `c` (QuadContourSet)

**Other Parameters**

- `corner_mask` (bool, optional)
  - Enable/disable corner masking, which only has an effect if `Z` is a masked array. If `False`, any quad touching a masked point is masked out. If `True`, only the triangular corners of quads nearest those points are always masked out, other triangular corners comprising three unmasked points are contoured as usual.
  - Defaults to `rcParams["contour.corner_mask"]`, which defaults to `True`.

- `colors` (color string or sequence of colors, optional)
  - The colors of the levels, i.e., the lines for `contour` and the areas for `contourf`.
  - The sequence is cycled for the levels in ascending order. If the sequence is shorter than the number of levels, it’s repeated.
  - As a shortcut, single color strings may be used in place of one-element lists, i.e., `'red'` instead of `['red']` to color all levels with the same color.
  - This shortcut does only work for color strings, not for other ways of specifying colors.
  - By default (value `None`), the colormap specified by `cmap` will be used.

- `alpha` (float, optional)
  - The alpha blending value, between 0 (transparent) and 1 (opaque).
**cmap** [str or *Colormap*, optional] A *Colormap* instance or registered colormap name. The colormap maps the level values to colors. Defaults to *rcParams*["image.cmap"].

If given, *colors* take precedence over *cmap*.

**norm** [*Normalize*, optional] If a colormap is used, the *Normalize* instance scales the level values to the canonical colormap range [0, 1] for mapping to colors. If not given, the default linear scaling is used.

**vmin, vmax** [float, optional] If not *None*, either or both of these values will be supplied to the *Normalize* instance, overriding the default color scaling based on *levels*.

**origin** [{*None*, ‘upper’, ‘lower’, ‘image’}, optional] Determines the orientation and exact position of Z by specifying the position of Z[0, 0]. This is only relevant, if X, Y are not given.

- *None*: Z[0, 0] is at X=0, Y=0 in the lower left corner.
- ‘lower’: Z[0, 0] is at X=0.5, Y=0.5 in the lower left corner.
- ‘upper’: Z[0, 0] is at X=N+0.5, Y=0.5 in the upper left corner.
- ‘image’: Use the value from *rcParams*["image.origin"].

**extent** [(x0, x1, y0, y1), optional] If *origin* is not *None*, then *extent* is interpreted as in *imshow*: it gives the outer pixel boundaries. In this case, the position of Z[0,0] is the center of the pixel, not a corner. If *origin* is *None*, then (x0, y0) is the position of Z[0,0], and (x1, y1) is the position of Z[-1,-1].

This argument is ignored if X and Y are specified in the call to contour.

**locator** [ticker.Locator subclass, optional] The locator is used to determine the contour levels if they are not given explicitly via *levels*. Defaults to *MaxNLocator*.

**extend** [{‘neither’, ‘both’, ‘min’, ‘max’}, optional, default: ‘neither’] Determines the *contourf*-coloring of values that are outside the *levels* range.

If ‘neither’, values outside the *levels* range are not colored. If ‘min’, ‘max’ or ‘both’, color the values below, above or below and above the *levels* range.

Values below min(*levels*) and above max(*levels*) are mapped to the under/over values of the *Colormap*. Note, that most colormaps do not have dedicated colors for these by default, so that the over and under values are the edge values of the colormap. You may want to set these values explicitly using *Colormap.set_under* and *Colormap.set_over*.

**Note:** An existing *QuadContourSet* does not get notified if properties of its colormap are changed. Therefore, an explicit call *QuadContourSet*.changed() is needed after modifying the colormap. The explicit call can be left out, if a colorbar is assigned to the *QuadContourSet* because it internally calls *QuadContourSet*.changed().

Example:
x = np.arange(1, 10)
y = x.reshape(-1, 1)
h = x * y

cs = plt.contourf(h, levels=[10, 30, 50],
                  colors=['#808080', '#A0A0A0', '#C0C0C0'], extend='both')
cs.cmap.set_over('red')
cs.cmap.set_under('blue')
cs.changed()

**xunits, yunits** [registered units, optional] Override axis units by specifying an instance of a *matplotlib.units.ConversionInterface*.

**antialiased** [bool, optional] Enable antialiasing, overriding the defaults. For filled contours, the default is *True*. For line contours, it is taken from *rcParams*[/"lines.antialiased"].

**Nchunk** [int >= 0, optional] If 0, no subdivision of the domain. Specify a positive integer to divide the domain into subdomains of *nchunk* by *nchunk* quads. Chunking reduces the maximum length of polygons generated by the contouring algorithm which reduces the rendering workload passed on to the backend and also requires slightly less RAM. It can however introduce rendering artifacts at chunk boundaries depending on the backend, the *antialiased* flag and value of *alpha*.

**linewidths** [float or sequence of float, optional] *Only applies to contour*. The line width of the contour lines. If a number, all levels will be plotted with this linewidth. If a sequence, the levels in ascending order will be plotted with the linewidths in the order specified. Defaults to *rcParams*[/"lines.linewidth"]/.

**linestyles** [{None, ‘solid’, ‘dashed’, ‘dashdot’, ‘dotted’}, optional] *Only applies to contour*. If *linestyles* is *None*, the default is ‘solid’ unless the lines are monochrome. In that case, negative contours will take their linestyle from *rcParams*[/"contour.negative_linestyle"] setting.

*linestyles* can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

**hatches** [List[str], optional] *Only applies to contour*. A list of cross hatch patterns to use on the filled areas. If None, no hatching will be added to the contour. Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

**Notes**

1. *contourf* differs from the MATLAB version in that it does not draw the polygon edges. To draw edges, add line contours with calls to *contour*.
2. `contourf` fills intervals that are closed at the top; that is, for boundaries \( z1 \) and \( z2 \), the filled region is:

\[
z1 < Z \leq z2
\]

except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

**Examples using matplotlib.pyplot.contour**

- sphx_glr_gallery_images_contours_and_fields_contour_corner_mask.py
- sphx_glr_gallery_images_contours_and_fields_contour_demo.py
- sphx_glr_gallery_images_contours_and_fields_contour_image.py

- sphx_glr_gallery_images_contours_and_fields_contourf_demo.py
- sphx_glr_gallery_images_contours_and_fields_image_transparency_blend.py
- sphx_glr_gallery_images_contours_and_fields_irregulardatagrid.py
- sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py

**matplotlib.pyplot.contourf**

```python
matplotlib.pyplot.contourf(*args, data=None, **kwargs)
```

Plot contours.

Call signature:

```
contour([X, Y], Z, [levels], **kwargs)
```

`contour` and `contourf` draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.

**Parameters**

- **X, Y** [array-like, optional] The coordinates of the values in \( Z \).
  
  \( X \) and \( Y \) must both be 2-D with the same shape as \( Z \) (e.g. created via `numpy.meshgrid`), or they must both be 1-D such that `len(X) == M` is the number of columns in \( Z \) and `len(Y) == N` is the number of rows in \( Z \).
  
  If not given, they are assumed to be integer indices, i.e. \( X = \text{range}(M), Y = \text{range}(N) \).

- **Z** [array-like(N, M)] The height values over which the contour is drawn.

- **levels** [int or array-like, optional] Determines the number and positions of the contour lines / regions.

  If an int \( n \), use \( n \) data intervals; i.e. draw \( n+1 \) contour lines. The level heights are automatically chosen.

  If array-like, draw contour lines at the specified levels. The values must be in increasing order.
Returns

- `c` : `QuadContourSet`

Other Parameters

- `corner_mask` [bool, optional]: Enable/disable corner masking, which only has an effect if `Z` is a masked array. If `False`, any quad touching a masked point is masked out. If `True`, only the triangular corners of quads nearest those points are always masked out, other triangular corners comprising three unmasked points are contoured as usual.

  Defaults to `rcParams['contour.corner_mask']`, which defaults to `True`.

- `colors` [color string or sequence of colors, optional]: The colors of the levels, i.e. the lines for `contour` and the areas for `contourf`.

  The sequence is cycled for the levels in ascending order. If the sequence is shorter than the number of levels, it's repeated.

  As a shortcut, single color strings may be used in place of one-element lists, i.e. `'red'` instead of `['red']` to color all levels with the same color.

  This shortcut does only work for color strings, not for other ways of specifying colors.

  By default (value `None`), the colormap specified by `cmap` will be used.

- `alpha` [float, optional]: The alpha blending value, between 0 (transparent) and 1 (opaque).

- `cmap` [str or `Colormap`, optional]: A `Colormap` instance or registered colormap name. The colormap maps the level values to colors. Defaults to `rcParams['image.cmap']`.

  If given, `colors` take precedence over `cmap`.

- `norm` [`Normalize`, optional]: If a colormap is used, the `Normalize` instance scales the level values to the canonical colormap range [0, 1] for mapping to colors. If not given, the default linear scaling is used.

- `vmin, vmax` [float, optional]: If not `None`, either or both of these values will be supplied to the `Normalize` instance, overriding the default color scaling based on `levels`.

- `origin` [{`None`, ‘upper’, ‘lower’, ‘image’}, optional]: Determines the orientation and exact position of `Z` by specifying the position of `Z[0, 0]`.

  This is only relevant, if `X, Y` are not given.

  - `None`: `Z[0, 0]` is at `X=0, Y=0` in the lower left corner.
  - ‘lower’: `Z[0, 0]` is at `X=0.5, Y=0.5` in the lower left corner.
  - ‘upper’: `Z[0, 0]` is at `X=N+0.5, Y=0.5` in the upper left corner.
  - ‘image’: Use the value from `rcParams['image.origin']`.

- `extent` [(`x0`, `x1`, `y0`, `y1`), optional]: If `origin` is not `None`, then `extent` is interpreted as in `imshow`: it gives the outer pixel boundaries. In this case, the position of `Z[0,0]` is the center of the pixel, not a corner. If `origin` is `None`, then `(x0, y0)` is the position of `Z[0,0]`, and `(x1, y1)` is the position of `Z[-1,-1]`.

  This argument is ignored if `X and Y` are specified in the call to `contour`.
**locator** [ticker.Locator subclass, optional] The locator is used to determine the contour levels if they are not given explicitly via `levels`. Defaults to `MaxNLocator`.

**extend** [{'neither', 'both', 'min', 'max'}, optional, default: ‘neither’] Determines the `contourf`-coloring of values that are outside the `levels` range.

- If ‘neither’, values outside the `levels` range are not colored.
- If ‘min’, ‘max’ or ‘both’, color the values below, above or below and above the `levels` range.

Values below `min(levels)` and above `max(levels)` are mapped to the under/over values of the `Colormap`. Note, that most colormaps do not have dedicated colors for these by default, so that the over and under values are the edge values of the colormap. You may want to set these values explicitly using `Colormap.set_under` and `Colormap.set_over`.

**Note:** An exising `QuadContourSet` does not get notified if properties of its colormap are changed. Therefore, an explicit call `QuadContourSet.changed()` is needed after modifying the colormap. The explicit call can be left out, if a colorbar is assigned to the `QuadContourSet` because it internally calls `QuadContourSet.changed()`.

**Example:**

```python
x = np.arange(1, 10)
y = x.reshape(-1, 1)
h = x * y

cs = plt.contourf(h, levels=[10, 30, 50],
                 colors=["#808080", "#A0A0A0", "#C0C0C0"], extend='both')

cs.cmap.set_over('red')
cs.cmap.set_under('blue')
cs.changed()
```

**xunits, yunits** [registered units, optional] Override axis units by specifying an instance of a `matplotlib.units.ConversionInterface`.

**antialiased** [bool, optional] Enable antialiasing, overriding the defaults. For filled contours, the default is `True`. For line contours, it is taken from `rcParams["lines.antialiased"]`.

**Nchunk** [int >= 0, optional] If 0, no subdivision of the domain. Specify a positive integer to divide the domain into subdomains of `nchunk` by `nchunk` quads. Chunking reduces the maximum length of polygons generated by the contouring algorithm which reduces the rendering workload passed on to the backend and also requires slightly less RAM. It can however introduce rendering artifacts at chunk boundaries depending on the backend, the `antialiased` flag and value of `alpha`.

**linewidths** [float or sequence of float, optional] Only applies to `contour`. The line width of the contour lines.

- If a number, all levels will be plotted with this linewidth.
If a sequence, the levels in ascending order will be plotted with the linewidths in the order specified. Defaults to `rcParams["lines.linewidth"]`.

If **linestyles** is None, the default is ‘solid’ unless the lines are monochrome. In that case, negative contours will take their linestyle from `rcParams["contour.negative_linestyle"]` setting.

**linestyles** can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

**hatches** [List[str], optional] *Only applies to* contourf.

A list of cross hatch patterns to use on the filled areas. If None, no hatching will be added to the contour. Hatching is supported in the PostScript, PDF, SVG and Agg backends only.

**Notes**

1. **contourf** differs from the MATLAB version in that it does not draw the polygon edges. To draw edges, add line contours with calls to `contour`.
2. **contourf** fills intervals that are closed at the top; that is, for boundaries $z_1$ and $z_2$, the filled region is:

   \[
   z_1 < Z \leq z_2
   \]

   except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

**Examples using** matplotlib.pyplot.contourf

- sphx_glr_gallery_images_contours_and_fields_contour_corner_mask.py
- sphx_glr_gallery_images_contours_and_fields_contourf_demo.py
- sphx_glr_gallery_images_contours_and_fields_contourf_hatching.py
- sphx_glr_gallery_images_contours_and_fields_contourf_log.py
- sphx_glr_gallery_images_contours_and_fields_irregulardatagrid.py
- sphx_glr_gallery_images_contours_and_fields_pcolormesh_levels.py
- sphx_glr_gallery_images_contours_and_fields_triinterp_demo.py

**matplotlib.pyplot.cool**

`matplotlib.pyplot.cool()`

Set the colormap to “cool”. This changes the default colormap as well as the colormap of the current image if there is one. See `help(colormaps)` for more information.
**matplotlib.pyplot.copper**

```python
def matplotlib.pyplot.copper():
    
    Set the colormap to "copper".
    
    This changes the default colormap as well as the colormap of the current image if there
    is one. See help(colormaps) for more information.
```

**matplotlib.pyplot.csd**

```python
def matplotlib.pyplot.csd(x, y, NFFT=None, Fs=None, Fc=None, detrend=None, window=None, noverlap=None, pad_to=None, sides=None, scale_by_freq=None, return_line=None, *, data=None, **kwargs):
    
    Plot the cross-spectral density.
    
    The cross spectral density \( P_{xy} \) by Welch’s average periodogram method. The vectors \( x \) and \( y \) are divided into \( NFFT \) length segments. Each segment is detrended by function \( \text{detrend} \) and windowed by function \( \text{window} \). \( \text{noverlap} \) gives the length of the overlap between segments. The product of the direct FFTs of \( x \) and \( y \) are averaged over each segment to compute \( P_{xy} \), with a scaling to correct for power loss due to windowing.
    
    If \( \text{len}(x) < NFFT \) or \( \text{len}(y) < NFFT \), they will be zero padded to \( NFFT \).

    **Parameters**
    
    \( x, y \) [1-D arrays or sequences] Arrays or sequences containing the data.
    
    \( Fs \) [scalar] The sampling frequency (samples per time unit). It is used to
    calculate the Fourier frequencies, freqs, in cycles per time unit. The
    default value is 2.
    
    \( \text{window} \) [callable or ndarray] A function or a vector of length \( NFFT \). To
    create window vectors see \( \text{window_hanning}, \text{window_none}, \text{numpy.blackman}, \text{numpy.hamming}, \text{numpy.bartlett}, \text{scipy.signal}, \text{scipy.signal.get_window}, \text{etc}. \) The default is \( \text{window_hanning} \). If a function is passed as the argument,
    it must take a data segment as an argument and return the
    windowed version of the segment.
    
    \( \text{sides} \) [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the
    spectrum to return. Default gives the default behavior, which returns
    one-sided for real data and both for complex data. ‘onesided’ forces
    the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
    
    \( \text{pad_to} \) [int] The number of points to which the data segment is padded
    when performing the FFT. This can be different from \( NFFT \), which
    specifies the number of data points used. While not increasing the
    actual resolution of the spectrum (the minimum distance between re-
    solvable peaks), this can give more points in the plot, allowing for more
detail. This corresponds to the \( n \) parameter in the call to \( \text{fft}() \). The
    default is None, which sets \( \text{pad_to} \) equal to \( NFFT \)
    
    \( \text{NFFT} \) [int] The number of data points used in each block for the FFT. A
    power 2 is most efficient. The default value is 256. This should \( \text{NOT} \) be
    used to get zero padding, or the scaling of the result will be incorrect.
    Use \( \text{pad_to} \) for this instead.
**detrend** ['none', 'mean', 'linear'] or callable, default 'none' The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the `detrend` parameter is a vector, in Matplotlib is it a function. The `mlab` module defines `detrend_none`, `detrend_mean`, and `detrend_linear`, but you can use a custom function as well. You can also use a string to choose one of the functions: 'none' calls `detrend_none`, 'mean' calls `detrend_mean`, 'linear' calls `detrend_linear`.

**scale_by_freq** [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

**noverlap** [int] The number of points of overlap between segments. The default value is 0 (no overlap).

**Fc** [int] The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsamped to baseband.

**return_line** [bool] Whether to include the line object plotted in the returned values. Default is False.

**Returns**

- **Pxy** [1-D array] The values for the cross spectrum $P_{xy}$ before scaling (complex valued).
- **freqs** [1-D array] The frequencies corresponding to the elements in $P_{xy}$.
- **line** [a Line2D instance] The line created by this function. Only returned if return_line is True.

**Other Parameters**

**kwargs** Keyword arguments control the Line2D properties:

See also:

psd() is the equivalent to setting y=x.

Notes

For plotting, the power is plotted as $10 \log_{10}(P_{xy})$ for decibels, though $P_{xy}$ itself is returned.

References

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’, ‘y’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).
**matplotlib.pyplot.delaxes**

`matplotlib.pyplot.delaxes(ax=None)`

Remove the `Axes` `ax` (defaulting to the current axes) from its figure.

A `KeyError` is raised if the axes doesn’t exist.

**matplotlib.pyplot.disconnect**

`matplotlib.pyplot.disconnect(cid)`

Disconnect callback id `cid`

**Examples**

Usage:

```python
cid = canvas.mpl_connect('button_press_event', on_press)
#. later
canvas.mpl_disconnect(cid)
```

**Examples using matplotlib.pyplot.disconnect**

- sphx_glr_gallery_event_handling_coords_demo.py

**matplotlib.pyplot.draw**

`matplotlib.pyplot.draw()`

Redraw the current figure.

This is used to update a figure that has been altered, but not automatically re-drawn. If interactive mode is on (`.ion()`), this should be only rarely needed, but there may be ways to modify the state of a figure without marking it as `stale`. Please report these cases as bugs.

A more object-oriented alternative, given any `Figure` instance, `fig`, that was created using a `pyplot` function, is:

```python
fig.canvas.draw_idle()
```

**Examples using matplotlib.pyplot.draw**

- sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py
- sphx_glr_gallery_mplot3d_rotate_axes3d_sgskip.py
- sphx_glr_gallery_widgets_buttons.py
- sphx_glr_gallery_widgets_check_buttons.py
- sphx_glr_gallery_widgets_radio_buttons.py
Matplotlib, Release 3.1.1

• sphx_glr_gallery_widgets_textbox.py

matplotlib.pyplot.errorbar

matplotlib.pyplot.errorbar(x, y, yerr=None, xerr=None, fmt="", ecolor=None, elinewidth=None, capsize=None, barsabove=False, lolims=False, uplims=False, xlolims=False, xuplims=False, errorevery=1, capthick=None, *, data=None, **kwargs)

Plot y versus x as lines and/or markers with attached errorbars.

x, y define the data locations, xerr, yerr define the errorbar sizes. By default, this draws the data markers/lines as well the errorbars. Use fmt='none' to draw errorbars without any data markers.

**Parameters**

x, y [scalar or array-like] The data positions.

xerr, yerr [scalar or array-like, shape(N,) or shape(2,N), optional] The errorbar sizes:

- scalar: Symmetric +/- values for all data points.
- shape(N,): Symmetric +/- values for each data point.

- shape(2,N): Separate - and + values for each bar. First row contains the lower errors, the second row contains the upper errors.

- None: No errorbar.

Note that all error arrays should have positive values.

See /gallery/statistics/errorbar_features for an example on the usage of xerr and yerr.

fmt [plot format string, optional, default: "]] The format for the data points / data lines. See plot for details.

Use 'none' (case insensitive) to plot errorbars without any data markers.

ecolor [mpl color, optional, default: None] A matplotlib color arg which gives the color the errorbar lines. If None, use the color of the line connecting the markers.

elinewidth [scalar, optional, default: None] The linewidth of the errorbar lines. If None, the linewidth of the current style is used.

capsize [scalar, optional, default: None] The length of the error bar caps in points. If None, it will take the value from rcParams["errorbar.capsize"].

capthick [scalar, optional, default: None] An alias to the keyword argument markeredgewidth (a.k.a. mew). This setting is a more sensible name for the property that controls the thickness of the error bar cap in points. For backwards compatibility, if mew or markeredgewidth are given, then they will over-ride capthick. This may change in future releases.
barsabove [bool, optional, default: False] If True, will plot the errorbars above the plot symbols. Default is below.

lolims, uplims, xlolims, xuplims [bool, optional, default: False] These arguments can be used to indicate that a value gives only upper/lower limits. In that case a caret symbol is used to indicate this. lims-arguments may be of the same type as xerr and yerr. To use limits with inverted axes, set_xlim() or set_ylim() must be called before errorbar().

errorevery [positive integer, optional, default: 1] Subsamples the errorbars. e.g., if errorevery=5, errorbars for every 5-th datapoint will be plotted. The data plot itself still shows all data points.

Returns

container [ErrorbarContainer] The container contains:

- plotline: Line2D instance of x, y plot markers and/or line.
- caplines: A tuple of Line2D instances of the error bar caps.
- barlinecols: A tuple of LineCollection with the horizontal and vertical error ranges.

Other Parameters

**kwargs All other keyword arguments are passed on to the plot command for the markers. For example, this code makes big red squares with thick green edges:

```python
x, y, yerr = rand(3, 10)
errorbar(x, y, yerr, marker='s', mfc='red', mec='green', ms=20, mew=4)
```

where mfc, mec, ms and mew are aliases for the longer property names, markerfacecolor, markeredgecolor, markersize and markeredgewidth.

Valid kwargs for the marker properties are Lines2D properties:

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’, ‘xerr’, ‘y’, ‘yerr’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.pyplot.errorbar

- sphx_glr_gallery_lines_bars_and_markers_errorbar_limits_simple.py
matplotlib.pyplot.eventplot

matplotlib.pyplot.eventplot(positions, orientation='horizontal', lineoffsets=1, linelengths=1, linewidths=None, colors=None, linestyles='solid', *, data=None, **kwargs)

Plot identical parallel lines at the given positions.

positions should be a 1D or 2D array-like object, with each row corresponding to a row or column of lines.

This type of plot is commonly used in neuroscience for representing neural events, where it is usually called a spike raster, dot raster, or raster plot.

However, it is useful in any situation where you wish to show the timing or position of multiple sets of discrete events, such as the arrival times of people to a business on each day of the month or the date of hurricanes each year of the last century.

Parameters

positions [1D or 2D array-like object] Each value is an event. If positions is a 2D array-like, each row corresponds to a row or a column of lines (depending on the orientation parameter).

orientation [{‘horizontal’, ‘vertical’}, optional] Controls the direction of the event collections:
• ‘horizontal’: the lines are arranged horizontally in rows, and are vertical.
• ‘vertical’: the lines are arranged vertically in columns, and are horizontal.

lineoffsets [scalar or sequence of scalars, optional, default: 1] The offset of the center of the lines from the origin, in the direction orthogonal to orientation.

linelengths [scalar or sequence of scalars, optional, default: 1] The total height of the lines (i.e. the lines stretches from lineoffset - linelength/2 to lineoffset + linelength/2).

linewidths [scalar, scalar sequence or None, optional, default: None] The line width(s) of the event lines, in points. If it is None, defaults to its rcParams setting.

colors [color, sequence of colors or None, optional, default: None] The color(s) of the event lines. If it is None, defaults to its rcParams setting.

linestyles [str or tuple or a sequence of such values, optional] Default is ‘solid’. Valid strings are [‘solid’, ‘dashed’, ‘dashdot’, ‘dotted’, ‘-’, ‘–’, ‘-‘, ‘–‘]. Dash tuples should be of the form:

(offset, onoffseq),

where onoffseq is an even length tuple of on and off ink in points.

**kwargs [optional] Other keyword arguments are line collection properties. See LineCollection for a list of the valid properties.

Returns

list [A list of EventCollection objects.] Contains the EventCollection that were added.
Notes

For linelengths, linewidths, colors, and linestyles, if only a single value is given, that value is applied to all lines. If an array-like is given, it must have the same length as positions, and each value will be applied to the corresponding row of the array.

Examples

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: 'colors', 'linelengths', 'lineoffsets', 'linestyles', 'linewidths', 'positions'.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

```
matplotlib.pyplot.figimage

matplotlib.pyplot.figimage(*args, **kwargs)

Add a non-resampled image to the figure.
```
The image is attached to the lower or upper left corner depending on `origin`.

**Parameters**

- **X** The image data. This is an array of one of the following shapes:
  - MxN: luminance (grayscale) values
  - MxNx3: RGB values
  - MxNx4: RGBA values

- **xo, yo** [int] The x/y image offset in pixels.

- **alpha** [None or float] The alpha blending value.

- **norm** [matplotlib.colors.Normalize] A Normalize instance to map the luminance to the interval [0, 1].

- **vmin, vmax** [scalar] If `norm` is not given, these values set the data limits for the colormap.

- **origin** [{"upper", "lower"}] Indicates where the [0, 0] index of the array is in the upper left or lower left corner of the axes. Defaults to `rcParams["image.origin"]`.

- **resize** [bool] If True, resize the figure to match the given image size.

**Returns**

- `matplotlib.image.FigureImage`

**Other Parameters**

- ****kwargs** Additional kwargs are Artist kwargs passed on to FigureImage.

**Notes**

`figimage` complements the axes image (`imshow()`) which will be resampled to fit the current axes. If you want a resampled image to fill the entire figure, you can define an Axes with extent [0,0,1,1].

**Examples:**

```python
f = plt.figure()
nx = int(f.get_figwidth() * f.dpi)
ny = int(f.get_figheight() * f.dpi)
data = np.random.random((ny, nx))
f.figimage(data)
plt.show()
```

**Examples using matplotlib.pyplot.figimage**

- sphx_glr_gallery_images_contours_and_fields_figimage_demo.py
**matplotlib.pyplot.figlegend**

matplotlib.pyplot.figlegend(*args, **kwargs)

Place a legend on the figure.

To make a legend from existing artists on every axes:

```python
figlegend()
```

To make a legend for a list of lines and labels:

```python
figlegend(
    (line1, line2, line3),
    ('label1', 'label2', 'label3'),
    loc='upper right')
```

These can also be specified by keyword:

```python
figlegend(
    handles=(line1, line2, line3),
    labels=('label1', 'label2', 'label3'),
    loc='upper right')
```

**Parameters**

- **handles** [sequence of Artist, optional] A list of Artists (lines, patches) to be added to the legend. Use this together with **labels**, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.

  The length of handles and labels should be the same in this case. If they are not, they are truncated to the smaller length.

- **labels** [sequence of strings, optional] A list of labels to show next to the artists. Use this together with **handles**, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.

**Returns**

*matplotlib.legend.Legend* instance

**Other Parameters**

- **loc** [str or pair of floats, default: `rcParams["legend.loc"]` ("best" for axes, "upper right" for figures)] The location of the legend.

  The strings 'upper left', 'upper right', 'lower left', 'lower right' place the legend at the corresponding corner of the axes/figure.

  The strings 'upper center', 'lower center', 'center left', 'center right' place the legend at the center of the corresponding edge of the axes/figure.

  The string 'center' places the legend at the center of the axes/figure.

  The string 'best' places the legend at the location, among the nine locations defined so far, with the minimum overlap with other drawn artists. This option can be quite slow for plots with large amounts of
data; your plotting speed may benefit from providing a specific location.

The location can also be a 2-tuple giving the coordinates of the lower-left corner of the legend in axes coordinates (in which case bbox_to_anchor will be ignored).

For back-compatibility, 'center right' (but no other location) can also be spelled 'right', and each "string" locations can also be given as a numeric value:

<table>
<thead>
<tr>
<th>Location String</th>
<th>Location Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>'best'</td>
<td>0</td>
</tr>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>

bbox_to_anchor [bboxBase, 2-tuple, or 4-tuple of floats] Box that is used to position the legend in conjunction with loc. Defaults to axes.bbox (if called as a method to Axes.legend) or figure.bbox (if Figure.legend). This argument allows arbitrary placement of the legend.

Bbox coordinates are interpreted in the coordinate system given by bbox_transform, with the default transform Axes or Figure coordinates, depending on which legend is called.

If a 4-tuple or BboxBase is given, then it specifies the bbox (x, y, width, height) that the legend is placed in. To put the legend in the best location in the bottom right quadrant of the axes (or figure):

`loc='best', bbox_to_anchor=(0.5, 0.5, 0.5)`

A 2-tuple (x, y) places the corner of the legend specified by loc at x, y. For example, to put the legend’s upper right-hand corner in the center of the axes (or figure) the following keywords can be used:

`loc='upper right', bbox_to_anchor=(0.5, 0.5)`

ncol [integer] The number of columns that the legend has. Default is 1.

prop [None or matplotlib.font_manager.FontProperties or dict] The font properties of the legend. If None (default), the current matplotlib.rcParams will be used.

fontsize [int or float or {'xx-small', 'x-small', 'small', 'medium', 'large', 'x-large', 'xx-large'}] Controls the font size of the legend. If the value is numeric the size will be the absolute font size in points. String values are relative to the current default font size. This argument is only used if prop is not specified.
numpoints [None or int] The number of marker points in the legend when creating a legend entry for a Line2D (line). Default is None, which will take the value from rcParams["legend.numpoints"].

scatterpoints [None or int] The number of marker points in the legend when creating a legend entry for a PathCollection (scatter plot). Default is None, which will take the value from rcParams["legend.scatterpoints"].

scatteryoffsets [iterable of floats] The vertical offset (relative to the font size) for the markers created for a scatter plot legend entry. 0.0 is at the base the legend text, and 1.0 is at the top. To draw all markers at the same height, set to [0.5]. Default is [0.375, 0.5, 0.3125].

markerscale [None or int or float] The relative size of legend markers compared with the originally drawn ones. Default is None, which will take the value from rcParams["legend.markerscale"].

markerfirst [bool] If True, legend marker is placed to the left of the legend label. If False, legend marker is placed to the right of the legend label. Default is True.

frameon [None or bool] Control whether the legend should be drawn on a patch (frame). Default is None, which will take the value from rcParams["legend.frameon"].

fancybox [None or bool] Control whether round edges should be enabled around the FancyBboxPatch which makes up the legend’s background. Default is None, which will take the value from rcParams["legend.fancybox"].

shadow [None or bool] Control whether to draw a shadow behind the legend. Default is None, which will take the value from rcParams["legend.shadow"].

framealpha [None or float] Control the alpha transparency of the legend’s background. Default is None, which will take the value from rcParams["legend.framealpha"]. If shadow is activated and framealpha is None, the default value is ignored.

facecolor [None or “inherit” or a color spec] Control the legend’s background color. Default is None, which will take the value from rcParams["legend.facecolor"]. If “inherit”, it will take rcParams["axes.facecolor"].

edgcolor [None or “inherit” or a color spec] Control the legend’s background patch edge color. Default is None, which will take the value from rcParams["legend.edgecolor"]. If "inherit", it will take rcParams["axes.edgecolor"].

mode [{“expand”, None}] If mode is set to "expand" the legend will be horizontally expanded to fill the axes area (or bbox_to_anchor if defines the legend’s size).

bbox_transform [None or matplotlib.transforms.Transform] The transform for the bounding box (bbox_to_anchor). For a value of None (default) the Axes’ transAxes transform will be used.

title [str or None] The legend’s title. Default is no title (None).
**title_fontsize:** *str or None* The fontsize of the legend’s title. Default is the default fontsize.

**borderpad** [float or None] The fractional whitespace inside the legend border. Measured in font-size units. Default is *None*, which will take the value from `rcParams["legend.borderpad"]`.

**labelspacing** [float or None] The vertical space between the legend entries. Measured in font-size units. Default is *None*, which will take the value from `rcParams["legend.labelspacing"]`.

**handlelength** [float or None] The length of the legend handles. Measured in font-size units. Default is *None*, which will take the value from `rcParams["legend.handlelength"]`.

**handletextpad** [float or None] The pad between the legend handle and text. Measured in font-size units. Default is *None*, which will take the value from `rcParams["legend.handletextpad"]`.

**borderaxespad** [float or None] The pad between the axes and legend border. Measured in font-size units. Default is *None*, which will take the value from `rcParams["legend.borderaxespad"]`.

**columnspacing** [float or None] The spacing between columns. Measured in font-size units. Default is *None*, which will take the value from `rcParams["legend.columnspacing"]`.

**handler_map** [dict or None] The custom dictionary mapping instances or types to a legend handler. This *handler_map* updates the default handler map found at `matplotlib.legend.Legend.get_legend_handler_map()`.

**Notes**

Not all kinds of artist are supported by the legend command. See *Legend guide* for details.

**matplotlib.pyplot.fignum_exists**

`matplotlib.pyplot.fignum_exists(num)`

Return whether the figure with the given id exists.

**matplotlib.pyplot.figtext**

`matplotlib.pyplot.figtext(x, y, s, *args, **kwargs)`

Add text to figure.

**Parameters**

- **x, y** [float] The position to place the text. By default, this is in figure coordinates, floats in [0, 1]. The coordinate system can be changed using the *transform* keyword.
- **s** [str] The text string.
fontdict [dictionary, optional, default: None] A dictionary to override the default text properties. If fontdict is None, the defaults are determined by your rc parameters. A property in kwargs override the same property in fontdict.

Returns
text [Text]

Other Parameters

**kwargs [Text properties] Other other miscellaneous text parameters.

Examples using matplotlib.pyplot.figtext

- sphx_glr_gallery_text_labels_and_annotations_fonts_demo.py
- sphx_glr_gallery_text_labels_and_annotations_fonts_demo_kw.py

matplotlib.pyplot.figure

```
matplot.pyplot.figure(num=None, figsize=None, dpi=None, facecolor=None, edgecolor=None, frameon=True, FigureClass=<class 'matplotlib.figure.Figure'>, clear=False, **kwargs)
```

Create a new figure.

**Parameters**

- **num** [integer or string, optional, default: None] If not provided, a new figure will be created, and the figure number will be incremented. The figure object holds this number in a **number** attribute. If *num* is provided, and a figure with this id already exists, make it active, and returns a reference to it. If this figure does not exist, create it and return it. If *num* is a string, the window title will be set to this figure’s name.

- **figsize** [(float, float), optional, default: None] width, height in inches. If not provided, defaults to rcParams["figure.figsize"] = [6.4, 4.8].

- **dpi** [integer, optional, default: None] resolution of the figure. If not provided, defaults to rcParams["figure.dpi"] = 100.

- **facecolor** [color spec] the background color. If not provided, defaults to rcParams["figure.facecolor"] = 'w'.

- **edgecolor** [color spec] the border color. If not provided, defaults to rcParams["figure.edgecolor"] = 'w'.

- **frameon** [bool, optional, default: True] If False, suppress drawing the figure frame.

- **FigureClass** [subclass of Figure] Optionally use a custom Figure instance.

- **clear** [bool, optional, default: False] If True and the figure already exists, then it is cleared.
Returns

figure [Figure] The Figure instance returned will also be passed to new_figure_manager in the backends, which allows to hook custom Figure classes into the pyplot interface. Additional kwargs will be passed to the Figure init function.

Notes

If you are creating many figures, make sure you explicitly call pyplot.close() on the figures you are not using, because this will enable pyplot to properly clean up the memory. rcParams defines the default values, which can be modified in the matplotlibrc file.

matplotlib.pyplot.fill

matplotlib.pyplot.fill(*args, data=None, **kwargs)
Plot filled polygons.

Parameters

*args [sequence of x, y, [color]] Each polygon is defined by the lists of x and y positions of its nodes, optionally followed by a color specifier. See matplotlib.colors for supported color specifiers. The standard color cycle is used for polygons without a color specifier.

You can plot multiple polygons by providing multiple x, y, [color] groups.

For example, each of the following is legal:

```
ax.fill(x, y)  # a polygon with default color
ax.fill(x, y, "b")  # a blue polygon
ax.fill(x, y, x2, y2)  # two polygons
ax.fill(x, y, "b", x2, y2, "r")  # a blue and a red polygon
```

data [indexable object, optional] An object with labelled data. If given, provide the label names to plot in x and y, e.g.:

```
ax.fill("time", "signal",
data={"time": [0, 1, 2], "signal": [0, 1, 0])
```

Returns

a list of Polygon

Other Parameters

**kwargs [Polygon properties]

Notes

Use fill_between() if you would like to fill the region between two curves.

Examples using matplotlib.pyplot.fill

- sphx_glr_gallery_lines_bars_and_markers_fill.py
- sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py
- sphx_glr_gallery_misc_fill_spiral.py
Fill the area between two horizontal curves.

The curves are defined by the points \((x, y_1)\) and \((x, y_2)\). This creates one or multiple polygons describing the filled area.

You may exclude some horizontal sections from filling using \(where\).

By default, the edges connect the given points directly. Use \(step\) if the filling should be a step function, i.e. constant in between \(x\).

**Parameters**

- \(x\) [array (length N)] The \(x\) coordinates of the nodes defining the curves.
- \(y_1\) [array (length N) or scalar] The \(y\) coordinates of the nodes defining the first curve.
- \(y_2\) [array (length N) or scalar, optional, default: 0] The \(y\) coordinates of the nodes defining the second curve.
- \(where\) [array of bool (length N), optional, default: None] Define \(where\) to exclude some horizontal regions from being filled. The filled regions are defined by the coordinates \(x[where]\). More precisely, fill between \(x[i]\) and \(x[i+1]\) if \(where[i]\) and \(where[i+1]\). Note that this definition implies that an isolated \(True\) value between two \(False\) values in \(where\) will not result in filling. Both sides of the \(True\) position remain unfilled due to the adjacent \(False\) values.
- \(interpolate\) [bool, optional] This option is only relevant if \(where\) is used and the two curves are crossing each other.

  Semantically, \(where\) is often used for \(y_1 > y_2\) or similar. By default, the nodes of the polygon defining the filled region will only be placed at the positions in the \(x\) array. Such a polygon cannot describe the above semantics close to the intersection. The \(x\)-sections containing the intersection are simply clipped.

  Setting \(interpolate\) to \(True\) will calculate the actual intersection point and extend the filled region up to this point.

- \(step\) [{‘pre’, ‘post’, ‘mid’}, optional] Define \(step\) if the filling should be a step function, i.e. constant in between \(x\). The value determines where the step will occur:
  - ‘pre’: The \(y\) value is continued constantly to the left from every \(x\) position, i.e. the interval \((x[i-1], x[i])\) has the value \(y[i]\).
  - ‘post’: The \(y\) value is continued constantly to the right from every \(x\) position, i.e. the interval \([x[i], x[i+1])\) has the value \(y[i]\).
  - ‘mid’: Steps occur half-way between the \(x\) positions.

**Returns**

- \(PolyCollection\) A \(PolyCollection\) containing the plotted polygons.

**Other Parameters**
**kwargs  All other keyword arguments are passed on to PolyCollection. They control the Polygon properties:

See also:

fill_betweenx  Fill between two sets of x-values.

Notes

Note: In addition to the above described arguments, this function can take a data key-word argument. If such a data argument is given, the following arguments are replaced...
by `data[<arg>]`:  
- All arguments with the following names: `where`, `x`, `y1`, `y2`.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

Examples using `matplotlib.pyplot.fill_between`

- `sphx_glr_gallery_text_labels_and_annotations_mathtext_examples.py`

```
matplotlib.pyplot.fill_betweenx
```

`matplotlib.pyplot.fill_betweenx(y, x1, x2=0, where=None, step=None, interpolate=False, *, data=None, **kwargs)`

Fill the area between two vertical curves.

The curves are defined by the points $(x1, y)$ and $(x2, y)$. This creates one or multiple polygons describing the filled area.

You may exclude some vertical sections from filling using `where`.

By default, the edges connect the given points directly. Use `step` if the filling should be a step function, i.e. constant in between $y$.

**Parameters**

- **y** [array (length N)] The $y$ coordinates of the nodes defining the curves.
- **x1** [array (length N) or scalar] The $x$ coordinates of the nodes defining the first curve.
- **x2** [array (length N) or scalar, optional, default: 0] The $x$ coordinates of the nodes defining the second curve.
- **where** [array of bool (length N), optional, default: None] Define `where` to exclude some vertical regions from being filled. The filled regions are defined by the coordinates $y[where]$. More precisely, fill between $y[i]$ and $y[i+1]$ if $where[i]$ and $where[i+1]$. Note that this definition implies that an isolated `True` value between two `False` values in `where` will not result in filling. Both sides of the `True` position remain unfilled due to the adjacent `False` values.
- **interpolate** [bool, optional] This option is only relevant if `where` is used and the two curves are crossing each other.

Semantically, `where` is often used for $x1 > x2$ or similar. By default, the nodes of the polygon defining the filled region will only be placed at the positions in the $y$ array. Such a polygon cannot describe the above semantics close to the intersection. The $y$-sections containing the intersection are simply clipped.

Setting `interpolate` to `True` will calculate the actual intersection point and extend the filled region up to this point.

- **step** [{‘pre’, ‘post’, ‘mid’}, optional] Define `step` if the filling should be a step function, i.e. constant in between $y$. The value determines where the step will occur:
Matplotlib, Release 3.1.1

- 'pre': The y value is continued constantly to the left from every x position, i.e. the interval \((x_{i-1}, x_i]\) has the value \(y_i\).
- 'post': The y value is continued constantly to the right from every x position, i.e. the interval \([x_i, x_{i+1})\) has the value \(y_i\).
- 'mid': Steps occur half-way between the x positions.

Returns

_PolyCollection_ A _PolyCollection_ containing the plotted polygons.

Other Parameters

**kwargs All other keyword arguments are passed on to _PolyCollection_.

They control the _Polygon_ properties:

*fill_between* Fill between two sets of y-values.

Notes

**Note:** In addition to the above described arguments, this function can take a *data* keyword argument. If such a *data* argument is given, the following arguments are replaced by *data*[<arg>]:

- All arguments with the following names: ‘where’, ‘x1’, ‘x2’, ‘y’.

Objects passed as *data* must support item access (*data*[<arg>]) and membership test (<arg> in data).

*matplotlib.pyplot.findobj*

*matplotlib.pyplot.findobj*(*o=None, match=None, include_self=True*)

Find artist objects.

Recursively find all *Artist* instances contained in the artist.

**Parameters**

- **match** A filter criterion for the matches. This can be
  - *None*: Return all objects contained in artist.
  - A function with signature def match(artist: Artist) -> bool. The result will only contain artists for which the function returns *True*.
  - A class instance: e.g., Line2D. The result will only contain artists of this class or its subclasses (isinstance check).

- **include_self** [bool] Include *self* in the list to be checked for a match.

**Returns**

- **artists** [list of *Artist*]

*matplotlib.pyplot.flag*

*matplotlib.pyplot.flag()*

Set the colormap to “flag”.

This changes the default colormap as well as the colormap of the current image if there is one. See help(colormaps) for more information.
Get the current Axes instance on the current figure matching the given keyword args, or create one.

**See also:**

- `matplotlib.figure.Figure(gca)` The figure's gca method.

**Examples**

To get the current polar axes on the current figure:

```python
gca(projection='polar')
```

If the current axes doesn’t exist, or isn’t a polar one, the appropriate axes will be created and then returned.

**Examples using `matplotlib.pyplot.gca`**

- sphx_glr_gallery_images_contours_and_fields_image.annotated_Heatmap.py
- sphx_glr_gallery_subplots_axes_and_figures_multiple_figs_demo.py

- sphx_glr_gallery_text_labels_and_annotations_usetex_demo.py
- sphx_glr_gallery_text_labels_and_annotations_usetex_fonteffects.py
- sphx_glr_gallery_pyplots_pyplot_scales.py
- sphx_glr_gallery_axes_grid1_simple_anchored_artists.py
- sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py
- sphx_glr_gallery_event_handling_trifinder_event_demo.py
- sphx_glr_gallery_misc_anchored_artists.py
- sphx_glr_gallery_misc_set_and_get.py
- sphx_glr_gallery_scales_custom_scale.py
- sphx_glr_gallery_scales_symlog_demo.py
- sphx_glr_gallery_specialty_plots_hinton_demo.py
- Pyplot tutorial
- Legend guide
- Tight Layout guide
matplotlib.pyplot.gcf

matplotlib.pyplot.gcf()
    Get the current figure.
    If no current figure exists, a new one is created using figure().

Examples using matplotlib.pyplot.gcf

- sphx_glr_gallery_text_labels_and_annotations_arrow_demo.py
- sphx_glr_gallery_event_handling_trifinder_event_demo.py
- Tight Layout guide

matplotlib.pyplot.gci

matplotlib.pyplot.gci()
    Get the current colorable artist. Specifically, returns the current ScalarMappable instance (image or patch collection), or None if no images or patch collections have been defined. The commands imshow() and figimage() create Image instances, and the commands pcolor() and scatter() create Collection instances. The current image is an attribute of the current axes, or the nearest earlier axes in the current figure that contains an image.

Notes

Historically, the only colorable artists were images; hence the name gci (get current image).

matplotlib.pyplot.get_current_fig_manager

matplotlib.pyplot.get_current_fig_manager()
    Return the figure manager of the current figure.
    The figure manager is a container for the actual backend-dependent window that displays the figure on screen.
    If if no current figure exists, a new one is created an its figure manager is returned.

    Returns

    manager [FigureManagerBase or backend-dependent subclass thereof]

Examples using matplotlib.pyplot.get_current_fig_manager

- sphx_glr_gallery_misc_agg_buffer.py

17.37. matplotlib.pyplot
matplotlib.pyplot.get_figlabels

```
matplotlib.pyplot.get_figlabels()
Return a list of existing figure labels.
```

matplotlib.pyplot.get_fignums

```
matplotlib.pyplot.get_fignums()
Return a list of existing figure numbers.
```

matplotlib.pyplot.get_plot_commands

```
matplotlib.pyplot.get_plot_commands()
Get a sorted list of all of the plotting commands.
```

matplotlib.pyplot.ginput

```
matplotlib.pyplot.ginput(*args, **kwargs)
Blocking call to interact with a figure.
Wait until the user clicks n times on the figure, and return the coordinates of each click
in a list.
There are three possible interactions:
  • Add a point.
  • Remove the most recently added point.
  • Stop the interaction and return the points added so far.
The actions are assigned to mouse buttons via the arguments mouse_add, mouse_pop
and mouse_stop. Mouse buttons are defined by the numbers:
  • 1: left mouse button
  • 2: middle mouse button
  • 3: right mouse button
  • None: no mouse button

Parameters

- **n** [int, optional, default: 1] Number of mouse clicks to accumulate. If
  negative, accumulate clicks until the input is terminated manually.
- **timeout** [scalar, optional, default: 30] Number of seconds to wait before
timing out. If zero or negative will never timeout.
- **show_clicks** [bool, optional, default: True] If True, show a red cross at
  the location of each click.
- **mouse_add** [{1, 2, 3, None}, optional, default: 1 (left click)] Mouse but-
  ton used to add points.
**mouse_pop** [{1, 2, 3, None}, optional, default: 3 (right click)] Mouse button used to remove the most recently added point.

**mouse_stop** [{1, 2, 3, None}, optional, default: 2 (middle click)] Mouse button used to stop input.

**Returns**

**points** [list of tuples] A list of the clicked (x, y) coordinates.

**Notes**

The keyboard can also be used to select points in case your mouse does not have one or more of the buttons. The delete and backspace keys act like right clicking (i.e., remove last point), the enter key terminates input and any other key (not already used by the window manager) selects a point.

**Examples using matplotlib.pyplot.ginput**

- sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py

**matplotlib.pyplot.gray**

**matplotlib.pyplot.gray()**

Set the colormap to "gray".

This changes the default colormap as well as the colormap of the current image if there is one. See help(colormaps) for more information.

**matplotlib.pyplot.grid**

**matplotlib.pyplot.grid(b=None, which='major', axis='both', **kwargs)**

Configure the grid lines.

**Parameters**

- **b** [bool or None, optional] Whether to show the grid lines. If any `kwargs` are supplied, it is assumed you want the grid on and `b` will be set to True.

  If `b` is `None` and there are no `kwargs`, this toggles the visibility of the lines.

- **which** [{‘major’, ‘minor’, ‘both’}, optional] The grid lines to apply the changes on.

- **axis** [{‘both’, ‘x’, ‘y’}, optional] The axis to apply the changes on.

- ****kwargs [Line2D properties] Define the line properties of the grid, e.g.:

  ```python
  grid(color='r', linestyle='-', linewidth=2)
  ```

  Valid `kwargs` are

</table>

**Notes**

The axis is drawn as a unit, so the effective zorder for drawing the grid is determined by the zorder of each axis, not by the zorder of the `Line2D` objects comprising the grid. Therefore, to set grid zorder, use `set_axisbelow` or, for more control, call the `set_zorder` method of each axis.

`Pyplot tutorial`

`matplotlib.pyplot.hexbin`

```python
matplotlib.pyplot.hexbin(x, y, C=None, gridsize=100, bins=None, xscale='linear', yscale='linear', extent=None, cmap=None, norm=None, vmin=None, vmax=None, alpha=None, linewidths=None, edgecolors='face', reduce_C_function=<function mean at 0x7f6977bac268>, mincnt=None, marginals=False, *, data=None, **kwargs)
```

Make a hexagonal binning plot.

Make a hexagonal binning plot of \( x \) versus \( y \), where \( x, y \) are 1-D sequences of the same length, \( N \). If \( C \) is None (the default), this is a histogram of the number of occurrences of the observations at \((x[i],y[i])\).

If \( C \) is specified, it specifies values at the coordinate \((x[i], y[i])\). These values are accumulated for each hexagonal bin and then reduced according to \( \text{reduce}_C\text{function} \), which defaults to `numpy.mean`. (If \( C \) is specified, it must also be a 1-D sequence of the same length as \( x \) and \( y \).)

**Parameters**

- **x, y** [array or masked array]
- **C** [array or masked array, optional, default is `None`]
- **gridsize** [int or (int, int), optional, default is 100] The number of hexagons in the x-direction, default is 100. The corresponding number of hexagons in the y-direction is chosen such that the hexagons are approximately regular. Alternatively, gridsize can be a tuple with two elements specifying the number of hexagons in the x-direction and the y-direction.
**bins** ['log' or int or sequence, optional, default is None] If None, no binning is applied; the color of each hexagon directly corresponds to its count value.

If ‘log’, use a logarithmic scale for the color map. Internally, \( \log_{10}(i + 1) \) is used to determine the hexagon color.

If an integer, divide the counts in the specified number of bins, and color the hexagons accordingly.

If a sequence of values, the values of the lower bound of the bins to be used.

**xscale** ['linear', 'log'], optional, default is 'linear'] Use a linear or log10 scale on the horizontal axis.

**yscale** ['linear', 'log'], optional, default is 'linear'] Use a linear or log10 scale on the vertical axis.

**mincnt** [int > 0, optional, default is None] If not None, only display cells with more than mincnt number of points in the cell.

**marginals** [bool, optional, default is False] if marginals is True, plot the marginal density as colormapped rectangles along the bottom of the x-axis and left of the y-axis.

**extent** [scalar, optional, default is None] The limits of the bins. The default assigns the limits based on gridsize, x, y, xscale and yscale.

If xscale or yscale is set to ‘log’, the limits are expected to be the exponent for a power of 10. E.g. for x-limits of 1 and 50 in ‘linear’ scale and y-limits of 10 and 1000 in ‘log’ scale, enter (1, 50, 1, 3). Order of scalars is (left, right, bottom, top).

**Returns**

**polycollection** A PolyCollection instance; use PolyCollection.get_array on this to get the counts in each hexagon.

If marginals is True, horizontal bar and vertical bar (both PolyCollections) will be attached to the return collection as attributes hbar and vbar.

**Other Parameters**

**cmap** [object, optional, default is None] a matplotlib.colors.Colormap instance. If None, defaults to rc image.cmap.

**norm** [object, optional, default is None] matplotlib.colors.Normalize instance is used to scale luminance data to 0,1.

**vmin, vmax** [scalar, optional, default is None] vmin and vmax are used in conjunction with norm to normalize luminance data. If None, the min and max of the color array C are used. Note if you pass a norm instance your settings for vmin and vmax will be ignored.

**alpha** [scalar between 0 and 1, optional, default is None] the alpha value for the patches.

**linewidths** [scalar, optional, default is None] If None, defaults to 1.0.

**edgecolors** [{‘face’, ‘none’, None} or color, optional] If ‘face’ (the default), draws the edges in the same color as the fill color.
If ‘none’, no edge is drawn; this can sometimes lead to unsightly unpainted pixels between the hexagons.

If None, draws outlines in the default color.

If a matplotlib color arg, draws outlines in the specified color.

Notes

</table>
Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’, ‘y’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

matplotlib.pyplot.hist

matplotlib.pyplot.hist(x, bins=None, range=None, density=None, weights=None, cumulative=False, bottom=None, histtype='bar', align='mid', orientation='vertical', rwidth=None, log=False, color=None, label=None, stacked=False, normed=None, *, data=None, **kwargs)

Plot a histogram.

Compute and draw the histogram of x. The return value is a tuple (n, bins, patches) or ([n0, n1, ...], bins, [patches0, patches1, ...]) if the input contains multiple data. See the documentation of the weights parameter to draw a histogram of already-binned data.

Multiple data can be provided via x as a list of datasets of potentially different length ([x0, x1, ...]), or as a 2-D ndarray in which each column is a dataset. Note that the ndarray form is transposed relative to the list form.

Masked arrays are not supported at present.

Parameters

x [(n,) array or sequence of (n,) arrays] Input values, this takes either a single array or a sequence of arrays which are not required to be of the same length.

bins [int or sequence or str, optional] If an integer is given, bins + 1 bin edges are calculated and returned, consistent with numpy.histogram.

If bins is a sequence, gives bin edges, including left edge of first bin and right edge of last bin. In this case, bins is returned unmodified.

All but the last (righthand-most) bin is half-open. In other words, if bins is:

[1, 2, 3, 4]

then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which includes 4.

Unequally spaced bins are supported if bins is a sequence.

With Numpy 1.11 or newer, you can alternatively provide a string describing a binning strategy, such as ‘auto’, ‘sturges’, ‘fd’, ‘doane’, ‘scott’, ‘rice’ or ‘sqrt’, see numpy.histogram.

The default is taken from rcParams["hist.bins"].
range [tuple or None, optional] The lower and upper range of the bins. Lower and upper outliers are ignored. If not provided, range is \((x.\min(), x.\max())\). Range has no effect if bins is a sequence.

If bins is a sequence or range is specified, autoscaling is based on the specified bin range instead of the range of x.

Default is None

density [bool, optional] If True, the first element of the return tuple will be the counts normalized to form a probability density, i.e., the area (or integral) under the histogram will sum to 1. This is achieved by dividing the count by the number of observations times the bin width and not dividing by the total number of observations. If stacked is also True, the sum of the histograms is normalized to 1.

Default is None for both normed and density. If either is set, then that value will be used. If neither are set, then the args will be treated as False.

If both density and normed are set an error is raised.

weights [(n, ) array_like or None, optional] An array of weights, of the same shape as x. Each value in x only contributes its associated weight towards the bin count (instead of 1). If normed or density is True, the weights are normalized, so that the integral of the density over the range remains 1.

Default is None.

This parameter can be used to draw a histogram of data that has already been binned, e.g. using np.histogram (by treating each bin as a single point with a weight equal to its count)

```python
counts, bins = np.histogram(data)
plt.hist(bins[:-1], bins, weights=counts)
```

(or you may alternatively use bar()).

cumulative [bool, optional] If True, then a histogram is computed where each bin gives the counts in that bin plus all bins for smaller values. The last bin gives the total number of datapoints. If normed or density is also True then the histogram is normalized such that the last bin equals 1. If cumulative evaluates to less than 0 (e.g., -1), the direction of accumulation is reversed. In this case, if normed and/or density is also True, then the histogram is normalized such that the first bin equals 1.

Default is False

bottom [array_like, scalar, or None] Location of the bottom baseline of each bin. If a scalar, the base line for each bin is shifted by the same amount. If an array, each bin is shifted independently and the length of bottom must match the number of bins. If None, defaults to 0.

Default is None

• 'bar' is a traditional bar-type histogram. If multiple data are given the bars are arranged side by side.

• 'barstacked' is a bar-type histogram where multiple data are stacked on top of each other.

• 'step' generates a lineplot that is by default unfilled.

• 'stepfilled' generates a lineplot that is by default filled.

Default is 'bar'

align [{‘left’, ‘mid’, ‘right’}, optional] Controls how the histogram is plotted.

• 'left': bars are centered on the left bin edges.

• 'mid': bars are centered between the bin edges.

• 'right': bars are centered on the right bin edges.

Default is 'mid'

orientation [{‘horizontal’, ‘vertical’}, optional] If ‘horizontal’, barh will be used for bar-type histograms and the bottom kwarg will be the left edges.

rwidth [scalar or None, optional] The relative width of the bars as a fraction of the bin width. If None, automatically compute the width.

Ignored if histtype is 'step' or 'stepfilled'.

Default is None

log [bool, optional] If True, the histogram axis will be set to a log scale. If log is True and x is a 1D array, empty bins will be filtered out and only the non-empty (n, bins, patches) will be returned.

Default is False

color [color or array_like of colors or None, optional] Color spec or sequence of color specs, one per dataset. Default (None) uses the standard line color sequence.

Default is None

label [str or None, optional] String, or sequence of strings to match multiple datasets. Bar charts yield multiple patches per dataset, but only the first gets the label, so that the legend command will work as expected.

default is None

stacked [bool, optional] If True, multiple data are stacked on top of each other. If False multiple data are arranged side by side if histtype is 'bar' or on top of each other if histtype is 'step'

Default is False

normed [bool, optional] Deprecated; use the density keyword argument instead.

Returns
n [array or list of arrays] The values of the histogram bins. See density and weights for a description of the possible semantics. If input x is an array, then this is an array of length nbins. If input is a sequence of arrays [data1, data2, ...], then this is a list of arrays with the values of the histograms for each of the arrays in the same order. The dtype of the array n (or of its element arrays) will always be float even if no weighting or normalization is used.

bins [array] The edges of the bins. Length nbins + 1 (nbins left edges and right edge of last bin). Always a single array even when multiple data sets are passed in.

patches [list or list of lists] Silent list of individual patches used to create the histogram or list of such list if multiple input datasets.

Other Parameters
**kwargs [Patch properties]

See also:

hist2d 2D histograms

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘weights’, ‘x’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.pyplot.hist

- sphx_glr_gallery_subplots_axes_and_figures_axes_demo.py
- sphx_glr_gallery_pyplots_pyplot_text.py
- sphx_glr_gallery_user_interfaces_svg_histogram_sgskip.py
- Pyplot tutorial
- Image tutorial

matplotlib.pyplot.hist2d

matplotlib.pyplot.hist2d(x, y, bins=10, range=None, density=False, weights=None, cmin=None, cmax=None, *, data=None, **kwargs)

Make a 2D histogram plot.

Parameters

x, y [array_like, shape (n, )] Input values
bins [None or int or [int, int] or array_like or [array, array]] The bin specification:

- If int, the number of bins for the two dimensions (nx=ny=bins).
- If [int, int], the number of bins in each dimension (nx, ny = bins).
- If array_like, the bin edges for the two dimensions (x_edges=y_edges=bins).
- If [array, array], the bin edges in each dimension (x_edges, y_edges = bins).

The default value is 10.

range [array_like shape(2, 2), optional, default: None] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the bins parameters): [[xmin, xmax], [ymin, ymax]]. All values outside of this range will be considered outliers and not tallied in the histogram.

density [bool, optional, default: False] Normalize histogram. normed is a deprecated synonym for this parameter.

weights [array_like, shape (n, ), optional, default: None] An array of values w_i weighing each sample (x_i, y_i).

cmin [scalar, optional, default: None] All bins that has count less than cmin will not be displayed and these count values in the return value count histogram will also be set to nan upon return

cmax [scalar, optional, default: None] All bins that has count more than cmax will not be displayed (set to none before passing to imshow) and these count values in the return value count histogram will also be set to nan upon return

Returns

h [2D array] The bi-dimensional histogram of samples x and y. Values in x are histogrammed along the first dimension and values in y are histogrammed along the second dimension.

xedges [1D array] The bin edges along the x axis.

yedges [1D array] The bin edges along the y axis.

image [QuadMesh]

Other Parameters

- norm [Normalize, optional] A colors.Normalize instance is used to scale luminance data to [0, 1]. If not set, defaults to colors.Normalize().

- vmin/vmax [None or scalar, optional] Arguments passed to the Normalize instance.

- alpha [0 <= scalar <= 1 or None, optional] The alpha blending value.

See also:

hist 1D histogram plotting
Notes

- Currently `hist2d` calculates its own axis limits, and any limits previously set are ignored.
- Rendering the histogram with a logarithmic color scale is accomplished by passing a `colors.LogNorm` instance to the `norm` keyword argument. Likewise, power-law normalization (similar in effect to gamma correction) can be accomplished with `colors.PowerNorm`.

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘weights’, ‘x’, ‘y’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

Examples using `matplotlib.pyplot.hist2d`

- `sphx_glr_gallery_scales_power_norm.py`

`matplotlib.pyplot.hlines`

`matplotlib.pyplot.hlines(y, xmin, xmax, colors='k', linestyles='solid', label='', *, data=None, **kwargs)`

Plot horizontal lines at each `y` from `xmin` to `xmax`.

**Parameters**

- `y` [scalar or sequence of scalar] y-indexes where to plot the lines.
- `xmin, xmax` [scalar or 1D array_like] Respective beginning and end of each line. If scalars are provided, all lines will have same length.
- `colors` [array_like of colors, optional, default: ‘k’]
- `linestyles` [{‘solid’, ‘dashed’, ‘dashdot’, ‘dotted’}, optional]
- `label` [string, optional, default: “”]

**Returns**

- `lines` [LineCollection]

**Other Parameters**

- `**kwargs` [LineCollection properties.]

**See also:**

- `vlines` vertical lines
- `axhline` horizontal line across the axes
Notes

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘colors’, ‘xmax’, ‘xmin’, ‘y’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

matplotlib.pyplot.hot

matplotlib.pyplot.hot()

Set the colormap to “hot”.

This changes the default colormap as well as the colormap of the current image if there is one. See help(colormaps) for more information.

matplotlib.pyplot.hsv

matplotlib.pyplot.hsv()

Set the colormap to “hsv”.

This changes the default colormap as well as the colormap of the current image if there is one. See help(colormaps) for more information.

matplotlib.pyplot.imread

matplotlib.pyplot.imread(fname, format=None)

Read an image from a file into an array.

Parameters

fname [str or file-like] The image file to read. This can be a filename, a URL or a Python file-like object opened in read-binary mode.

format [str, optional] The image file format assumed for reading the data. If not given, the format is deduced from the filename. If nothing can be deduced, PNG is tried.

Returns

imagedata [numpy.array] The image data. The returned array has shape

- (M, N) for grayscale images.
- (M, N, 3) for RGB images.
- (M, N, 4) for RGBA images.
Notes

Matplotlib can only read PNGs natively. Further image formats are supported via the optional dependency on Pillow. Note, URL strings are not compatible with Pillow. Check the Pillow documentation for more information.

Examples using matplotlib.pyplot.imread

- sphx_glr_gallery_images_contours_and_fields_image_clip_path.py
- sphx_glr_gallery_images_contours_and_fields_image_demo.py
- sphx_glr_gallery_images_contours_and_fields_watermark_image.py
- sphx_glr_gallery_text_labels_and_annotations_demo_annotation_box.py
- sphx_glr_gallery_text_labels_and_annotations_demo_text_path.py
- sphx_glr_gallery_misc_demo_ribbon_box.py

matplotlib.pyplot.imsave

matplotlib.pyplot.imsave(fname, arr, **kwargs)
Save an array as an image file.

Parameters

fname [str or PathLike file-like] A path or a Python file-like object to store the image in. If format is not set, then the output format is inferred from the extension of fname, if any, and from rcParams["savefig.format"] otherwise. If format is set, it determines the output format.

arr [array-like] The image data. The shape can be one of MxN (luminance), MxNx3 (RGB) or MxNx4 (RGBA).

vmin, vmax [scalar, optional] vmin and vmax set the color scaling for the image by fixing the values that map to the colormap color limits. If either vmin or vmax is None, that limit is determined from the arr min/max value.

cmap [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps scalar data to colors. It is ignored for RGB(A) data. Defaults to rcParams["image.cmap"] (‘viridis’).

format [str, optional] The file format, e.g. ‘png’, ‘pdf’, ‘svg’, ... The behavior when this is unset is documented under fname.

origin [{‘upper’, ‘lower’}, optional] Indicates whether the (0, 0) index of the array is in the upper left or lower left corner of the axes. Defaults to rcParams["image.origin"] (‘upper’).

dpi [int] The DPI to store in the metadata of the file. This does not affect the resolution of the output image.
Display an image, i.e. data on a 2D regular raster.

**Parameters**

- **X** [array-like or PIL image] The image data. Supported array shapes are:
  - (M, N): an image with scalar data. The data is visualized using a colormap.
  - (M, N, 3): an image with RGB values (0-1 float or 0-255 int).
  - (M, N, 4): an image with RGBA values (0-1 float or 0-255 int), i.e. including transparency.

  The first two dimensions (M, N) define the rows and columns of the image.

  Out-of-range RGB(A) values are clipped.

- **cmap** [str or Colormap, optional] The Colormap instance or registered colormap name used to map scalar data to colors. This parameter is ignored for RGB(A) data. Defaults to `rcParams["image.cmap"]`.

- **norm** [Normalize, optional] The Normalize instance used to scale scalar data to the [0, 1] range before mapping to colors using `cmap`. By default, a linear scaling mapping the lowest value to 0 and the highest to 1 is used. This parameter is ignored for RGB(A) data.

- **aspect** [{‘equal’, ‘auto’} or float, optional] Controls the aspect ratio of the axes. The aspect is of particular relevance for images since it may distort the image, i.e. pixel will not be square.

  This parameter is a shortcut for explicitly calling `Axes.set_aspect`. See there for further details.

  - ‘equal’: Ensures an aspect ratio of 1. Pixels will be square (unless pixel sizes are explicitly made non-square in data coordinates using `extent`).

  - ‘auto’: The axes is kept fixed and the aspect is adjusted so that the data fit in the axes. In general, this will result in non-square pixels.

  If not given, use `rcParams["image.aspect"]` (default: ‘equal’).

- **interpolation** [str, optional] The interpolation method used. If None `rcParams["image.interpolation"]` is used, which defaults to ‘nearest’.

  If `interpolation` is ‘none’, then no interpolation is performed on the Agg, ps, pdf and svg backends. Other backends will fall back to ‘nearest’. Note that most SVG renders perform interpolation at rendering and that the default interpolation method they implement may differ.
See /gallery/images_contours_and_fields/interpolation_methods for an overview of the supported interpolation methods.

Some interpolation methods require an additional radius parameter, which can be set by filterrad. Additionally, the antigrain image resize filter is controlled by the parameter filternorm.

**alpha** [scalar, optional] The alpha blending value, between 0 (transparent) and 1 (opaque). This parameter is ignored for RGBA input data.

**vmin, vmax** [scalar, optional] When using scalar data and no explicit norm, vmin and vmax define the data range that the colormap covers. By default, the colormap covers the complete value range of the supplied data. vmin, vmax are ignored if the norm parameter is used.

**origin** [{‘upper’, ‘lower’}, optional] Place the [0,0] index of the array in the upper left or lower left corner of the axes. The convention ‘upper’ is typically used for matrices and images. If not given, rcParams["image.origin"] is used, defaulting to ‘upper’.

Note that the vertical axes points upward for ‘lower’ but downward for ‘upper’.

See the origin and extent in imshow tutorial for examples and a more detailed description.

**extent** [scalars (left, right, bottom, top), optional] The bounding box in data coordinates that the image will fill. The image is stretched individually along x and y to fill the box.

The default extent is determined by the following conditions. Pixels have unit size in data coordinates. Their centers are on integer coordinates, and their center coordinates range from 0 to columns-1 horizontally and from 0 to rows-1 vertically.

Note that the direction of the vertical axis and thus the default values for top and bottom depend on origin:

- For origin == ‘upper’ the default is (-0.5, numcols-0.5, numrows-0.5, -0.5).
- For origin == ‘lower’ the default is (-0.5, numcols-0.5, -0.5, numrows-0.5).

See the origin and extent in imshow tutorial for examples and a more detailed description.

**filternorm** [bool, optional, default: True] A parameter for the antigrain image resize filter (see the antigrain documentation). If filternorm is set, the filter normalizes integer values and corrects the rounding errors. It doesn’t do anything with the source floating point values, it corrects only integers according to the rule of 1.0 which means that any sum of pixel weights must be equal to 1.0. So, the filter function must produce a graph of the proper shape.

**filterrad** [float > 0, optional, default: 4.0] The filter radius for filters that have a radius parameter, i.e. when interpolation is one of: ‘sinc’, ‘lanczos’ or ‘blackman’.

**resample** [bool, optional] When True, use a full resampling method. When False, only resample when the output image is larger than the
input image.

url [str, optional] Set the url of the created AxesImage. See Artist.set_url.

Returns

image [AxesImage]

Other Parameters

**kwargs [Artist properties] These parameters are passed on to the constructor of the AxesImage artist.

See also:

matshow Plot a matrix or an array as an image.

Notes

Unless extent is used, pixel centers will be located at integer coordinates. In other words: the origin will coincide with the center of pixel (0, 0).

There are two common representations for RGB images with an alpha channel:

- Straight (unassociated) alpha: R, G, and B channels represent the color of the pixel, disregarding its opacity.
- Premultiplied (associated) alpha: R, G, and B channels represent the color of the pixel, adjusted for its opacity by multiplication.

imshow expects RGB images adopting the straight (unassociated) alpha representation.

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[arg]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[arg]) and membership test (<arg> in data).

**matplotlib.pyplot.inferno**

`matplotlib.pyplot.inferno()`

Set the colormap to "inferno".

This changes the default colormap as well as the colormap of the current image if there is one. See `help(colormaps)` for more information.

**matplotlib.pyplot.install_repl_displayhook**

`matplotlib.pyplot.install_repl_displayhook()`

Install a repl display hook so that any stale figure are automatically redrawn when control is returned to the repl.

This works both with IPython and with vanilla python shells.

**matplotlib.pyplot.ioff**

`matplotlib.pyplot.ioff()`

Turn the interactive mode off.

**Examples using matplotlib.pyplot.ioff**

- *Usage Guide*

**matplotlib.pyplot.ion**

`matplotlib.pyplot.ion()`

Turn the interactive mode on.
Examples using `matplotlib.pyplot.ion`

- **Usage Guide**

`matplotlib.pyplot.isinteractive`

`matplotlib.pyplot.isinteractive()`

Return the status of interactive mode.

`matplotlib.pyplot.jet`

`matplotlib.pyplot.jet()`

Set the colormap to "jet".

This changes the default colormap as well as the colormap of the current image if there is one. See `help(colormaps)` for more information.

`matplotlib.pyplot.legend`

`matplotlib.pyplot.legend(*args, **kwargs)`

Place a legend on the axes.

Call signatures:

```python
legend()
legend(labels)
legend(handles, labels)
```

The call signatures correspond to three different ways how to use this method.

1. **Automatic detection of elements to be shown in the legend**

The elements to be added to the legend are automatically determined, when you do not pass in any extra arguments.

In this case, the labels are taken from the artist. You can specify them either at artist creation or by calling the `set_label()` method on the artist:

```python
line, = ax.plot([1, 2, 3], label='Inline label')
ax.legend()
```

or:

```python
line, = ax.plot([1, 2, 3])
line.set_label('Label via method')
ax.legend()
```

Specific lines can be excluded from the automatic legend element selection by defining a label starting with an underscore. This is default for all artists, so calling `Axes.legend` without any arguments and without setting the labels manually will result in no legend being drawn.

2. **Labeling existing plot elements**
To make a legend for lines which already exist on the axes (via plot for instance), simply call this function with an iterable of strings, one for each legend item. For example:

```python
ax.plot([1, 2, 3])
ax.legend(['A simple line'])
```

Note: This way of using is discouraged, because the relation between plot elements and labels is only implicit by their order and can easily be mixed up.

### 3. Explicitly defining the elements in the legend

For full control of which artists have a legend entry, it is possible to pass an iterable of legend artists followed by an iterable of legend labels respectively:

```python
legend((line1, line2, line3), ('label1', 'label2', 'label3'))
```

#### Parameters

- **handles** [sequence of Artist, optional] A list of Artists (lines, patches) to be added to the legend. Use this together with **labels**, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.

  The length of handles and labels should be the same in this case. If they are not, they are truncated to the smaller length.

- **labels** [sequence of strings, optional] A list of labels to show next to the artists. Use this together with **handles**, if you need full control on what is shown in the legend and the automatic mechanism described above is not sufficient.

#### Returns

*matplotlib.legend.Legend* instance

#### Other Parameters

- **loc** [str or pair of floats, default: `rcParams["legend.loc"]` ('best' for axes, 'upper right' for figures)] The location of the legend.

  The strings 'upper left', 'upper right', 'lower left', 'lower right' place the legend at the corresponding corner of the axes/figure.

  The strings 'upper center', 'lower center', 'center left', 'center right' place the legend at the center of the corresponding edge of the axes/figure.

  The string 'center' places the legend at the center of the axes/figure.

  The string 'best' places the legend at the location, among the nine locations defined so far, with the minimum overlap with other drawn artists. This option can be quite slow for plots with large amounts of data; your plotting speed may benefit from providing a specific location.

  The location can also be a 2-tuple giving the coordinates of the lower-left corner of the legend in axes coordinates (in which case `bbox_to_anchor` will be ignored).
For back-compatibility, 'center right' (but no other location) can also be spelled 'right', and each "string" locations can also be given as a numeric value:

<table>
<thead>
<tr>
<th>Location String</th>
<th>Location Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>'best'</td>
<td>0</td>
</tr>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>

bbox_to_anchor [BboxBase, 2-tuple, or 4-tuple of floats] Box that is used to position the legend in conjunction with loc. Defaults to axes.bbox (if called as a method to Axes.legend) or figure.bbox (if Figure.legend). This argument allows arbitrary placement of the legend.

Bbox coordinates are interpreted in the coordinate system given by bbox_transform, with the default transform Axes or Figure coordinates, depending on which legend is called.

If a 4-tuple or BboxBase is given, then it specifies the bbox (x, y, width, height) that the legend is placed in. To put the legend in the best location in the bottom right quadrant of the axes (or figure):

```
loc='best', bbox_to_anchor=(0.5, 0., 0.5, 0.5)
```

A 2-tuple (x, y) places the corner of the legend specified by loc at x, y. For example, to put the legend’s upper right-hand corner in the center of the axes (or figure) the following keywords can be used:

```
loc='upper right', bbox_to_anchor=(0.5, 0.5)
```

ncol [integer] The number of columns that the legend has. Default is 1.

prop [None or matplotlib.font_manager.FontProperties or dict] The font properties of the legend. If None (default), the current matplotlib.rcParams will be used.

fontsize [int or float or {'xx-small', 'x-small', 'small', 'medium', 'large', 'x-large', 'xx-large'}] Controls the font size of the legend. If the value is numeric the size will be the absolute font size in points. String values are relative to the current default font size. This argument is only used if prop is not specified.

numpoints [None or int] The number of marker points in the legend when creating a legend entry for a Line2D (line). Default is None, which will take the value from rcParams["legend.markersize"].

scatterpoints [None or int] The number of marker points in the legend when creating a legend entry for a PathCollection (scatter plot).
Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.scatterpoints"]}.

**scatteryoffsets** [iterable of floats] The vertical offset (relative to the font size) for the markers created for a scatter plot legend entry. 0.0 is at the base the legend text, and 1.0 is at the top. To draw all markers at the same height, set to [0.5]. Default is [0.375, 0.5, 0.3125].

**markerscale** [None or int or float] The relative size of legend markers compared with the originally drawn ones. Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.markerscale"]}.

**markerfirst** [bool] If \texttt{True}, legend marker is placed to the left of the legend label. If \texttt{False}, legend marker is placed to the right of the legend label. Default is \texttt{True}.

**frameon** [None or bool] Control whether the legend should be drawn on a patch (frame). Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.frameon"]}.

**fancybox** [None or bool] Control whether round edges should be enabled around the \texttt{FancyBboxPatch} which makes up the legend’s background. Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.fancybox"]}.

**shadow** [None or bool] Control whether to draw a shadow behind the legend. Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.shadow"]}.

**framealpha** [None or float] Control the alpha transparency of the legend’s background. Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.framealpha"]}. If shadow is activated and \texttt{framealpha} is \texttt{None}, the default value is ignored.

**facecolor** [None or “inherit” or a color spec] Control the legend’s background color. Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.facecolor"]}. If “inherit”, it will take \texttt{rcParams["axes.facecolor"]}.

**edgecolor** [None or “inherit” or a color spec] Control the legend’s background patch edge color. Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.edgecolor"]}. If “inherit”, it will take \texttt{rcParams["axes.edgecolor"]}.

**mode** [{“expand”, \texttt{None}}] If \texttt{mode} is set to "expand" the legend will be horizontally expanded to fill the axes area (or \texttt{bbox_to_anchor} if defines the legend’s size).

**bbox_transform** [None or \texttt{matplotlib.transforms.Transform}] The transform for the bounding box (\texttt{bbox_to_anchor}). For a value of \texttt{None} (default) the Axes’ \texttt{transAxes} transform will be used.

**title** [str or \texttt{None}] The legend’s title. Default is no title (\texttt{None}).

**title_fontsize**: \texttt{str} or \texttt{None} The fontsize of the legend’s title. Default is the default fontsize.

**borderpad** [float or \texttt{None}] The fractional whitespace inside the legend border. Measured in font-size units. Default is \texttt{None}, which will take the value from \texttt{rcParams["legend.borderpad"]}.  

\texttt{17.37. \texttt{matplotlib.pyplot}}
**labelspsacing** [float or None] The vertical space between the legend entries. Measured in font-size units. Default is None, which will take the value from `rcParams["legend.labelspacing"]`.

**handlelength** [float or None] The length of the legend handles. Measured in font-size units. Default is None, which will take the value from `rcParams["legend.handlelength"]`.

**handletextpad** [float or None] The pad between the legend handle and text. Measured in font-size units. Default is None, which will take the value from `rcParams["legend.handletextpad"]`.

**borderaxespad** [float or None] The pad between the axes and legend border. Measured in font-size units. Default is None, which will take the value from `rcParams["legend.borderaxespad"]`.

**columnspacing** [float or None] The spacing between columns. Measured in font-size units. Default is None, which will take the value from `rcParams["legend.columnspacing"]`.

**handler_map** [dict or None] The custom dictionary mapping instances or types to a legend handler. This `handler_map` updates the default handler map found at `matplotlib.legend.Legend.get_legend_handler_map()`.

**Notes**

Not all kinds of artist are supported by the legend command. See *Legend guide* for details.

**Examples**

- sphx_glr_gallery_axes_grid1_parasite_simple.py
matplotlib.pyplot.locator_params

`matplotlib.pyplot.locator_params(axis=’both’, tight=None, **kwargs)`

Control behavior of major tick locators.

Because the locator is involved in autoscaling, `autoscale_view` is called automatically after the parameters are changed.

**Parameters**

- `axis` [{‘both’, ‘x’, ‘y’}, optional] The axis on which to operate.
tight [bool or None, optional] Parameter passed to autoscale_view. Default is None, for no change.

Other Parameters

**kwargs Remaining keyword arguments are passed to directly to the set_params() method of the locator. Supported keywords depend on the type of the locator. See for example set_params for the ticker. MaxNLocator used by default for linear axes.

Examples

When plotting small subplots, one might want to reduce the maximum number of ticks and use tight bounds, for example:

```python
ax.locator_params(tight=True, nbins=4)
```

matplotlib.pyplot.loglog

```python
matplotlib.pyplot.loglog(*args, **kwargs)
```

Make a plot with log scaling on both the x and y axis.

Call signatures:

```python
loglog([x], y, [fmt], data=None, **kwargs)
loglog([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
```

This is just a thin wrapper around plot which additionally changes both the x-axis and the y-axis to log scaling. All of the concepts and parameters of plot can be used here as well.

The additional parameters basex/y, subsx/y and nonposx/y control the x/y-axis properties. They are just forwarded to Axes.set_xscale and Axes.set_yscale.

Parameters

- **basex**, **basey** [scalar, optional, default 10] Base of the x/y logarithm.
- **subsx**, **subsy** [sequence, optional] The location of the minor x/y ticks. If None, reasonable locations are automatically chosen depending on the number of decades in the plot. See Axes.set_xscale / Axes.set_yscale for details.
- **nonposx**, **nonposy** [{'mask', 'clip'}, optional, default 'mask'] Non-positive values in x or y can be masked as invalid, or clipped to a very small positive number.

Returns

- **lines** A list of Line2D objects representing the plotted data.

Other Parameters

- **kwargs** All parameters supported by plot.
**matplotlib.pyplot.magma**

```python
matplotlib.pyplot.magma()
```

Set the colormap to “magma”.

This changes the default colormap as well as the colormap of the current image if there is one. See `help(colormaps)` for more information.

**matplotlib.pyplot.magnitude_spectrum**

```python
matplotlib.pyplot.magnitude_spectrum(x, Fs=None, Fc=None, window=None, pad_to=None, sides=None, scale=None, *, data=None, **kwargs)
```

Plot the magnitude spectrum.

Compute the magnitude spectrum of `x`. Data is padded to a length of `pad_to` and the windowing function `window` is applied to the signal.

**Parameters**

- **x** [1-D array or sequence] Array or sequence containing the data.
- **Fs** [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, `freqs`, in cycles per time unit. The default value is 2.
- **window** [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- **sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
- **pad_to** [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to the length of the input signal (i.e. no padding).
- **scale** [{‘default’, ‘linear’, ‘dB’}] The scaling of the values in the `spec`. ‘linear’ is no scaling. ‘dB’ returns the values in dB scale, i.e., the dB amplitude (20 * log10). ‘default’ is ‘linear’.
- **Fc** [int] The center frequency of `x` (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**Returns**

- **spectrum** [1-D array] The values for the magnitude spectrum before scaling (real valued).
**freqs** [1-D array] The frequencies corresponding to the elements in spectrum.

**line** [a Line2D instance] The line created by this function.

**Other Parameters**

**kwargs** Keyword arguments control the Line2D properties:

</table>

**See also:**
`psd()` plots the power spectral density.

`angle_spectrum()` plots the angles of the corresponding frequencies.

`phase_spectrum()` plots the phase (unwrapped angle) of the corresponding frequencies.

`specgram()` can plot the magnitude spectrum of segments within the signal in a colormap.

Notes

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: `x`.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

```
matplotlib.pyplot.margins
```

`matplotlib.pyplot.margins(*margins, x=None, y=None, tight=True)`
Set or retrieve autoscaling margins.

The padding added to each limit of the axes is the margin times the data interval. All input parameters must be floats within the range [0, 1]. Passing both positional and keyword arguments is invalid and will raise a TypeError. If no arguments (positional or otherwise) are provided, the current margins will remain in place and simply be returned.

Specifying any margin changes only the autoscaling; for example, if `xmargin` is not None, then `xmargin` times the X data interval will be added to each end of that interval before it is used in autoscaling.

**Parameters**

* `*margins` [float, optional] If a single positional argument is provided, it specifies both margins of the x-axis and y-axis limits. If two positional arguments are provided, they will be interpreted as `xmargin`, `ymargin`. If setting the margin on a single axis is desired, use the keyword arguments described below.

* `x`, `y` [float, optional] Specific margin values for the x-axis and y-axis, respectively. These cannot be used with positional arguments, but can be used individually to alter on e.g., only the y-axis.

* `tight` [bool or None, default is True] The `tight` parameter is passed to `autoscale_view()`, which is executed after a margin is changed; the default here is `True`, on the assumption that when margins are specified, no additional padding to match tick marks is usually desired. Set `tight` to `None` will preserve the previous setting.

**Returns**

`xmargin`, `ymargin` [float]
Notes

If a previously used Axes method such as `pcolor()` has set `use_sticky_edges` to `True`, only the limits not set by the "sticky artists" will be modified. To force all of the margins to be set, set `use_sticky_edges` to `False` before calling `margins()`.

Examples using `matplotlib.pyplot.margins`

- sphx_glr_gallery_subplots_axes_and_figures_axes_margins.py
- sphx_glr_gallery_ticks_and_spines_ticklabels_rotation.py

`matplotlib.pyplot.matshow`

```python
matplotlib.pyplot.matshow(A, fignum=None, **kwargs)
```

Display an array as a matrix in a new figure window.

The origin is set at the upper left hand corner and rows (first dimension of the array) are displayed horizontally. The aspect ratio of the figure window is that of the array, unless this would make an excessively short or narrow figure.

Tick labels for the xaxis are placed on top.

**Parameters**

- **A** [array-like(M, N)] The matrix to be displayed.
- **fignum** [None or int or False] If None, create a new figure window with automatic numbering.
  - If a nonzero integer, draw into the figure with the given number (create it if it does not exist).
  - If 0, use the current axes (or create one if it does not exist).

**Note:** Because of how `Axes.matshow` tries to set the figure aspect ratio to be the one of the array, strange things may happen if you reuse an existing figure.

**Returns**

- **image** [AxesImage]

**Other Parameters**

- ****kwargs [imshow arguments]

Examples using `matplotlib.pyplot.matshow`

- sphx_glr_gallery_images_contours_and_fields_matshow.py
matplotlib.pyplot.minorticks_off

matplotlib.pyplot.minorticks_off()
Remove minor ticks from the axes.

matplotlib.pyplot.minorticks_on

matplotlib.pyplot.minorticks_on()
Display minor ticks on the axes.
Displaying minor ticks may reduce performance; you may turn them off using
minorticks_off() if drawing speed is a problem.

matplotlib.pyplot.nipy_spectral

matplotlib.pyplot.nipy_spectral()
Set the colormap to "nipy_spectral".
This changes the default colormap as well as the colormap of the current image if there
is one. See help(colormaps) for more information.

matplotlib.pyplot.pause

matplotlib.pyplot.pause(interval)
Pause for interval seconds.
If there is an active figure, it will be updated and displayed before the pause, and the
GUI event loop (if any) will run during the pause.
This can be used for crude animation. For more complex animation, see matplotlib.
animation.

Notes
This function is experimental; its behavior may be changed or extended in a future re-
lease.

Examples using matplotlib.pyplot.pause

• sphx_glr_gallery_animation_animation_demo.py
• sphx_glr_gallery_mplot3d_rotate_axes3d_sgskip.py
• sphx_glr_gallery_mplot3d_wire3d_animation_sgskip.py
Create a pseudocolor plot with a non-regular rectangular grid.

Call signature:
```
pcolor([X, Y], C, **kwargs)
```

X and Y can be used to specify the corners of the quadrilaterals.

**Parameters**

- **C** [array_like] A scalar 2-D array. The values will be color-mapped.
- **X, Y** [array_like, optional] The coordinates of the quadrilateral corners. The quadrilateral for \( C[i,j] \) has corners at:

  \[
  (X[i, j], Y[i, j]) \quad (X[i+1, j], \quad Y[i, j+1]) \\
  (X[i+1, j], \quad Y[i+1, j+1]) \\
  (X[i, j], \quad Y[i+1, j+1])
  \]

  Note that the column index corresponds to the x-coordinate, and the row index corresponds to y. For details, see the Notes section below.

  The dimensions of X and Y should be one greater than those of C. Alternatively, X, Y and C may have equal dimensions, in which case the last row and column of C will be ignored.

  If X and/or Y are 1-D arrays or column vectors they will be expanded as needed into the appropriate 2-D arrays, making a rectangular grid.

- **cmap** [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps the C values to colors. Defaults to rcParams["image.cmap"].

- **norm** [Normalize, optional] The Normalize instance scales the data values to the canonical colormap range \([0, 1]\) for mapping to colors. By default, the data range is mapped to the colorbar range using linear scaling.

- **vmin, vmax** [scalar, optional, default: None] The colorbar range. If None, suitable min/max values are automatically chosen by the Normalize instance (defaults to the respective min/max values of C in case of the default linear scaling).

- **edgecolors** [{‘none’, None, ‘face’, color, color sequence}, optional] The color of the edges. Defaults to ‘none’. Possible values:

  - ‘none’ or ‘’: No edge.
None: rcParams["patch.edgecolor"] will be used. Note that currently rcParams["patch.force_edgecolor"] has to be True for this to work.

• 'face': Use the adjacent face color.

• An mpl color or sequence of colors will set the edge color.

The singular form edgecolor works as an alias.

alpha [scalar, optional, default: None] The alpha blending value of the face color, between 0 (transparent) and 1 (opaque). Note: The edge-color is currently not affected by this.

snap [bool, optional, default: False] Whether to snap the mesh to pixel boundaries.

Returns
collection [matplotlib.collections.Collection]

Other Parameters

antialiaseds [bool, optional, default: False] The default antialiaseds is False if the default edgecolors="none" is used. This eliminates artificial lines at patch boundaries, and works regardless of the value of alpha. If edgecolors is not "none", then the default antialiaseds is taken from rcParams["patch.antialiased"], which defaults to True. Stroking the edges may be preferred if alpha is 1, but will cause artifacts otherwise.

**kwargs Additionally, the following arguments are allowed. They are passed along to the PolyCollection constructor:

<table>

- `imshow` If X and Y are each equidistant, `imshow` can be a faster alternative.

Notes

Masked arrays

X, Y and C may be masked arrays. If either C[i, j], or one of the vertices surrounding C[i,j] (X or Y at [i, j], [i+1, j], [i, j+1], [i+1, j+1]) is masked, nothing is plotted.

Grid orientation

The grid orientation follows the standard matrix convention: An array C with shape (nrows, ncolumns) is plotted with the column number as X and the row number as Y.

Handling of pcolor() end-cases

pcolor() displays all columns of C if X and Y are not specified, or if X and Y have one more column than C. If X and Y have the same number of columns as C then the last column of C is dropped. Similarly for the rows.

Note: This behavior is different from MATLAB’s pcolor(), which always discards the last row and column of C.

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).
Examples using matplotlib.pyplot.pcolor

- sphx_glr_gallery_images_contours_and_fields_pcolor_demo.py
- sphx_glr_gallery_subplots_axes_and_figures_axes_margins.py

matplotlib.pyplot.pcolormesh

matplotlib.pyplot.pcolormesh(*args, alpha=None, norm=None, cmap=None, vmin=None, vmax=None, shading='flat', antialiased=False, data=None, **kwargs)

Create a pseudocolor plot with a non-regular rectangular grid.

Call signature:

pcolor([X, Y], C, **kwargs)

X and Y can be used to specify the corners of the quadrilaterals.

**Note:** pcolormesh() is similar to pcolor(). It’s much faster and preferred in most cases.
For a detailed discussion on the differences see Differences between pcolor() and pcolormesh().

**Parameters**

- **C** [array_like] A scalar 2-D array. The values will be color-mapped.
- **X, Y** [array_like, optional] The coordinates of the quadrilateral corners.
  The quadrilateral for \( C[i,j] \) has corners at:

  \[
  (X[i+1, j], Y[i+1, j]) \quad (X[i+1, j+1], Y[i+1, j+1]) \\
  +-------+ \\
  | C[i,j] | \\
  +-------+
  
  (X[i, j], Y[i, j]) \quad (X[i, j+1], Y[i, j+1]),
  
Note that the column index corresponds to the x-coordinate, and the row index corresponds to y. For details, see the Notes section below.

The dimensions of \( X \) and \( Y \) should be one greater than those of \( C \). Alternatively, \( X, Y \) and \( C \) may have equal dimensions, in which case the last row and column of \( C \) will be ignored.

If \( X \) and/or \( Y \) are 1-D arrays or column vectors they will be expanded as needed into the appropriate 2-D arrays, making a rectangular grid.

- **cmap** [str or Colormap, optional] A Colormap instance or registered colormap name. The colormap maps the \( C \) values to colors. Defaults to rcParams["image.cmap"].

- **norm** [Normalize, optional] The Normalize instance scales the data values to the canonical colormap range \([0, 1]\) for mapping to colors. By default, the data range is mapped to the colorbar range using linear scaling.
**Vmin, Vmax** [scalar, optional, default: None] The colorbar range. If None, suitable min/max values are automatically chosen by the Normalize instance (defaults to the respective min/max values of C in case of the default linear scaling).

**Edgecolors** [{‘none’, None, ‘face’, color, color sequence}, optional] The color of the edges. Defaults to ‘none’. Possible values:

- ‘none’ or ‘’ : No edge.
- None: rcParams["patch.edgecolor"] will be used. Note that currently rcParams["patch.force_edgecolor"] has to be True for this to work.
- ‘face’: Use the adjacent face color.
- An mpl color or sequence of colors will set the edge color.

The singular form edgecolor works as an alias.

**Alpha** [scalar, optional, default: None] The alpha blending value, between 0 (transparent) and 1 (opaque).

**Shading** [{‘flat’, ‘gouraud’}, optional] The fill style. Possible values:

- ‘flat’: A solid color is used for each quad. The color of the quad (i, j), (i+1, j), (i, j+1), (i+1, j+1) is given by C[i, j].
- ‘gouraud’: Each quad will be Gouraud shaded: The color of the corners (i’, j’) are given by C[i’, j’]. The color values of the area in between is interpolated from the corner values. When Gouraud shading is used, edgecolors is ignored.

**Snap** [bool, optional, default: False] Whether to snap the mesh to pixel boundaries.

**Returns**

**Mesh** [matplotlib.collections.QuadMesh]

**Other Parameters**

****Kwargs** Additionally, the following arguments are allowed. They are passed along to the QuadMesh constructor:

<table>

pcolor An alternative implementation with slightly different features. For a detailed discussion on the differences see Differences between pcolor() and pcolormesh().

imshow If X and Y are each equidistant, imshow can be a faster alternative.

Notes

Masked arrays

C may be a masked array. If C[i, j] is masked, the corresponding quadrilateral will be transparent. Masking of X and Y is not supported. Use pcolor if you need this functionality.

Grid orientation

The grid orientation follows the standard matrix convention: An array C with shape (nrows, ncolumns) is plotted with the column number as X and the row number as Y.

Differences between pcolor() and pcolormesh()

Both methods are used to create a pseudocolor plot of a 2-D array using quadrilaterals.

The main difference lies in the created object and internal data handling: While pcolor returns a PolyCollection, pcolormesh returns a QuadMesh. The latter is more specialized for the given purpose and thus is faster. It should almost always be preferred.

There is also a slight difference in the handling of masked arrays. Both pcolor and pcolormesh support masked arrays for C. However, only pcolor supports masked arrays...
for X and Y. The reason lies in the internal handling of the masked values. `pcolor` leaves out the respective polygons from the PolyCollection. `pcolormesh` sets the facecolor of the masked elements to transparent. You can see the difference when using edgecolors. While all edges are drawn irrespective of masking in a QuadMesh, the edge between two adjacent masked quadrilaterals in `pcolor` is not drawn as the corresponding polygons do not exist in the PolyCollection.

Another difference is the support of Gouraud shading in `pcolormesh`, which is not available with `pcolor`.

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]:`

- All positional and all keyword arguments.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).

**Examples using `matplotlib.pyplot.pcolormesh`**

- sphx_glr_gallery_images_contours_and_fields_pcolor_demo.py
- sphx_glr_gallery_images_contours_and_fields_pcolormesh_levels.py
- sphx_glr_gallery_images_contours_and_fields_quadmesh_demo.py

**matplotlib.pyplot.phase_spectrum**

`matplotlib.pyplot.phase_spectrum(x, Fs=None, Fc=None, window=None, pad_to=None, sides=None, *, data=None, **kwargs)`

Plot the phase spectrum.

Compute the phase spectrum (unwrapped angle spectrum) of x. Data is padded to a length of `pad_to` and the windowing function `window` is applied to the signal.

**Parameters**

- `x` [1-D array or sequence] Array or sequence containing the data
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.
- `window` [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hanning`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.
- `sides` [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.
**pad_to** [int] The number of points to which the data segment is padded when performing the FFT. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to the length of the input signal (i.e. no padding).

**Fc** [int] The center frequency of `x` (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**Returns**

- **spectrum** [1-D array] The values for the phase spectrum in radians (real valued).
- **freqs** [1-D array] The frequencies corresponding to the elements in `spectrum`.
- **line** [a Line2D instance] The line created by this function.

**Other Parameters**

****kwargs** Keyword arguments control the Line2D properties:

 magnitude_spectrum() magnitude_spectrum() plots the magnitudes of the corresponding frequencies.

 angle_spectrum() angle_spectrum() plots the wrapped version of this function.

 specgram() specgram() can plot the phase spectrum of segments within the signal in a colormap.

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

matplotlib.pyplot.pie

matplotlib.pyplot.pie(x, explode=None, labels=None, colors=None, autopct=None, pctdistance=0.6, shadow=False, labeldistance=1.1, startangle=None, radius=None, counterclock=True, wedgeprops=None, textprops=None, center=(0, 0), frame=False, rotatelabels=False, *, data=None)

Plot a pie chart.

Make a pie chart of array x. The fractional area of each wedge is given by x/sum(x). If sum(x) < 1, then the values of x give the fractional area directly and the array will not be normalized. The resulting pie will have an empty wedge of size 1 - sum(x).

The wedges are plotted counterclockwise, by default starting from the x-axis.

Parameters
x [array-like] The wedge sizes.

explode [array-like, optional, default: None] If not None, is a `len(x)` array which specifies the fraction of the radius with which to offset each wedge.

labels [list, optional, default: None] A sequence of strings providing the labels for each wedge

colors [array-like, optional, default: None] A sequence of matplotlib color args through which the pie chart will cycle. If None, will use the colors in the currently active cycle.

autopct [None (default), string, or function, optional] If not None, is a string or function used to label the wedges with their numeric value. The label will be placed inside the wedge. If it is a format string, the label will be `fmt%pct`. If it is a function, it will be called.

pctdistance [float, optional, default: 0.6] The ratio between the center of each pie slice and the start of the text generated by autopct. Ignored if autopct is None.

shadow [bool, optional, default: False] Draw a shadow beneath the pie.

labeldistance [float or None, optional, default: 1.1] The radial distance at which the pie labels are drawn. If set to None, label are not drawn, but are stored for use in legend().

startangle [float, optional, default: None] If not None, rotates the start of the pie chart by angle degrees counterclockwise from the x-axis.

radius [float, optional, default: None] The radius of the pie, if radius is None it will be set to 1.

counterclock [bool, optional, default: True] Specify fractions direction, clockwise or counterclockwise.

wedgeprops [dict, optional, default: None] Dict of arguments passed to the wedge objects making the pie. For example, you can pass in wedgeprops = {'linewidth': 3} to set the width of the wedge border lines equal to 3. For more details, look at the doc/arguments of the wedge object. By default clip_on=False.

textprops [dict, optional, default: None] Dict of arguments to pass to the text objects.

center [list of float, optional, default: (0, 0)] Center position of the chart. Takes value (0, 0) or is a sequence of 2 scalars.

frame [bool, optional, default: False] Plot axes frame with the chart if true.

rotatelabels [bool, optional, default: False] Rotate each label to the angle of the corresponding slice if true.

Returns

patches [list] A sequence of matplotlib.patches.Wedge instances

texts [list] A list of the label matplotlib.text.Text instances.

autotexts [list] A list of Text instances for the numeric labels. This will only be returned if the parameter autopct is not None.
Notes

The pie chart will probably look best if the figure and axes are square, or the Axes aspect
is equal. This method sets the aspect ratio of the axis to "equal". The axes aspect ratio
can be controlled with Axes.set_aspect.

**Note:** In addition to the above described arguments, this function can take a data
keyword argument. If such a data argument is given, the following arguments are replaced
by data[arg]:

- All arguments with the following names: ‘colors’, ‘explode’, ‘labels’, ‘x’.

Objects passed as data must support item access (data[arg]) and membership test
(arg in data).

Examples using matplotlib.pyplot.pie

- sphx_glr_gallery_pie_and_polar_charts_pie_features.py
- sphx_glr_gallery_pie_and_polar_charts_pie_demo2.py
- sphx_glr_gallery_pie_and_polar_charts_nested_pie.py
- sphx_glr_gallery_pie_and_polar_charts_pie_and_donut_labels.py

matplotlib.pyplot.pink

matplotlib.pyplot.pink()
Set the colormap to "pink".

This changes the default colormap as well as the colormap of the current image if there
is one. See help(colormaps) for more information.

matplotlib.pyplot.plasma

matplotlib.pyplot.plasma()
Set the colormap to "plasma".

This changes the default colormap as well as the colormap of the current image if there
is one. See help(colormaps) for more information.

matplotlib.pyplot.plot

matplotlib.pyplot.plot(*args, scalex=True, scaley=True, data=None, **kwargs)
Plot y versus x as lines and/or markers.

Call signatures:

```python
plot([x], y, [fmt], *, data=None, **kwargs)
plot([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
```
The coordinates of the points or line nodes are given by \( x, y \).

The optional parameter \( fmt \) is a convenient way for defining basic formatting like color, marker and linestyle. It’s a shortcut string notation described in the Notes section below.

```python
>>> plot(x, y)   # plot x and y using default line style and color
>>> plot(x, y, 'bo')   # plot x and y using blue circle markers
>>> plot(y)   # plot y using x as index array 0..N-1
>>> plot(y, 'r+')   # ditto, but with red plusses
```

You can use `Line2D` properties as keyword arguments for more control on the appearance. Line properties and \( fmt \) can be mixed. The following two calls yield identical results:

```python
>>> plot(x, y, 'go--', linewidth=2, markersize=12)
>>> plot(x, y, color='green', marker='o', linestyle='dashed', ...
    linewidth=2, markersize=12)
```

When conflicting with \( fmt \), keyword arguments take precedence.

**Plotting labelled data**

There’s a convenient way for plotting objects with labelled data (i.e. data that can be accessed by index \( \text{obj}[\text{'y'}] \)). Instead of giving the data in \( x \) and \( y \), you can provide the object in the \( data \) parameter and just give the labels for \( x \) and \( y \):

```python
>>> plot('xlabel', 'ylabel', data=obj)
```

All indexable objects are supported. This could e.g. be a `dict`, a `pandas.DataFrame` or a structured numpy array.

**Plotting multiple sets of data**

There are various ways to plot multiple sets of data.

- The most straightforward way is just to call `plot` multiple times. Example:

  ```python
  >>> plot(x1, y1, 'bo')
  >>> plot(x2, y2, 'go')
  ```

- Alternatively, if your data is already a 2d array, you can pass it directly to \( x, y \). A separate data set will be drawn for every column.

  Example: an array \( a \) where the first column represents the \( x \) values and the other columns are the \( y \) columns:

  ```python
  >>> plot(a[0], a[1:])
  ```

- The third way is to specify multiple sets of \( [x], [y], [fmt] \) groups:

  ```python
  >>> plot(x1, y1, 'g^', x2, y2, 'g-')
  ```

  In this case, any additional keyword argument applies to all datasets. Also this syntax cannot be combined with the \( data \) parameter.

By default, each line is assigned a different style specified by a ‘style cycle’. The \( fmt \) and line property parameters are only necessary if you want explicit deviations from these defaults. Alternatively, you can also change the style cycle using the ‘axes.prop_cycle’ rcParam.

**Parameters**
x, y [array-like or scalar] The horizontal / vertical coordinates of the data points. x values are optional and default to \( \text{range(len(y))} \).

Commonly, these parameters are 1D arrays.

They can also be scalars, or two-dimensional (in that case, the columns represent separate data sets).

These arguments cannot be passed as keywords.

fmt [str, optional] A format string, e.g. ‘ro’ for red circles. See the Notes section for a full description of the format strings.

Format strings are just an abbreviation for quickly setting basic line properties. All of these and more can also be controlled by keyword arguments.

This argument cannot be passed as keyword.

data [indexable object, optional] An object with labelled data. If given, provide the label names to plot in x and y.

**Note:** Technically there’s a slight ambiguity in calls where the second label is a valid fmt. \( \text{plot('n', 'o', data=obj)} \) could be \( \text{plt(x, y)} \) or \( \text{plt(y, fmt)} \). In such cases, the former interpretation is chosen, but a warning is issued. You may suppress the warning by adding an empty format string \( \text{plot('n', 'o', '', data=obj)} \).

Returns

lines A list of Line2D objects representing the plotted data.

Other Parameters

scalex, scaley [bool, optional, default: True] These parameters determined if the view limits are adapted to the data limits. The values are passed on to autoscale_view.

**kwargs [Line2D properties, optional] kwargs are used to specify properties like a line label (for auto legends), linewidth, antialiasing, marker face color. Example:

```python
>>> plot([[1,2,3], [1,2,3], 'go-', label='line 1', linewidth=2)
>>> plot([[1,2,3], [1,4,9], 'rs', label='line 2'])
```

If you make multiple lines with one plot command, the kwargs apply to all those lines.

Here is a list of available Line2D properties:

**See also:**

*scatter* XY scatter plot with markers of varying size and/or color (sometimes also called bubble chart).

**Notes**

**Format Strings**

A format string consists of a part for color, marker and line:

```python
fmt = ' [marker] [line] [color]
```

Each of them is optional. If not provided, the value from the style cycle is used. Exception: If `line` is given, but no `marker`, the data will be a line without markers.
Other combinations such as [color][marker][line] are also supported, but note that their parsing may be ambiguous.

Markers

<table>
<thead>
<tr>
<th>character</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>point marker</td>
</tr>
<tr>
<td>,</td>
<td>pixel marker</td>
</tr>
<tr>
<td>o</td>
<td>circle marker</td>
</tr>
<tr>
<td>v</td>
<td>triangle_down marker</td>
</tr>
<tr>
<td>^</td>
<td>triangle_up marker</td>
</tr>
<tr>
<td>&lt;</td>
<td>triangle_left marker</td>
</tr>
<tr>
<td>&gt;</td>
<td>triangle_right marker</td>
</tr>
<tr>
<td>1</td>
<td>tri_down marker</td>
</tr>
<tr>
<td>2</td>
<td>tri_up marker</td>
</tr>
<tr>
<td>3</td>
<td>tri_left marker</td>
</tr>
<tr>
<td>4</td>
<td>tri_right marker</td>
</tr>
<tr>
<td>s</td>
<td>square marker</td>
</tr>
<tr>
<td>p</td>
<td>pentagon marker</td>
</tr>
<tr>
<td>*</td>
<td>star marker</td>
</tr>
<tr>
<td>h</td>
<td>hexagon1 marker</td>
</tr>
<tr>
<td>H</td>
<td>hexagon2 marker</td>
</tr>
<tr>
<td>+</td>
<td>plus marker</td>
</tr>
<tr>
<td>x</td>
<td>x marker</td>
</tr>
<tr>
<td>D</td>
<td>diamond marker</td>
</tr>
<tr>
<td>d</td>
<td>thin_diamond marker</td>
</tr>
<tr>
<td>1</td>
<td>vline marker</td>
</tr>
<tr>
<td>_</td>
<td>hline marker</td>
</tr>
</tbody>
</table>

Line Styles

<table>
<thead>
<tr>
<th>character</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>solid line style</td>
</tr>
<tr>
<td>--</td>
<td>dashed line style</td>
</tr>
<tr>
<td>-.</td>
<td>dash-dot line style</td>
</tr>
<tr>
<td>:</td>
<td>dotted line style</td>
</tr>
</tbody>
</table>

Example format strings:

'b'  # blue markers with default shape
'or' # red circles
'g'  # green solid line
'--' # dashed line with default color
'^k:' # black triangle_up markers connected by a dotted line

Colors

The supported color abbreviations are the single letter codes
and the 'CN' colors that index into the default property cycle.

If the color is the only part of the format string, you can additionally use any matplotlib.colors spec, e.g. full names ('green') or hex strings ('#008000').

Plot data that contains dates.

Similar to `plot`, this plots $y$ vs. $x$ as lines or markers. However, the axis labels are formatted as dates depending on `xdate` and `ydate`.

**Parameters**

- **x, y** [array-like] The coordinates of the data points. If `xdate` or `ydate` is `True`, the respective values $x$ or $y$ are interpreted as Matplotlib dates.
- **fmt** [str, optional] The plot format string. For details, see the corresponding parameter in `plot`.
- **tz** [[None | timezone string | tzinfo instance]] The time zone to use in labeling dates. If `None`, defaults to rcParam `timezone`.
- **xdate** [bool, optional, default: `True`] If `True`, the x-axis will be interpreted as Matplotlib dates.
- **ydate** [bool, optional, default: `False`] If `True`, the y-axis will be interpreted as Matplotlib dates.

**Returns**

- **lines** A list of `Line2D` objects representing the plotted data.

**Other Parameters**

****kwargs** Keyword arguments control the `Line2D` properties:

<table>

- [matplotlib.dates](#) Helper functions on dates.
- [matplotlib.dates.date2num](#) Convert dates to num.
- [matplotlib.dates.num2date](#) Convert num to dates.
- [matplotlib.dates.drange](#) Create an equally spaced sequence of dates.

### Notes

If you are using custom date tickers and formatters, it may be necessary to set the formatters/locators after the call to `plot_date`. `plot_date` will set the default tick locator to `AutoDateLocator` (if the tick locator is not already set to a `DateLocator` instance) and the default tick formatter to `AutoDateFormatter` (if the tick formatter is not already set to a `DateFormatter` instance).

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘x’, ‘y’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).
Examples using `matplotlib.pyplot.plot_date`

- `sphx_glr_gallery_ticks_and_spines_date_demo_rrule.py`

`matplotlib.pyplot.plotfile`

```python
matplotlib.pyplot.plotfile(fname, cols=(0, ), plotfuncs=None, comments='#',
                          skiprows=0, checkrows=5, delimiter=' ', names=None,
                          subplots=True, newfig=True, **kwargs)
```

Plot the data in a file.

cols is a sequence of column identifiers to plot. An identifier is either an int or a string. If it is an int, it indicates the column number. If it is a string, it indicates the column header. `matplotlib` will make column headers lower case, replace spaces with underscores, and remove all illegal characters; so 'Adj Close*' will have name 'adj_close'.

- If `len(cols) == 1`, only that column will be plotted on the y axis.
- If `len(cols) > 1`, the first element will be an identifier for data for the x axis and the remaining elements will be the column indexes for multiple subplots if `subplots` is `True` (the default), or for lines in a single subplot if `subplots` is `False`.

plotfuncs, if not None, is a dictionary mapping identifier to an `Axes` plotting function as a string. Default is 'plot', other choices are 'semilogy', 'fill', 'bar', etc. You must use the same type of identifier in the cols vector as you use in the plotfuncs dictionary, e.g., integer column numbers in both or column names in both. If subplots is False, then including any function such as 'semilogy' that changes the axis scaling will set the scaling for all columns.

- `comments`: the character used to indicate the start of a comment in the file, or None to switch off the removal of comments
- `skiprows`: is the number of rows from the top to skip
- `checkrows`: is the number of rows to check to validate the column data type. When set to zero all rows are validated.
- `delimiter`: is the character(s) separating row items
- `names`: if not None, is a list of header names. In this case, no header will be read from the file

If newfig is True, the plot always will be made in a new figure; if False, it will be made in the current figure if one exists, else in a new figure.

kwargs are passed on to plotting functions.

Example usage:

```python
# plot the 2nd and 4th column against the 1st in two subplots
plotfile(fname, (0,1,3))

# plot using column names; specify an alternate plot type for volume
plotfile(fname, ('date', 'volume', 'adj_close'),
         plotfuncs={'volume': 'semilogy'})
```

Note: `plotfile` is intended as a convenience for quickly plotting data from flat files; it is not intended as an alternative interface to general plotting with `pyplot` or `matplotlib`.

17.37. `matplotlib.pyplot`
Examples using `matplotlib.pyplot.plotfile`

- sphx_glr_gallery_misc_plotfile_demo.py

### `matplotlib.pyplot.polar`

```python
matplotlib.pyplot.polar(*args, **kwargs)
```

Make a polar plot.

call signature:

```
polar(theta, r, **kwargs)
```

Multiple `theta, r` arguments are supported, with format strings, as in `plot()`.

Examples using `matplotlib.pyplot.polar`

- sphx_glr_gallery_misc_transoffset.py

### `matplotlib.pyplot.prism`

```python
matplotlib.pyplot.prism()
```

Set the colormap to "prism".

This changes the default colormap as well as the colormap of the current image if there is one. See `help(colormaps)` for more information.

### `matplotlib.pyplot.psd`

```python
matplotlib.pyplot.psd(x, NFFT=None, Fs=None, Fc=None, detrend=None, window=None, noverlap=None, pad_to=None, sides=None, scale_by_freq=None, return_line=None, *, data=None, **kwargs)
```

Plot the power spectral density. The power spectral density $P_{xx}$ by Welch's average periodogram method. The vector `x` is divided into `NFFT` length segments. Each segment is detrended by function `detrend` and windowed by function `window`. `noverlap` gives the length of the overlap between segments. The $|fft(i)|^2$ of each segment $i$ are averaged to compute $P_{xx}$, with a scaling to correct for power loss due to windowing.

If `len(x) < NFFT`, it will be zero padded to `NFFT`.

**Parameters**

- `x` [1-D array or sequence] Array or sequence containing the data
- `Fs` [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, fregs, in cycles per time unit. The default value is 2.
**window** [callable or ndarray] A function or a vector of length `NFFT`. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hamming`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

**sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

**pad_to** [int] The number of points to which the data segment is padded when performing the FFT. This can be different from `NFFT`, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the `n` parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to `NFFT`.

**NFFT** [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use `pad_to` for this instead.

**detrend** [{‘none’, ‘mean’, ‘linear’} or callable, default ‘none’] The function applied to each segment before fft-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the `detrend` parameter is a vector, in Matplotlib it is a function. The `mlab` module defines `detrend_none`, `detrend_mean`, and `detrend_linear`, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls `detrend_none`. ‘mean’ calls `detrend_mean`. ‘linear’ calls `detrend_linear`.

**scale_by_freq** [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

**noverlap** [int] The number of points of overlap between segments. The default value is 0 (no overlap).

**Fc** [int] The center frequency of `x` (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

**return_line** [bool] Whether to include the line object plotted in the returned values. Default is False.

**Returns**

- **Pxx** [1-D array] The values for the power spectrum $P_{xx}$ before scaling (real valued).
- **freqs** [1-D array] The frequencies corresponding to the elements in `Pxx`.
- **line** [a `Line2D` instance] The line created by this function. Only returned if `return_line` is True.

**Other Parameters**
**kwargs** Keyword arguments control the Line2D properties:

**See also:**

`spectrogram()` differs in the default overlap; in not returning the mean of the segment periodograms; in returning the times of the segments; and in plotting a colormap instead of a line.

`magnitude_spectrum()` plots the magnitude spectrum.
csd() plots the spectral density between two signals.

Notes

For plotting, the power is plotted as $10 \log_{10}(P_{xx})$ for decibels, though $P_{xx}$ itself is returned.

References

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘x’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.pyplot.psd

- sphx_glr_gallery_lines_bars_and_markers_psd_demo.py

matplotlib.pyplot.quiver

matplotlib.pyplot.quiver(*args, data=None, **kw)

Plot a 2D field of arrows.

Call signature:

```
quiver([X, Y], U, V, [C], **kw)
```

Where X, Y define the arrow locations, U, V define the arrow directions, and C optionally sets the color.

Arrow size

The default settings auto-scales the length of the arrows to a reasonable size. To change this behavior see the scale and scale_units parameters.

Arrow shape

The defaults give a slightly swept-back arrow; to make the head a triangle, make headaxislength the same as headlength. To make the arrow more pointed, reduce headwidth or increase headlength and headaxislength. To make the head smaller relative to the shaft, scale down all the head parameters. You will probably do best to leave minshaft alone.

Arrow outline

linewidths and edgecolors can be used to customize the arrow outlines.
Parameters

**X, Y** [1D or 2D array-like, optional] The x and y coordinates of the arrow locations.

If not given, they will be generated as a uniform integer meshgrid based on the dimensions of *U* and *V*.

If *X* and *Y* are 1D but *U, V* are 2D, *X, Y* are expanded to 2D using *x, y = np.meshgrid(X, Y)*. In this case, *len(X)* and *len(Y)* must match the column and row dimensions of *U* and *V*.

**U, V** [1D or 2D array-like] The x and y direction components of the arrow vectors.

**C** [1D or 2D array-like, optional] Numeric data that defines the arrow colors by colormapping via `norm` and `cmap`.

This does not support explicit colors. If you want to set colors directly, use `color` instead.

**units** [‘width’, ‘height’, ‘dots’, ‘inches’, ‘x’, ‘y’, ‘xy’], default: ‘width’] The arrow dimensions (except for length) are measured in multiples of this unit.

The following values are supported:

- ‘width’, ‘height’: The width or height of the axis.
- ‘dots’, ‘inches’: Pixels or inches based on the figure dpi.
- ‘x’, ‘y’, ‘xy’: X, Y or \( \sqrt{X^2 + Y^2} \) in data units.

The arrows scale differently depending on the units. For ‘x’ or ‘y’, the arrows get larger as one zooms in; for other units, the arrow size is independent of the zoom state. For ‘width’ or ‘height’, the arrow size increases with the width and height of the axes, respectively, when the window is resized; for ‘dots’ or ‘inches’, resizing does not change the arrows.

**angles** [‘uv’, ‘xy’] or array-like, optional, default: ‘uv’] Method for determining the angle of the arrows.

- ‘uv’: The arrow axis aspect ratio is 1 so that if *U == V* the orientation of the arrow on the plot is 45 degrees counter-clockwise from the horizontal axis (positive to the right).

  Use this if the arrows symbolize a quantity that is not based on *X, Y* data coordinates.

- ‘xy’: Arrows point from (x,y) to (x+u, y+v). Use this for plotting a gradient field, for example.

  Alternatively, arbitrary angles may be specified explicitly as an array of values in degrees, counter-clockwise from the horizontal axis.

  In this case *U, V* is only used to determine the length of the arrows.

Note: inverting a data axis will correspondingly invert the arrows only with `angles='xy'`. 
scale [float, optional] Number of data units per arrow length unit, e.g., m/s per plot width; a smaller scale parameter makes the arrow longer. Default is None.

If None, a simple autoscaling algorithm is used, based on the average vector length and the number of vectors. The arrow length unit is given by the scale_units parameter.

scale_units [{‘width’, ‘height’, ‘dots’, ‘inches’, ‘x’, ‘y’, ‘xy’}, optional] If the scale kwarg is None, the arrow length unit. Default is None.

e.g. scale_units is ‘inches’, scale is 2.0, and (u,v) = (1,0), then the vector will be 0.5 inches long.

If scale_units is ‘width’ or ‘height’, then the vector will be half the width/height of the axes.

If scale_units is ‘x’ then the vector will be 0.5 x-axis units. To plot vectors in the x-y plane, with u and v having the same units as x and y, use angles='xy', scale_units='xy', scale=1.

width [float, optional] Shaft width in arrow units; default depends on choice of units, above, and number of vectors; a typical starting value is about 0.005 times the width of the plot.

headwidth [float, optional, default: 3] Head width as multiple of shaft width.

headlength [float, optional, default: 5] Head length as multiple of shaft width.

headaxislength [float, optional, default: 4.5] Head length at shaft intersection.

minshaft [float, optional, default: 1] Length below which arrow scales, in units of head length. Do not set this to less than 1, or small arrows will look terrible!

minlength [float, optional, default: 1] Minimum length as a multiple of shaft width; if an arrow length is less than this, plot a dot (hexagon) of this diameter instead.

pivot [{‘tail’, ‘mid’, ‘middle’, ‘tip’}, optional, default: ‘tail’] The part of the arrow that is anchored to the X, Y grid. The arrow rotates about this point.

‘mid’ is a synonym for ‘middle’.

color [color or color sequence, optional] Explicit color(s) for the arrows. If C has been set, color has no effect.

This is a synonym for the PolyCollection facecolor parameter.

Other Parameters

**kwargs [PolyCollection properties, optional] All other keyword arguments are passed on to PolyCollection:

quiverkey Add a key to a quiver plot.

Examples using matplotlib.pyplot.quiver

- sphx_glr_gallery_images_contours_and_fields_quiver_demo.py
- sphx_glr_gallery_images_contours_and_fields_quiver_simple_demo.py
- sphx_glr_gallery_images_contours_and_fields_trigradient_demo.py
matplotlib.pyplot.quiverkey

matplotlib.pyplot.quiverkey(Q, X, Y, U, label, **kw)
Add a key to a quiver plot.
Call signature:
quiverkey(Q, X, Y, U, label, **kw)

Arguments:

Q: The Quiver instance returned by a call to quiver.
X, Y: The location of the key; additional explanation follows.
U: The length of the key
label: A string with the length and units of the key

Keyword arguments:

angle = 0 The angle of the key arrow. Measured in degrees anti-clockwise from the x-axis.
coordinates = [‘axes’ | ‘figure’ | ‘data’ | ‘inches’ ] Coordinate system and units for X, Y: ‘axes’ and ‘figure’ are normalized coordinate systems with 0,0 in the lower left and 1,1 in the upper right; ‘data’ are the axes data coordinates (used for the locations of the vectors in the quiver plot itself); ‘inches’ is position in the figure in inches, with 0,0 at the lower left corner.
color: overrides face and edge colors from Q.
labelpos = [‘N’ | ‘S’ | ‘E’ | ‘W’ ] Position the label above, below, to the right, to the left of the arrow, respectively.
labelsep: Distance in inches between the arrow and the label. Default is 0.1
labelcolor: defaults to default Text color.
fontproperties: A dictionary with keyword arguments accepted by the FontProperties initializer: family, style, variant, size, weight

Any additional keyword arguments are used to override vector properties taken from Q.
The positioning of the key depends on X, Y, coordinates, and labelpos. If labelpos is ‘N’ or ‘S’, X, Y give the position of the middle of the key arrow. If labelpos is ‘E’, X, Y positions the head, and if labelpos is ‘W’, X, Y positions the tail; in either of these two cases, X, Y is somewhere in the middle of the arrow+label key object.

Examples using matplotlib.pyplot.quiverkey

• sphx_glr_gallery_images_contours_and_fields_quiver_demo.py
• sphx_glr_gallery_images_contours_and_fields_quiver_simple_demo.py
matplotlib.pyplot.rc

```
matplotlib.pyplot.rc(group, **kwargs)
```

Set the current rc params. `group` is the grouping for the rc, e.g., for `lines.linewidth` the group is `lines`, for `axes.facecolor`, the group is `axes`, and so on. Group may also be a list or tuple of group names, e.g., `(xtick, ytick)`. `kwargs` is a dictionary attribute name/value pairs, e.g.:

```
rc('lines', linewidth=2, color='r')
```

sets the current rc params and is equivalent to:

```
rcParams['lines.linewidth'] = 2
rcParams['lines.color'] = 'r'
```

The following aliases are available to save typing for interactive users:

<table>
<thead>
<tr>
<th>Alias</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>lw</td>
<td>'linewidth'</td>
</tr>
<tr>
<td>ls</td>
<td>'linestyle'</td>
</tr>
<tr>
<td>c</td>
<td>'color'</td>
</tr>
<tr>
<td>fc</td>
<td>'facecolor'</td>
</tr>
<tr>
<td>ec</td>
<td>'edgecolor'</td>
</tr>
<tr>
<td>mew</td>
<td>'markeredgewidth'</td>
</tr>
<tr>
<td>aa</td>
<td>'antialiased'</td>
</tr>
</tbody>
</table>

Thus you could abbreviate the above rc command as:

```
rc('lines', lw=2, c='r')
```

Note you can use python’s kwargs dictionary facility to store dictionaries of default parameters. e.g., you can customize the font rc as follows:

```
font = {'family': 'monospace',
        'weight': 'bold',
        'size': 'larger'}
rc('font', **font)  # pass in the font dict as kwargs
```

This enables you to easily switch between several configurations. Use `matplotlib.style.use('default')` or `rcdefaults()` to restore the default rc params after changes.

**Examples using matplotlib.pyplot.rc**

- sphx_glr_gallery_pie_and_polar_charts_polar_legend.py
- sphx_glr_gallery_text_labels_and_annotations_usetex_demo.py
- sphx_glr_gallery_color_color_cycler.py
- sphx_glr_gallery_misc_customize_rc.py
- sphx_glr_gallery_misc_multipage_pdf.py
- **Styling with cycler**
matplotlib.pyplot.rc_context

matplotlib.pyplot.rc_context(rc=None, fname=None)
   Return a context manager for managing rc settings.
   This allows one to do:

   ```python
   with mpl.rc_context(fname='screen.rc'):
       plt.plot(x, a)
   with mpl.rc_context(fname='print.rc'):
       plt.plot(x, b)
   plt.plot(x, c)
   ```

   The 'a' vs 'x' and 'c' vs 'x' plots would have settings from 'screen.rc', while the 'b' vs 'x'
   plot would have settings from 'print.rc'.

   A dictionary can also be passed to the context manager:

   ```python
   with mpl.rc_context(rc={'text.usetex': True}, fname='screen.rc'):
       plt.plot(x, a)
   ```

   The 'rc' dictionary takes precedence over the settings loaded from 'fname'. Passing a
   dictionary only is also valid. For example a common usage is:

   ```python
   with mpl.rc_context(rc={'interactive': False}):
       fig, ax = plt.subplots()
       ax.plot(range(3), range(3))
       fig.savefig('A.png', format='png')
       plt.close(fig)
   ```

Examples using matplotlib.pyplot.rc_context

- sphx_glr_gallery_text_labels_and_annotations_usetex_baseline_test.py
- sphx_glr_gallery_misc_logos2.py
- sphx_glr_gallery_ticks_and_spines_auto_ticks.py

matplotlib.pyplot.rcdefaults

matplotlib.pyplot.rcdefaults()
   Restore the rc params from Matplotlib’s internal default style.
   Style-blacklisted rc params (defined in matplotlib.style.core.STYLE_BLACKLIST) are not
   updated.

   See also:

   rc_file_defaults Restore the rc params from the rc file originally loaded by Matplotlib.
   matplotlib.style.use Use a specific style file. Call style.use('default') to restore the
default style.
Examples using matplotlib.pyplot.rcdefaults

- sphx_glr_gallery_lines_bars_and_markers_barh.py
- sphx_glr_gallery_misc_customize_rc.py

matplotlib.pyplot.rgrids

matplotlib.pyplot.rgrids(*args, **kwargs)
Get or set the radial gridlines on the current polar plot.

Call signatures:

```
lines, labels = rgrids()
lines, labels = rgrids(radii, labels=None, angle=22.5, fmt=None, **kwargs)
```

When called with no arguments, rgrids simply returns the tuple (lines, labels). When called with arguments, the labels will appear at the specified radial distances and angle.

Parameters

- **radii** [tuple with floats] The radii for the radial gridlines
- **labels** [tuple with strings or None] The labels to use at each radial gridline. The matplotlib.ticker.ScalarFormatter will be used if None.
- **angle** [float] The angular position of the radius labels in degrees.
- **fmt** [str or None] Format string used in matplotlib.ticker.FormatStrFormatter. For example '%f'.

Returns

- **lines**, **labels** [list of lines.Line2D, list of text.Text] lines are the radial gridlines and labels are the tick labels.

Other Parameters

- ****kwargs kwargs are optional Text properties for the labels.

See also:

- pyplot.thetagrids
- projections.polar.PolarAxes.set_rgrids
- Axis.get_gridlines
- Axis.get_ticklabels

Examples

```
# set the locations of the radial gridlines
lines, labels = rgrids((0.25, 0.5, 1.0))

# set the locations and labels of the radial gridlines
lines, labels = rgrids((0.25, 0.5, 1.0), ('Tom', 'Dick', 'Harry'))
```
**matplotlib.pyplot.savefig**

Save the current figure.

Call signature:

```python
savefig(fname, dpi=None, facecolor='w', edgecolor='w', orientation='portrait', papertype=None, format=None, transparent=False, bbox_inches=None, pad_inches=0.1, frameon=None, metadata=None)
```

The output formats available depend on the backend being used.

**Parameters**

- **fname** [str or PathLike or file-like object] A path, or a Python file-like object, or possibly some backend-dependent object such as `matplotlib.backends.backend_pdf.PdfPages`.

If `format` is not set, then the output format is inferred from the extension of `fname`, if any, and from `rcParams["savefig.format"]` otherwise. If `format` is set, it determines the output format.

Hence, if `fname` is not a path or has no extension, remember to specify `format` to ensure that the correct backend is used.

**Other Parameters**

- **dpi** [[None | scalar > 0 | ‘figure’]] The resolution in dots per inch. If `None`, defaults to `rcParams["savefig.dpi"]`. If ‘figure’, uses the figure’s dpi value.

- **quality** [[None | 1 <= scalar <= 100]] The image quality, on a scale from 1 (worst) to 95 (best). Applicable only if `format` is jpg or jpeg, ignored otherwise. If `None`, defaults to `rcParams["savefig.jpeg_quality"]` (95 by default). Values above 95 should be avoided; 100 completely disables the JPEG quantization stage.

- **optimize** [bool] If True, indicates that the JPEG encoder should make an extra pass over the image in order to select optimal encoder settings. Applicable only if `format` is jpg or jpeg, ignored otherwise. Is False by default.

- **progressive** [bool] If True, indicates that this image should be stored as a progressive JPEG file. Applicable only if `format` is jpg or jpeg, ignored otherwise. Is False by default.

- **facecolor** [color spec or None, optional] The facecolor of the figure; if `None`, defaults to `rcParams["savefig.facecolor"]`.

- **edgecolor** [color spec or None, optional] The edgecolor of the figure; if `None`, defaults to `rcParams["savefig.edgecolor"]`.

- **orientation** [{‘landscape’, ‘portrait’}] Currently only supported by the postscript backend.

**format** [str] The file format, e.g. ‘png’, ‘pdf’, ‘svg’, ... The behavior when this is unset is documented under *fname*.

**transparent** [bool] If True, the axes patches will all be transparent; the figure patch will also be transparent unless facecolor and/or edgecolor are specified via kwargs. This is useful, for example, for displaying a plot on top of a colored background on a web page. The transparency of these patches will be restored to their original values upon exit of this function.

**bbox_inches** [str or *Bbox*, optional] Bbox in inches. Only the given portion of the figure is saved. If ‘tight’, try to figure out the tight bbox of the figure. If None, use savefig.bbox

**pad_inches** [scalar, optional] Amount of padding around the figure when bbox_inches is ‘tight’. If None, use savefig.pad_inches

**bbox_extra_artists** [list of *Artist*, optional] A list of extra artists that will be considered when the tight bbox is calculated.

**metadata** [dict, optional] Key/value pairs to store in the image metadata. The supported keys and defaults depend on the image format and backend:

- ‘png’ with Agg backend: See the parameter metadata of *print_png*.
- ‘pdf’ with pdf backend: See the parameter metadata of *PdfPages*.
- ‘eps’ and ‘ps’ with PS backend: Only ‘Creator’ is supported.

**pil_kwargs** [dict, optional] Additional keyword arguments that are passed to PIL.Image.save when saving the figure. Only applicable for formats that are saved using Pillow, i.e. JPEG, TIFF, and (if the keyword is set to a non-None value) PNG.

**Examples using matplotlib.pyplot.savefig**

- sphx_glr_gallery_text_labels_and_annotations_usetex_fonteffects.py
- sphx_glr_gallery_misc_print_stdout_sgskip.py
- sphx_glr_gallery_misc_rasterization_demo.py
- sphx_glr_gallery_misc_svg_filter_line.py
- sphx_glr_gallery_misc_svg_filter_pie.py
- sphx_glr_gallery_user_interfaces_svg_histogram_sgskip.py
- sphx_glr_gallery_user_interfaces_svg_tooltip_sgskip.py
- sphx_glr_gallery_userdemo_pgf_fonts.py
- sphx_glr_gallery_userdemo_pgf_preamble_sgskip.py
- sphx_glr_gallery_userdemo_pgf_texsystem.py

**matplotlib.pyplot.sca**

`matplotlib.pyplot.sca(ax)`

Set the current Axes instance to *ax*.
The current Figure is updated to the parent of `ax`.

```python
matplotlib.pyplot.scatter

matplotlib.pyplot.scatter(x, y, s=None, c=None, marker=None, cmap=None, norm=None, vmin=None, vmax=None, alpha=None, linewidths=None, verts=None, edgecolors=None, *, plotnonfinite=False, data=None, **kwargs)
```

A scatter plot of `y` vs `x` with varying marker size and/or color.

**Parameters**

- **x**, **y** [array_like, shape (n, )] The data positions.
- **s** [scalar or array_like, shape (n, ), optional] The marker size in points**2. Default is `rcParams['lines.markersize'] ** 2`.
- **c** [color, sequence, or sequence of color, optional] The marker color. Possible values:
  - A single color format string.
  - A sequence of color specifications of length n.
  - A sequence of n numbers to be mapped to colors using `cmap` and `norm`.
  - A 2-D array in which the rows are RGB or RGBA.

Note that `c` should not be a single numeric RGB or RGBA sequence because that is indistinguishable from an array of values to be color-mapped. If you want to specify the same RGB or RGBA value for all points, use a 2-D array with a single row. Otherwise, value-matching will have precedence in case of a size matching with `x` and `y`.

Defaults to `None`. In that case the marker color is determined by the value of `color`, `facecolor` or `facecolors`. In case those are not specified or `None`, the marker color is determined by the next color of the axes’ current “shape and fill” color cycle. This cycle defaults to `rcParams['axes.prop_cycle']`.

- **marker** [MarkerStyle, optional] The marker style. `marker` can be either an instance of the class or the text shorthand for a particular marker. Defaults to `None`, in which case it takes the value of `rcParams['scatter.marker']` = `'o'`. See `markers` for more information about marker styles.

- **cmap** [Colormap, optional, default: None] A Colormap instance or registered colormap name. `cmap` is only used if `c` is an array of floats. If `None`, defaults to `rc image.cmap`.

- **norm** [Normalize, optional, default: None] A Normalize instance is used to scale luminance data to 0, 1. `norm` is only used if `c` is an array of floats. If `None`, use the default `colors.Normalize`.

- **vmin, vmax** [scalar, optional, default: None] `vmin` and `vmax` are used in conjunction with `norm` to normalize luminance data. If `None`, the respective min and max of the color array is used. `vmin` and `vmax` are ignored if you pass a `norm` instance.
**alpha** [scalar, optional, default: None] The alpha blending value, between 0 (transparent) and 1 (opaque).

**linewidths** [scalar or array_like, optional, default: None] The linewidth of the marker edges. Note: The default `edgecolors` is 'face'. You may want to change this as well. If `None`, defaults to `rcParams['lines.linewidth']`.

**edgecolors** [{'face', 'none', None} or color or sequence of color, optional.] The edge color of the marker. Possible values:
- 'face': The edge color will always be the same as the face color.
- 'none': No patch boundary will be drawn.
- A Matplotlib color or sequence of color.

Defaults to `None`, in which case it takes the value of `rcParams['scatter.edgecolors']` = 'face'. For non-filled markers, the `edgecolors` kwarg is ignored and forced to 'face' internally.

**plotnonfinite** [boolean, optional, default: False] Set to plot points with nonfinite `c`, in conjunction with `set_bad`.

**Returns**
- **paths** [PathCollection]

**Other Parameters**
- ****kwargs** [Collection properties]

**See also:**
- `plot` To plot scatter plots when markers are identical in size and color.

**Notes**

- The `plot` function will be faster for scatterplots where markers don’t vary in size or color.
- Any or all of `x`, `y`, `s`, and `c` may be masked arrays, in which case all masks will be combined and only unmasked points will be plotted.
- Fundamentally, scatter works with 1-D arrays; `x`, `y`, `s`, and `c` may be input as 2-D arrays, but within scatter they will be flattened. The exception is `c`, which will be flattened only if its size matches the size of `x` and `y`.

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:
- All arguments with the following names: 'c', 'color', 'edgecolors', 'facecolor', 'facecolors', 'linewidths', 's', 'x', 'y'.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).
Examples using `matplotlib.pyplot.scatter`

- `sphx_glr_gallery_lines_bars_and_markers_scatter_masked.py`
- `sphx_glr_gallery_lines_bars_and_markers_scatter_piecharts.py`
- `sphx_glr_gallery_lines_bars_and_markers_scatter_star_poly.py`
- `sphx_glr_gallery_lines_bars_and_markers_scatter_symbol.py`
- `sphx_glr_gallery_lines_bars_and_markers_scatter_with_legend.py`
- `sphx_glr_gallery_line_and_polar_charts_polar_scatter.py`
- `sphx_glr_gallery_shapes_and_collections_scatter.py`
- `sphx_glr_gallery_misc_hyperlinks_sgskip.py`
- `sphx_glr_gallery_misc_zorder_demo.py`
- `Pyplot tutorial`

`matplotlib.pyplot.sci`

`matplotlib.pyplot.sci(im)`

Set the current image.

This image will be the target of colormap functions like `viridis`, and other functions such as `clim`. The current image is an attribute of the current axes.

Examples using `matplotlib.pyplot.sci`

- `sphx_glr_gallery_shapes_and_collections_line_collection.py`

`matplotlib.pyplot.semilogx`

`matplotlib.pyplot.semilogx(*args, **kwargs)`

Make a plot with log scaling on the x axis.

Call signatures:

```
semilogx([x], y, [fmt], data=None, **kwargs)
semilogx([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)
```

This is just a thin wrapper around `plot` which additionally changes the x-axis to log scaling. All of the concepts and parameters of plot can be used here as well.

The additional parameters `base`, `subx` and `nonposx` control the x-axis properties. They are just forwarded to `Axes.set_xscale`.

**Parameters**

- `base` [scalar, optional, default 10] Base of the x logarithm.
- `subx` [array_like, optional] The location of the minor xticks. If `None`, reasonable locations are automatically chosen depending on the number of decades in the plot. See `Axes.set_xscale` for details.
nonposx ['mask', 'clip'], optional, default 'mask'] Non-positive values in x can be masked as invalid, or clipped to a very small positive number.

Returns

lines A list of Line2D objects representing the plotted data.

Other Parameters

**kwargs All parameters supported by plot.

matplotlib.pyplot.semilogy

matplotlib.pyplot.semilogy(*args, **kwargs)

Make a plot with log scaling on the y axis.

Call signatures:

semilogy([x], y, [fmt], data=None, **kwargs)
semilogy([x], y, [fmt], [x2], y2, [fmt2], ..., **kwargs)

This is just a thin wrapper around plot which additionally changes the y-axis to log scaling. All of the concepts and parameters of plot can be used here as well.

The additional parameters basey, subsy and nonposy control the y-axis properties. They are just forwarded to Axes.set_yscale.

Parameters

basey [scalar, optional, default 10] Base of the y logarithm.

subsy [array_like, optional] The location of the minor yticks. If None, reasonable locations are automatically chosen depending on the number of decades in the plot. See Axes.set_yscale for details.

nonposy ['mask', 'clip'], optional, default 'mask'] Non-positive values in y can be masked as invalid, or clipped to a very small positive number.

Returns

lines A list of Line2D objects representing the plotted data.

Other Parameters

**kwargs All parameters supported by plot.

matplotlib.pyplot.set_cmap

matplotlib.pyplot.set_cmap(cmap)

Set the default colormap. Applies to the current image if any. See help(colormaps) for more information.

cmap must be a Colormap instance, or the name of a registered colormap.

See matplotlib.cm.register_cmap() and matplotlib.cm.get_cmap().
**matplotlib.pyplot.setp**

```python
matplotlib.pyplot.setp(obj, *args, **kwargs)
```

Set a property on an artist object.

matplotlib supports the use of `setp()` ("set property") and `getp()` to set and get object properties, as well as to do introspection on the object. For example, to set the linestyle of a line to be dashed, you can do:

```python
def line, = plot([1,2,3])
def setp(line, linestyle='--')
```

If you want to know the valid types of arguments, you can provide the name of the property you want to set without a value:

```python
def setp(line, 'linestyle')
    linestyle: [ '-' | '--' | '-.' | ':' | 'steps' | 'None' ]
```

If you want to see all the properties that can be set, and their possible values, you can do:

```python
def setp(line)
    ... long output listing omitted
```

You may specify another output file to `setp` if `sys.stdout` is not acceptable for some reason using the `file` keyword-only argument:

```python
def with fopen('output.log') as f:
    def setp(line, file=f)
```

`setp()` operates on a single instance or a iterable of instances. If you are in query mode introspecting the possible values, only the first instance in the sequence is used. When actually setting values, all the instances will be set. e.g., suppose you have a list of two lines, the following will make both lines thicker and red:

```python
def x = arange(0,1.0,0.01)
def y1 = sin(2*pi*x)
def y2 = sin(4*pi*x)
def lines = plot(x, y1, x, y2)
def setp(lines, linewidth=2, color='r')
```

`setp()` works with the MATLAB style string/value pairs or with python kwargs. For example, the following are equivalent:

```python
def setp(lines, 'linewidth', 2, 'color', 'r') # MATLAB style
def setp(lines, linewidth=2, color='r') # python style
```

**Examples using `matplotlib.pyplot.setp`**

- sphx_glr_gallery_lines_bars_and_markers_masked_demo.py
- sphx_glr_gallery_lines_bars_and_markers_timeline.py
- sphx_glr_gallery_images_contours_and_fields_contour_demo.py
matplotlib.pyplot.show

```python
matplotlib.pyplot.show(*args, **kw)

Display a figure.

When running in ipython with its pylab mode, display all figures and return to the ipython prompt.

In non-interactive mode, display all figures and block until the figures have been closed; in interactive mode it has no effect unless figures were created prior to a change from non-interactive to interactive mode (not recommended). In that case it displays the figures but does not block.

A single experimental keyword argument, block, may be set to True or False to override the blocking behavior described above.
```

matplotlib.pyplot.specgram

matplotlib.pyplot.specgram(x, NFFT=None, Fs=None, Fc=None, detrend=None, window=None, noverlap=None, cmap=None, xextent=None, pad_to=None, sides=None, scale_by_freq=None, mode=None, scale=None, vmin=None, vmax=None, *, data=None, **kwargs)

Plot a spectrogram.

Compute and plot a spectrogram of data in x. Data are split into NFFT length segments and the spectrum of each section is computed. The windowing function window is applied to each segment, and the amount of overlap of each segment is specified with noverlap. The spectrogram is plotted as a colormap (using imshow).
Parameters

**x** [1-D array or sequence] Array or sequence containing the data.

**Fs** [scalar] The sampling frequency (samples per time unit). It is used to calculate the Fourier frequencies, freqs, in cycles per time unit. The default value is 2.

**window** [callable or ndarray] A function or a vector of length *NFFT*. To create window vectors see `window_hanning`, `window_none`, `numpy.blackman`, `numpy.hanning`, `numpy.bartlett`, `scipy.signal`, `scipy.signal.get_window`, etc. The default is `window_hanning`. If a function is passed as the argument, it must take a data segment as an argument and return the windowed version of the segment.

**sides** [{‘default’, ‘onesided’, ‘twosided’}] Specifies which sides of the spectrum to return. Default gives the default behavior, which returns one-sided for real data and both for complex data. ‘onesided’ forces the return of a one-sided spectrum, while ‘twosided’ forces two-sided.

**pad_to** [int] The number of points to which the data segment is padded when performing the FFT. This can be different from *NFFT*, which specifies the number of data points used. While not increasing the actual resolution of the spectrum (the minimum distance between resolvable peaks), this can give more points in the plot, allowing for more detail. This corresponds to the *n* parameter in the call to `fft()`. The default is None, which sets `pad_to` equal to *NFFT*

**NFFT** [int] The number of data points used in each block for the FFT. A power 2 is most efficient. The default value is 256. This should NOT be used to get zero padding, or the scaling of the result will be incorrect. Use `pad_to` for this instead.

**detrend** [{‘none’, ‘mean’, ‘linear’} or callable, default ‘none’] The function applied to each segment before `fft()-ing, designed to remove the mean or linear trend. Unlike in MATLAB, where the `detrend` parameter is a vector, in Matplotlib is it a function. The `mlab` module defines `detrend_none`, `detrend_mean`, and `detrend_linear`, but you can use a custom function as well. You can also use a string to choose one of the functions: ‘none’ calls `detrend_none`. ‘mean’ calls `detrend_mean`. ‘linear’ calls `detrend_linear`.

**scale_by_freq** [bool, optional] Specifies whether the resulting density values should be scaled by the scaling frequency, which gives density in units of Hz^-1. This allows for integration over the returned frequency values. The default is True for MATLAB compatibility.

**mode** [{‘default’, ‘psd’, ‘magnitude’, ‘angle’, ‘phase’}] What sort of spectrum to use. Default is ‘psd’, which takes the power spectral density. ‘magnitude’ returns the magnitude spectrum. ‘angle’ returns the phase spectrum without unwrapping. ‘phase’ returns the phase spectrum with unwrapping.

**noverlap** [int] The number of points of overlap between blocks. The default value is 128.

**scale** [{‘default’, ‘linear’, ‘dB’}] The scaling of the values in the `spec`. ‘linear’ is no scaling. ‘dB’ returns the values in dB scale. When `mode` is ‘psd’, this is dB power (10 * log10). Otherwise this is dB amplitude (20
* \log\log_{10}. 'default' is 'dB' if mode is 'psd' or 'magnitude' and 'linear' otherwise. This must be 'linear' if mode is 'angle' or 'phase'.

Fc [int] The center frequency of x (defaults to 0), which offsets the x extents of the plot to reflect the frequency range used when a signal is acquired and then filtered and downsampled to baseband.

cmap A matplotlib.colors.Colormap instance; if None, use default determined by rc

xextent [None or (xmin, xmax)] The image extent along the x-axis. The default sets xmin to the left border of the first bin (spectrum column) and xmax to the right border of the last bin. Note that for noverlap>0 the width of the bins is smaller than those of the segments.

**kwargs Additional kwargs are passed on to imshow which makes the specgram image.

Returns

spectrum [2-D array] Columns are the periodograms of successive segments.

defs [1-D array] The frequencies corresponding to the rows in spectrum.

t [1-D array] The times corresponding to midpoints of segments (i.e., the columns in spectrum).

im [instance of class AxesImage] The image created by imshow containing the spectrogram

See also:

psd() psd() differs in the default overlap; in returning the mean of the segment periodograms; in not returning times; and in generating a line plot instead of colormap.

magnitude_spectrum() A single spectrum, similar to having a single segment when mode is 'magnitude'. Plots a line instead of a colormap.

angle_spectrum() A single spectrum, similar to having a single segment when mode is 'angle'. Plots a line instead of a colormap.

phase_spectrum() A single spectrum, similar to having a single segment when mode is 'phase'. Plots a line instead of a colormap.

Notes

The parameters detrend and scale_by_freq do only apply when mode is set to 'psd'.

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: 'x'.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).
Examples using matplotlib.pyplot.specgram

- sphx_glr_gallery_images_contours_and_fields_specgram_demo.py

matplotlib.pyplot.spring

```python
matplotlib.pyplot.spring()
```

Set the colormap to "spring".

This changes the default colormap as well as the colormap of the current image if there
is one. See help(colormaps) for more information.

matplotlib.pyplot.spy

```python
matplotlib.pyplot.spy(Z, precision=0, marker=None, markersize=None, aspect='equal', origin='upper', **kwargs)
```

Plot the sparsity pattern of a 2D array.

This visualizes the non-zero values of the array.

Two plotting styles are available: image and marker. Both are available for full arrays,
but only the marker style works for scipy.sparse.spmatrix instances.

**Image style**

If marker and markersize are None, imshow is used. Any extra remaining kwargs are
passed to this method.

**Marker style**

If Z is a scipy.sparse.spmatrix or marker or markersize are None, a Line2D object will
be returned with the value of marker determining the marker type, and any remaining
kwargs passed to plot.

**Parameters**

- **Z** [array-like (M, N)] The array to be plotted.
- **precision** [float or 'present', optional, default: 0] If precision is 0, any
  non-zero value will be plotted. Otherwise, values of |Z| > precision will
  be plotted.
  
  For scipy.sparse.spmatrix instances, you can also pass 'present'. In
  this case any value present in the array will be plotted, even if it is
  identically zero.
- **origin** [{‘upper’, ‘lower’}, optional] Place the [0,0] index of the array in
  the upper left or lower left corner of the axes. The convention ‘upper’ is
  typically used for matrices and images. If not given, rcParams["image.
  origin"] is used, defaulting to ‘upper’.
- **aspect** [{‘equal’, ‘auto’, None} or float, optional] Controls the aspect ratio
  of the axes. The aspect is of particular relevance for images since it
  may distort the image, i.e. pixel will not be square.
  
  This parameter is a shortcut for explicitly calling Axes.set_aspect. See
  there for further details.
  
  - ‘equal’: Ensures an aspect ratio of 1. Pixels will be square.
• 'auto': The axes is kept fixed and the aspect is adjusted so that the
data fit in the axes. In general, this will result in non-square pixels.

• None: Use rcParams["image.aspect"] (default: 'equal').

Default: 'equal'

Returns

ret [AxesImage or Line2D] The return type depends on the plotting style
(see above).

Other Parameters

**kwargs The supported additional parameters depend on the plotting
style.

For the image style, you can pass the following additional parameters of
imshow:

• cmap
• alpha
• url
• any Artist properties (passed on to the AxesImage)

For the marker style, you can pass any Line2D property except for
linestyle:

Examples using `matplotlib.pyplot.spy`

- sphx_glr_gallery_images_contours_and_fields.spy_demos.py

`matplotlib.pyplot.stackplot`

`matplotlib.pyplot.stackplot(x, *args, labels=(), colors=None, baseline='zero', data=None, **kwargs)`

Draw a stacked area plot.

**Parameters**

- `x` [1d array of dimension N]
- `y` [2d array (dimension MxN), or sequence of 1d arrays (each dimension 1xN)] The data is assumed to be unstacked. Each of the following calls is legal:

  ```
  stackplot(x, y)  # where y is MxN
  stackplot(x, y1, y2, y3, y4)  # where y1, y2, y3, y4, are all 1xNm
  ```

- `baseline` [{‘zero’, ‘sym’, ‘wiggle’, ‘weighted_wiggle’}] Method used to calculate the baseline:
  - ‘zero’: Constant zero baseline, i.e. a simple stacked plot.
  - ‘sym’: Symmetric around zero and is sometimes called ‘ThemeRiver’.
  - ‘wiggle’: Minimizes the sum of the squared slopes.
  - ‘weighted_wiggle’: Does the same but weights to account for size of each layer. It is also called ‘Streamgraph’-layout. More details can be found at [http://leebyron.com/streamgraph/](http://leebyron.com/streamgraph/).

- `labels` [Length N sequence of strings] Labels to assign to each data series.
colors [Length N sequence of colors] A list or tuple of colors. These will be cycled through and used to colour the stacked areas.

**kwargs All other keyword arguments are passed to Axes.fill_between().

Returns

list [list of PolyCollection] A list of PolyCollection instances, one for each element in the stacked area plot.

Notes

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

matplotlib.pyplot.stem

matplotlib.pyplot.stem(*args, linefmt=None, markerfmt=None, basefmt=None, bottom=0, label=None, use_line_collection=False, data=None)

Create a stem plot.

A stem plot plots vertical lines at each x location from the baseline to y, and places a marker there.

Call signature:

stem([x,] y, linefmt=None, markerfmt=None, basefmt=None)

The x-positions are optional. The formats may be provided either as positional or as keyword-arguments.

Parameters

x [array-like, optional] The x-positions of the stems. Default: (0, 1, ..., len(y) - 1).

y [array-like] The y-values of the stem heads.

linefmt [str, optional] A string defining the properties of the vertical lines.

Usually, this will be a color or a color and a linestyle:

<table>
<thead>
<tr>
<th>Character</th>
<th>Line Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>'-'</td>
<td>solid line</td>
</tr>
<tr>
<td>'--'</td>
<td>dashed line</td>
</tr>
<tr>
<td>'-.'</td>
<td>dash-dot line</td>
</tr>
<tr>
<td>':'</td>
<td>dotted line</td>
</tr>
</tbody>
</table>

Default: ‘C0-’, i.e. solid line with the first color of the color cycle.
Note: While it is technically possible to specify valid formats other than color or color and linestyle (e.g. ‘rx’ or ‘-.’), this is beyond the intention of the method and will most likely not result in a reasonable plot.

**markerfmt** [str, optional] A string defining the properties of the markers at the stem heads. Default: ‘C0o’, i.e. filled circles with the first color of the color cycle.

**basefmt** [str, optional] A format string defining the properties of the baseline.

    Default: ‘C3-’ (‘C2-’ in classic mode).

**bottom** [float, optional, default: 0] The y-position of the baseline.

**label** [str, optional, default: None] The label to use for the stems in legends.

**use_line_collection** [bool, optional, default: False] If True, store and plot the stem lines as a LineCollection instead of individual lines. This significantly increases performance, and will become the default option in Matplotlib 3.3. If False, defaults to the old behavior of using a list of Line2D objects.

**Returns**

**container** [StemContainer] The container may be treated like a tuple

    (markerline, stemlines, baseline)

**Notes**

**See also:**

The MATLAB function *stem* which inspired this method.

**Note:** In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All positional and all keyword arguments.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

**Examples using matplotlib.pyplot.stem**

- sphx_glr_gallery_lines_bars_and_markers_stem_plot.py

**matplotlib.pyplot.step**

**matplotlib.pyplot.step**(x, y, *args, where='pre', data=None, **kwargs)

    Make a step plot.

    Call signatures:
This is just a thin wrapper around `plot` which changes some formatting options. Most of the concepts and parameters of `plot` can be used here as well.

### Parameters

- **x** [array_like] 1-D sequence of x positions. It is assumed, but not checked, that it is uniformly increasing.
- **y** [array_like] 1-D sequence of y levels.
- **fmt** [str, optional] A format string, e.g. ‘g’ for a green line. See `plot` for a more detailed description.
  
  Note: While full format strings are accepted, it is recommended to only specify the color. Line styles are currently ignored (use the keyword argument `linestyle` instead). Markers are accepted and plotted on the given positions, however, this is a rarely needed feature for step plots.
- **data** [indexable object, optional] An object with labelled data. If given, provide the label names to plot in x and y.
- **where** [{‘pre’, ‘post’, ‘mid’}, optional, default ‘pre’] Define where the steps should be placed:
  
  - ‘pre’: The y value is continued constantly to the left from every x position, i.e. the interval (x[i-1], x[i]) has the value y[i].
  - ‘post’: The y value is continued constantly to the right from every x position, i.e. the interval [x[i], x[i+1]) has the value y[i].
  - ‘mid’: Steps occur half-way between the x positions.

### Returns

- **lines** A list of `Line2D` objects representing the plotted data.

### Other Parameters

- **kwargs** Additional parameters are the same as those for `plot`.

### Notes

Examples using `matplotlib.pyplot.step`

- sphx_glr_gallery_lines_bars_and_markers_step_demo.py

`matplotlib.pyplot.streamplot`

`matplotlib.pyplot.streamplot(x, y, u, v, density=1, linewidth=None, color=None, cmap=None, norm=None, arrowhead=1, arrowstyle='-', minlength=0.1, transform=None, zorder=None, start_points=None, maxlength=4.0, integration_direction='both', *, data=None)`

Draw streamlines of a vector flow.
Parameters

- **x, y** [1D arrays] An evenly spaced grid.
- **u, v** [2D arrays] x and y-velocities. The number of rows and columns must match the length of y and x, respectively.
- **density** [float or (float, float)] Controls the closeness of streamlines. When density = 1, the domain is divided into a 30x30 grid. density linearly scales this grid. Each cell in the grid can have, at most, one traversing streamline. For different densities in each direction, use a tuple (density_x, density_y).
- **linewidth** [float or 2D array] The width of the stream lines. With a 2D array the line width can be varied across the grid. The array must have the same shape as u and v.
- **color** [matplotlib color code, or 2D array] The streamline color. If given an array, its values are converted to colors using cmap and norm. The array must have the same shape as u and v.
- **cmap** [Colormap] Colormap used to plot streamlines and arrows. This is only used if color is an array.
- **norm** [Normalize] Normalize object used to scale luminance data to 0, 1. If None, stretch (min, max) to (0, 1). This is only used if color is an array.
- **arrowsize** [float] Scaling factor for the arrow size.
- **minlength** [float] Minimum length of streamline in axes coordinates.
- **start_points** [Nx2 array] Coordinates of starting points for the streamlines in data coordinates (the same coordinates as the x and y arrays).
- **zorder** [int] The zorder of the stream lines and arrows. Artists with lower zorder values are drawn first.
- **maxlength** [float] Maximum length of streamline in axes coordinates.
- **integration_direction** [{‘forward’, ‘backward’, ‘both’}] Integrate the streamline in forward, backward or both directions. default is ‘both’.

Returns

- **stream_container** [StreamplotSet] Container object with attributes
  - lines: LineCollection of streamlines
  - arrows: PatchCollection containing FancyArrowPatch objects representing the arrows half-way along stream lines.

This container will probably change in the future to allow changes to the colormap, alpha, etc. for both lines and arrows, but these changes should be backward compatible.

Notes
Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘start_points’, ‘u’, ‘v’, ‘x’, ‘y’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.pyplot.streamplot

- sphx_glr_gallery_images_contours_and_fields_plot_streamplot.py

`matplotlib.pyplot.subplot`

`matplotlib.pyplot.subplot(*args, **kwargs)`

Add a subplot to the current figure.

Wrapper of `Figure.add_subplot` with a difference in behavior explained in the notes section.

Call signatures:

```
subplot(nrows, ncols, index, **kwargs)
subplot(pos, **kwargs)
subplot(ax)
```

**Parameters**

*args Either a 3-digit integer or three separate integers describing the position of the subplot. If the three integers are `nrows`, `ncols`, and `index` in order, the subplot will take the `index` position on a grid with `nrows` rows and `ncols` columns. `index` starts at 1 in the upper left corner and increases to the right.

`pos` is a three digit integer, where the first digit is the number of rows, the second the number of columns, and the third the index of the subplot. i.e. `fig.add_subplot(235)` is the same as `fig.add_subplot(2, 3, 5)`. Note that all integers must be less than 10 for this form to work.

`polar` [boolean, optional] If True, equivalent to projection=‘polar’.

`sharex, sharey` [Axes, optional] Share the x or y axis with sharex and/or sharey. The axis will have the same limits, ticks, and scale as the axis of the shared axes.

`label` [str] A label for the returned axes.

**Returns**
axes [an `axes.SubplotBase` subclass of `Axes` (or a subclass of `Axes`)] The axes of the subplot. The returned axes base class depends on the projection used. It is `Axes` if rectilinear projection are used and `projections.polar.PolarAxes` if polar projection are used. The returned axes is then a subplot subclass of the base class.

Other Parameters

**kwargs This method also takes the keyword arguments for the returned axes base class. The keyword arguments for the rectilinear base class `Axes` can be found in the following table but there might also be other keyword arguments if another projection is used.

*Figure.add_subplot*

*pyplot.subplots*

*pyplot.axes*

*Figure.subplots*

Notes

Creating a subplot will delete any pre-existing subplot that overlaps with it beyond sharing a boundary:

```python
import matplotlib.pyplot as plt
# plot a line, implicitly creating a subplot(111)
plt.plot([[1,2,3]])
# now create a subplot which represents the top plot of a grid
# with 2 rows and 1 column. Since this subplot will overlap the
# first, the plot (and its axes) previously created, will be removed
plt.subplot(211)
```

If you do not want this behavior, use the *Figure.add_subplot* method or the *pyplot.axes* function instead.

If the figure already has a subplot with key (*args, kwargs*) then it will simply make that subplot current and return it. This behavior is deprecated. Meanwhile, if you do not want this behavior (i.e., you want to force the creation of a new subplot), you must use a unique set of args and kwargs. The axes *label* attribute has been exposed for this purpose: if you want two subplots that are otherwise identical to be added to the figure, make sure you give them unique labels.

In rare circumstances, *add_subplot* may be called with a single argument, a subplot axes instance already created in the present figure but not in the figure’s list of axes.
Examples

```python
plt.subplot(221)

# equivalent but more general
ax1=plt.subplot(2, 2, 1)

# add a subplot with no frame
ax2=plt.subplot(22, frameon=False)

# add a polar subplot
plt.subplot(223, projection='polar')

# add a red subplot that shares the x-axis with ax1
plt.subplot(224, sharex=ax1, facecolor='red')

# delete ax2 from the figure
plt.delaxes(ax2)

# add ax2 to the figure again
plt.subplot(ax2)
```

- sphx_glr_gallery_pyplots_whats_new_98_4_legend.py
- sphx_glr_gallery_shapes_and_collections_ellipse_demo.py
Create an axis at specific location inside a regular grid.

Parameters

- **shape** [sequence of 2 ints] Shape of grid in which to place axis. First entry is number of rows, second entry is number of columns.
- **loc** [sequence of 2 ints] Location to place axis within grid. First entry is row number, second entry is column number.
- **rowspan** [int] Number of rows for the axis to span to the right.
- **colspan** [int] Number of columns for the axis to span downwards.
- **fig** [Figure, optional] Figure to place axis in. Defaults to current figure.
- ****kwars** Additional keyword arguments are handed to add_subplot.

Notes

The following call

```
subplot2grid(shape, loc, rowspan=1, colspan=1)
```
is identical to

```
gridspec=GridSpec(shape[0], shape[1])
subplotspec=gridspec.new_subplotspec(loc, rowspan, colspan)
subplot(subplotspec)
```

**Examples using matplotlib.pyplot.subplot2grid**

- sphx_glr_gallery_subplots_axes_and_figures_demo_tight_layout.py
- sphx_glr_gallery_userdemo_demo_gridspec01.py
- *Constrained Layout Guide*
- *Tight Layout guide*

**matplotlib.pyplot.subplot_tool**

```
matplotlib.pyplot.subplot_tool(targetfig=None)
```

Launch a subplot tool window for a figure.
A `matplotlib.widgets.SubplotTool` instance is returned.

**Examples using matplotlib.pyplot.subplot_tool**

- sphx_glr_gallery_subplots_axes_and_figures_subplot_toolbar.py

**matplotlib.pyplot.subplots**

```
matplotlib.pyplot.subplots(nrows=1, ncols=1, sharex=False, sharey=False, squeeze=True, subplot_kw=None, gridspec_kw=None, **fig_kw)
```

Create a figure and a set of subplots.
This utility wrapper makes it convenient to create common layouts of subplots, including the enclosing figure object, in a single call.

**Parameters**

- **nrows, ncols** [int, optional, default: 1] Number of rows/columns of the subplot grid.
- **sharex, sharey** [bool or {'none', 'all', 'row', 'col'}, default: False] Controls sharing of properties among x (sharex) or y (sharey) axes:
  - True or 'all': x- or y-axis will be shared among all subplots.
  - False or 'none': each subplot x- or y-axis will be independent.
  - 'row': each subplot row will share an x- or y-axis.
  - 'col': each subplot column will share an x- or y-axis.
When subplots have a shared x-axis along a column, only the x tick
labels of the bottom subplot are created. Similarly, when subplots have
a shared y-axis along a row, only the y tick labels of the first column
subplot are created. To later turn other subplots’ ticklabels on, use
tick_params.

**squeeze** [bool, optional, default: True]

- If True, extra dimensions are squeezed out from the returned array
  of Axes:
  - if only one subplot is constructed (nrows=ncols=1), the resulting
    single Axes object is returned as a scalar.
  - for Nx1 or 1xM subplots, the returned object is a 1D numpy object
    array of Axes objects.
  - for NxM, subplots with N>1 and M>1 are returned as a 2D array.
- If False, no squeezing at all is done: the returned Axes object is
  always a 2D array containing Axes instances, even if it ends up
  being 1x1.

**num** [integer or string, optional, default: None] A pyplot.figure keyword
that sets the figure number or label.

**subplot_kw** [dict, optional] Dict with keywords passed to the add_subplot
call used to create each subplot.

**gridspec_kw** [dict, optional] Dict with keywords passed to the GridSpec
constructor used to create the grid the subplots are placed on.

****fig_kw** All additional keyword arguments are passed to the pyplot.
figure call.

**Returns**

**fig** [Figure]

**ax** [axes.Axes object or array of Axes objects.] ax can be either a single
Axes object or an array of Axes objects if more than one subplot was
created. The dimensions of the resulting array can be controlled with
the squeeze keyword, see above.

**See also:**

pyplot.figure
pyplot.subplot
pyplot.axes
Figure.subplots
Figure.add_subplot

**Examples**

```
# First create some toy data:
x = np.linspace(0, 2*np.pi, 400)
y = np.sin(x**2)
```
# Creates just a figure and only one subplot
fig, ax = plt.subplots()
ax.plot(x, y)
ax.set_title('Simple plot')

# Creates two subplots and unpacks the output array immediately
f, (ax1, ax2) = plt.subplots(1, 2, sharey=True)
ax1.plot(x, y)
ax1.set_title('Sharing Y axis')
ax2.scatter(x, y)

# Creates four polar axes, and accesses them through the returned array
fig, axes = plt.subplots(2, 2, subplot_kw=dict(polar=True))
axes[0, 0].plot(x, y)
axes[1, 1].scatter(x, y)

# Share a X axis with each column of subplots
plt.subplots(2, 2, sharex='col')

# Share a Y axis with each row of subplots
plt.subplots(2, 2, sharey='row')

# Share both X and Y axes with all subplots
plt.subplots(2, 2, sharex='all', sharey='all')

# Note that this is the same as
plt.subplots(2, 2, sharex=True, sharey=True)

# Creates figure number 10 with a single subplot # and clears it if it already exists.
fig, ax = plt.subplots(num=10, clear=True)

```python
matplotlib.pyplot.subplots_adjust

matplotlib.pyplot.subplots_adjust(left=None, bottom=None, right=None, top=None, wspace=None, hspace=None)
```

Tune the subplot layout.

The parameter meanings (and suggested defaults) are:

```
left = 0.125  # the left side of the subplots of the figure
right = 0.9   # the right side of the subplots of the figure
bottom = 0.1  # the bottom of the subplots of the figure
top = 0.9     # the top of the subplots of the figure
wspace = 0.2  # the amount of width reserved for space between subplots,
              # expressed as a fraction of the average axis width
hspace = 0.2  # the amount of height reserved for space between subplots,
              # expressed as a fraction of the average axis height
```

The actual defaults are controlled by the rc file

Set the colormap to "summer". This changes the default colormap as well as the colormap of the current image if there is one. See help(colormaps) for more information.

Add a centered title to the figure.

**Parameters**

- **t** [str] The title text.
- **x** [float, default 0.5] The x location of the text in figure coordinates.
- **y** [float, default 0.98] The y location of the text in figure coordinates.
- **horizontalalignment**, **ha** [{‘center’, ‘left’, ‘right’}, default: ‘center’] The horizontal alignment of the text relative to (x, y).
- **verticalalignment**, **va** [{‘top’, ‘center’, ‘bottom’, ‘baseline’}, default: ‘top’] The vertical alignment of the text relative to (x, y).
- **fontsize**, **size** [default: rcParams["figure.titlesize"]] The font size of the text. See Text.set_size for possible values.
- **fontweight**, **weight** [default: rcParams["figure.titleweight"]]] The font weight of the text. See Text.set_weight for possible values.

**Returns**

- **text** The Text instance of the title.

**Other Parameters**

- **fontproperties** [None or dict, optional] A dict of font properties. If fontproperties is given the default values for font size and weight are taken from the FontProperties defaults. rcParams["figure.titlesize"] and rcParams["figure.titleweight"] are ignored in this case.
**kwargs Additional kwargs are matplotlib.text.Text properties.

Examples

```python
>>> fig.suptitle('This is the figure title', fontsize=12)
```

Examples using matplotlib.pyplot.suptitle

• sphx_glr_gallery_subplots_axes_and_figures_gridspec_nested.py
• Pyplot tutorial

matplotlib.pyplot.switch_backend

```python
matplotlib.pyplot.switch_backend(newbackend)
```

Close all open figures and set the Matplotlib backend.

The argument is case-insensitive. Switching to an interactive backend is possible only if no event loop for another interactive backend has started. Switching to and from non-interactive backends is always possible.

**Parameters**

- `newbackend` [str] The name of the backend to use.

matplotlib.pyplot.table

```python
matplotlib.pyplot.table(cellText=None, cellColours=None, cellLoc='right', colWidths=None, rowLabels=None, rowColours=None, rowLoc='left', colLabels=None, colColours=None, colLoc='center', loc='bottom', bbox=None, edges='closed', **kwargs)
```

Add a table to an Axes.

At least one of `cellText` or `cellColours` must be specified. These parameters must be 2D lists, in which the outer lists define the rows and the inner list define the column values per row. Each row must have the same number of elements.

The table can optionally have row and column headers, which are configured using `rowLabels`, `rowColours`, `rowLoc` and `colLabels`, `colColours`, `colLoc` respectively.

For finer grained control over tables, use the `Table` class and add it to the axes with `Axes.add_table`.

**Parameters**

- `cellText` [2D list of str, optional] The texts to place into the table cells. 
  
  *Note:* Line breaks in the strings are currently not accounted for and will result in the text exceeding the cell boundaries.

- `cellColours` [2D list of matplotlib color specs, optional] The background colors of the cells.
cellLoc [{‘left’, ‘center’, ‘right’}, default: ‘right’] The alignment of the
text within the cells.

colWidths [list of float, optional] The column widths in units of the axes.
If not given, all columns will have a width of 1 / ncols.

rowLabels [list of str, optional] The text of the row header cells.

rowColours [list of matplotlib color specs, optional] The colors of the row
header cells.

rowLoc [{‘left’, ‘center’, ‘right’}, optional, default: ‘left’] The text align-
ment of the row header cells.

colLabels [list of str, optional] The text of the column header cells.

colColours [list of matplotlib color specs, optional] The colors of the col-
umn header cells.

colLoc [{‘left’, ‘center’, ‘right’}, optional, default: ‘left’] The text align-
ment of the column header cells.

loc [str, optional] The position of the cell with respect to ax. This must be
one of the codes.

bbox [Bbox, optional] A bounding box to draw the table into. If this is not
None, this overrides loc.

edges [substring of ‘BRTL’ or {‘open’, ‘closed’, ‘horizontal’, ‘vertical’}] The
cell edges to be drawn with a line. See also visible_edges.

Returns

table [Table] The created table.

Other Parameters

**kwargs Table properties.

Examples using matplotlib.pyplot.table

- sphx_glr_gallery_misc_table_demo.py

matplotlib.pyplot.text

matplotlib.pyplot.text(x, y, s, fontdict=None, withdash=<deprecated parameter>, **kwargs)

Add text to the axes.

Add the text s to the axes at location x, y in data coordinates.

Parameters

- x, y [scalars] The position to place the text. By default, this is in data coordinates. The coordinate system can be changed using the transform parameter.
- s [str] The text.
- fontdict [dictionary, optional, default: None] A dictionary to override the default text properties. If fontdict is None, the defaults are determined by your rc parameters.

Returns

- text [Text] The created Text instance.
**Other Parameters**

**kwargs [Text properties.] Other miscellaneous text parameters.

Examples

Individual keyword arguments can be used to override any given parameter:

```python
>>> text(x, y, s, fontsize=12)
```

The default transform specifies that text is in data coords, alternatively, you can specify text in axis coords (0,0 is lower-left and 1,1 is upper-right). The example below places text in the center of the axes:

```python
>>> text(0.5, 0.5, 'matplotlib', horizontalalignment='center',
       ...  verticalalignment='center', transform=ax.transAxes)
```

You can put a rectangular box around the text instance (e.g., to set a background color) by using the keyword `bbox`. `bbox` is a dictionary of `Rectangle` properties. For example:

```python
>>> text(x, y, s, bbox=dict(facecolor='red', alpha=0.5))
```

Get or set the theta gridlines on the current polar plot.

Call signatures:

```python
lines, labels = theagrids()
lines, labels = theagrids(angles, labels=None, fmt=None, **kwargs)
```

When called with no arguments, `thetagrids` simply returns the tuple `lines, labels`. When called with arguments, the labels will appear at the specified angles.

**Parameters**

- `angles` [tuple with floats, degrees] The angles of the theta gridlines.
- `labels` [tuple with strings or None] The labels to use at each radial gridline. The `projections.polar.ThetaFormatter` will be used if None.
- `fmt` [str or None] Format string used in `matplotlib.ticker.FormatStrFormatter`. For example '%f'. Note that the angle in radians will be used.

**Returns**

- `lines, labels` [list of `lines.Line2D`, list of `text.Text`] `lines` are the theta gridlines and `labels` are the tick labels.

**Other Parameters**

- `**kwargs` `kwargs` are optional `Text` properties for the labels.

**See also:**

- `pyplot.rgrids`
- `projections.polar.PolarAxes.set_thetagrids`
- `Axis.get_gridlines`
- `Axis.get_ticklabels`

**Examples**

```python
# set the locations of the angular gridlines
lines, labels = theagrids( range(45, 360, 90) )

# set the locations and labels of the angular gridlines
lines, labels = theagrids( range(45, 360, 90), ('NE', 'NW', 'SW', 'SE') )
```
axis [{‘x’, ‘y’, ‘both’}, optional] Which axis to apply the parameters to.

Other Parameters

axis [{‘x’, ‘y’, ‘both’}] Axis on which to operate; default is ‘both’.
reset [bool] If True, set all parameters to defaults before processing other
keyword arguments. Default is False.
which [{‘major’, ‘minor’, ‘both’}] Default is ‘major’; apply arguments to
which ticks.
direction [{‘in’, ‘out’, ‘inout’}] Puts ticks inside the axes, outside the
axes, or both.
length [float] Tick length in points.
width [float] Tick width in points.
color [color] Tick color; accepts any mpl color spec.
pad [float] Distance in points between tick and label.
labelsiz e [float or str] Tick label font size in points or as a string (e.g.,
‘large’).
labelcolor [color] Tick label color; mpl color spec.
colors [color] Changes the tick color and the label color to the same value:
mpl color spec.
zorder [float] Tick and label zorder.
bottom, top, left, right [bool] Whether to draw the respective ticks.
labelbottom, labeltop, labelleft, labelright [bool] Whether to draw
the respective tick labels.
labelrotation [float] Tick label rotation
grid_color [color] Changes the gridline color to the given mpl color spec.
grid_alpha [float] Transparency of gridlines: 0 (transparent) to 1
(opaque).
grid_linewidth [float] Width of gridlines in points.
grid linestyle [string] Any valid Line2D line style spec.

Examples

Usage

```python
ax.tick_params(direction='out', length=6, width=2, colors='r',
               grid_color='r', grid_alpha=0.5)
```

This will make all major ticks be red, pointing out of the box, and with dimensions 6
points by 2 points. Tick labels will also be red. Gridlines will be red and translucent.
matplotlib.pyplot.ticklabel_format

matplotlib.pyplot.ticklabel_format(*args, **kwargs)

Change the ScalarFormatter used by default for linear axes.

Optional keyword arguments:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>axis</td>
<td>[’x’</td>
</tr>
<tr>
<td>style</td>
<td>[’sci’ (or ’scientific’)</td>
</tr>
<tr>
<td>scilimits</td>
<td>(m, n), pair of integers; if style is ’sci’, scientific notation will be used for numbers outside the range $10^m$ to $10^n$. Use (0,0) to include all numbers. Use (m,m) where m &lt;&gt; 0 to fix the order of magnitude to $10^m$.</td>
</tr>
<tr>
<td>useOffset</td>
<td>[bool</td>
</tr>
<tr>
<td>useLocale</td>
<td>If True, format the number according to the current locale. This affects things such as the character used for the decimal separator. If False, use C-style (English) formatting. The default setting is controlled by the axes.formatter.use_locale rcparam.</td>
</tr>
<tr>
<td>useMathText</td>
<td>If True, render the offset and scientific notation in mathtext</td>
</tr>
</tbody>
</table>

Only the major ticks are affected. If the method is called when the ScalarFormatter is not the Formatter being used, an AttributeError will be raised.

matplotlib.pyplot.tight_layout

matplotlib.pyplot.tight_layout(*args, **kwargs)

Automatically adjust subplot parameters to give specified padding.

Parameters

- **pad** [float] Padding between the figure edge and the edges of subplots, as a fraction of the font size.
- **h_pad, w_pad** [float, optional] Padding (height/width) between edges of adjacent subplots, as a fraction of the font size. Defaults to pad.
- **rect** [tuple (left, bottom, right, top), optional] A rectangle (left, bottom, right, top) in the normalized figure coordinate that the whole subplots area (including labels) will fit into. Default is (0, 0, 1, 1).

Examples using matplotlib.pyplot.tight_layout

- sphx_glr_gallery_lines_bars_and_markers_linestyles.py
- sphx_glr_gallery_lines_bars_and_markers_nan_test.py
- sphx_glr_gallery_images_contours_and_fields_image_annotated_heatmap.py
**matplotlib.pyplot.title**

```python
matplotlib.pyplot.title(label, fontdict=None, loc='center', pad=None, **kwargs)
```

Set a title for the axes.

Set one of the three available axes titles. The available titles are positioned above the axes in the center, flush with the left edge, and flush with the right edge.

**Parameters**

- **label** [str] Text to use for the title
- **fontdict** [dict] A dictionary controlling the appearance of the title text, the default fontdict is:
  ```python
  {'fontsize': rcParams['axes.titlesize'],
   'fontweight': rcParams['axes.titleweight'],
   'verticalalignment': 'baseline',
   'horizontalalignment': loc}
  ```
- **loc** [{‘center’, ‘left’, ‘right’}, str, optional] Which title to set, defaults to ‘center’
- **pad** [float] The offset of the title from the top of the axes, in points. Default is None to use rcParams['axes.titlepad'].

**Returns**

- **text** [Text] The matplotlib text instance representing the title

**Other Parameters**

- **kwargs** [Text properties] Other keyword arguments are text properties, see Text for a list of valid text properties.

---

**`matplotlib.pyplot.tricontour`**

`matplotlib.pyplot.tricontour(*args, **kwargs)`

Draw contours on an unstructured triangular grid.

`tricontour` and `tricontourf` draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions.
The triangulation can be specified in one of two ways; either

```python
tricontour(triangulation, ...)
```

where `triangulation` is a `matplotlib.tri.Triangulation` object, or

```python
tricontour(x, y, ...)
tricontour(x, y, triangles, ...)
tricontour(x, y, triangles=triangles, ...)
tricontour(x, y, mask=mask, ...)
tricontour(x, y, triangles, mask=mask, ...)
```

in which case a `Triangulation` object will be created. See that class’ docstring for an explanation of these cases.

The remaining arguments may be:

```python
tricontour(..., Z)
```

where `Z` is the array of values to contour, one per point in the triangulation. The level values are chosen automatically.

```python
tricontour(..., Z, N)
```

contour up to \( N+1 \) automatically chosen contour levels (\( N \) intervals).

```python
tricontour(..., Z, V)
```

draw contour lines at the values specified in sequence `V`, which must be in increasing order.

```python
tricontourf(..., Z, V)
```

fill the \((\text{len}(V)-1)\) regions between the values in `V`, which must be in increasing order.

```python
tricontour(Z, **kwargs)
```

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details. 

```
tricontour(...) returns a TriContourSet object.
```

Optional keyword arguments:

- `colors`: [ `None` | string | (mpl_colors) ] If `None`, the colormap specified by `cmap` will be used.
  
  If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.
  
  If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be plotted in different colors in the order specified.

- `alpha`: float The alpha blending value

- `cmap`: [ `None` | Colormap ] A cm `Colormap` instance or `None`. If `cmap` is `None` and `colors` is `None`, a default Colormap is used.

- `norm`: [ `None` | Normalize ] A `matplotlib.colors.Normalize` instance for scaling data values to colors. If `norm` is `None` and `colors` is `None`, the default linear scaling is used.
levels [level0, level1, ..., leveln] A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass levels=[0]

origin: [ None | 'upper' | 'lower' | 'image' ] If None, the first value of Z will correspond to the lower left corner, location (0,0). If 'image', the rc value for image.origin will be used.

This keyword is not active if X and Y are specified in the call to contour.

extent: [ None | (x0,x1,y0,y1) ]

If origin is not None, then extent is interpreted as in matplotlib.pyplot.imshow(): it gives the outer pixel boundaries. In this case, the position of Z[0,0] is the center of the pixel, not a corner. If origin is None, then (x0, y0) is the position of Z[0,0], and (x1, y1) is the position of Z[-1,-1].

This keyword is not active if X and Y are specified in the call to contour.

locator: [ None | ticker.Locator subclass ] If locator is None, the default MaxNLocator is used. The locator is used to determine the contour levels if they are not given explicitly via the V argument.

extend: ['neither' | 'both' | 'min' | 'max'] Unless this is 'neither', contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via matplotlib.colors.Colormap.set_under() and matplotlib.colors.Colormap.set_over() methods.

xunits, yunits: [ None | registered units ] Override axis units by specifying an instance of a matplotlib.units.ConversionInterface.

tricontour-only keyword arguments:

linewidths: [ None | number | tuple of numbers ] If linewidths is None, defaults to rc:lines.linewidth.

If a number, all levels will be plotted with this linewidth.

If a tuple, different levels will be plotted with different linewidths in the order specified.

linestyles: [ None | 'solid' | 'dashed' | 'dashdot' | 'dotted' ] If linestyles is None, the 'solid' is used.

linestyles can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

If contour is using a monochrome colormap and the contour level is less than 0, then the linestyle specified in rcParams["contour.negative_linestyle"] will be used.

tricontourf-only keyword arguments:

antialiased: bool enable antialiasing

Note: tricontourf fills intervals that are closed at the top; that is, for boundaries z1 and z2, the filled region is:

\[ z1 < Z \leq z2 \]
except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

Examples using matplotlib.pyplot.tricontour

- sphx_glr_gallery_images_contours_and_fields_irregulardatagrid.py
- sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_delaunay.py
- sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_user.py
- sphx_glr_gallery_images_contours_and_fields_trigradient_demo.py

matplotlib.pyplot.tricontourf

draw contours on an unstructured triangular grid.

tricontour and tricontourf draw contour lines and filled contours, respectively. Except as noted, function signatures and return values are the same for both versions. The triangulation can be specified in one of two ways; either

tricontour(triangulation, ...)

where triangulation is a matplotlib.tri.Triangulation object, or

tricontour(x, y, ...)  
tricontour(x, y, triangles, ...)  
tricontour(x, y, triangles=triangles, ...)  
tricontour(x, y, mask=mask, ...)  
tricontour(x, y, triangles, mask=mask, ...)

in which case a Triangulation object will be created. See that class’ docstring for an explanation of these cases.

The remaining arguments may be:

tricontour(..., Z)

where Z is the array of values to contour, one per point in the triangulation. The level values are chosen automatically.

tricontour(..., Z, N)

contour up to N+1 automatically chosen contour levels (N intervals).

tricontour(..., Z, V)

draw contour lines at the values specified in sequence V, which must be in increasing order.

tricontourf(..., Z, V)

fill the (len(V)-1) regions between the values in V, which must be in increasing order.
tricontour(Z, **kwargs)

Use keyword args to control colors, linewidth, origin, cmap ... see below for more details.
tricontour(...) returns a TriContourSet object.

Optional keyword arguments:

- **colors** 
  [None | string | (mpl_colors)] If None, the colormap specified by cmap will be used.
  If a string, like ‘r’ or ‘red’, all levels will be plotted in this color.
  If a tuple of matplotlib color args (string, float, rgb, etc), different levels will be plotted in different colors in the order specified.

- **alpha**
  float The alpha blending value

- **cmap** 
  [None | Colormap] A cm Colormap instance or None. If cmap is None and colors is None, a default Colormap is used.

- **norm** 
  [None | Normalize] A matplotlib.colors.Normalize instance for scaling data values to colors. If norm is None and colors is None, the default linear scaling is used.

- **levels** [level0, level1, ..., leveln] A list of floating point numbers indicating the level curves to draw, in increasing order; e.g., to draw just the zero contour pass levels=[0]

- **origin** 
  [None | ‘upper’ | ‘lower’ | ‘image’] If None, the first value of Z will correspond to the lower left corner, location (0,0). If ‘image’, the rc value for image.origin will be used.

  This keyword is not active if X and Y are specified in the call to contour.

- **extent** [None | (x0,x1,y0,y1)]

  If origin is not None, then extent is interpreted as in matplotlib.pyplot.imshow(): it gives the outer pixel boundaries. In this case, the position of Z[0,0] is the center of the pixel, not a corner. If origin is None, then (x0, y0) is the position of Z[0,0], and (x1, y1) is the position of Z[-1,-1].

  This keyword is not active if X and Y are specified in the call to contour.

- **locator** 
  [None | ticker.Locator subclass] If locator is None, the default MaxNLocator is used. The locator is used to determine the contour levels if they are not given explicitly via the V argument.

- **extend** [‘neither’ | ‘both’ | ‘min’ | ‘max’] Unless this is ‘neither’, contour levels are automatically added to one or both ends of the range so that all data are included. These added ranges are then mapped to the special colormap values which default to the ends of the colormap range, but can be set via matplotlib.colors.Colormap.set_under() and matplotlib.colors.Colormap.set_over() methods.

- **xunits**, **yunits** [None | registered units] Override axis units by specifying an instance of a matplotlib.units.ConversionInterface.

tricontour-only keyword arguments:

- **linewidths** [None | number | tuple of numbers] If linewidths is None, defaults to rc:lines.linewidth.
If a number, all levels will be plotted with this linewidth.

If a tuple, different levels will be plotted with different line widths in the order specified

`linestyles`: [None | ‘solid’ | ‘dashed’ | ‘dashdot’ | ‘dotted’] If `linestyles` is None, the ‘solid’ is used.

`linestyles` can also be an iterable of the above strings specifying a set of linestyles to be used. If this iterable is shorter than the number of contour levels it will be repeated as necessary.

If contour is using a monochrome colormap and the contour level is less than 0, then the linestyle specified in `rcParams["contour.negative_linestyle"]` will be used.

`tricontourf`-only keyword arguments:

`antialiased`: bool enable antialiasing

Note: `tricontourf` fills intervals that are closed at the top; that is, for boundaries `z1` and `z2`, the filled region is:

```
z1 < Z <= z2
```

except for the lowest interval, which is closed on both sides (i.e. it includes the lowest value).

Examples using `matplotlib.pyplot.tricontourf`

- sphx_glr_gallery_images_contours_and_fields_irregulardatagrid.py
- sphx_glr_gallery_images_contours_and_fields_tricontour_demo.py
- sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_delaunay.py
- sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_user.py
- sphx_glr_gallery_images_contours_and_fields_triinterp_demo.py

`matplotlib.pyplot.tripcolor`

`matplotlib.pyplot.tripcolor(*args, alpha=1.0, norm=None, cmap=None, vmin=None, vmax=None, shading='flat', facecolors=None, **kwargs)`

Create a pseudocolor plot of an unstructured triangular grid.

The triangulation can be specified in one of two ways; either:

```
tripcolor(triangulation, ...)
```

where `triangulation` is a `matplotlib.tri.Triangulation` object, or

```
tripcolor(x, y, ...)
tripcolor(x, y, triangles, ...)
tripcolor(x, y, triangles=triangles, ...)
tripcolor(x, y, mask=mask, ...)
tripcolor(x, y, triangles, mask=mask, ...)
```
in which case a Triangulation object will be created. See Triangulation for a explanation of these possibilities.

The next argument must be $C$, the array of color values, either one per point in the triangulation if color values are defined at points, or one per triangle in the triangulation if color values are defined at triangles. If there are the same number of points and triangles in the triangulation it is assumed that color values are defined at points; to force the use of color values at triangles use the kwarg `facecolors=C` instead of just $C$.

`shading` may be ‘flat’ (the default) or ‘gouraud’. If `shading` is ‘flat’ and $C$ values are defined at points, the color values used for each triangle are from the mean $C$ of the triangle’s three points. If `shading` is ‘gouraud’ then color values must be defined at points.

The remaining kwargs are the same as for `pcolor()`.

**Examples using matplotlib.pyplot.tripcolor**

- sphx_glr_gallery_images_contours_and_fields_tripcolor_demo.py

**matplotlib.pyplot.triplot**

```python
matplotlib.pyplot.triplot(*args, **kwargs)
```

Draw a unstructured triangular grid as lines and/or markers.

The triangulation to plot can be specified in one of two ways; either:

```python
triplot(triangulation, ...)
```

where triangulation is a `matplotlib.tri.Triangulation` object, or

```python
triplot(x, y, ...)
triplot(x, y, triangles, ...)
triplot(x, y, triangles=triangles, ...)
triplot(x, y, mask=mask, ...)
triplot(x, y, triangles, mask=mask, ...)
```

in which case a Triangulation object will be created. See Triangulation for a explanation of these possibilities.

The remaining args and kwargs are the same as for `plot()`.

Return a list of 2 `Line2D` containing respectively:

- the lines plotted for triangles edges
- the markers plotted for triangles nodes

**Examples using matplotlib.pyplot.triplot**

- sphx_glr_gallery_images_contours_and_fields_tricontour_smooth_delaunay.py
- sphx_glr_gallery_images_contours_and_fields_trigradient_demo.py
- sphx_glr_gallery_images_contours_and_fields_triinterp_demo.py
- sphx_glr_gallery_images_contours_and_fields_triplot_demo.py
- sphx_glr_gallery_event_handling_trifinder_event_demo.py

**matplotlib.pyplot.twinx**

matplotlib.pyplot.twinx(ax=None)

Make and return a second axes that shares the x-axis. The new axes will overlay ax (or the current axes if ax is None), and its ticks will be on the right.

**Examples**

/gallery/subplots_axes_and_figures/two_scales

**matplotlib.pyplot.twiny**

matplotlib.pyplot.twiny(ax=None)

Make and return a second axes that shares the y-axis. The new axes will overlay ax (or the current axes if ax is None), and its ticks will be on the top.

**Examples**

/gallery/subplots_axes_and_figures/two_scales

**matplotlib.pyplot.uninstall_repl_displayhook**

matplotlib.pyplot.uninstall_repl_displayhook()

Uninstall the matplotlib display hook.

**matplotlib.pyplot.violinplot**

matplotlib.pyplot.violinplot(dataset, positions=None, vert=True, widths=0.5, showmeans=False, showextrema=True, showmedians=False, points=100, bw_method=None, *, data=None)

Make a violin plot.

Make a violin plot for each column of dataset or each vector in sequence dataset. Each filled area extends to represent the entire data range, with optional lines at the mean, the median, the minimum, and the maximum.

**Parameters**

- **dataset** [Array or a sequence of vectors.] The input data.
- **positions** [array-like, default = [1, 2, ..., n]] Sets the positions of the violins. The ticks and limits are automatically set to match the positions.
- **vert** [bool, default = True.] If true, creates a vertical violin plot. Otherwise, creates a horizontal violin plot.
widths [array-like, default = 0.5] Either a scalar or a vector that sets the maximal width of each horizontal violin. The default is 0.5, which uses about half of the available horizontal space.

showmeans [bool, default = False] If True, will toggle rendering of the means.

showextrema [bool, default = True] If True, will toggle rendering of the extrema.

showmedians [bool, default = False] If True, will toggle rendering of the medians.

points [scalar, default = 100] Defines the number of points to evaluate each of the gaussian kernel density estimations at.

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be ‘scott’, ‘silverman’, a scalar constant or a callable. If a scalar, this will be used directly as kde.factor. If a callable, it should take a GaussianKDE instance as its only parameter and return a scalar. If None (default), ‘scott’ is used.

Returns

result [dict] A dictionary mapping each component of the violinplot to a list of the corresponding collection instances created. The dictionary has the following keys:

- bodies: A list of the matplotlib.collections.PolyCollection instances containing the filled area of each violin.
- cmeans: A matplotlib.collections.LineCollection instance created to identify the mean values of each of the violin’s distribution.
- cmins: A matplotlib.collections.LineCollection instance created to identify the bottom of each violin’s distribution.
- cmaxes: A matplotlib.collections.LineCollection instance created to identify the top of each violin’s distribution.
- cbars: A matplotlib.collections.LineCollection instance created to identify the centers of each violin’s distribution.
- cmedians: A matplotlib.collections.LineCollection instance created to identify the median values of each of the violin’s distribution.

Notes

Note: In addition to the above described arguments, this function can take a data keyword argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:

- All arguments with the following names: ‘dataset’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).
**matplotlib.pyplot.viridis**

```python
colors = 'viridis()
```

Set the colormap to “viridis”.

This changes the default colormap as well as the colormap of the current image if there is one. See `help(colormaps)` for more information.

**matplotlib.pyplot.vlines**

```python
vlines(x, ymin, ymax, colors='k', linestyles='solid', label='', data=None, **kwargs)
```

Plot vertical lines.

Plot vertical lines at each `x` from `ymin` to `ymax`.

**Parameters**

- `x` [scalar or 1D array_like] x-indexes where to plot the lines.
- `ymin, ymax` [scalar or 1D array_like] Respective beginning and end of each line. If scalars are provided, all lines will have same length.
- `colors` [array_like of colors, optional, default: 'k']
- `linestyles` [{‘solid’, ‘dashed’, ‘dashdot’, ‘dotted’}, optional]
- `label` [string, optional, default: ‘’]

**Returns**

- `lines` [LineCollection]

**Other Parameters**

- `**kwargs` [LineCollection properties.]

**See also:**

- `hlines` horizontal lines
- `axvline` vertical line across the axes

**Notes**

**Note:** In addition to the above described arguments, this function can take a `data` keyword argument. If such a `data` argument is given, the following arguments are replaced by `data[<arg>]`:

- All arguments with the following names: ‘colors’, ‘x’, ‘ymax’, ‘ymin’.

Objects passed as `data` must support item access (`data[<arg>]`) and membership test (`<arg> in data`).
matplotlib.pyplot.waitforbuttonpress

matplotlib.pyplot.waitforbuttonpress(*args, **kwargs)

Blocking call to interact with the figure.

This will return True if a key was pressed, False if a mouse button was pressed and None if timeout was reached without either being pressed.

If timeout is negative, does not timeout.

Examples using matplotlib.pyplot.waitforbuttonpress

• sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py

matplotlib.pyplot.winter

matplotlib.pyplot.winter()

Set the colormap to “winter”.

This changes the default colormap as well as the colormap of the current image if there is one. See help(colormaps) for more information.

matplotlib.pyplot.xcorr

matplotlib.pyplot.xcorr(x, y, normed=True, detrend=<function detrend_none at 0x7f69881a1378>, usevlines=True, maxlags=10, *, data=None, **kwargs)

Plot the cross correlation between x and y.

The correlation with lag k is defined as \( \sum_n x[n+k] \cdot y^*[n] \), where \( y^* \) is the complex conjugate of \( y \).

Parameters

x [array-like of length n]
y [array-like of length n]
detrend [callable, optional, default: mlab.detrend_none] x and y are detrended by the detrend callable. This must be a function x = detrend(x) accepting and returning an numpy.array. Default is no normalization.
normed [bool, optional, default: True] If True, input vectors are normalised to unit length.
usevlines [bool, optional, default: True] Determines the plot style.

If True, vertical lines are plotted from 0 to the xcorr value using Axes.vlines. Additionally, a horizontal line is plotted at y=0 using Axes.axhline.

If False, markers are plotted at the xcorr values using Axes.plot.

maxlags [int, optional, default: 10] Number of lags to show. If None, will return all \( 2 \cdot \text{len}(x) - 1 \) lags.

Returns
lags [array (length 2*maxlags+1)] The lag vector.
c [array (length 2*maxlags+1)] The auto correlation vector.
line [LineCollection or Line2D] Artist added to the axes of the correlation:
  • LineCollection if usevlines is True.
  • Line2D if usevlines is False.
b [Line2D or None] Horizontal line at 0 if usevlines is True None usevlines is False.

Other Parameters

linestyle [Line2D property, optional] The linestyle for plotting the data points. Only used if usevlines is False.
marker [str, optional, default: ‘o’] The marker for plotting the data points. Only used if usevlines is False.

Notes

The cross correlation is performed with numpy.correlate() with mode = "full".

Note: In addition to the above described arguments, this function can take a data key-word argument. If such a data argument is given, the following arguments are replaced by data[<arg>]:
  • All arguments with the following names: ‘x’, ‘y’.

Objects passed as data must support item access (data[<arg>]) and membership test (<arg> in data).

Examples using matplotlib.pyplot.xcorr

• sphx_glr_gallery_lines_bars_and_markers_xcorr_acorr_demo.py

matplotlib.pyplot.xkcd

matplotlib.pyplot.xkcd(scale=1, length=100, randomness=2)

Turn on xkcd sketch-style drawing mode. This will only have effect on things drawn after this function is called.

For best results, the “Humor Sans” font should be installed: it is not included with matplotlib.

Parameters

scale [float, optional] The amplitude of the wiggle perpendicular to the source line.
length [float, optional] The length of the wiggle along the line.
randomness [float, optional] The scale factor by which the length is shrunken or expanded.
Notes

This function works by a number of rcParams, so it will probably override others you have set before.

If you want the effects of this function to be temporary, it can be used as a context manager, for example:

```python
with plt.xkcd():
    # This figure will be in XKCD-style
    fig1 = plt.figure()
    # ...

# This figure will be in regular style
fig2 = plt.figure()
```

Examples using matplotlib.pyplot.xkcd

- sphx_glr_gallery_showcase_xkcd.py

**matplotlib.pyplot.xlabel**

```python
matplotlib.pyplot.xlabel(xlabel, fontdict=None, labelpad=None, **kwargs)
```

Set the label for the x-axis.

**Parameters**

- `xlabel` [str] The label text.
- `labelpad` [scalar, optional, default: None] Spacing in points from the axes bounding box including ticks and tick labels.

**Other Parameters**

- `**kwargs` [Text properties] Text properties control the appearance of the label.

**See also:**

text for information on how override and the optional args work

Examples using matplotlib.pyplot.xlabel

- sphx_glr_gallery_lines_bars_and_markers_nan_test.py
- sphx_glr_gallery_lines_bars_and_markers_scatter_symbol.py
- sphx_glr_gallery_subplots_axes_and_figures_axes_demo.py
- sphx_glr_gallery_subplots_axes_and_figures_invert_axes.py
- sphx_glr_gallery_subplots_axes_and_figures_subplot.py
- sphx_glr_gallery_text_labels_and_annotations_multiline.py
- sphx_glr_gallery_text_labels_and_annotations_text_fontdict.py
• sphx_glr_gallery_pylots_pylot_mathtext.py
• sphx_glr_gallery_pylots_pylot_text.py
• sphx_glr_gallery_style_sheets_plot_solarizedlight2.py
• sphx_glr_gallery_misc_findobj_demo.py

• sphx_glr_gallery_scales_custom_scale.py
• sphx_glr_gallery_userdemo_pgf_fonts.py
• sphx_glr_gallery_userdemo_pgf_preamble_sgskip.py
• sphx_glr_gallery_userdemo_pgf_texsystem.py
• Usage Guide
• Pyplot tutorial

matplotlib.pyplot.xlim

matplotlib.pyplot.xlim(*args, **kwargs)
Get or set the x limits of the current axes.

Call signatures:

```
left, right = xlim()  # return the current xlim
xlim((left, right))  # set the xlim to left, right
xlim(left, right)    # set the xlim to left, right
```

If you do not specify args, you can pass left or right as kwargs, i.e.:

```
xlim(right=3)  # adjust the right leaving left unchanged
xlim(left=1)   # adjust the left leaving right unchanged
```

Setting limits turns autoscaling off for the x-axis.

**Returns**

left, right A tuple of the new x-axis limits.

**Notes**

Calling this function with no arguments (e.g. xlim()) is the pyplot equivalent of calling get_xlim on the current axes. Calling this function with arguments is the pyplot equivalent of calling set_xlim on the current axes. All arguments are passed through.

**Examples using matplotlib.pyplot.xlim**

• sphx_glr_gallery_subplots_axes_and_figures_axes_demo.py
• sphx_glr_gallery_subplots_axes_and_figures_invert_axes.py
• sphx_glr_gallery_subplots_axes_and_figures_shared_axis_demo.py
• sphx_glr_gallery_text_labels_and_annotations_arrow_demo.py
matplotlib.pyplot.xscale

matplotlib.pyplot.xscale(value, **kwargs)
Set the x-axis scale.

Parameters

value [{"linear", "log", "symlog", "logit", ...}] The axis scale type to apply.

**kwargs Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:

• matplotlib.scale.LinearScale
• matplotlib.scale.LogScale
• matplotlib.scale.SymmetricalLogScale
• matplotlib.scale.LogitScale

Notes

By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using matplotlib.scale.register_scale. These scales can then also be used here.

Examples using matplotlib.pyplot.xscale

• sphx_glr_gallery_scales_symlog_demo.py

matplotlib.pyplot.xticks

matplotlib.pyplot.xticks(ticks=None, labels=None, **kwargs)
Get or set the current tick locations and labels of the x-axis.

Call signatures:

locs, labels = xticks() # Get locations and labels
xticks(ticks, [labels], **kwargs) # Set locations and labels

Parameters

ticks [array like] A list of positions at which ticks should be placed. You can pass an empty list to disable xticks.
**labels** [array_like, optional] A list of explicit labels to place at the given locs.

**kwargs** Text properties can be used to control the appearance of the labels.

**Returns**

**locs** An array of label locations.

**labels** A list of Text objects.

**Notes**

Calling this function with no arguments (e.g. `xticks()`) is the pyplot equivalent of calling `get_xticks` and `get_xticklabels` on the current axes. Calling this function with arguments is the pyplot equivalent of calling `set_xticks` and `set_xticklabels` on the current axes.

**Examples**

Get the current locations and labels:

```python
>>> locs, labels = xticks()
```

Set label locations:

```python
>>> xticks(np.arange(0, 1, step=0.2))
```

Set text labels:

```python
>>> xticks(np.arange(5), ('Tom', 'Dick', 'Harry', 'Sally', 'Sue'))
```

Set text labels and properties:

```python
>>> xticks(np.arange(12), calendar.month_name[1:13], rotation=20)
```

Disable xticks:

```python
>>> xticks([])
```
matplotlib.pyplot.ylabel

matplotlib.pyplot.ylabel(ylabel, fontdict=None, labelpad=None, **kwargs)
Set the label for the y-axis.

Parameters

tylabel [str] The label text.

labelpad [scalar, optional, default: None] Spacing in points from the axes bounding box including ticks and tick labels.

Other Parameters

**kwargs [Text properties] Text properties control the appearance of the label.

See also:
text for information on how override and the optional args work

Examples using matplotlib.pyplot.ylabel

• sphx_glr_gallery_lines_bars_and_markers_bar_stacked.py
• sphx_glr_gallery_lines_bars_and_markers_nan_test.py

• sphx_glr_gallery_userdemo_pgf_preamble_sgskip.py
• Usage Guide
• Pyplot tutorial

matplotlib.pyplot.ylim

matplotlib.pyplot.ylim(*args, **kwargs)
Get or set the y-limits of the current axes.

Call signatures:

```python
bottom, top = ylim()  # return the current ylim
ylim((bottom, top))  # set the ylim to bottom, top
ylim(bottom, top)    # set the ylim to bottom, top
```

If you do not specify args, you can alternatively pass `bottom` or `top` as kwargs, i.e.:

```python
ylim(top = 3)  # adjust the top leaving bottom unchanged
ylim(bottom = 1)  # adjust the bottom leaving top unchanged
```

Setting limits turns autoscaling off for the y-axis.

**Returns**

`bottom, top` A tuple of the new y-axis limits.

**Notes**

Calling this function with no arguments (e.g. `ylim()`) is the pyplot equivalent of calling `get_ylim` on the current axes. Calling this function with arguments is the pyplot equivalent of calling `set_ylim` on the current axes. All arguments are passed through.

**Examples using** matplotlib.pyplot.ylim

- sphx_glr_gallery_subplots_axes_and_figures_axes_demo.py
- sphx_glr_gallery_text_labels_and_annotations_arrow_demo.py
- sphx_glr_gallery_text_labels_and_annotations_usetex_fonteffects.py
- sphx_glr_gallery_pyplots_pyplot_text.py
- sphx_glr_gallery_shapes_and_collections_ellipse_demo.py
- Frame grabbing
- sphx_glr_gallery_event_handling_ginput_manual_clabel_sgskip.py
- sphx_glr_gallery_misc_findobj_demo.py
- Pyplot tutorial
matplotlib.pyplot.yscale

`matplotlib.pyplot.yscale(value, **kwargs)`
Set the y-axis scale.

**Parameters**

- `value` [{“linear”, “log”, “symlog”, “logit”, ...}] The axis scale type to apply.
- `**kwargs` Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:
  - `matplotlib.scale.LinearScale`
  - `matplotlib.scale.LogScale`
  - `matplotlib.scale.SymmetricalLogScale`
  - `matplotlib.scale.LogitScale`

**Notes**

By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using `matplotlib.scale.register_scale`. These scales can then also be used here.

**Examples using matplotlib.pyplot.yscale**

- sphx_glr_gallery_pyplots_pyplot_scales.py
- sphx_glr_gallery_scales_symlog_demo.py
- Pyplot tutorial

matplotlib.pyplot.yticks

`matplotlib.pyplot.yticks(ticks=None, labels=None, **kwargs)`
Get or set the current tick locations and labels of the y-axis.

Call signatures:

```
locs, labels = yticks() # Get locations and labels
yticks(ticks, [labels], **kwargs) # Set locations and labels
```

**Parameters**

- `ticks` [array_like] A list of positions at which ticks should be placed. You can pass an empty list to disable yticks.
- `labels` [array_like, optional] A list of explicit labels to place at the given `locs`.
- `**kwargs` Text properties can be used to control the appearance of the labels.

**Returns**
locs  An array of label locations.
labels  A list of Text objects.

Notes

Calling this function with no arguments (e.g. yticks()) is the pyplot equivalent of calling
get_yticks and get_yticklabels on the current axes. Calling this function with arguments
is the pyplot equivalent of calling set_yticks and set_yticklabels on the current axes.

Examples

Get the current locations and labels:

```python
>>> locs, labels = yticks()
```

Set label locations:

```python
>>> yticks(np.arange(0, 1, step=0.2))
```

Set text labels:

```python
>>> yticks(np.arange(5), ('Tom', 'Dick', 'Harry', 'Sally', 'Sue'))
```

Set text labels and properties:

```python
>>> yticks(np.arange(12), calendar.month_name[1:13], rotation=45)
```

Disable yticks:

```python
>>> yticks([])
```

Examples using matplotlib.pyplot.yticks

- sphx_glr_gallery_lines_bars_and_markers_bar_stacked.py
- sphx_glr_gallery_subplots_axes_and_figures_axes_demo.py
- sphx_glr_gallery_text_labels_and_annotations_arrow_demo.py
- sphx_glr_gallery_text_labels_and_annotations_usetex_demo.py
- sphx_glr_gallery_axes_grid1_demo_colorbar_of_inset_axes.py
- sphx_glr_gallery_misc_table_demo.py

### 17.37.2 Colors in Matplotlib

There are many colormaps you can use to map data onto color values. Below we list several ways in which color can be utilized in Matplotlib.

For a more in-depth look at colormaps, see the *Choosing Colormaps in Matplotlib* tutorial.

```python
import matplotlib.pyplot as plt

# Matplotlib provides a number of colormaps, and others can be added using
# register_cmap(). This function documents the built-in colormaps, and will also return
# a list of all registered colormaps if called.

# You can set the colormap for an image, pcolor, scatter, etc, using a keyword argument:

plt.imshow(X, cmap=cm.hot)

# or using the set_cmap() function:

plt.imshow(X)
plt.set_cmap('hot')
plt.set_cmap('jet')
```
In interactive mode, \texttt{set_cmap()} will update the colormap post-hoc, allowing you to see which one works best for your data.

All built-in colormaps can be reversed by appending \_\texttt{r}: For instance, \texttt{gray\_r} is the reverse of \texttt{gray}.

There are several common color schemes used in visualization:

\textbf{Sequential schemes} for unipolar data that progresses from low to high

\textbf{Diverging schemes} for bipolar data that emphasizes positive or negative deviations from a central value

\textbf{Cyclic schemes} for plotting values that wrap around at the endpoints, such as phase angle, wind direction, or time of day

\textbf{Qualitative schemes} for nominal data that has no inherent ordering, where color is used only to distinguish categories

Matplotlib ships with 4 perceptually uniform color maps which are the recommended color maps for sequential data:

<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inferno</td>
<td>perceptually uniform shades of black-red-yellow</td>
</tr>
<tr>
<td>magma</td>
<td>perceptually uniform shades of black-red-white</td>
</tr>
<tr>
<td>plasma</td>
<td>perceptually uniform shades of blue-red-yellow</td>
</tr>
<tr>
<td>viridis</td>
<td>perceptually uniform shades of blue-green-yellow</td>
</tr>
</tbody>
</table>

The following colormaps are based on the \texttt{ColorBrewer} color specifications and designs developed by Cynthia Brewer:

ColorBrewer Diverging (luminance is highest at the midpoint, and decreases towards differently-colored endpoints):

<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BrBG</td>
<td>brown, white, blue-green</td>
</tr>
<tr>
<td>PiYG</td>
<td>pink, white, yellow-green</td>
</tr>
<tr>
<td>PRGn</td>
<td>purple, white, green</td>
</tr>
<tr>
<td>PuOr</td>
<td>orange, white, purple</td>
</tr>
<tr>
<td>RdBu</td>
<td>red, white, blue</td>
</tr>
<tr>
<td>RdGy</td>
<td>red, white, gray</td>
</tr>
<tr>
<td>RdYrBu</td>
<td>red, yellow, blue</td>
</tr>
<tr>
<td>RdYGrn</td>
<td>red, yellow, green</td>
</tr>
<tr>
<td>Spectral</td>
<td>red, orange, yellow, green, blue</td>
</tr>
</tbody>
</table>

ColorBrewer Sequential (luminance decreases monotonically):
<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blues</td>
<td>white to dark blue</td>
</tr>
<tr>
<td>BuGn</td>
<td>white, light blue, dark green</td>
</tr>
<tr>
<td>BuPu</td>
<td>white, light blue, dark purple</td>
</tr>
<tr>
<td>GnBu</td>
<td>white, light green, dark blue</td>
</tr>
<tr>
<td>Greens</td>
<td>white to dark green</td>
</tr>
<tr>
<td>Greys</td>
<td>white to black (not linear)</td>
</tr>
<tr>
<td>Oranges</td>
<td>white, orange, dark brown</td>
</tr>
<tr>
<td>OrRd</td>
<td>white, orange, dark red</td>
</tr>
<tr>
<td>PuBu</td>
<td>white, light purple, dark blue</td>
</tr>
<tr>
<td>PuBuGn</td>
<td>white, light purple, dark green</td>
</tr>
<tr>
<td>PuRd</td>
<td>white, light purple, dark red</td>
</tr>
<tr>
<td>Purples</td>
<td>white to dark purple</td>
</tr>
<tr>
<td>RdPu</td>
<td>white, pink, dark purple</td>
</tr>
<tr>
<td>Reds</td>
<td>white to dark red</td>
</tr>
<tr>
<td>YlGn</td>
<td>light yellow, dark green</td>
</tr>
<tr>
<td>YlGnBu</td>
<td>light yellow, light green, dark blue</td>
</tr>
<tr>
<td>YlOrBr</td>
<td>light yellow, orange, dark brown</td>
</tr>
<tr>
<td>YlOrRd</td>
<td>light yellow, orange, dark red</td>
</tr>
</tbody>
</table>

ColorBrewer Qualitative:

(For plotting nominal data, ListedColormap is used, not LinearSegmentedColormap. Different sets of colors are recommended for different numbers of categories.)

- Accent
- Dark2
- Paired
- Pastel1
- Pastel2
- Set1
- Set2
- Set3

A set of colormaps derived from those of the same name provided with Matlab are also included:
<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>autumn</td>
<td>sequential linearly-increasing shades of red-orange-yellow</td>
</tr>
<tr>
<td>bone</td>
<td>sequential increasing black-white color map with a tinge of blue, to emulate X-ray film</td>
</tr>
<tr>
<td>cool</td>
<td>linearly-decreasing shades of cyan-magenta</td>
</tr>
<tr>
<td>copper</td>
<td>sequential increasing shades of black-copper</td>
</tr>
<tr>
<td>flag</td>
<td>repetitive red-white-blue-black pattern (not cyclic at endpoints)</td>
</tr>
<tr>
<td>gray</td>
<td>sequential linearly-increasing black-to-white grayscale</td>
</tr>
<tr>
<td>hot</td>
<td>sequential black-red-yellow-white, to emulate blackbody radiation from an object at increasing temperatures</td>
</tr>
<tr>
<td>jet</td>
<td>a spectral map with dark endpoints, blue-cyan-yellow-red; based on a fluid-jet simulation by NCSA</td>
</tr>
<tr>
<td>pink</td>
<td>sequential increasing pastel black-pink-white, meant for sepia tone colorization of photographs</td>
</tr>
<tr>
<td>prism</td>
<td>repetitive red-yellow-green-blue-purple-...-green pattern (not cyclic at endpoints)</td>
</tr>
<tr>
<td>spring</td>
<td>linearly-increasing shades of magenta-yellow</td>
</tr>
<tr>
<td>summer</td>
<td>sequential linearly-increasing shades of green-yellow</td>
</tr>
<tr>
<td>winter</td>
<td>linearly-increasing shades of blue-green</td>
</tr>
</tbody>
</table>

A set of palettes from the Yorick scientific visualisation package, an evolution of the GIST package, both by David H. Munro are included:

<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gist_earth</td>
<td>mapmaker’s colors from dark blue deep ocean to green lowlands to brown highlands to white mountains</td>
</tr>
<tr>
<td>gist_heat</td>
<td>sequential increasing black-red-orange-white, to emulate blackbody radiation from an iron bar as it grows hotter</td>
</tr>
<tr>
<td>gist_ncar</td>
<td>pseudo-spectral black-blue-green-yellow-red-purple-white colormap from National Center for Atmospheric Research</td>
</tr>
<tr>
<td>gist_rainbow</td>
<td>runs through the colors in spectral order from red to violet at full saturation (like hsv but not cyclic)</td>
</tr>
<tr>
<td>gist_stern</td>
<td>“Stern special” color table from Interactive Data Language software</td>
</tr>
</tbody>
</table>

A set of cyclic color maps:

---

1 Rainbow colormaps, jet in particular, are considered a poor choice for scientific visualization by many researchers: Rainbow Color Map (Still) Considered Harmful
2 Resembles “BkBlAqGrYeOrReViWh200” from NCAR Command Language. See Color Table Gallery
<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hsv</td>
<td>red-yellow-green-cyan-blue-magenta-red, formed by changing the hue component in the HSV color space</td>
</tr>
<tr>
<td>twilight</td>
<td>perceptually uniform shades of white-blue-black-red-white</td>
</tr>
<tr>
<td>twilight_shifted</td>
<td>perceptually uniform shades of black-blue-white-red-black</td>
</tr>
</tbody>
</table>

Other miscellaneous schemes:

<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>afmhot</td>
<td>sequential black-orange-yellow-white blackbody spectrum, commonly used in atomic force microscopy</td>
</tr>
<tr>
<td>brg</td>
<td>blue-red-green</td>
</tr>
<tr>
<td>bwr</td>
<td>diverging blue-white-red</td>
</tr>
<tr>
<td>coolwarm</td>
<td>diverging blue-gray-red, meant to avoid issues with 3D shading, color blindness, and ordering of colors</td>
</tr>
<tr>
<td>CM-Rmap</td>
<td>&quot;Default colormaps on color images often reproduce to confusing grayscale images. The proposed colormap maintains an aesthetically pleasing color image that automatically reproduces to a monotonic grayscale with discrete, quantifiable saturation levels.&quot;</td>
</tr>
<tr>
<td>cubehelix</td>
<td>Unlike most other color schemes cubehelix was designed by D.A. Green to be monotonically increasing in terms of perceived brightness. Also, when printed on a black and white postscript printer, the scheme results in a greyscale with monotonically increasing brightness. This color scheme is named cubehelix because the r,g,b values produced can be visualised as a squashed helix around the diagonal in the r,g,b color cube.</td>
</tr>
<tr>
<td>gnuplot</td>
<td>gnuplot's traditional pm3d scheme (black-blue-red-yellow)</td>
</tr>
<tr>
<td>gnuplot2</td>
<td>sequential color printable as gray (black-blue-violet-yellow-white)</td>
</tr>
<tr>
<td>ocean</td>
<td>green-blue-white</td>
</tr>
<tr>
<td>rainbow</td>
<td>spectral purple-blue-green-yellow-orange-red colormap with diverging luminance</td>
</tr>
<tr>
<td>seismic</td>
<td>diverging blue-white-red</td>
</tr>
<tr>
<td>nipy</td>
<td>black-purple-blue-green-yellow-red-white spectrum, originally from the Neuroimaging in Python project</td>
</tr>
<tr>
<td>terrain</td>
<td>mapmaker's colors, blue-green-yellow-brown-white, originally from IGOR Pro</td>
</tr>
</tbody>
</table>

The following colormaps are redundant and may be removed in future versions. It’s recommended to use the names in the descriptions instead, which produce identical output:

<table>
<thead>
<tr>
<th>Colormap</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gist_gray</td>
<td>identical to gray</td>
</tr>
<tr>
<td>gist_yarg</td>
<td>identical to gray_r</td>
</tr>
<tr>
<td>binary</td>
<td>identical to gray_r</td>
</tr>
</tbody>
</table>

---

4 See A Color Map for Effective Black-and-White Rendering of Color-Scale Images by Carey Rappaport
17.38 matplotlib.projections

class matplotlib.projections.ProjectionRegistry
   Bases: object

   Manages the set of projections available to the system.

   get_projection_class(self, name)
      Get a projection class from its name.

   get_projection_names(self)
      Get a list of the names of all projections currently registered.

   register(self, *projections)
      Register a new set of projections.

matplotlib.projections.get_projection_class(projection=None)
   Get a projection class from its name.
   If projection is None, a standard rectilinear projection is returned.

matplotlib.projections.get_projection_names()
   Get a list of acceptable projection names.

matplotlib.projections.process_projection_requirements(figure, *args, **kwargs)
   [Deprecated]

Notes

Deprecated since version 3.1:
matplotlib.projections.register_projection(cls)

17.39 matplotlib.projections.polar

class matplotlib.projections.polar.InvertedPolarTransform(axis=None, use_rmin=True, apply_theta_transforms=True)
   Bases: matplotlib.transforms.Transform

   The inverse of the polar transform, mapping Cartesian coordinate space x and y back to theta and r.

   input_dims = 2

   inverted(self)
      Return the corresponding inverse transformation.
      The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.
      x === self.inverted().transform(self.transform(x))

   is_separable = False

   output_dims = 2
transform_non_affine(self, xy)

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

class matplotlib.projections.polar.PolarAffine(scale_transform, limits)

Bases: matplotlib.transforms.Affine2DBase

The affine part of the polar projection. Scales the output so that maximum radius rests on the edge of the axes circle.

limits is the view limit of the data. The only part of its bounds that is used is the y limits (for the radius limits). The theta range is handled by the non-affine transform.

get_matrix(self)

Get the Affine transformation array for the affine part of this transform.

class matplotlib.projections.polar.PolarAxes(*args, theta_offset=0, theta_direction=1, rlabel_position=22.5, **kwargs)

Bases: matplotlib.axes._axes.Axes

A polar graph projection, where the input dimensions are theta, r.

Theta starts pointing east and goes anti-clockwise.

class InvertedPolarTransform(axis=None, use_rmin=True, _apply_thetatransforms=True)

Bases: matplotlib.transforms.Transform

The inverse of the polar transform, mapping Cartesian coordinate space x and y back to theta and r.

input_dims = 2

inverted(self)

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

x === self.inverted().transform(self.transform(x))

is_separable = False

output_dims = 2

transform_non_affine(self, xy)

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).
Alternatively, accepts a numpy array of length \texttt{input_dims} and returns a numpy array of length \texttt{output_dims}.

class PolarAffine(scale_transform, limits)
Bases: matplotlib.transforms.Affine2DBase

The affine part of the polar projection. Scales the output so that maximum radius rests on the edge of the axes circle.

\textit{limits} is the view limit of the data. The only part of its bounds that is used is the y limits (for the radius limits). The theta range is handled by the non-affine transform.

def get_matrix(self)
    Get the Affine transformation array for the affine part of this transform.

class PolarTransform(axis=None, use_rmin=True, _apply_theta_transforms=True)
Bases: matplotlib.transforms.Transform

The base polar transform. This handles projection \textit{theta} and \textit{r} into Cartesian coordinate space \textit{x} and \textit{y}, but does not perform the ultimate affine transformation into the correct position.

\texttt{input_dims} = 2

\texttt{inverted}(self)
    Return the corresponding inverse transformation.

    The return value of this method should be treated as temporary. An update to \texttt{self} does not cause a corresponding update to its inverted copy.

    \texttt{x} \equiv \texttt{self.inverted().transform(self.transform(x))}

\texttt{is_separable} = False

\texttt{output_dims} = 2

\texttt{transform_non_affine}(self, tr)
    Performs only the non-affine part of the transformation.

    \texttt{transform(values)} is always equivalent to \texttt{transform_affine(transform_non_affine(values))}.

    In non-affine transformations, this is generally equivalent to \texttt{transform(values)}.
    In affine transformations, this is always a no-op.

    Accepts a numpy array of shape (N x \texttt{input_dims}) and returns a numpy array of shape (N x \texttt{output_dims}).

    Alternatively, accepts a numpy array of length \texttt{input_dims} and returns a numpy array of length \texttt{output_dims}.

\texttt{transform_path_non_affine}(self, path)
    Returns a path, transformed only by the non-affine part of this transform.

    \texttt{path}: a \texttt{Path} instance.

    \texttt{transform_path(path)} is equivalent to \texttt{transform_path_affine(transform_path_non_affine(values))}.

class RadialLocator(base, axes=None)
Bases: matplotlib.ticker.Locator

Used to locate radius ticks.

Ensures that all ticks are strictly positive. For all other tasks, it delegates to the base \texttt{Locator} (which may be different depending on the scale of the \textit{r}-axis.)
autoscale(self)
    autoscale the view limits

pan(self, numsteps)
    Pan numticks (can be positive or negative)

refresh(self)
    refresh internal information based on current lim

view_limits(self, vmin, vmax)
    Select a scale for the range from vmin to vmax.
    Subclasses should override this method to change locator behaviour.

zoom(self, direction)
    Zoom in/out on axis; if direction is >0 zoom in, else zoom out

class ThetaFormatter
    Bases: matplotlib.ticker.Formatter

    Used to format the theta tick labels. Converts the native unit of radians into degrees
    and adds a degree symbol.

class ThetaLocator(base)
    Bases: matplotlib.ticker.Locator

    Used to locate theta ticks.
    This will work the same as the base locator except in the case that the view spans
    the entire circle. In such cases, the previously used default locations of every 45
    degrees are returned.

autoscale(self)
    autoscale the view limits

pan(self, numsteps)
    Pan numticks (can be positive or negative)

refresh(self)
    refresh internal information based on current lim

set_axis(self, axis)

view_limits(self, vmin, vmax)
    Select a scale for the range from vmin to vmax.
    Subclasses should override this method to change locator behaviour.

zoom(self, direction)
    Zoom in/out on axis; if direction is >0 zoom in, else zoom out

can_pan(self)
    Return True if this axes supports the pan/zoom button functionality.
    For polar axes, this is slightly misleading. Both panning and zooming are performed
    by the same button. Panning is performed in azimuth while zooming is done along
    the radial.

can_zoom(self)
    Return True if this axes supports the zoom box button functionality.
    Polar axes do not support zoom boxes.

cla(self)
    Clear the current axes.
drag_pan(self, button, key, x, y)
Called when the mouse moves during a pan operation.

button is the mouse button number:
- 1: LEFT
- 2: MIDDLE
- 3: RIGHT

key is a "shift" key
x, y are the mouse coordinates in display coords.

Note: Intended to be overridden by new projection types.

draw(self, *args, **kwargs)
Draw everything (plot lines, axes, labels)

draw(self, *args, **kwargs)
Draw everything (plot lines, axes, labels)

end_pan(self)
Called when a pan operation completes (when the mouse button is up.)

Note: Intended to be overridden by new projection types.

format_coord(self, theta, r)
Return a format string formatting the coordinate using Unicode characters.

get_data_ratio(self)
Return the aspect ratio of the data itself. For a polar plot, this should always be 1.0

get_rlabel_position(self)
Returns
float The theta position of the radius labels in degrees.

get_rmax(self)
Returns
float Outer radial limit.

get_rmin(self)
Returns
float The inner radial limit.

get_rorigin(self)
Returns
float

get_rsign(self)

get_theta_direction(self)
Get the direction in which theta increases.
-1: Theta increases in the clockwise direction
1: Theta increases in the counterclockwise direction
get_theta_offset(self)
Get the offset for the location of 0 in radians.

get_thetamax(self)
get_thetamin(self)
get_xaxis_text1_transform(self, pad)

Returns

transform [Transform] The transform used for drawing x-axis labels, which will add pad_points of padding (in points) between the axes and the label. The x-direction is in data coordinates and the y-direction is in axis coordinates.

valign [{'center', 'top', 'bottom', 'baseline', 'center_baseline'}] The text vertical alignment.

halign [{'center', 'left', 'right'}] The text horizontal alignment.

Notes

This transformation is primarily used by the Axis class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

get_xaxis_text2_transform(self, pad)

Returns

transform [Transform] The transform used for drawing secondary x-axis labels, which will add pad_points of padding (in points) between the axes and the label. The x-direction is in data coordinates and the y-direction is in axis coordinates.

valign [{'center', 'top', 'bottom', 'baseline', 'center_baseline'}] The text vertical alignment.

halign [{'center', 'left', 'right'}] The text horizontal alignment.

Notes

This transformation is primarily used by the Axis class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

get_xaxis_transform(self, which='grid')
Get the transformation used for drawing x-axis labels, ticks and gridlines. The x-direction is in data coordinates and the y-direction is in axis coordinates.

Note: This transformation is primarily used by the Axis class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

get_yaxis_text1_transform(self, pad)

Returns
**transform** [Transform] The transform used for drawing y-axis labels, which will add \textit{pad_points} of padding (in points) between the axes and the label. The x-direction is in axis coordinates and the y-direction is in data coordinates.

**valign** [{’center’, ‘top’, ‘bottom’, ‘baseline’, ‘center_baseline’}] The text vertical alignment.

**halign** [{’center’, ‘left’, ‘right’}] The text horizontal alignment.

**Notes**

This transformation is primarily used by the \textit{Axes} class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

**get_yaxis_text2_transform**(\textit{self}, \textit{pad})

**Returns**

**transform** [Transform] The transform used for drawing secondar y-axis labels, which will add \textit{pad_points} of padding (in points) between the axes and the label. The x-direction is in axis coordinates and the y-direction is in data coordinates.

**valign** [{’center’, ‘top’, ‘bottom’, ‘baseline’, ‘center_baseline’}] The text vertical alignment.

**halign** [{’center’, ‘left’, ‘right’}] The text horizontal alignment.

**Notes**

This transformation is primarily used by the \textit{Axes} class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

**get_yaxis_transform**(\textit{self}, \textit{which}=	extquoteleft grid	extquoteright)

Get the transformation used for drawing y-axis labels, ticks and gridlines. The x-direction is in axis coordinates and the y-direction is in data coordinates.

**Note:** This transformation is primarily used by the \textit{Axes} class, and is meant to be overridden by new kinds of projections that may need to place axis elements in different locations.

```
name = 'polar'
```

**set_rgrids**(\textit{self}, \textit{radii}, \textit{labels}=	extit{None}, \textit{angle}=	extit{None}, \textit{fmt}=	extit{None}, **\textit{kwargs})

Set the radial gridlines on a polar plot.

**Parameters**

\textbf{radii} [tuple with floats] The radii for the radial gridlines

\textbf{labels} [tuple with strings or \textit{None}] The labels to use at each radial gridline. The \texttt{matplotlib.ticker.ScalarFormatter} will be used if \textit{None}.

\textbf{angle} [float] The angular position of the radius labels in degrees.
fmt [str or None] Format string used in matplotlib.ticker.FormatStrFormatter. For example '%f'.

Returns

lines, labels [list of lines.Line2D, list of text.Text] lines are the radial gridlines and labels are the tick labels.

Other Parameters

**kwargs kwargs are optional Text properties for the labels.

See also:

PolarAxes.set_thetagrids
Axis.get_gridlines
Axis.get_ticklabels

set_rlabel_position(self, value)
Updates the theta position of the radius labels.

Parameters

value [number] The angular position of the radius labels in degrees.

set_rlim(self, bottom=None, top=None, emit=True, auto=False, **kwargs)
See set_ylim.

set_rmax(self, rmax)
Set the outer radial limit.

Parameters

rmax [float]

set_rmin(self, rmin)
Set the inner radial limit.

Parameters

rmin [float]

set_rorigin(self, rorigin)
Update the radial origin.

Parameters

rorigin [float]

set_rscale(self, *args, **kwargs)

set_rticks(self, *args, **kwargs)

set_theta_direction(self, direction)
Set the direction in which theta increases.

clockwise, -1: Theta increases in the clockwise direction

counterclockwise, anticlockwise, 1: Theta increases in the counterclockwise direction

set_theta_offset(self, offset)
Set the offset for the location of 0 in radians.
set_theta_zero_location(self, loc, offset=0.0)
Sets the location of theta’s zero. (Calls set_theta_offset with the correct value in radians under the hood.)

loc [str] May be one of “N”, “NW”, “W”, “SW”, “S”, “SE”, “E”, or “NE”.

offset [float, optional] An offset in degrees to apply from the specified loc. Note: this offset is always applied counter-clockwise regardless of the direction setting.

set_thetagrids(self, angles, labels=None, fmt=None, **kwargs)
Set the theta gridlines in a polar plot.

Parameters

angles [tuple with floats, degrees] The angles of the theta gridlines.
labels [tuple with strings or None] The labels to use at each theta gridline. The projections.polar.ThetaFormatter will be used if None.
fmt [str or None] Format string used in matplotlib.ticker.FormatStrFormatter. For example '%f'. Note that the angle that is used is in radians.

Returns

lines, labels [list of lines.Line2D, list of text.Text] lines are the theta gridlines and labels are the tick labels.

Other Parameters

**kwargs kwargs are optional Text properties for the labels.

See also:

PolarAxes.set_rgrids
Axis.get_gridlines
Axis.get_ticklabels

set_thetalim(self, *args, **kwargs)
Set the minimum and maximum theta values.

Parameters

thetamax [float] Maximum value in degrees.

set_thetamax(self, thetamax)
set_thetamin(self, thetamin)

set_xscale(self, scale, *args, **kwargs)
Set the x-axis scale.

Parameters

value [{“linear”, “log”, “symlog”, “logit”, ...}] The axis scale type to apply.

**kwargs Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:

• matplotlib.scale.LinearScale
• `matplotlib.scale.LogScale`
• `matplotlib.scale.SymmetricalLogScale`
• `matplotlib.scale.LogitScale`

Notes

By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using `matplotlib.scale.register_scale`. These scales can then also be used here.

```python
set_ylim(self, bottom=None, top=None, emit=True, auto=False, *, ymin=None, ymax=None)
```
Set the data limits for the radial axis.

Parameters

- `bottom` [scalar, optional] The bottom limit (default: None, which leaves the bottom limit unchanged). The bottom and top ylims may be passed as the tuple `(bottom, top)` as the first positional argument (or as the `bottom` keyword argument).
- `top` [scalar, optional] The top limit (default: None, which leaves the top limit unchanged).
- `emit` [bool, optional] Whether to notify observers of limit change (default: True).
- `auto` [bool or None, optional] Whether to turn on autoscaling of the y-axis. True turns on, False turns off (default action), None leaves unchanged.
- `ymin, ymax` [scalar, optional] These arguments are deprecated and will be removed in a future version. They are equivalent to `bottom` and `top` respectively, and it is an error to pass both `ymin` and `bottom` or `ymax` and `top`.

Returns

- `bottom, top` [(float, float)] The new y-axis limits in data coordinates.

```python
set_yscale(self, *args, **kwargs)
```
Set the y-axis scale.

Parameters

- `value` ["linear", "log", "symlog", "logit", ...] The axis scale type to apply.
- `**kwargs` Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:
  - `matplotlib.scale.LinearScale`
  - `matplotlib.scale.LogScale`
  - `matplotlib.scale.SymmetricalLogScale`
  - `matplotlib.scale.LogitScale`
Notes

By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using `matplotlib.scale.register_scale`. These scales can then also be used here.

```python
def start_pan(self, x, y, button):
    Called when a pan operation has started.
    x, y are the mouse coordinates in display coords. button is the mouse button number:
    • 1: LEFT
    • 2: MIDDLE
    • 3: RIGHT
```

`start_pan` is intended to be overridden by new projection types.

```python
class matplotlib.projections.polar.PolarTransform(axis=None, use_rmin=True, apply_theta_transforms=True):
    Bases: matplotlib.transforms.Transform

    The base polar transform. This handles projection theta and r into Cartesian coordinate space x and y, but does not perform the ultimate affine transformation into the correct position.

    input_dims = 2
    inverted(self):
        Return the corresponding inverse transformation.
        The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.
        x == self.inverted().transform(self.transform(x))
    is_separable = False
    output_dims = 2
    transform_non_affine(self, tr):
        Performs only the non-affine part of the transformation.
        transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
        In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.
        Accepts a numpy array of shape (N x inputDims) and returns a numpy array of shape (N x output_dims).
        Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.
    transform_path_non_affine(self, path):
        Returns a path, transformed only by the non-affine part of this transform.
        path: a Path instance.
        transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).
```
class matplotlib.projections.polar.RadialAxis(*args, **kwargs)
    Bases: matplotlib.axis.YAxis

    A radial Axis.

    This overrides certain properties of a YAxis to provide special-casing for a radial axis.

    axis_name = 'radius'

cla(self)
    clear the current axis

class matplotlib.projections.polar.RadialLocator(base, axes=None)
    Bases: matplotlib.ticker.Locator

    Used to locate radius ticks.

    Ensures that all ticks are strictly positive. For all other tasks, it delegates to the base
    Locator (which may be different depending on the scale of the r-axis).

    autoscale(self)
        autoscale the view limits

    pan(self, numsteps)
        Pan numticks (can be positive or negative)

    refresh(self)
        refresh internal information based on current lim

    view_limits(self, vmin, vmax)
        Select a scale for the range from vmin to vmax.

        Subclasses should override this method to change locator behaviour.

    zoom(self, direction)
        Zoom in/out on axis; if direction is >0 zoom in, else zoom out

class matplotlib.projections.polar.RadialTick(axes, loc, label, size=None, width=None, color=None, tickdir=None, pad=None, labelsize=None, labelcolor=None, zorder=None, gridOn=None, tick1On=True, tick2On=True, label1On=True, label2On=False, major=True, labelrotation=0, grid_color=None, grid linestyle=None, grid linewidth=None, grid alpha=None, **kw)
    Bases: matplotlib.axis.YTick

    A radial-axis tick.

    This subclass of YTick provides radial ticks with some small modification to their re-
    positioning such that ticks are rotated based on axes limits. This results in ticks that are
    correctly perpendicular to the spine. Labels are also rotated to be perpendicular to the
    spine, when 'auto' rotation is enabled.

    bbox is the Bound2D bounding box in display coords of the Axes loc is the tick location
    in data coords size is the tick size in points

    update_position(self, loc)
        Set the location of tick in data coords with scalar loc.
class matplotlib.projections.polar.ThetaAxis(axes, pickradius=15)
    Bases: matplotlib.axis.XAxis

A theta Axis.

This overrides certain properties of an XAxis to provide special-casing for an angular axis.

**Parameters**

- **axes** [matplotlib.axes.Axes] The Axes to which the created Axis belongs.
- **pickradius** [float] The acceptance radius for containment tests. See also Axis.contains.

    axis_name = 'theta'

cla(self)
    clear the current axis

class matplotlib.projections.polar.ThetaFormatter
    Bases: matplotlib.ticker.Formatter

    Used to format the theta tick labels. Converts the native unit of radians into degrees and adds a degree symbol.

class matplotlib.projections.polar.ThetaLocator(base)
    Bases: matplotlib.ticker.Locator

    Used to locate theta ticks.

    This will work the same as the base locator except in the case that the view spans the entire circle. In such cases, the previously used default locations of every 45 degrees are returned.

    autoscale(self)
        autoscale the view limits

    pan(self, numsteps)
        Pan numticks (can be positive or negative)

    refresh(self)
        refresh internal information based on current lim

    set_axis(self, axis)

    view_limits(self, vmin, vmax)
        Select a scale for the range from vmin to vmax.
        Subclasses should override this method to change locator behaviour.

    zoom(self, direction)
        Zoom in/out on axis; if direction is >0 zoom in, else zoom out

class matplotlib.projections.polar.ThetaTick(axes, *args, **kwargs)
    Bases: matplotlib.axis.XTick

A theta-axis tick.

This subclass of XTick provides angular ticks with some small modification to their repositioning such that ticks are rotated based on tick location. This results in ticks that are correctly perpendicular to the arc spine.
When ‘auto’ rotation is enabled, labels are also rotated to be parallel to the spine. The label padding is also applied here since it’s not possible to use a generic axes transform to produce tick-specific padding.

```python
update_position(self, loc)
    Set the location of tick in data coords with scalar loc.
```

### 17.40 matplotlib.rcsetup

The rcsetup module contains the default values and the validation code for customization using matplotlib’s rc settings.

Each rc setting is assigned a default value and a function used to validate any attempted changes to that setting. The default values and validation functions are defined in the rcsetup module, and are used to construct the rcParams global object which stores the settings and is referenced throughout matplotlib.

These default values should be consistent with the default matplotlibrc file that actually reflects the values given here. Any additions or deletions to the parameter set listed here should also be visited to the `matplotlibrc.template` in matplotlib’s root source directory.

```python
class matplotlib.rcsetup.ValidateInStrings(key, valid, ignorecase=False)
    Bases: object
    valid is a list of legal strings

class matplotlib.rcsetup.ValidateInterval(vmin, vmax, closedmin=True, closedmax=True)
    Bases: object
    Value must be in interval
```

```python
matplotlib.rcsetup.cycler(*args, **kwargs)
    Creates a Cycler object much like `cycler.cycler()`, but includes input validation.
    Call signatures:
    ```
cycler(cycler)
cycler(label=values[, label2=values2[, ...]])
cycler(label, values)
```  
Form 1 copies a given Cycler object.

Form 2 creates a Cycler which cycles over one or more properties simultaneously. If multiple properties are given, their value lists must have the same length.

Form 3 creates a Cycler for a single property. This form exists for compatibility with the original cycler. Its use is discouraged in favor of the kwarg form, i.e. `cycler(label=values).

**Parameters**

- `cycler` [Cycler] Copy constructor for Cycler.
- `label` [str] The property key. Must be a valid `Artist` property. For example, ‘color’ or ‘linestyle’. Aliases are allowed, such as ‘c’ for ‘color’ and ‘lw’ for ‘linewidth’.
- `values` [iterable] Finite-length iterable of the property values. These values are validated and will raise a ValueError if invalid.
Returns

cycler [Cycler] A new Cycler for the given properties.

Examples

Creating a cycler for a single property:

```python
>>> c = cycler(color=['red', 'green', 'blue'])
```

Creating a cycler for simultaneously cycling over multiple properties (e.g. red circle, green plus, blue cross):

```python
>>> c = cycler(color=['red', 'green', 'blue'],
            marker=['o', '+', 'x'])
```
matplotlib.rcsetup.validate_float(s)
    Convert s to float or raise.
matplotlib.rcsetup.validate_float_or_None(s)
    Convert s to float, None or raise.
matplotlib.rcsetup.validate_floatlist(s)
    Convert s to float or raise.
matplotlib.rcsetup.validate_font_properties(s)
matplotlib.rcsetup.validate_fontsize(s)
matplotlib.rcsetup.validate_fontsize_None(s)
matplotlib.rcsetup.validate_fontsizelist(s)
matplotlib.rcsetup.validate_fonttype(s)
    Confirm that this is a Postscript or PDF font type that we know how to convert to.
matplotlib.rcsetup.validate_hatch(s)
    Validate a hatch pattern. A hatch pattern string can have any sequence of the following
    characters: \ / | - + * . x o O.
matplotlib.rcsetup.validate_hatchlist(s)
    Validate a hatch pattern. A hatch pattern string can have any sequence of the following
    characters: \ / | - + * . x o O.
matplotlib.rcsetup.validate_hinting(s)
matplotlib.rcsetup.validate_hist_bins(s)
matplotlib.rcsetup.validate_int(s)
    Convert s to int or raise.
matplotlib.rcsetup.validate_int_or_None(s)
    Return None if s is None or return int(s), otherwise raise.
matplotlib.rcsetup.validate_joinstylelist(s)
matplotlib.rcsetup.validate_markevery(s)
    Validate the markevery property of a Line2D object.

**Parameters**

- **s** [None, int, float, slice, length-2 tuple of ints,] length-2 tuple of floats, list of ints

**Returns**

- **s** [None, int, float, slice, length-2 tuple of ints,] length-2 tuple of floats, list of ints

matplotlib.rcsetup.validate_markeverylist(s)
    Validate the markevery property of a Line2D object.

**Parameters**

- **s** [None, int, float, slice, length-2 tuple of ints,] length-2 tuple of floats, list of ints

**Returns**

- **s** [None, int, float, slice, length-2 tuple of ints,] length-2 tuple of floats, list of ints
matplotlib.rcsetup.validate_mathtext_default(s)

class matplotlib.rcsetup.validate_nseq_float(n=None, allow_none=False):
    Bases: object

class matplotlib.rcsetup.validate_nseq_int(n=None):
    Bases: object

matplotlib.rcsetup.validate_path_exists(s)
    If s is a path, return s, else False

matplotlib.rcsetup.validate_ps_distiller(s)

matplotlib.rcsetup.validate_qt4(s)
    [Deprecated]

Notes

Deprecated since version 3.1:

    [Deprecated]

Notes

Deprecated since version 3.1:

matplotlib.rcsetup.validate_sketch(s)

matplotlib.rcsetup.validate_string(s)

matplotlib.rcsetup.validate_string_or_None(s)
    Convert s to string or raise.

matplotlib.rcsetup.validate_stringlist(s)
    return a list

matplotlib.rcsetup.validate_svg_fonttype(s)

matplotlib.rcsetup.validate_toolbar(s)

matplotlib.rcsetup.validate_verbose(s)
    [Deprecated]

Notes

Deprecated since version 3.1:

matplotlib.rcsetup.validate_webagg_address(s)

matplotlib.rcsetup.validate_whiskers(s)

17.41 matplotlib.sankey

Module for creating Sankey diagrams using Matplotlib.
class matplotlib.sankey.Sankey(ax=None, scale=1.0, unit="", format='%G', gap=0.25, radius=0.1, shoulder=0.03, offset=0.15, head_angle=100, margin=0.4, tolerance=1e-06, **kwargs)

Bases: object

Sankey diagram.

Sankey diagrams are a specific type of flow diagram, in which the width of the arrows is shown proportionally to the flow quantity. They are typically used to visualize energy or material or cost transfers between processes. Wikipedia (6/1/2011)

Create a new Sankey instance.

Optional keyword arguments:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ax</td>
<td>axes onto which the data should be plotted If ax isn’t provided, new axes will be created.</td>
</tr>
<tr>
<td>scale</td>
<td>scaling factor for the flows scale sizes the width of the paths in order to maintain proper layout. The same scale is applied to all subdiagrams. The value should be chosen such that the product of the scale and the sum of the inputs is approximately 1.0 (and the product of the scale and the sum of the outputs is approximately -1.0).</td>
</tr>
<tr>
<td>unit</td>
<td>string representing the physical unit associated with the flow quantities If unit is None, then none of the quantities are labeled.</td>
</tr>
<tr>
<td>format</td>
<td>a Python number formatting string to be used in labeling the flow as a quantity (i.e., a number times a unit, where the unit is given)</td>
</tr>
<tr>
<td>gap</td>
<td>space between paths that break in/break away to/from the top or bottom</td>
</tr>
<tr>
<td>radius</td>
<td>inner radius of the vertical paths</td>
</tr>
<tr>
<td>shoulder</td>
<td>size of the shoulders of output arrowS</td>
</tr>
<tr>
<td>offset</td>
<td>text offset (from the dip or tip of the arrow)</td>
</tr>
<tr>
<td>head</td>
<td>angle of the arrow heads (and negative of the angle of the tails) [deg]</td>
</tr>
<tr>
<td>margin</td>
<td>minimum space between Sankey outlines and the edge of the plot area</td>
</tr>
<tr>
<td>tolerance</td>
<td>acceptable maximum of the magnitude of the sum of flows The magnitude of the sum of connected flows cannot be greater than tolerance.</td>
</tr>
</tbody>
</table>

The optional arguments listed above are applied to all subdiagrams so that there is consistent alignment and formatting.

If Sankey is instantiated with any keyword arguments other than those explicitly listed above (**kwargs), they will be passed to add(), which will create the first subdiagram.

In order to draw a complex Sankey diagram, create an instance of Sankey by calling it without any kwargs:

```python
sankey = Sankey()
```

Then add simple Sankey sub-diagrams:
sankey.add() # 1
sankey.add() # 2
#...
sankey.add() # n

Finally, create the full diagram:

sankey.finish()

Or, instead, simply daisy-chain those calls:

Sankey().add().add... .add().finish()

See also:

Sankey.add

Sankey.finish

Examples

The default settings produce a diagram like this.

```
add(self, patchlabel="", flows=None, orientations=None, labels="", trunklength=1.0, pathlengths=0.25, prior=None, connect=(0, 0), rotation=0, **kwargs)
```

Add a simple Sankey diagram with flows at the same hierarchical level.
Parameters

**patchlabel** [str] Label to be placed at the center of the diagram. Note that label (not *patchlabel*) can be passed as keyword argument to create an entry in the legend.

**flows** [list of float] Array of flow values. By convention, inputs are positive and outputs are negative.

Flows are placed along the top of the diagram from the inside out in order of their index within *flows*. They are placed along the sides of the diagram from the top down and along the bottom from the outside in.

If the sum of the inputs and outputs is nonzero, the discrepancy will appear as a cubic Bezier curve along the top and bottom edges of the trunk.

**orientations** [list of {-1, 0, 1}] List of orientations of the flows (or a single orientation to be used for all flows). Valid values are 0 (inputs from the left, outputs to the right), 1 (from and to the top) or -1 (from and to the bottom).

**labels** [list of (str or None)] List of labels for the flows (or a single label to be used for all flows). Each label may be *None* (no label), or a labeling string. If an entry is a (possibly empty) string, then the quantity for the corresponding flow will be shown below the string. However, if the *unit* of the main diagram is None, then quantities
Two Systems

are never shown, regardless of the value of this argument.

**trunklength** [float] Length between the bases of the input and output groups (in data-space units).

**pathlengths** [list of float] List of lengths of the vertical arrows before break-in or after break-away. If a single value is given, then it will be applied to the first (inside) paths on the top and bottom, and the length of all other arrows will be justified accordingly. The *pathlengths* are not applied to the horizontal inputs and outputs.

**prior** [int] Index of the prior diagram to which this diagram should be connected.

**connect** [(int, int)] A (prior, this) tuple indexing the flow of the prior diagram and the flow of this diagram which should be connected. If this is the first diagram or *prior* is *None*, *connect* will be ignored.

**rotation** [float] Angle of rotation of the diagram in degrees. The interpretation of the *orientations* argument will be rotated accordingly (e.g., if *rotation* == 90, an *orientations* entry of 1 means to/from the left). *rotation* is ignored if this diagram is connected to an existing one (using *prior* and *connect*).

**Returns**

Sankey The current Sankey instance.

**Other Parameters**
**kwargs Additional keyword arguments set *matplotlib.patches*. *PathPatch* properties, listed below. For example, one may want to use `fill=False` or `label="A legend entry"`.

<table>

See also:

Sankey.finish

```python
finish(self)
```

Adjust the axes and return a list of information about the Sankey subdiagram(s).

Return value is a list of subdiagrams represented with the following fields:
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>patch</td>
<td>Sankey outline (an instance of PathPatch)</td>
</tr>
<tr>
<td>flows</td>
<td>values of the flows (positive for input, negative for output)</td>
</tr>
<tr>
<td>angles</td>
<td>list of angles of the arrows [deg/90] For example, if the diagram has not been rotated, an input to the top side will have an angle of 3 (DOWN), and an output from the top side will have an angle of 1 (UP). If a flow has been skipped (because its magnitude is less than tolerance), then its angle will be None.</td>
</tr>
<tr>
<td>tips</td>
<td>array in which each row is an [x, y] pair indicating the positions of the tips (or &quot;dips&quot;) of the flow paths If the magnitude of a flow is less the tolerance for the instance of Sankey, the flow is skipped and its tip will be at the center of the diagram.</td>
</tr>
<tr>
<td>text</td>
<td>Text instance for the label of the diagram</td>
</tr>
<tr>
<td>texts</td>
<td>list of Text instances for the labels of flows</td>
</tr>
</tbody>
</table>

Sankey.add

### 17.42 matplotlib.scale

#### class matplotlib.scale.FuncScale

**class**: matplotlib.scale.FuncScale(axis, functions)

**Bases**: matplotlib.scale.ScaleBase

Provide an arbitrary scale with user-supplied function for the axis.

**Parameters**

- **axis**: the axis for the scale
- **functions**: [(callable, callable)] two-tuple of the forward and inverse functions for the scale. The forward function must be monotonic.

Both functions must have the signature:

```python
def forward(values: array-like) -> array-like
```

**get_transform(self)**

The transform for arbitrary scaling

```python
name = 'function'
```

**set_default_locators_and_formatters(self, axis)**

Set the locators and formatters to the same defaults as the linear scale.

#### class matplotlib.scale.FuncScaleLog

**class**: matplotlib.scale.FuncScaleLog(axis, functions, base=10)

**Bases**: matplotlib.scale.LogScale

Provide an arbitrary scale with user-supplied function for the axis and then put on a logarithmic axes.

**Parameters**

- **axis**: the axis for the scale
functions [(callable, callable)] two-tuple of the forward and inverse functions for the scale. The forward function must be monotonic.

Both functions must have the signature:

```python
def forward(values: array-like) -> array-like
```

base [float] logarithmic base of the scale (default = 10)

get_transform(self)
   The transform for arbitrary scaling

name = 'functionlog'

class matplotlib.scale.FuncTransform(forward, inverse)
   Bases: matplotlib.transforms.Transform

   A simple transform that takes and arbitrary function for the forward and inverse transform.

   Parameters
   forward [callable] The forward function for the transform. This function
   must have an inverse and, for best behavior, be monotonic. It must
   have the signature:
   ```python
def forward(values: array-like) -> array-like
```

   inverse [callable] The inverse of the forward function. Signature as
   forward.

   has_inverse = True

input_dims = 1

inverted(self)
   Return the corresponding inverse transformation.
   The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.
   ```python
x === self.inverted().transform(self.transform(x))
```

is_separable = True

output_dims = 1

transform_non_affine(self, values)
   Performs only the non-affine part of the transformation.
   ```python
transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
```

In non-affine transformations, this is generally equivalent to transform(values). In
affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape
(N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array
of length output_dims.
**matplotlib.scale.InvertedLog10Transform**(**kwargs)

**Bases:** matplotlib.scale.InvertedLogTransformBase

[Deprecated]

**Notes**

Deprecated since version 3.1:

```python
base = 10.0

inverted(self)
Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

x === self.inverted().transform(self.transform(x))
```

** matplotlib.scale.InvertedLog2Transform**(**kwargs)

**Bases:** matplotlib.scale.InvertedLogTransformBase

[Deprecated]

**Notes**

Deprecated since version 3.1:

```python
base = 2.0

inverted(self)
Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

x === self.inverted().transform(self.transform(x))
```

** matplotlib.scale.InvertedLogTransform**(base)

**Bases:** matplotlib.scale.InvertedLogTransformBase

```python
has_inverse = True
input_dims = 1

inverted(self)
Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

x === self.inverted().transform(self.transform(x))

is_separable = True
output_dims = 1

transform_non_affine(self, a)
Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
```
In non-affine transformations, this is generally equivalent to `transform(values)`. In affine transformations, this is always a no-op.

Accepts a numpy array of shape `(N x input_dims)` and returns a numpy array of shape `(N x output_dims)`.

Alternatively, accepts a numpy array of length `input_dims` and returns a numpy array of length `output_dims`.

class matplotlib.scale.InvertedLogTransformBase(**kwargs)
    Bases: matplotlib.transforms.Transform

    [Deprecated]

    Notes

    Deprecated since version 3.1:
    
    base_inverse = True
    input_dims = 1
    is_separable = True
    output_dims = 1

    transform_non_affine(self, a)
        Performs only the non-affine part of the transformation.
        `transform(values)` is always equivalent to `transform_affine(transform_non_affine(values))`.

        In non-affine transformations, this is generally equivalent to `transform(values)`. In affine transformations, this is always a no-op.

        Accepts a numpy array of shape `(N x input_dims)` and returns a numpy array of shape `(N x output_dims)`.

        Alternatively, accepts a numpy array of length `input_dims` and returns a numpy array of length `output_dims`.

class matplotlib.scale.InvertedNaturalLogTransform(**kwargs)
    Bases: matplotlib.scale.InvertedLogTransformBase

    [Deprecated]

    Notes

    Deprecated since version 3.1:
    
    base = 2.718281828459045

    inverted(self)
        Return the corresponding inverse transformation.

        The return value of this method should be treated as temporary. An update to `self` does not cause a corresponding update to its inverted copy.

        `x === self.inverted().transform(self.transform(x))`

class matplotlib.scale.InvertedSymmetricalLogTransform(base, linthresh, linscale)
    Bases: matplotlib.transforms.Transform
has_inverse = True
input_dims = 1

inverted(self)
    Return the corresponding inverse transformation.
    
The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.

    x === self.inverted().transform(self.transform(x))

is_separable = True
output_dims = 1

transform_non_affine(self, a)
    Performs only the non-affine part of the transformation.

    transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
In non-affine transformations, this is generally equivalent to transform(values). In
affine transformations, this is always a no-op.

    Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape
(N x output_dims).

    Alternatively, accepts a numpy array of length input_dims and returns a numpy array
of length output_dims.

class matplotlib.scale.LinearScale(axis, **kwargs)
    Bases: matplotlib.scale.ScaleBase

    The default linear scale.

    get_transform(self)
        The transform for linear scaling is just the IdentityTransform.

    name = 'linear'

set_default_locators_and_formatters(self, axis)
    Set the locators and formatters to reasonable defaults for linear scaling.

class matplotlib.scale.Log10Transform(**kwargs)
    Bases: matplotlib.scale.LogTransformBase

    [Deprecated]

Notes

Deprecated since version 3.1:

base = 10.0

inverted(self)
    Return the corresponding inverse transformation.

    The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.

    x === self.inverted().transform(self.transform(x))
class matplotlib.scale.Log2Transform(**kwargs)
    Bases: matplotlib.scale.LogTransformBase
    [Deprecated]

Notes

Deprecated since version 3.1:

base = 2.0

inverted(self)
    Return the corresponding inverse transformation.
    The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.
    x === self.inverted().transform(self.transform(x))

class matplotlib.scale.LogScale(axis, **kwargs)
    Bases: matplotlib.scale.ScaleBase
    A standard logarithmic scale. Care is taken to only plot positive values.

baseX/baseY: The base of the logarithm
nonposX/nonposY: {'mask', 'clip'} non-positive values in x or y can be masked as in-
valid, or clipped to a very small positive number
subX/subY: Where to place the subticks between each major tick. Should be a se-
quence of integers. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9]
    will place 8 logarithmically spaced minor ticks between each major tick.

class InvertedLog10Transform(**kwargs)
    Bases: matplotlib.scale.InvertedLogTransformBase
    [Deprecated]

Notes

Deprecated since version 3.1:

base = 10.0

inverted(self)
    Return the corresponding inverse transformation.
    The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.
    x === self.inverted().transform(self.transform(x))

class InvertedLog2Transform(**kwargs)
    Bases: matplotlib.scale.InvertedLogTransformBase
    [Deprecated]
Notes

In non-affine transformations, this is generally equivalent to `transform(values)`. In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x `input_dims`) and returns a numpy array of shape (N x `output_dims`).

Alternatively, accepts a numpy array of length `input_dims` and returns a numpy array of length `output_dims`.

class matplotlib.scale.LogisticTransform(nonpos='mask')
Bases: matplotlib.transforms.Transform

has_inverse = True
input_dims = 1

inverted(self)
    Return the corresponding inverse transformation.
    The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.
    x === self.inverted().transform(self.transform(x))

is_separable = True
output_dims = 1

transform_non_affine(self, a)
    logistic transform (base 10)

class matplotlib.scale.LogitScale(axis, nonpos='mask')
Bases: matplotlib.scale.ScaleBase

Logit scale for data between zero and one, both excluded.
This scale is similar to a log scale close to zero and to one, and almost linear around 0.5. It maps the interval ]0, 1[ onto ]-infty, +infty[.

nonpos: {'mask', 'clip'} values beyond ]0, 1[ can be masked as invalid, or clipped to a number very close to 0 or 1

get_transform(self)
    Return a LogitTransform instance.

limit_range_for_scale(self, vmin, vmax, minpos)
    Limit the domain to values between 0 and 1 (excluded).

name = 'logit'

set_default_locators_and_formatters(self, axis)
    Set the Locator and Formatter objects on the given axis to match this scale.

class matplotlib.scale.LogitTransform(nonpos='mask')
Bases: matplotlib.transforms.Transform

has_inverse = True
input_dims = 1

inverted(self)
    Return the corresponding inverse transformation.
    The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.
x === self.inverted().transform(self.transform(x))

is_separable = True
output_dims = 1

transform_non_affine(self, a)
    logit transform (base 10), masked or clipped

class matplotlib.scale.NaturalLogTransform(**kwargs)
    Bases: matplotlib.scale.LogTransformBase

    [Deprecated]

Notes

Deprecated since version 3.1:

base = 2.718281828459045

inverted(self)
    Return the corresponding inverse transformation.
    The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.
    x === self.inverted().transform(self.transform(x))

class matplotlib.scale.ScaleBase(axis, **kwargs)
    Bases: object

The base class for all scales.
Scales are separable transformations, working on a single dimension.
Any subclasses will want to override:
    • name
    • get_transform()
    • set_default_locators_and_formatters()

And optionally:
    • limit_range_for_scale()

Construct a new scale.

Notes

The following note is for scale implementors.
For back-compatibility reasons, scales take an Axis object as first argument. However,
this argument should not be used: a single scale object should be usable by multiple
Axes at the same time.

get_transform(self)
    Return the Transform object associated with this scale.
limit_range_for_scale(self, vmin, vmax, minpos)

Returns the range vmin, vmax, possibly limited to the domain supported by this scale.

**minpos should be the minimum positive value in the data.** This is used by log scales to determine a minimum value.

set_default_locators_and_formatters(self, axis)

Set the Locator and Formatter objects on the given axis to match this scale.

class matplotlib.scale.SymmetricalLogScale(axis, **kwargs)

**Bases:** matplotlib.scale.ScaleBase

The symmetrical logarithmic scale is logarithmic in both the positive and negative directions from the origin.

Since the values close to zero tend toward infinity, there is a need to have a range around zero that is linear. The parameter linthresh allows the user to specify the size of this range (-linthresh, linthresh).

**Parameters**

- **basex, basey** [float] The base of the logarithm. Defaults to 10.
- **linthreshx, linthreshy** [float] Defines the range (-x, x), within which the plot is linear. This avoids having the plot go to infinity around zero. Defaults to 2.
- **subsx, subsy** [sequence of int] Where to place the subticks between each major tick. For example, in a log10 scale: [2, 3, 4, 5, 6, 7, 8, 9] will place 8 logarithmically spaced minor ticks between each major tick.
- **linscalex, linscaley** [float, optional] This allows the linear range (-linthresh, linthresh) to be stretched relative to the logarithmic range. Its value is the number of decades to use for each half of the linear range. For example, when linscale == 1.0 (the default), the space used for the positive and negative halves of the linear range will be equal to one decade in the logarithmic range.

class InvertedSymmetricalLogTransform(base, linthresh, linscale)

**Bases:** matplotlib.transforms.Transform

**has_inverse** = True

**input_dims** = 1

**inverted(self)**

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

x === self.inverted().transform(self.transform(x))

**is_separable** = True

**output_dims** = 1

**transform_non_affine(self, a)**

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

class SymmetricalLogTransform(base, linthresh, linscale)
Bases: matplotlib.transforms.Transform

has_inverse = True
input_dims = 1

inverted(self)
Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self does not cause a corresponding update to its inverted copy.

x === self.inverted().transform(self.transform(x))

is_separable = True
output_dims = 1

transform_non_affine(self, a)
Perform only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values).
In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

get_transform(self)
Return a SymmetricalLogTransform instance.

name = 'symlog'

set_default_locators_and_formatters(self, axis)
Set the locators and formatters to specialized versions for symmetrical log scaling.
output_dims = 1

transform_non_affine(self, a)

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In
affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape
(N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array
of length output_dims.

matplotlib.scale.get_scale_docs()

[Deprecated] Helper function for generating docstrings related to scales.

Notes

Deprecated since version 3.1: get_scale_docs() is considered private API since 3.1 and
will be removed from the public API in 3.3.

matplotlib.scale.get_scale_names()

matplotlib.scale.register_scale(scale_class)

Register a new kind of scale.

scale_class must be a subclass of ScaleBase.

matplotlib.scale.scale_factory(scale, axis, **kwargs)

Return a scale class by name.

Parameters

scale [{function, functionlog, linear, log, logit, symlog}]
axis [Axis]

17.43 matplotlib.spines

class matplotlib.spines.Spine(axes, spine_type, path, **kwargs)

Bases: matplotlib.patches.Patch

an axis spine – the line noting the data area boundaries

Spines are the lines connecting the axis tick marks and noting the boundaries of the
data area. They can be placed at arbitrary positions. See function: set_position for more
information.

The default position is ('outward', 0).

Spines are subclasses of class: Patch, and inherit much of their behavior.

Spines draw a line, a circle, or an arc depending if function: set_patch_line, func-
tion: set_patch_circle, or function: set_patch_arc has been called. Line-like is the default.

- axes : the Axes instance containing the spine
- spine_type : a string specifying the spine type
• **path**: the path instance used to draw the spine

Valid kwargs are:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>

</tbody>
</table>

**classmethod arc_spine(**axes, spine_type, center, radius, theta1, theta2, **kwargs)**

(classmethod) Returns an arc **Spine**.

**classmethod circular_spine(**axes, center, radius, **kwargs)**

(staticmethod) Returns a circular **Spine**.

**cla**(self)

Clear the current spine.

**draw**(self, renderer)

Draw the **Patch** to the given **renderer**.

**get_bounds**(self)

Get the bounds of the spine.

**get_patch_transform**(self)

Return the **Transform** instance which takes patch coordinates to data coordinates.
For example, one may define a patch of a circle which represents a radius of 5 by providing coordinates for a unit circle, and a transform which scales the coordinates (the patch coordinate) by 5.

```python
get_path(self)
    Return the path of this patch

get_position(self)
    Return the spine position.

get_smart_bounds(self)
    Return whether the spine has smart bounds.

get_spine_transform(self)
    Return the spine transform.

get_window_extent(self, renderer=None)
    Return the window extent of the spines in display space, including padding for ticks (but not their labels)

See also:

generalisation.Axes.get_tightbbox
matplotlib.axes.Axes.get_window_extent

is_frame_like(self)
    [Deprecated] Return True if directly on axes frame.
    This is useful for determining if a spine is the edge of an old style MPL plot. If so, this function will return True.

Notes

Deprecated since version 3.1.

classmethod linear_spine(axes, spine_type, **kwargs)
    (staticmethod) Returns a linear Spine.

register_axis(self, axis)
    Register an axis.
    An axis should be registered with its corresponding spine from the Axes instance. This allows the spine to clear any axis properties when needed.

set_bounds(self, low, high)
    Set the bounds of the spine.

set_color(self, c)
    Set the edgecolor.

Parameters

c [color]

Notes

This method does not modify the facecolor (which defaults to “none”), unlike the Patch.set_color method defined in the parent class. Use Patch.set_facecolor to set
the facecolor.

set_patch_arc(self, center, radius, theta1, theta2)
Set the spine to be arc-like.

set_patch_circle(self, center, radius)
Set the spine to be circular.

set_patch_line(self)
Set the spine to be linear.

set_position(self, position)
Set the position of the spine.

Spine position is specified by a 2 tuple of (position type, amount). The position types are:
- ‘outward’: place the spine out from the data area by the specified number of points. (Negative values specify placing the spine inward.)
- ‘axes’: place the spine at the specified Axes coordinate (from 0.0-1.0).
- ‘data’: place the spine at the specified data coordinate.

Additionally, shorthand notations define a special positions:
- ‘center’ -> (‘axes’,0.5)
- ‘zero’ -> (‘data’, 0.0)

set_smart_bounds(self, value)
Set the spine and associated axis to have smart bounds.

17.44 matplotlib.style

matplotlib.style.context(style, after_reset=False)
Context manager for using style settings temporarily.

Parameters

style [str, dict, or list] A style specification. Valid options are:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
<td>The name of a style or a path/URL to a style file. For a list of available style names, see style.available.</td>
</tr>
<tr>
<td>dict</td>
<td>Dictionary with valid key/value pairs for matplotlib.rcParams.</td>
</tr>
<tr>
<td>list</td>
<td>A list of style specifiers (str or dict) applied from first to last in the list.</td>
</tr>
</tbody>
</table>

after_reset [bool] If True, apply style after resetting settings to their defaults; otherwise, apply style on top of the current settings.

matplotlib.style.reload_library()
Reload style library.

matplotlib.style.use(style)
Use matplotlib style settings from a style specification.

The style name of 'default' is reserved for reverting back to the default style settings.

Parameters
**style** [str, dict, or list] A style specification. Valid options are:

| str   | The name of a style or a path/URL to a style file. For a list of available style names, see `style.available`.
|-------|------------------------------------------------------------------------------------------------------------------|
| dict  | Dictionary with valid key/value pairs for `matplotlib.rcParams`.
| list  | A list of style specifiers (str or dict) applied from first to last in the list.

`matplotlib.style.library`
Dictionary of available styles

`matplotlib.style.available`
List of available styles

### 17.45 matplotlib.table

This module provides functionality to add a table to a plot.

Use the factory function `table` to create a ready-made table from texts. If you need more control, use the `Table` class and its methods.

The table consists of a grid of cells, which are indexed by (row, column). The cell (0, 0) is positioned at the top left.

Thanks to John Gill for providing the class and table.

```python
class matplotlib.table.Cell(xy, width, height, edgecolor='k', facecolor='w', fill=True, text='', loc=None, fontproperties=None)
```

A cell is a `Rectangle` with some associated `Text`.

**Parameters**

- **xy** [2-tuple] The position of the bottom left corner of the cell.
- **width** [float] The cell width.
- **height** [float] The cell height.
- **edgecolor** [color spec] The color of the cell border.
- **facecolor** [color spec] The cell facecolor.
- **fill** [bool] Whether the cell background is filled.
- **text** [str] The cell text.
- **loc** [{‘left’, ‘center’, ‘right’}, default: ‘right’] The alignment of the text within the cell.
- **fontproperties** [dict] A dict defining the font properties of the text. Supported keys and values are the keyword arguments accepted by `FontProperties`.

PAD = 0.1
Padding between text and rectangle.

```python
auto_set_font_size(self, renderer)
```
Shrink font size until the text fits into the cell width.
draw(self, renderer)
    Draw the Patch to the given renderer.

get_fontsize(self)
    Return the cell fontsize.

get_required_width(self, renderer)
    Return the minimal required width for the cell.

get_text(self)
    Return the cell Text instance.

get_text_bounds(self, renderer)
    Return the text bounds as (x, y, width, height) in table coordinates.

set_figure(self, fig)
    Set the Figure instance the artist belongs to.

Parameters

    fig [Figure]

set_fontsize(self, size)
    Set the text fontsize.

set_text_props(self, **kwargs)
    Update the text properties.

Valid kwargs are

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg_filter</td>
<td>a filter function, which takes a (m, n, 3) float array and a dpi value, and</td>

</tbody>
</table>
**ax** [matplotlib.axes.Axes] The `Axes` to plot the table into.

**loc** [str] The position of the cell with respect to `ax`. This must be one of the `codes`.

**bbox** [Bbox or None] A bounding box to draw the table into. If this is not `None`, this overrides `loc`.

**Other Parameters**

**kwargs** `Artist` properties.

**AXESPAD** = 0.02

The border between the `Axes` and the table edge in `Axes` units.

**FONTSIZE** = 10

`add_cell(self, row, col, *args, **kwargs)`

Create a cell and add it to the table.

**Parameters**

row [int] Row index.

col [int] Column index.

*args, **kwargs All other parameters are passed on to `Cell`.

**Returns**

cell [CustomCell] The created cell.

`auto_set_column_width(self, col)`

Automatically set the widths of given columns to optimal sizes.

**Parameters**

col [int or sequence of ints] The indices of the columns to auto-scale.

`auto_set_font_size(self, value=True)`

Automatically set font size.

**codes** = {'best': 0, 'bottom': 17, 'bottom left': 12, 'bottom right': 13, 'center': 9, 'center left': 5, 'center right': 6, 'left': 1, 'right': 14, 'top': 16, 'top left': 11, 'top right': 10, 'upper center': 8, 'upper left': 2, 'upper right': 1}'

Possible values where to place the table relative to the `Axes`.

`contains(self, mouse_event)`

Test whether the artist contains the mouse event.

**Parameters**

mouseevent [matplotlib.backend_bases.MouseEvent]

**Returns**

contains [bool] Whether any values are within the radius.

details [dict] An artist-specific dictionary of details of the event context, such as which points are contained in the pick radius. See the individual `Artist` subclasses for details.

**See also:**

set_contains, get_contains
**draw**(self, renderer)

Draw the Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (*Artist.get_visible* is False).

**Parameters**

renderer [RendererBase subclass.]

**edges**

The default value of *visible_edges* for newly added cells using *add_cell*.

**Notes**

This setting does currently only affect newly created cells using *add_cell*. To change existing cells, you have to set their edges explicitly:

```python
for c in tab.get_celld().values():
    c.visible_edges = 'horizontal'
```

**get_celld**(self)

Return a dict of cells in the table mapping *(row, column)* to *Cells*.

**Notes**

You can also directly index into the Table object to access individual cells:

```python
cell = table[row, col]
```

**get_child_artists**(self)

[Deprecated] Return the Artists contained by the table.

**Notes**

Deprecated since version 3.0.

**get_children**(self)

Return the Artists contained by the table.

**get_window_extent**(self, renderer)

Return the bounding box of the table in window coords.

**scale**(self, xscale, yscale)

Scale column widths by *xscale* and row heights by *yscale*.

**set_fontsize**(self, size)

Set the font size, in points, of the cell text.

**Parameters**

size [float]
Notes

As long as auto font size has not been disabled, the value will be clipped such that
the text fits horizontally into the cell.

You can disable this behavior using `auto_set_font_size`.

```python
>>> the_table.auto_set_font_size(False)
>>> the_table.set_fontsize(20)
```

However, there is no automatic scaling of the row height so that the text may exceed
the cell boundary.

```python
matplotlib.table.table(ax, cellText=None, cellColours=None, cellLoc='right',
                      colWidths=None, rowLabels=None, rowColours=None,
                      rowLoc='left', colLabels=None, colColours=None, col-
                      Loc='center', loc='bottom', bbox=None, edges='closed',
                      **kwargs)
```

Add a table to an `Axes`.

At least one of `cellText` or `cellColours` must be specified. These parameters must be 2D
lists, in which the outer lists define the rows and the inner list define the column values
per row. Each row must have the same number of elements.

The table can optionally have row and column headers, which are configured using

For finer grained control over tables, use the `Table` class and add it to the axes with
`Axes.add_table`.

**Parameters**

- `cellText` [2D list of str, optional] The texts to place into the table cells.
  
  *Note*: Line breaks in the strings are currently not accounted for and
  will result in the text exceeding the cell boundaries.

- `cellColours` [2D list of matplotlib color specs, optional] The background
colors of the cells.

- `cellLoc` [{‘left’, ‘center’, ‘right’}, default: ‘right’] The alignment of the
text within the cells.

- `colWidths` [list of float, optional] The column widths in units of the axes.
  If not given, all columns will have a width of 1 / `ncols`.

- `rowLabels` [list of str, optional] The text of the row header cells.

- `rowColours` [list of matplotlib color specs, optional] The colors of the row
header cells.

- `rowLoc` [{‘left’, ‘center’, ‘right’}, optional, default: ‘left’] The text align-
ment of the row header cells.

- `colLabels` [list of str, optional] The text of the column header cells.

- `colColours` [list of matplotlib color specs, optional] The colors of the col-
umn header cells.

- `rowLoc` [{‘left’, ‘center’, ‘right’}, optional, default: ‘left’] The text align-
ment of the column header cells.
**loc** [str, optional] The position of the cell with respect to `ax`. This must be one of the `codes`.

**bbox** [Bbox, optional] A bounding box to draw the table into. If this is not `None`, this overrides `loc`.

**edges** [substring of 'BRTL' or {'open', 'closed', 'horizontal', 'vertical'}] The cell edges to be drawn with a line. See also `visible_edges`.

**Returns**

**table** [Table] The created table.

**Other Parameters**

****kwargs Table properties.

**17.46 matplotlib.testing**

**17.46.1 matplotlib.testing**

Helper functions for testing.

`matplotlib.testing.is_called_from_pytest()`

Whether we are in a pytest run.

`matplotlib.testing.set_font_settings_for_testing()`

`matplotlib.testing.set_reproducibility_for_testing()`

`matplotlib.testing.setup()`
**17.46.2 matplotlib.testing.compare**

Provides a collection of utilities for comparing (image) results.

```python
matplotlib.testing.compare.compare_float(expected, actual, relTol=None, absTol=None)
```

*Deprecated* Fail if the floating point values are not close enough, with the given message.

You can specify a relative tolerance, absolute tolerance, or both.

**Notes**

Deprecated since version 3.0.

```python
matplotlib.testing.compare.compare_images(expected, actual, tol, in_decorator=False)
```

Compare two “image” files checking differences within a tolerance.

The two given filenames may point to files which are convertible to PNG via the `converter` dictionary. The underlying RMS is calculated with the `calculate_rms` function.

**Parameters**

- `expected` [str] The filename of the expected image.
- `actual` [str] The filename of the actual image.
- `tol` [float] The tolerance (a color value difference, where 255 is the maximal difference). The test fails if the average pixel difference is greater than this value.
- `in_decorator` [bool] Determines the output format. If called from `image_comparison` decorator, this should be True. (default=False)

**Returns**

- `comparison_result` [None or dict or str] Return `None` if the images are equal within the given tolerance.

If the images differ, the return value depends on `in_decorator`. If `in_decorator` is true, a dict with the following entries is returned:

  - `rms`: The RMS of the image difference.
  - `expected`: The filename of the expected image.
  - `actual`: The filename of the actual image.
  - `diff_image`: The filename of the difference image.
  - `tol`: The comparison tolerance.

Otherwise, a human-readable multi-line string representation of this information is returned.

**Examples**

```python
img1 = "./baseline/plot.png"
img2 = "./output/plot.png"
compare_images(img1, img2, 0.001)
```
matplotlib.testing.compare.comparable_formats()

Return the list of file formats that `compare_images` can compare on this system.

**Returns**

- **supported_formats** [list of str] E.g. ['png', 'pdf', 'svg', 'eps'].

### 17.46.3 matplotlib.testing.decorators

```python
class matplotlib.testingdecorators.CleanupTest(**kwargs)
    Bases: object

    [Deprecated]

    Notes

    Deprecated since version 3.0:
    - `classmethod setup_class()`
    - `classmethod teardown_class()`
    - `test(self)`

class matplotlib.testing.decorators.CleanupTestCase(methodName='runTest')
    Bases: unittest.case.TestCase

    A wrapper for unittest.TestCase that includes cleanup operations.
    Create an instance of the class that will use the named test method when executed.
    Raises a ValueError if the instance does not have a method with the specified name.
    - `classmethod setUpClass()`
      Hook method for setting up class fixture before running tests in the class.
    - `classmethod tearDownClass()`
      Hook method for deconstructing the class fixture after running all tests in the class.

class matplotlib.testing.decorators.ImageComparisonTest(**kwargs)
    Bases: matplotlib.testing.decorators.CleanupTest, matplotlib.testing.decorators._ImageComparisonBase

    [Deprecated] Nose-based image comparison class

    This class generates tests for a nose-based testing framework. Ideally, this class would not be public, and the only publicly visible API would be the `image_comparison()` decorator. Unfortunately, there are existing downstream users of this class (e.g., pytest-mpl) so it cannot yet be removed.

    Notes

    Deprecated since version 3.0.
    - `nose_runner(self)`
    - `setup(self)`
    - `teardown(self)`
```
Decorator for test cases that generate and compare two figures.

The decorated function must take two arguments, `fig_test` and `fig_ref`, and draw the test and reference images on them. After the function returns, the figures are saved and compared.

This decorator should be preferred over `image_comparison` when possible in order to keep the size of the test suite from ballooning.

**Parameters**

- `extensions` [list, default: `["png", "pdf", "svg"]]` The extensions to test.
- `tol` [float] The RMS threshold above which the test is considered failed.

**Examples**

Check that calling `Axes.plot` with a single argument plots it against `[0, 1, 2, ...]`:

```python
@check_figures_equal()
def test_plot(fig_test, fig_ref):
    fig_test.subplots().plot([1, 3, 5])
    fig_ref.subplots().plot([0, 1, 2], [1, 3, 5])
```

A decorator to ensure that any global state is reset before running a test.

**Parameters**

- `style` [str, optional] The name of the style to apply.

A decorator to compare images generated by the test with those specified in `baseline_images`, which must correspond, else an `ImageComparisonFailure` exception will be raised.

**Parameters**

- `baseline_images` [list or None] A list of strings specifying the names of the images generated by calls to `matplotlib.figure.savefig()`.
  
  If `None`, the test function must use the `baseline_images` fixture, either as a parameter or with `pytest.mark.usefixtures`. This value is only allowed when using pytest.

- `extensions` [None or list of str] The list of extensions to test, e.g. `["png", "pdf"]`.
  
  If `None`, defaults to all supported extensions: png, pdf, and svg.

In order to keep the size of the test suite from ballooning, we only include the `svg` or `pdf` outputs if the test is explicitly exercising a feature dependent on that backend (see also the `check_figures_equal` decorator for that purpose).
tol [float, optional, default: 0] The RMS threshold above which the test is considered failed.

freetype_version [str or tuple] The expected freetype version or range of versions for this test to pass.

remove_text [bool] Remove the title and tick text from the figure before comparison. This is useful to make the baseline images independent of variations in text rendering between different versions of FreeType. This does not remove other, more deliberate, text, such as legends and annotations.

savefig_kwarg [dict] Optional arguments that are passed to the savefig method.

style [string] Optional name for the base style to apply to the image test. The test itself can also apply additional styles if desired. Defaults to the '_classic_test' style.

matplotlib.testing.decorators.remove_ticks_and_titles(figure)

matplotlib.testing.decorators.skip_if_command_unavailable(cmd)

    [Deprecated] skips a test if a command is unavailable.

Parameters

cmd [list of str] must be a complete command which should not return a non zero exit code, something like ["latex", ",-version"]

Notes

Deprecated since version 3.0.

matplotlib.testing.decorators.switch_backend(backend)

    [Deprecated]

Notes

Deprecated since version 3.1:

17.46.4 matplotlib.testing.disable_internet

matplotlib.testing.disable_internet.check_internet_off(original_function)

Wraps original_function, which in most cases is assumed to be a socket.socket method, to raise an IOError for any operations on non-local AF_INET sockets.

matplotlib.testing.disable_internet.no_internet(verbos=False)

Context manager to temporarily disable internet access (if not already disabled). If it was already disabled before entering the context manager (i.e. turn_off_internet was called previously) then this is a no-op and leaves internet access disabled until a manual call to turn_on_internet.

matplotlib.testing.disable_internet.turn_off_internet(verbos=False)

Disable internet access via python by preventing connections from being created using the socket module. Presumably this could be worked around by using some other means
of accessing the internet, but all default python modules (urllib, requests, etc.) use
socket [citation needed].

```python
matplotlib.testing.disable_internet.turn_on_internet(verbose=False)
```

Restore internet access. Not used, but kept in case it is needed.

### 17.46.5 matplotlib.testing.exceptions

```python
exception matplotlib.testing.exceptions.ImageComparisonFailure
Bases: AssertionError
```

Raise this exception to mark a test as a comparison between two images.

### 17.47 matplotlib.text

Classes for including text in a figure.

```python
class matplotlib.text.Annotation(text, xy, xytex=None, xycoords='data',
    textcoords=None, arrowprops=None, annotation_clip=None, **kwargs)
```

**Attributes**

- `xy` The annotated position.
- `xycoords` The coordinate system for `xy`.
- `arrow_patch` A `FancyArrowPatch` to point from `xytext` to `xy`.

An `Annotation` is a `Text` that can refer to a specific position `xy`. Optionally an arrow pointing from the text to `xy` can be drawn.

**Parameters**

- `text` [str] The text of the annotation. `s` is a deprecated synonym for this parameter.
- `xy` [(float, float)] The point `(x,y)` to annotate.
- `xytext` [(float, float), optional] The position `(x,y)` to place the text at. If `None`, defaults to `xy`.
- `xycoords` [str, `Artist`, `Transform`, callable or tuple, optional] The coordinate system that `xy` is given in. The following types of values are supported:
  - One of the following strings:
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'figure points'</td>
<td>Points from the lower left of the figure</td>
</tr>
<tr>
<td>'figure pixels'</td>
<td>Pixels from the lower left of the figure</td>
</tr>
<tr>
<td>'figure fraction'</td>
<td>Fraction of figure from lower left</td>
</tr>
<tr>
<td>'axes points'</td>
<td>Points from lower left corner of axes</td>
</tr>
<tr>
<td>'axes pixels'</td>
<td>Pixels from lower left corner of axes</td>
</tr>
<tr>
<td>'axes fraction'</td>
<td>Fraction of axes from lower left</td>
</tr>
<tr>
<td>'data'</td>
<td>Use the coordinate system of the object being annotated (default)</td>
</tr>
<tr>
<td>'polar'</td>
<td>((\theta, r)) if not native 'data' coordinates</td>
</tr>
</tbody>
</table>

- An *Artist*: `xy` is interpreted as a fraction of the artists `Bbox`. E.g. \((0, 0)\) would be the lower left corner of the bounding box and \((0.5, 1)\) would be the center top of the bounding box.

- A *Transform* to transform `xy` to screen coordinates.

- A function with one of the following signatures:

  ```python
def transform(renderer) -> Bbox
def transform(renderer) -> Transform
  ```

  where `renderer` is a `RendererBase` subclass.

  The result of the function is interpreted like the *Artist* and *Transform* cases above.

  - A tuple \((xcoords, ycoords)\) specifying separate coordinate systems for \(x\) and \(y\). \(xcoords\) and \(ycoords\) must each be of one of the above described types.

  See Advanced Annotation for more details.

  Defaults to 'data'.

  **textcoords** [str, *Artist*, *Transform*, callable or tuple, optional] The coordinate system that `xytext` is given in.

  All `xycoords` values are valid as well as the following strings:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'offset points'</td>
<td>Offset (in points) from the <code>xy</code> value</td>
</tr>
<tr>
<td>'offset pixels'</td>
<td>Offset (in pixels) from the <code>xy</code> value</td>
</tr>
</tbody>
</table>

  Defaults to the value of `xycoords`, i.e. use the same coordinate system for annotation point and text position.

  **arrowprops** [dict, optional] The properties used to draw a *FancyArrowPatch* arrow between the positions `xy` and `xytext`.

  If `arrowprops` does not contain the key 'arrowstyle' the allowed keys are:
<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>The width of the arrow in points</td>
</tr>
<tr>
<td>headwidth</td>
<td>The width of the base of the arrow head in points</td>
</tr>
<tr>
<td>headlength</td>
<td>The length of the arrow head in points</td>
</tr>
<tr>
<td>shrink</td>
<td>Fraction of total length to shrink from both ends</td>
</tr>
<tr>
<td>?</td>
<td>Any key to matplotlib.patches.FancyArrowPatch</td>
</tr>
</tbody>
</table>

If `arrowprops` contains the key ‘arrowstyle’ the above keys are forbidden. The allowed values of ‘arrowstyle’ are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Attrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘-’</td>
<td>None</td>
</tr>
<tr>
<td>‘-&gt;’</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>‘-['</td>
<td>widthB=1.0, lengthB=0.2, angleB=None</td>
</tr>
<tr>
<td>‘</td>
<td>-'</td>
</tr>
<tr>
<td>‘-</td>
<td>&gt;’</td>
</tr>
<tr>
<td>‘&lt;-'</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>‘&lt;-&gt;’</td>
<td>head_length=0.4, head_width=0.2</td>
</tr>
<tr>
<td>‘&lt;</td>
<td>-’</td>
</tr>
<tr>
<td>‘&lt;</td>
<td>-&gt;’</td>
</tr>
<tr>
<td>‘fancy’</td>
<td>head_length=0.4, head_width=0.4, tail_width=0.4</td>
</tr>
<tr>
<td>‘simple’</td>
<td>head_length=0.5, head_width=0.5, tail_width=0.2</td>
</tr>
<tr>
<td>‘wedge’</td>
<td>tail_width=0.3, shrink_factor=0.5</td>
</tr>
</tbody>
</table>

Valid keys for `FancyArrowPatch` are:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arrowstyle</td>
<td>the arrow style</td>
</tr>
<tr>
<td>connectionstyle</td>
<td>the connection style</td>
</tr>
<tr>
<td>relpos</td>
<td>default is (0.5, 0.5)</td>
</tr>
<tr>
<td>patchA</td>
<td>default is bounding box of the text</td>
</tr>
<tr>
<td>patchB</td>
<td>default is None</td>
</tr>
<tr>
<td>shrinkA</td>
<td>default is 2 points</td>
</tr>
<tr>
<td>shrinkB</td>
<td>default is 2 points</td>
</tr>
<tr>
<td>mutation_scale</td>
<td>default is text size (in points)</td>
</tr>
<tr>
<td>mutation_aspect</td>
<td>default is 1.</td>
</tr>
<tr>
<td>?</td>
<td>any key for matplotlib.patches.PathPatch</td>
</tr>
</tbody>
</table>

Defaults to None, i.e. no arrow is drawn.

**annotation_clip** [bool or None, optional] Whether to draw the annotation when the annotation point `xy` is outside the axes area.

- If `True`, the annotation will only be drawn when `xy` is within the axes.
- If `False`, the annotation will always be drawn.
- If `None`, the annotation will only be drawn when `xy` is within the axes and `xycoords` is ‘data’.

Defaults to `None`.

**kwargs** Additional kwargs are passed to `Text`. 
Returns

annotation [Annotation]

See also:

Advanced Annotation

anncoords
The coordinate system to use for Annotation.xyann.

arrow
[Deprecated]

Notes

Deprecated since version 3.0: arrow was deprecated in Matplotlib 3.0 and will be removed in 3.2. Use arrow_patch instead.

contains(self, event)
Test whether the mouse event occurred in the patch.
In the case of text, a hit is true anywhere in the axis-aligned bounding-box containing the text.

Returns

bool [bool]

draw(self, renderer)
Draw the Annotation object to the given renderer.

get_anncoords(self)
Return the coordinate system to use for Annotation.xyann.
See also xycoords in Annotation.

get_window_extent(self, renderer=None)
Return the Bbox bounding the text and arrow, in display units.

Parameters

renderer [Renderer, optional] A renderer is needed to compute the bounding box. If the artist has already been drawn, the renderer is cached; thus, it is only necessary to pass this argument when calling get_window_extent before the first draw. In practice, it is usually easier to trigger a draw first (e.g. by saving the figure).

set_anncoords(self, coords)
Set the coordinate system to use for Annotation.xyann.
See also xycoords in Annotation.

set_figure(self, fig)
Set the Figure instance the artist belongs to.

Parameters

fig [Figure]

update_positions(self, renderer)
Update the pixel positions of the annotated point and the text.
xyann
The the text position.
See also xytext in Annotation.

class matplotlib.text.OffsetFrom(artist, ref_coord, unit='points')
Bases: object
Callable helper class for working with Annotation

Parameters

artist [Artist, BboxBase, or Transform] The object to compute the offset from.
ref_coord [length 2 sequence] If artist is an Artist or BboxBase, this value is the location to of the offset origin in fractions of the artist bounding box.
If artist is a transform, the offset origin is the transform applied to this value.
unit [{‘points’, ‘pixels’}] The screen units to use (pixels or points) for the offset input.

get_unit(self)
The unit for input to the transform used by __call__

set_unit(self, unit)
The unit for input to the transform used by __call__

Parameters

unit [{‘points’, ‘pixels’}]

class matplotlib.text.Text(x=0, y=0, text='', color=None, verticalalignment='baseline', horizontalalignment='left', multialignment=None, fontproperties=None, rotation=None, linespacing=None, rotation_mode=None, usetex=None, wrap=False, **kwargs)
Bases: matplotlib.artist.Artist
Handle storing and drawing of text in window or data coordinates.
Create a Text instance at x, y with string text.
Valid kwargs are

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg_filter</td>
<td>a filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) float array</td>
</tr>
<tr>
<td>alpha</td>
<td>float</td>
</tr>
<tr>
<td>animated</td>
<td>bool</td>
</tr>
<tr>
<td>backgroundcolor</td>
<td>color</td>

`contains(self, mouseevent)`
Test whether the mouse event occurred in the patch.
In the case of text, a hit is true anywhere in the axis-aligned bounding-box containing the text.

**Returns**

`bool` [bool]

`draw(self, renderer)`
Draws the `Text` object to the given `renderer`.

`get_bbox_patch(self)`
Return the bbox Patch, or None if the `patches.FancyBboxPatch` is not made.

`get_c(self)`
Alias for `get_color`.

`get_color(self)`
 Return the color of the text
get_family(self)
    Alias for get_fontfamily.
get_font_properties(self)
    Alias for get_fontproperties.
get_fontfamily(self)
    Return the list of font families used for font lookup
    See also:
        font_manager.FontProperties.get_family
get_fontname(self)
    Return the font name as string
    See also:
        font_manager.FontProperties.get_name
get_fontproperties(self)
    Return the font_manager.FontProperties object
get_fontsize(self)
    Return the font size as integer
    See also:
        font_manager.FontProperties.get_size_in_points
get_fontstyle(self)
    Return the font style as string
    See also:
        font_manager.FontProperties.get_style
get_fontvariant(self)
    Return the font variant as a string
    See also:
        font_manager.FontProperties.get_variant
get_fontweight(self)
    Get the font weight as string or number
    See also:
        font_manager.FontProperties.get_weight
get_ha(self)
    Alias for get_horizontalalignment.
get_horizontalalignment(self)
    Return the horizontal alignment as string. Will be one of ‘left’, ‘center’ or ‘right’.
get_name(self)
    Alias for get_fontname.
get_position(self)
    Return the position of the text as a tuple (x, y)

get_prop_tup(self, renderer=None)
    Return a hashable tuple of properties.
    Not intended to be human readable, but useful for backends who want to cache
derived information about text (e.g., layouts) and need to know if the text has changed.

get_rotation(self)
    Return the text angle as float in degrees.

get_rotation_mode(self)
    Get the text rotation mode.

get_size(self)
    Alias for get_fontsize.

get_stretch(self)
    Get the font stretch as a string or number

    See also:

    font_manager.FontProperties.get_stretch

get_style(self)
    Alias for get_fontstyle.

get_text(self)
    Get the text as string

get_unitless_position(self)
    Return the unitless position of the text as a tuple (x, y)

gusetex(self)
    Return whether this Text object uses TeX for rendering.

get_va(self)
    Alias for get_verticalalignment.

get_variant(self)
    Alias for get_fontvariant.

get_verticalalignment(self)
    Return the vertical alignment as string. Will be one of ‘top’, ‘center’, ‘bottom’ or
‘baseline’.

get_weight(self)
    Alias for get_fontweight.

get_window_extent(self, renderer=None, dpi=None)
    Return the Bbox bounding the text, in display units.
    In addition to being used internally, this is useful for specifying clickable regions in
a png file on a web page.

    Parameters

    renderer [Renderer, optional] A renderer is needed to compute the
bounding box. If the artist has already been drawn, the renderer is
cached; thus, it is only necessary to pass this argument when calling
get_window_extent before the first draw. In practice, it is usually
easier to trigger a draw first (e.g. by saving the figure).
dpi [float, optional] The dpi value for computing the bbox, defaults to
self.figure.dpi (not the renderer dpi); should be set e.g. if to match
regions with a figure saved with a custom dpi value.

get_wrap(self)
   Return the wrapping state for the text.

static is_math_text(s, usetex=None)
   [Deprecated] Returns a cleaned string and a boolean flag. The flag indicates if
the given string s contains any mathtext, determined by counting unescaped dollar
signs. If no mathtext is present, the cleaned string has its dollar signs unescaped.
If usetex is on, the flag always has the value “TeX”.

Notes

Deprecated since version 3.1.

set_backgroundcolor(self, color)
   Set the background color of the text by updating the bbox.

   Parameters

   color [color]

   See also:

   set_bbox To change the position of the bounding box

set_bbox(self, rectprops)
   Draw a bounding box around self.

   Parameters

   rectprops [dict with properties for patches.FancyBboxPatch] The de-
default boxstyle is ‘square’. The mutation scale of the patches.
   FancyBboxPatch is set to the fontsize.

Examples

    t.set_bbox(dict(facecolor='red', alpha=0.5))

set_c(self, color)
   Alias for set_color.

set_clip_box(self, clipbox)
   Set the artist’s clip Bbox.

   Parameters

   clipbox [Bbox]

set_clip_on(self, b)
   Set whether the artist uses clipping.
   When False artists will be visible out side of the axes which can lead to unexpected
   results.

   Parameters
b [bool]

set_clip_path(self, path, transform=None)
Set the artist's clip path, which may be:

- a Patch (or subclass) instance; or
- a Path instance, in which case a Transform instance, which will be applied to the
  path before using it for clipping, must be provided; or
- None, to remove a previously set clipping path.

For efficiency, if the path happens to be an axis-aligned rectangle, this method will
set the clipping box to the corresponding rectangle and set the clipping path to None.

ACCEPTS: [(Path, Transform) | Patch | None]

set_color(self, color)
Set the foreground color of the text

Parameters

  color [color]

set_family(self, fontname)
Alias for set_fontfamily.

set_font_properties(self, fp)
Alias for set_fontproperties.

set_fontfamily(self, fontname)
Set the font family. May be either a single string, or a list of strings in decreasing
priority. Each string may be either a real font name or a generic font class name. If
the latter, the specific font names will be looked up in the corresponding rcParams.

If a Text instance is constructed with fontfamily=None, then the font is set to
rcParams["font.family"], and the same is done when set_fontfamily() is called on
an existing Text instance.

Parameters

  fontname [{FONTNAME, 'serif', 'sans-serif', 'cursive', 'fantasy',
    'monospace'}]

See also:

  font_manager.FontProperties.set_family

set_fontname(self, fontname)
Alias for set_family.

One-way alias only: the getter differs.

Parameters

  fontname [{FONTNAME, 'serif', 'sans-serif', 'cursive', 'fantasy',
    'monospace'}]

See also:

  font_manager.FontProperties.set_family

set_fontproperties(self, fp)
Set the font properties that control the text.
Parameters

\( \textbf{fp} \ [\texttt{font_manager.FontProperties}] \)

\texttt{set_fontsize(self, fontsize)}

Set the font size. May be either a size string, relative to the default font size, or an absolute font size in points.

**Parameters**

\( \textbf{fontsize} \ [\{'\texttt{xx-small}', '\texttt{x-small}', '\texttt{small}', '\texttt{medium}', '\texttt{large}', '\texttt{x-large}', '\texttt{xx-large}'\}] \)

See also:

\texttt{font_manager.FontProperties.set_size}

\texttt{set_fontstretch(self, stretch)}

Set the font stretch (horizontal condensation or expansion).

**Parameters**

\( \textbf{stretch} \ [\{'\texttt{ultra-condensed}', '\texttt{extra-condensed}', '\texttt{condensed}', '\texttt{semi-condensed}', '\texttt{normal}', '\texttt{semi-expanded}', '\texttt{expanded}', '\texttt{extra-expanded}', '\texttt{ultra-expanded}'\}] \)

See also:

\texttt{font_manager.FontProperties.set_stretch}

\texttt{set_fontstyle(self, fontstyle)}

Set the font style.

**Parameters**

\( \textbf{fontstyle} \ [\{'\texttt{normal}', '\texttt{italic}', '\texttt{oblique}'\}] \)

See also:

\texttt{font_manager.FontProperties.set_style}

\texttt{set_fontvariant(self, variant)}

Set the font variant, either 'normal' or 'small-caps'.

**Parameters**

\( \textbf{variant} \ [\{'\texttt{normal}', '\texttt{small-caps}'\}] \)

See also:

\texttt{font_manager.FontProperties.set_variant}

\texttt{set_fontweight(self, weight)}

Set the font weight.

**Parameters**

\( \textbf{weight} \ [\{'\texttt{ultralight}', '\texttt{light}', '\texttt{normal}', '\texttt{regular}', '\texttt{book}', '\texttt{medium}', '\texttt{roman}', '\texttt{semibold}', '\texttt{demibold}', '\texttt{demi}', '\texttt{bold}', '\texttt{heavy}', '\texttt{extra bold}', '\texttt{black}'\}] \)

See also:
font_manager.FontProperties.set_weight

set_ha(self, align)
   Alias for set_horizontalalignment.

set_horizontalalignment(self, align)
   Set the horizontal alignment to one of

   Parameters
   align [{'center', 'right', 'left'}]

set_linespacing(self, spacing)
   Set the line spacing as a multiple of the font size. Default is 1.2.

   Parameters
   spacing [float (multiple of font size)]

set_ma(self, align)
   Alias for set_multialignment.

set_multialignment(self, align)
   Set the alignment for multiple lines layout. The layout of the bounding box of all the
   lines is determined by the horizontalalignment and verticalalignment properties, but the multiline text within that box can be

   Parameters
   align [{'left', 'right', 'center'}]

set_name(self, fontname)
   Alias for set_fontname.

set_position(self, xy)
   Set the (x, y) position of the text.

   Parameters
   xy [(float, float)]

set_rotation(self, s)
   Set the rotation of the text.

   Parameters
   s [{angle in degrees, 'vertical', 'horizontal'}]

set_rotation_mode(self, m)
   Set text rotation mode.

   Parameters
   m [{None, 'default', 'anchor'}] If None or "default", the text will be
   first rotated, then aligned according to their horizontal and vertical
   alignments. If "anchor", then alignment occurs before rotation.

set_size(self, fontsize)
   Alias for set_fontsize.

set_stretch(self, stretch)
   Alias for set_fontstretch.

set_style(self, fontstyle)
   Alias for set_fontstyle.
set_text(self, s)
    Set the text string s.
    It may contain newlines (\n) or math in LaTeX syntax.

Parameters
    s [object] Any object gets converted to its str, except None which becomes ''.

set_usetex(self, usetex)
Parameters
    usetex [bool or None] Whether to render using TeX, None means to use
    rcParams["text.usetex"].

set_va(self, align)
    Alias for set_verticalalignment.

set_variant(self, variant)
    Alias for set_fontvariant.

set_verticalalignment(self, align)
    Set the vertical alignment

Parameters
    align [{'center', 'top', 'bottom', 'baseline', 'center_baseline'}]

set_weight(self, weight)
    Alias for set_fontweight.

set_wrap(self, wrap)
    Set the wrapping state for the text.

Parameters
    wrap [bool]

set_x(self, x)
    Set the x position of the text.

Parameters
    x [float]

set_y(self, y)
    Set the y position of the text.

Parameters
    y [float]

update(self, kwargs)
    Update properties from a dictionary.

update_bbox_position_size(self, renderer)
    Update the location and the size of the bbox.
    This method should be used when the position and size of the bbox needs to be
    updated before actually drawing the bbox.

update_from(self, other)
    Copy properties from other to self.
class matplotlib.text.TextWithDash(**kwargs)
Bases: matplotlib.text.Text

[Deprecated] This is basically a Text with a dash (drawn with a Line2D) before/after it. It is intended to be a drop-in replacement for Text, and should behave identically to it when dashlength = 0.0.

The dash always comes between the point specified by set_position() and the text. When a dash exists, the text alignment arguments (horizontalalignment, verticalalignment) are ignored.

dashlength is the length of the dash in canvas units. (default = 0.0).
dashdirection is one of 0 or 1, where 0 draws the dash after the text and 1 before. (default = 0).
dashrotation specifies the rotation of the dash, and should generally stay None. In this case get_dashrotation() returns get_rotation(). (i.e., the dash takes its rotation from the text’s rotation). Because the text center is projected onto the dash, major deviations in the rotation cause what may be considered visually unappealing results. (default = None)
dashpad is a padding length to add (or subtract) space between the text and the dash, in canvas units. (default = 3)
dashpush “pushes” the dash and text away from the point specified by set_position() by the amount in canvas units. (default = 0)

Note: The alignment of the two objects is based on the bounding box of the Text, as obtained by get_window_extent(). This, in turn, appears to depend on the font metrics as given by the rendering backend. Hence the quality of the “centering” of the label text with respect to the dash varies depending on the backend used.

Note: I’m not sure that I got the get_window_extent() right, or whether that’s sufficient for providing the object bounding box.

Notes

Deprecated since version 3.1.
draw(self, renderer)
    Draw the TextWithDash object to the given renderer.

get_dashdirection(self)
    Get the direction dash. 1 is before the text and 0 is after.

get_dashlength(self)
    Get the length of the dash.

get_dashpad(self)
    Get the extra spacing between the dash and the text, in canvas units.

get_dashpush(self)
    Get the extra spacing between the dash and the specified text position, in canvas units.
get_dashrotation(self)
    Get the rotation of the dash in degrees.

get_figure(self)
    return the figure instance the artist belongs to

get_position(self)
    Return the position of the text as a tuple (x, y)

get_prop_tup(self, renderer=None)
    Return a hashable tuple of properties.
    Not intended to be human readable, but useful for backends who want to cache de-
    rived information about text (e.g., layouts) and need to know if the text has changed.

get_unitless_position(self)
    Return the unitless position of the text as a tuple (x, y)

get_window_extent(self, renderer=None)
    Return a Bbox object bounding the text, in display units.
    In addition to being used internally, this is useful for specifying clickable regions in
    a png file on a web page.
    
    renderer defaults to the _renderer attribute of the text object. This is not assigned
    until the first execution of draw(), so you must use this kwarg if you want to call
    get_window_extent() prior to the first draw(). For getting web page regions, it is
    simpler to call the method after saving the figure.

set_dashdirection(self, dd)
    Set the direction of the dash following the text. 1 is before the text and 0 is after.
    The default is 0, which is what you’d want for the typical case of ticks below and on
    the left of the figure.

    Parameters
    dd [int (1 is before, 0 is after)]

set_dashlength(self, dl)
    Set the length of the dash, in canvas units.

    Parameters
    dl [float]

set_dashpad(self, dp)
    Set the “pad” of the TextWithDash, which is the extra spacing between the dash
    and the text, in canvas units.

    Parameters
    dp [float]

set_dashpush(self, dp)
    Set the “push” of the TextWithDash, which is the extra spacing between the begin-
    ning of the dash and the specified position.

    Parameters
    dp [float]

set_dashrotation(self, dr)
    Set the rotation of the dash, in degrees.

    Parameters
dr [float]

set_figure(self, fig)
    Set the figure instance the artist belongs to.

Parameters
    fig [matplotlib.figure.Figure]

set_position(self, xy)
    Set the (x, y) position of the TextWithDash.

Parameters
    xy [(float, float)]

set_transform(self, t)
    Set the matplotlib.transforms.Transform instance used by this artist.

Parameters
    t [matplotlib.transforms.Transform]

set_x(self, x)
    Set the x position of the TextWithDash.

Parameters
    x [float]

set_y(self, y)
    Set the y position of the TextWithDash.

Parameters
    y [float]

update_coords(self, renderer)
    Computes the actual x, y coordinates for text based on the input x, y and the dash-length. Since the rotation is with respect to the actual canvas’s coordinates we need to map back and forth.

matplotlib.text.get_rotation(rotation)
    Return the text angle as float between 0 and 360 degrees.

    rotation may be ‘horizontal’, ‘vertical’, or a numeric value in degrees.

17.48 matplotlib.textpath

class matplotlib.textpath.TextPath(xy, s, size=None, prop=None, _interpolation_steps=1, usetex=False, *args, **kwargs)
    Bases: matplotlib.path.Path

Create a path from the text.

Create a path from the text. Note that it simply is a path, not an artist. You need to use the PathPatch (or other artists) to draw this path onto the canvas.

Parameters
    xy [tuple or array of two float values] Position of the text. For no offset, use xy=(0, 0).
s [str] The text to convert to a path.
size [float, optional] Font size in points. Defaults to the size specified via
the font properties prop.
prop [matplotlib.font_manager.FontProperties, optional] Font property. If
not provided, will use a default FontProperties with parameters from
the rcParams.
_interpolation_steps [integer, optional] (Currently ignored)
usetex [bool, optional] Whether to use tex rendering. Defaults to False.

Examples

The following creates a path from the string "ABC" with Helvetica font face; and another
path from the latex fraction 1/2:

```python
from matplotlib.textpath import TextPath
from matplotlib.font_manager import FontProperties

fp = FontProperties(family="Helvetica", style="italic")
path1 = TextPath((12, 12), "ABC", size=12, prop=fp)
path2 = TextPath((0, 0), r"\frac{1}{2}", size=12, usetex=True)
```

Also see /gallery/text_labels_and_annotations/demo_text_path.

codes
Return the codes

get_size(self)
Get the text size.

is_math_text(self, s)
[Deprecated] Returns True if the given string s contains any mathtext.

Notes

Deprecated since version 3.1.

set_size(self, size)
Set the text size.

text_get_vertices_codes(self, prop, s, usetex)
[Deprecated] Convert string s to a (vertices, codes) pair using font property prop.

Notes

Deprecated since version 3.1.

vertices
Return the cached path after updating it if necessary.

class matplotlib.textpath.TextToPath
Bases: object
A class that converts strings to paths.
DPI = 72
FONT_SCALE = 100.0

get_glyphs_mathtext(self, prop, s, glyph_map=None, return_new_glyphs_only=False)
Parse mathtext string s and convert it to a (vertices, codes) pair.

glyph_to_path(self, font, currx=0.0)
[Deprecated] Convert the font’s current glyph to a (vertices, codes) pair.

Also see TextPath for a more direct way to create a path from a text.

get_text_width_height_descent(self, s, prop, ismath)

Parameters

s [str] The text to be converted.
ismath [{False, True, ”TeX”}] If True, use mathtext parser. If ”TeX”, use tex for rendering.

Returns

verts, codes [tuple of lists] verts is a list of numpy arrays containing the x and y coordinates of the vertices. codes is a list of path codes.

Examples

Create a list of vertices and codes from a text, and create a Path from those:

```python
from matplotlib.path import Path
from matplotlib.textpath import TextToPath
from matplotlib.font_manager import FontProperties

fp = FontProperties(family="Humor Sans", style="italic")
verts, codes = TextToPath().get_text_path(fp, "ABC")
path = Path(verts, codes, closed=False)
```

Also see TextPath for a more direct way to create a path from a text.
17.49 matplotlib.ticker

17.49.1 Tick locating and formatting

This module contains classes to support completely configurable tick locating and formatting. Although the locators know nothing about major or minor ticks, they are used by the Axis class to support major and minor tick locating and formatting. Generic tick locators and formatters are provided, as well as domain specific custom ones.

Default Formatter

The default formatter identifies when the x-data being plotted is a small range on top of a large offset. To reduce the chances that the ticklabels overlap, the ticks are labeled as deltas from a fixed offset. For example:

```python
ax.plot(np.arange(2000, 2010), range(10))
```

will have tick of 0-9 with an offset of +2e3. If this is not desired turn off the use of the offset on the default formatter:

```python
ax.get_xaxis().get_major_formatter().set_useOffset(False)
```

set the rcParam `axes.formatter.useoffset=False` to turn it off globally, or set a different formatter.

Tick locating

The Locator class is the base class for all tick locators. The locators handle autoscaling of the view limits based on the data limits, and the choosing of tick locations. A useful semi-automatic tick locator is `MultipleLocator`. It is initialized with a base, e.g., 10, and it picks axis limits and ticks that are multiples of that base.

The Locator subclasses defined here are

- `AutoLocator` `MaxNLocator` with simple defaults. This is the default tick locator for most plotting.
- `MaxNLocator` Finds up to a max number of intervals with ticks at nice locations.
- `LinearLocator` Space ticks evenly from min to max.
- `LogLocator` Space ticks logarithmically from min to max.
MultipleLocator  Ticks and range are a multiple of base; either integer or float.

FixedLocator  Tick locations are fixed.

IndexLocator  Locator for index plots (e.g., where \( x = \text{range}(\text{len}(y)) \)).

NullLocator  No ticks.

SymmetricalLogLocator  Locator for use with with the symlog norm; works like LogLocator for the part outside of the threshold and adds 0 if inside the limits.

LogitLocator  Locator for logit scaling.

OldAutoLocator  Choose a MultipleLocator and dynamically reassign it for intelligent ticking during navigation.

AutoMinorLocator  Locator for minor ticks when the axis is linear and the major ticks are uniformly spaced. Subdivides the major tick interval into a specified number of minor intervals, defaulting to 4 or 5 depending on the major interval.

There are a number of locators specialized for date locations - see the dates module.

You can define your own locator by deriving from Locator. You must override the \_\_call\_\_ method, which returns a sequence of locations, and you will probably want to override the autoscale method to set the view limits from the data limits.

If you want to override the default locator, use one of the above or a custom locator and pass it to the x or y axis instance. The relevant methods are:

```python
ax.xaxis.set_major_locator(xmajor_locator)
ax.xaxis.set_minor_locator(xminor_locator)
ax.yaxis.set_major_locator(ymajor_locator)
ax.yaxis.set_minor_locator(ymminor_locator)
```

The default minor locator is NullLocator, i.e., no minor ticks on by default.

Tick formatting

Tick formatting is controlled by classes derived from Formatter. The formatter operates on a single tick value and returns a string to the axis.

NullFormatter  No labels on the ticks.

IndexFormatter  Set the strings from a list of labels.

FixedFormatter  Set the strings manually for the labels.

FuncFormatter  User defined function sets the labels.

StrMethodFormatter  Use string \texttt{format} method.

FormatStrFormatter  Use an old-style sprintf format string.

ScalarFormatter  Default formatter for scalars: autopick the format string.

LogFormatter  Formatter for log axes.

LogFormatterExponent  Format values for log axis using \( \text{exponent} = \log_{\text{base}}(\text{value}) \).

LogFormatterMathtext  Format values for log axis using \( \text{exponent} = \log_{\text{base}}(\text{value}) \) using Math text.

LogFormatterSciNotation  Format values for log axis using scientific notation.
LogitFormatter Probability formatter.

EngFormatter Format labels in engineering notation

PercentFormatter Format labels as a percentage

You can derive your own formatter from the Formatter base class by simply overriding the __call__ method. The formatter class has access to the axis view and data limits.

To control the major and minor tick label formats, use one of the following methods:

```python
ax.xaxis.set_major_formatter(xmajor_formatter)
ax.xaxis.set_minor_formatter(xminor_formatter)
ax.yaxis.set_major_formatter(ymajor_formatter)
ax.yaxis.set_minor_formatter(ymminor_formatter)
```

See /gallery/ticks_and_spines/major_minor_demo for an example of setting major and minor ticks. See the matplotlib.dates module for more information and examples of using date locators and formatters.

class matplotlib.ticker.TickHelper
    Bases: object
    axis = None
    create_dummy_axis(self, **kwargs)
    set_axis(self, axis)
    set_bounds(self, vmin, vmax)
    set_data_interval(self, vmin, vmax)
    set_view_interval(self, vmin, vmax)

class matplotlib.ticker.Formatter
    Bases: matplotlib.ticker.TickHelper
    Create a string based on a tick value and location.
    fix_minus(self, s)
        Some classes may want to replace a hyphen for minus with the proper unicode symbol (U+2212) for typographical correctness. The default is to not replace it.
        Note, if you use this method, e.g., in format_data() or call, you probably don’t want to use it for format_data_short() since the toolbar uses this for interactive coord reporting and I doubt we can expect GUIs across platforms will handle the unicode correctly. So for now the classes that override fix_minus() should have an explicit format_data_short() method
    format_data(self, value)
        Returns the full string representation of the value with the position unspecified.
    format_data_short(self, value)
        Return a short string version of the tick value.
        Defaults to the position-independent long value.
    format_ticks(self, values)
        Return the tick labels for all the ticks at once.
    get_offset(self)
        locs = []
set_locs(self, locs)

class matplotlib.ticker.FixedFormatter(seq)
    Bases: matplotlib.ticker.Formatter
    Return fixed strings for tick labels based only on position, not value.
    Set the sequence of strings that will be used for labels.

    get_offset(self)
    set_offset_string(self, ofs)

class matplotlib.ticker.NullFormatter
    Bases: matplotlib.ticker.Formatter
    Always return the empty string.

class matplotlib.ticker.FuncFormatter(func)
    Bases: matplotlib.ticker.Formatter
    Use a user-defined function for formatting.
    The function should take in two inputs (a tick value x and a position pos), and return a
    string containing the corresponding tick label.

class matplotlib.ticker.FormatStrFormatter(fmt)
    Bases: matplotlib.ticker.Formatter
    Use an old-style ('%' operator) format string to format the tick.
    The format string should have a single variable format (%) in it. It will be applied to the
    value (not the position) of the tick.

class matplotlib.ticker.StrMethodFormatter(fmt)
    Bases: matplotlib.ticker.Formatter
    Use a new-style format string (as used by str.format()) to format the tick.
    The field used for the value must be labeled x and the field used for the position must be
    labeled pos.

class matplotlib.ticker.ScalarFormatter(useOffset=None, useMathText=None, useLocale=None)
    Bases: matplotlib.ticker.Formatter
    Format tick values as a number.
    Tick value is interpreted as a plain old number. If useOffset==True and the data range is
    much smaller than the data average, then an offset will be determined such that the tick
    labels are meaningful. Scientific notation is used for data < 10^-n or data >= 10^m, where
    n and m are the power limits set using set_powerlimits((n,m)). The defaults for these are
    controlled by the axes.formatter.limits rc parameter.

    fix_minus(self, s)
        Replace hyphens with a unicode minus.

    format_data(self, value)
        Return a formatted string representation of a number.

    format_data_short(self, value)
        Return a short formatted string representation of a number.

    get_offset(self)
        Return scientific notation, plus offset.
get_useLocale(self)
get_useMathText(self)
get_useOffset(self)
pprint_val(self, x)

[Deprecated]

Notes

Deprecated since version 3.1:

set_locs(self, locs)
Set the locations of the ticks.

set_powerlimits(self, lims)
Sets size thresholds for scientific notation.

Parameters

lims [(min_exp, max_exp)] A tuple containing the powers of 10 that
determine the switchover threshold. Numbers below 10**min_exp
and above 10**max_exp will be displayed in scientific notation.

For example, formatter.set_powerlimits((-3, 4)) sets the pre-2007
default in which scientific notation is used for numbers less than
1e-3 or greater than 1e4.

See also:

ScalarFormatter.set_scientific

set_scientific(self, b)
Turn scientific notation on or off.

See also:

ScalarFormatter.set_powerlimits

set_useLocale(self, val)
set_useMathText(self, val)
set_useOffset(self, val)
useLocale
useMathText
useOffset

class matplotlib.ticker.LogFormatter(base=10.0, labelOnlyBase=False, minor_thresholds=None, linthresh=None)

Bases: matplotlib.ticker.Formatter

Base class for formatting ticks on a log or symlog scale.

It may be instantiated directly, or subclassed.

Parameters
**base** [float, optional, default: 10.] Base of the logarithm used in all calculations.

**labelOnlyBase** [bool, optional, default: False] If True, label ticks only at integer powers of base. This is normally True for major ticks and False for minor ticks.

**minor_thresholds** [(subset, all), optional, default: (1, 0.4)] If labelOnlyBase is False, these two numbers control the labeling of ticks that are not at integer powers of base; normally these are the minor ticks. The controlling parameter is the log of the axis data range. In the typical case where base is 10 it is the number of decades spanned by the axis, so we can call it 'numdec'. If numdec <= all, all minor ticks will be labeled. If all < numdec <= subset, then only a subset of minor ticks will be labeled, so as to avoid crowding. If numdec > subset then no minor ticks will be labeled.

**linthresh** [None or float, optional, default: None] If a symmetric log scale is in use, its linthresh parameter must be supplied here.

**Notes**

The `set_locs` method must be called to enable the subsetting logic controlled by the `minor_thresholds` parameter.

In some cases such as the colorbar, there is no distinction between major and minor ticks; the tick locations might be set manually, or by a locator that puts ticks at integer powers of base and at intermediate locations. For this situation, disable the minor_thresholds logic by using `minor_thresholds=(np.inf, np.inf)`, so that all ticks will be labeled.

To disable labeling of minor ticks when 'labelOnlyBase' is False, use `minor_thresholds=(0, 0)`. This is the default for the “classic” style.

**Examples**

To label a subset of minor ticks when the view limits span up to 2 decades, and all of the ticks when zoomed in to 0.5 decades or less, use `minor_thresholds=(2, 0.5)`.

To label all minor ticks when the view limits span up to 1.5 decades, use `minor_thresholds=(1.5, 1.5)`.

```python
base(self, base)
    Change the base for labeling.
```

**Warning:** Should always match the base used for `LogLocator`.

```python
format_data(self, value)
    Returns the full string representation of the value with the position unspecified.

format_data_short(self, value)
    Return a short formatted string representation of a number.

label_minor(self, labelOnlyBase)
    Switch minor tick labeling on or off.
```
Parameters

**labelOnlyBase** [bool] If True, label ticks only at integer powers of base.

```python
def pprint_val(self, *args, **kwargs):
    [Deprecated]
```

Notes

Deprecated since version 3.1:

```python
set_locs(self, locs=None)
Use axis view limits to control which ticks are labeled.
The locs parameter is ignored in the present algorithm.
```

```python
class matplotlib.ticker.LogFormatterExponent(base=10.0, labelOnlyBase=False, minor_thresholds=None, linthresh=None)
    Bases: matplotlib.ticker.LogFormatter
Format values for log axis using exponent = log_base(value).
```

```python
class matplotlib.ticker.LogFormatterMathtext(base=10.0, labelOnlyBase=False, minor_thresholds=None, linthresh=None)
    Bases: matplotlib.ticker.LogFormatter
Format values for log axis using exponent = log_base(value).
```

```python
class matplotlib.ticker.IndexFormatter(labels)
    Bases: matplotlib.ticker.Formatter
Format the position x to the nearest i-th label where i = int(x + 0.5). Positions where
i < 0 or i > len(list) have no tick labels.
```

Parameters

**labels** [list] List of labels.

```python
class matplotlib.ticker.LogFormatterSciNotation(base=10.0, labelOnlyBase=False, minor_thresholds=None, linthresh=None)
    Bases: matplotlib.ticker.LogFormatterMathtext
Format values following scientific notation in a logarithmic axis.
```

```python
class matplotlib.ticker.LogitFormatter
    Bases: matplotlib.ticker.Formatter
Probability formatter (using Math text).
```

```python
format_data_short(self, value)
    return a short formatted string representation of a number
```

```python
class matplotlib.ticker.EngFormatter(unit='', places=None, sep=' ', *, useTex=None, useMathText=None)
    Bases: matplotlib.ticker.Formatter
Formats axis values using engineering prefixes to represent powers of 1000, plus a specified unit, e.g., 10 MHz instead of 1e7.
```

Parameters
**unit** [str (default: " ")]: Unit symbol to use, suitable for use with single-letter representations of powers of 1000. For example, ‘Hz’ or ‘m’.

**places** [int (default: None)]: Precision with which to display the number, specified in digits after the decimal point (there will be between one and three digits before the decimal point). If it is None, the formatting falls back to the floating point format ‘%g’, which displays up to 6 significant digits, i.e. the equivalent value for places varies between 0 and 5 (inclusive).

**sep** [str (default: " ")]: Separator used between the value and the prefix/unit. For example, one get ‘3.14 mV’ if sep is " " (default) and ‘3.14mV’ if sep is " "'. Besides the default behavior, some other useful options may be:

- sep="" to append directly the prefix/unit to the value;
- sep="\N{THIN SPACE}" (U+2009);
- sep="\N{NARROW NO-BREAK SPACE}" (U+202F);
- sep="\N{NO-BREAK SPACE}" (U+00A0).

**usetex** [bool (default: None)]: To enable/disable the use of TeX’s math mode for rendering the numbers in the formatter.

**useMathText** [bool (default: None)]: To enable/disable the use of mathtext for rendering the numbers in the formatter.

---

```python
def fix_minus(self, s):
    Replace hyphens with a unicode minus.

def format_eng(self, num)
    Formats a number in engineering notation, appending a letter representing the power of 1000 of the original number. Some examples:

    >>> format_eng(0)          # for self.places = 0
    '0'

    >>> format_eng(1000000)    # for self.places = 1
    '1.0 M'

    >>> format_eng("-1e-6")   # for self.places = 2
    '-1.00 µ'
```

---

**get_useMathText(self)**

**get_usetex(self)**

**set_useMathText(self, val)**

**set_usetex(self, val)**

**useMathText**

**usetex**

---

**class** matplotlib.ticker.PercentFormatter(xmax=100, decimals=None, symbol='%', is_latex=False)

Bases: matplotlib.ticker.Formatter
Format numbers as a percentage.

**Parameters**

- **xmax** [float] Determines how the number is converted into a percentage. `xmax` is the data value that corresponds to 100%. Percentages are computed as \( \frac{x}{xmax} \times 100 \). So if the data is already scaled to be percentages, `xmax` will be 100. Another common situation is where `xmax` is 1.0.

- **decimals** [None or int] The number of decimal places to place after the point. If `None` (the default), the number will be computed automatically.

- **symbol** [string or None] A string that will be appended to the label. It may be `None` or empty to indicate that no symbol should be used. LaTeX special characters are escaped in `symbol` whenever latex mode is enabled, unless `is_latex` is `True`.

- **is_latex** [bool] If `False`, reserved LaTeX characters in `symbol` will be escaped.

```python
convert_to_pct(self, x)
```

```python
format_pct(self, x, display_range)
```

Formats the number as a percentage number with the correct number of decimals and adds the percent symbol, if any.

If `self.decimals` is `None`, the number of digits after the decimal point is set based on the `display_range` of the axis as follows:

<table>
<thead>
<tr>
<th>display_range</th>
<th>decimals</th>
<th>sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;50</td>
<td>0</td>
<td>x = 34.5 \Rightarrow 35%</td>
</tr>
<tr>
<td>&gt;5</td>
<td>1</td>
<td>x = 34.5 \Rightarrow 34.5%</td>
</tr>
<tr>
<td>&gt;0.5</td>
<td>2</td>
<td>x = 34.5 \Rightarrow 34.50%</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

This method will not be very good for tiny axis ranges or extremely large ones. It assumes that the values on the chart are percentages displayed on a reasonable scale.

**symbol**

The configured percent symbol as a string.

If LaTeX is enabled via `rcParams["text.usetex"]`, the special characters `{#'', '$', '\%', '&', '~', '_', '^', '\', '{', '}`} are automatically escaped in the string.

```python
class matplotlib.ticker.Locator
    Bases: matplotlib.ticker.TickHelper

    Determine the tick locations;

    Note that the same locator should not be used across multiple `Axis` because the locator stores references to the Axis data and view limits.

    `MAXTICKS = 1000`

    `autoscale(self)`
    autoscale the view limits
```
nonsingular(self, v0, v1)
Expand a range as needed to avoid singularities.

pan(self, numsteps)
Pan numticks (can be positive or negative)

raise_if_exceeds(self, locs)
raise a RuntimeError if Locator attempts to create more than MAXTICKS locs

refresh(self)
refresh internal information based on current lim

set_params(self, **kwargs)
Do nothing, and raise a warning. Any locator class not supporting the set_params() function will call this.

tick_values(self, vmin, vmax)
Return the values of the located ticks given vmin and vmax.

Note: To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```

view_limits(self, vmin, vmax)
Select a scale for the range from vmin to vmax.
Subclasses should override this method to change locator behaviour.

zoom(self, direction)
Zoom in/out on axis; if direction is >0 zoom in, else zoom out

class matplotlib.ticker.IndexLocator(base, offset)
Bases: matplotlib.ticker.Locator

Place a tick on every multiple of some base number of points plotted, e.g., on every 5th point. It is assumed that you are doing index plotting; i.e., the axis is 0, len(data). This is mainly useful for x ticks.

place ticks on the i-th data points where (i-offset)%base==0

set_params(self, base=\texttt{None}, offset=\texttt{None})
Set parameters within this locator

tick_values(self, vmin, vmax)
Return the values of the located ticks given vmin and vmax.

Note: To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```
class matplotlib.ticker.FixedLocator(locs, nbins=None)
    Bases: matplotlib.ticker.Locator

    Tick locations are fixed. If nbins is not None, the array of possible positions will be
    subsampled to keep the number of ticks <= nbins +1. The subsampling will be done so
    as to include the smallest absolute value; for example, if zero is included in the array of
    possibilities, then it is guaranteed to be one of the chosen ticks.

    set_params(self, nbins=None)
        Set parameters within this locator.

    tick_values(self, vmin, vmax)
        "Return the locations of the ticks.

        Note: Because the values are fixed, vmin and vmax are not used in this method.

class matplotlib.ticker.NullLocator
    Bases: matplotlib.ticker.Locator

    No ticks

    tick_values(self, vmin, vmax)
        "Return the locations of the ticks.

        Note: Because the values are Null, vmin and vmax are not used in this method.

class matplotlib.ticker.LinearLocator(numticks=None, presets=None)
    Bases: matplotlib.ticker.Locator

    Determine the tick locations

    The first time this function is called it will try to set the number of ticks to make a nice tick
    partitioning. Thereafter the number of ticks will be fixed so that interactive navigation
    will be nice

    Use presets to set locs based on lom. A dict mapping vmin, vmax->locs

    set_params(self, numticks=None, presets=None)
        Set parameters within this locator.

    tick_values(self, vmin, vmax)
        Return the values of the located ticks given vmin and vmax.

        Note: To get tick locations with the vmin and vmax values defined automatically
        for the associated axis simply call the Locator instance:

        >>> print(type(loc))
        <type 'Locator'>
        >>> print(loc())
        [1, 2, 3, 4]

    view_limits(self, vmin, vmax)
        Try to choose the view limits intelligently
class matplotlib.ticker.LogLocator(base=10.0, subs=(1.0,), numdecs=4, numticks=None)

Bases: matplotlib.ticker.Locator

Determine the tick locations for log axes
Place ticks on the locations: subs[j] * base**i

Parameters
sub [None, string, or sequence of float, optional, default (1.0,)]
Gives the multiples of integer powers of the base at which to place ticks. The default places ticks only at integer powers of the base. The permitted string values are 'auto' and 'all', both of which use an algorithm based on the axis view limits to determine whether and how to put ticks between integer powers of the base. With 'auto', ticks are placed only between integer powers; with 'all', the integer powers are included. A value of None is equivalent to 'auto'.

base(self, base)
set the base of the log scaling (major tick every base**i, i integer)

nonsingular(self, vmin, vmax)
Expand a range as needed to avoid singularities.

set_params(self, base=None, subs=None, numdecs=None, numticks=None)
Set parameters within this locator.

subs(self, subs)
set the minor ticks for the log scaling every base**i*subs[j]

tick_values(self, vmin, vmax)
Return the values of the located ticks given vmin and vmax.

Note: To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```

view_limits(self, vmin, vmax)
Try to choose the view limits intelligently

class matplotlib.ticker.AutoLocator
Bases: matplotlib.ticker.MaxNLocator

Dynamically find major tick positions. This is actually a subclass of MaxNLocator, with parameters nbins = 'auto' and steps = [1, 2, 2.5, 5, 10].

To know the values of the non-public parameters, please have a look to the defaults of MaxNLocator.

class matplotlib.ticker.MultipleLocator(base=1.0)
Bases: matplotlib.ticker.Locator

Set a tick on each integer multiple of a base within the view interval.
Matplotlib, Release 3.1.1

```python
set_params(self, base)
Set parameters within this locator.

tick_values(self, vmin, vmax)
Return the values of the located ticks given vmin and vmax.

Note: To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
gt> print(type(loc))
<type 'Locator'>
gt> print(loc())
[1, 2, 3, 4]
```

view_limits(self, dmin, dmax)
Set the view limits to the nearest multiples of base that contain the data.

class matplotlib.ticker.MaxNLocator(*args, **kwargs)
Bases: matplotlib.ticker.Locator
Select no more than N intervals at nice locations.

Parameters

**nbins** [int or 'auto', optional, default: 10] Maximum number of intervals; one less than max number of ticks. If the string 'auto', the number of bins will be automatically determined based on the length of the axis.

**steps** [array-like, optional] Sequence of nice numbers starting with 1 and ending with 10; e.g., [1, 2, 4, 5, 10], where the values are acceptable tick multiples. i.e. for the example, 20, 40, 60 would be an acceptable set of ticks, as would 0.4, 0.6, 0.8, because they are multiples of 2. However, 30, 60, 90 would not be allowed because 3 does not appear in the list of steps.

**integer** [bool, optional, default: False] If True, ticks will take only integer values, provided at least min_n_ticks integers are found within the view limits.

**symmetric** [bool, optional, default: False] If True, autoscaling will result in a range symmetric about zero.

**prune** [{'lower', 'upper', 'both', None}, optional, default: None] Remove edge ticks - useful for stacked or ganged plots where the upper tick of one axes overlaps with the lower tick of the axes above it, primarily when rcParams["axes.autolimit_mode"] is 'round_numbers'. If prune=='lower', the smallest tick will be removed. If prune == 'upper', the largest tick will be removed. If prune == 'both', the largest and smallest ticks will be removed. If prune == None, no ticks will be removed.

**min_n_ticks** [int, optional, default: 2] Relax nbins and integer constraints if necessary to obtain this minimum number of ticks.

_default_params = {'integer': False, 'min_n_ticks': 2, 'nbins': 10, 'prune': None, 'steps': None}

set_params(self, **kwargs)
Set parameters for this locator.
```
Parameters

**nbins** [int or ‘auto’, optional] see *MaxNLocator*

**steps** [array-like, optional] see *MaxNLocator*

**integer** [bool, optional] see *MaxNLocator*

**symmetric** [bool, optional] see *MaxNLocator*

**prune** [{‘lower’, ‘upper’, ‘both’, None}, optional] see *MaxNLocator*

**min_n_ticks** [int, optional] see *MaxNLocator*

*tick_values*(self, vmin, vmax)

Return the values of the located ticks given *vmin* and *vmax*.

**Note:** To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```

*view_limits*(self, dmin, dmax)

Select a scale for the range from vmin to vmax.

Subclasses should override this method to change locator behaviour.

```python
class matplotlib.ticker.AutoMinorLocator(n=None)
Bases: matplotlib.ticker.Locator

Dynamically find minor tick positions based on the positions of major ticks. The scale must be linear with major ticks evenly spaced.

*n* is the number of subdivisions of the interval between major ticks; e.g., *n*=2 will place a single minor tick midway between major ticks.

If *n* is omitted or None, it will be set to 5 or 4.

*tick_values*(self, vmin, vmax)

Return the values of the located ticks given *vmin* and *vmax*.

**Note:** To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

```python
>>> print(type(loc))
<type 'Locator'>
>>> print(loc())
[1, 2, 3, 4]
```

```python
class matplotlib.ticker.SymmetricalLogLocator(transform=None, subs=None, linthresh=None, base=None)
Bases: matplotlib.ticker.Locator

Determine the tick locations for symmetric log axes

place ticks on the location= base**i*subs[j]
```
set_params(self, subs=None, numticks=None)
    Set parameters within this locator.

tick_values(self, vmin, vmax)
    Return the values of the located ticks given vmin and vmax.

    **Note:** To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

    ```
    >>> print(type(loc))
    <type 'Locator'>
    >>> print(loc())
    [1, 2, 3, 4]
    ```

view_limits(self, vmin, vmax)
    Try to choose the view limits intelligently

class matplotlib.ticker.LogitLocator(minor=False)
    Bases: matplotlib.ticker.Locator
    Determine the tick locations for logit axes
    place ticks on the logit locations

    nonsingular(self, vmin, vmax)
    Expand a range as needed to avoid singularities.

    set_params(self, minor=None)
    Set parameters within this locator.

    tick_values(self, vmin, vmax)
    Return the values of the located ticks given vmin and vmax.

    **Note:** To get tick locations with the vmin and vmax values defined automatically for the associated axis simply call the Locator instance:

    ```
    >>> print(type(loc))
    <type 'Locator'>
    >>> print(loc())
    [1, 2, 3, 4]
    ```

### 17.50 matplotlib.tight_layout

This module provides routines to adjust subplot params so that subplots are nicely fit in the figure. In doing so, only axis labels, tick labels, axes titles and offsetboxes that are anchored to axes are currently considered.

Internally, it assumes that the margins (left_margin, etc.) which are differences between ax.get_tightbbox and ax.bbox are independent of axes position. This may fail if Axes.adjustable is datalim. Also, This will fail for some cases (for example, left or right margin is affected by xlabel).
matplotlib.tight_layout.auto_adjust_subplotpars(fig, renderer, nrows_ncols, num1num2_list, subplot_list, ax_bbox_list=None, pad=1.08, h_pad=None, w_pad=None, rect=None)

Return a dict of subplot parameters to adjust spacing between subplots or None if resulting axes would have zero height or width.

Note that this function ignores geometry information of subplot itself, but uses what is given by the nrows_ncols and num1num2_list parameters. Also, the results could be incorrect if some subplots have adjustable=datalim.

Parameters

nrows_ncols [Tuple[int, int]] Number of rows and number of columns of the grid.

num1num2_list [List[int]] List of numbers specifying the area occupied by the subplot

subplot_list [list of subplots] List of subplots that will be used to calculate optimal subplot_params.

pad [float] Padding between the figure edge and the edges of subplots, as a fraction of the font size.

h_pad, w_pad [float] Padding (height/width) between edges of adjacent subplots, as a fraction of the font size. Defaults to pad.

rect [Tuple[float, float, float, float]] [left, bottom, right, top] in normalized (0, 1) figure coordinates.

matplotlib.tight_layout.get_renderer(fig)

matplotlib.tight_layout.get_subplotspec_list(axes_list, grid_spec=None)

Return a list of subplotspec from the given list of axes.

For an instance of axes that does not support subplotspec, None is inserted in the list.

If grid_spec is given, None is inserted for those not from the given grid_spec.

matplotlib.tight_layout.get_tight_layout_figure(fig, axes_list, subplotspec_list, renderer, pad=1.08, h_pad=None, w_pad=None, rect=None)

Return subplot parameters for tight-layouted-figure with specified padding.

Parameters

fig [Figure]

axes_list [list of Axes]

subplotspec_list [list of SubplotSpec] The subplotspecs of each axes.

renderer [renderer]

pad [float] Padding between the figure edge and the edges of subplots, as a fraction of the font size.

h_pad, w_pad [float] Padding (height/width) between edges of adjacent subplots. Defaults to pad.

rect [Tuple[float, float, float, float], optional] (left, bottom, right, top) rectangle in normalized figure coordinates that the whole subplots area (including labels) will fit into. Defaults to using the entire figure.
Returns

```
subplotspec or None subplotspec kwargs to be passed to Figure.
subplots_adjust or None if tight_layout could not be accomplished.
```

### 17.51 matplotlib.transforms

Matplotlib includes a framework for arbitrary geometric transformations that is used to determine the final position of all elements drawn on the canvas.

Transforms are composed into trees of `TransformNode` objects whose actual value depends on their children. When the contents of children change, their parents are automatically invalidated. The next time an invalidated transform is accessed, it is recomputed to reflect those changes. This invalidation/caching approach prevents unnecessary recomputations of transforms, and contributes to better interactive performance.

For example, here is a graph of the transform tree used to plot data to the graph:
The framework can be used for both affine and non-affine transformations. However, for speed, we want use the backend renderers to perform affine transformations whenever possible. Therefore, it is possible to perform just the affine or non-affine part of a transformation on a set of data. The affine is always assumed to occur after the non-affine. For any transform:

\[
\text{full transform} = \text{non-affine part} + \text{affine part}
\]

The backends are not expected to handle non-affine transformations themselves.
A mutable 2D affine transformation.

Initialize an Affine transform from a 3x3 numpy float array:

```
a c e
b d f
0 0 1
```

If `matrix` is None, initialize with the identity transform.

**clear(self)**
Reset the underlying matrix to the identity transform.

**static from_values(a, b, c, d, e, f)**
Create a new Affine2D instance from the given values:

```
a c e
b d f
0 0 1
```

**get_matrix(self)**
Get the underlying transformation matrix as a 3x3 numpy array:

```
a c e
b d f
0 0 1
```

**static identity()**
Return a new `Affine2D` object that is the identity transform.

Unless this transform will be mutated later on, consider using the faster `IdentityTransform` class instead.

**rotate(self, theta)**
Add a rotation (in radians) to this transform in place.

Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.

**rotate_around(self, x, y, theta)**
Add a rotation (in radians) around the point (x, y) in place.

Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.

**rotate_deg(self, degrees)**
Add a rotation (in degrees) to this transform in place.

Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.

**rotate_deg_around(self, x, y, degrees)**
Add a rotation (in degrees) around the point (x, y) in place.
Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.

```python
def scale(self, sx, sy=None):
    Adds a scale in place.
    If `sy` is None, the same scale is applied in both the x- and y-directions.
    Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.
```

```python
def set(self, other):
    Set this transformation from the frozen copy of another `Affine2DBase` object.
```

```python
def set_matrix(self, mtx):
    Set the underlying transformation matrix from a 3x3 numpy array:
```

```python
def skew(self, xShear, yShear):
    Adds a skew in place.
    `xShear` and `yShear` are the shear angles along the x- and y-axes, respectively, in radians.
    Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.
```

```python
def skew_deg(self, xShear, yShear):
    Adds a skew in place.
    `xShear` and `yShear` are the shear angles along the x- and y-axes, respectively, in degrees.
    Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.
```

```python
def translate(self, tx, ty):
    Adds a translation in place.
    Returns `self`, so this method can easily be chained with more calls to `rotate()`, `rotate_deg()`, `translate()` and `scale()`.
```

```python
class matplotlib.transforms.Affine2DBase(*args, **kwargs):
    Bases: matplotlib.transforms.AffineBase
    The base class of all 2D affine transformations.
    2D affine transformations are performed using a 3x3 numpy array:
```

```python
    a c e
    b d f
    0 0 1
```

This class provides the read-only interface. For a mutable 2D affine transformation, use `Affine2D`.

Subclasses of this class will generally only need to override a constructor and `get_matrix()` that generates a custom 3x3 matrix.
frozen(self)
   Returns a frozen copy of this transform node. The frozen copy will not update when
   its children change. Useful for storing a previously known state of a transform
   where copy.deepcopy() might normally be used.

has_inverse = True
input_dims = 2

inverted(self)
   Return the corresponding inverse transformation.
   The return value of this method should be treated as temporary. An update to self
   does not cause a corresponding update to its inverted copy.
   
   \[ x \equiv self.inverted().transform(self.transform(x)) \]

is_separable
   bool(x) -> bool
   Returns True when the argument x is true, False otherwise. The builtins True and
   False are the only two instances of the class bool. The class bool is a subclass of
   the class int, and cannot be subclassed.

static matrix_from_values(a, b, c, d, e, f)
   (staticmethod) Create a new transformation matrix as a 3x3 numpy array of the
   form:

   \[
   \begin{bmatrix}
   a & c & e \\
   b & d & f \\
   0 & 0 & 1
   \end{bmatrix}
   \]

output_dims = 2

to_values(self)
   Return the values of the matrix as an (a, b, c, d, e, f) tuple.

transform_affine(self, points)
   Performs only the affine part of this transformation on the given array of values.
   transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
   In non-affine transformations, this is generally a no-op. In affine transformations,
   this is equivalent to transform(values).
   Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape
   (N x output_dims).
   Alternatively, accepts a numpy array of length input_dims and returns a numpy array
   of length output_dims.

transform_point(self, point)
   A convenience function that returns the transformed copy of a single point.
   The point is given as a sequence of length input_dims. The transformed point is
   returned as a sequence of length output_dims.

class matplotlib.transforms.AffineBase(*args, **kwargs)
   Bases: matplotlib.transforms.Transform
   The base class of all affine transformations of any number of dimensions.

get_affine(self)
   Get the affine part of this transform.
is_affine = True

transform(self, values)
Performs the transformation on the given array of values.
Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).
Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_affine(self, values)
Performs only the affine part of this transformation on the given array of values.

In non-affine transformations, this is generally a no-op. In affine transformations, this is equivalent to transform(values).

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).
Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_non_affine(self, points)
Performs only the non-affine part of the transformation.

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).
Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_path(self, path)
Returns a transformed path.

path: a Path instance.

In some cases, this transform may insert curves into the path that began as line segments.

transform_path_affine(self, path)
Returns a path, transformed only by the affine part of this transform.

path: a Path instance.

transform_path affine(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).

transform_path_non_affine(self, path)
Returns a path, transformed only by the non-affine part of this transform.

path: a Path instance.

transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).

class matplotlib.transforms.Bbox(points, **kwargs)

Bases: matplotlib.transforms.BboxBase

A mutable bounding box.
Parameters

points [ndarray] A 2x2 numpy array of the form \([x_0, y_0], [x_1, y_1]\).

Notes

If you need to create a Bbox object from another form of data, consider the static methods
unit(), from_bounds() and from_extents().

bounds
Return \((x_0, y_0, width, height)\).

static from_bounds(x0, y0, width, height)
(staticmethod) Create a new Bbox from \(x_0, y_0, width\) and \(height\).
width and height may be negative.

static from_extents(*args)
(staticmethod) Create a new Bbox from \(left, bottom, right\) and \(top\).
The y-axis increases upwards.

get_points(self)
Get the points of the bounding box directly as a numpy array of the form:
\([[x_0, y_0], [x_1, y_1]]\).

ignore(self, value)
Set whether the existing bounds of the box should be ignored by subsequent calls
to update_from_data_xy().

value [bool]
- When True, subsequent calls to update_from_data_xy() will ignore the exist-
ing bounds of the Bbox.
- When False, subsequent calls to update_from_data_xy() will include the ex-
sting bounds of the Bbox.

intervalx
The pair of x coordinates that define the bounding box.
This is not guaranteed to be sorted from left to right.

intervaly
The pair of y coordinates that define the bounding box.
This is not guaranteed to be sorted from bottom to top.

minpos
minposx
minposy

mutated(self)
Return whether the bbox has changed since init.

mutatedx(self)
Return whether the x-limits have changed since init.

mutatedy(self)
Return whether the y-limits have changed since init.
static null()
    (staticmethod) Create a new null Bbox from (inf, inf) to (-inf, -inf).

p0
    The first pair of (x, y) coordinates that define the bounding box.
    This is not guaranteed to be the bottom-left corner (for that, use min).

p1
    The second pair of (x, y) coordinates that define the bounding box.
    This is not guaranteed to be the top-right corner (for that, use max).

set(self, other)
    Set this bounding box from the “frozen” bounds of another Bbox.

set_points(self, points)
    Set the points of the bounding box directly from a numpy array of the form: [[x0, y0], [x1, y1]]. No error checking is performed, as this method is mainly for internal use.

static unit()
    (staticmethod) Create a new unit Bbox from (0, 0) to (1, 1).

update_from_data_xy(self, xy, ignore=None, updatex=True, updatey=True)
    Update the bounds of the Bbox based on the passed in data. After updating, the bounds will have positive width and height; x0 and y0 will be the minimal values.

Parameters

xy [ndarray] A numpy array of 2D points.
ignore [bool, optional]
    • When True, ignore the existing bounds of the Bbox.
    • When False, include the existing bounds of the Bbox.
    • When None, use the last value passed to ignore().
updatex, updatey [bool, optional] When True, update the x/y values.

update_from_path(self, path, ignore=None, updatex=True, updatey=True)
    Update the bounds of the Bbox based on the passed in data. After updating, the bounds will have positive width and height; x0 and y0 will be the minimal values.

Parameters

path [Path]
ignore [bool, optional]
    • when True, ignore the existing bounds of the Bbox.
    • when False, include the existing bounds of the Bbox.
    • when None, use the last value passed to ignore().
updatex, updatey [bool, optional] When True, update the x/y values.

x0
    The first of the pair of x coordinates that define the bounding box.
    This is not guaranteed to be less than x1 (for that, use xmin).
x1
The second of the pair of x coordinates that define the bounding box.
This is not guaranteed to be greater than x0 (for that, use xmax).

y0
The first of the pair of y coordinates that define the bounding box.
This is not guaranteed to be less than y1 (for that, use ymin).

y1
The second of the pair of y coordinates that define the bounding box.
This is not guaranteed to be greater than y0 (for that, use ymax).

class matplotlib.transforms.BboxBase(shorthand_name=None)
   Bases: matplotlib.transforms.TransformNode
   This is the base class of all bounding boxes, and provides read-only access to its data. A
   mutable bounding box is provided by the Bbox class.
   The canonical representation is as two points, with no restrictions on their ordering.
   Convenience properties are provided to get the left, bottom, right and top edges and
   width and height, but these are not stored explicitly.
   Creates a new TransformNode.

Parameters
   shorthand_name [str] A string representing the “name” of the transform. The name carries no
   significance other than to improve the readability of str(transform) when DEBUG=True.

anchored(self, c, container=None)
   Return a copy of the Bbox, shifted to position c within a container.

Parameters
   c [(float, float) or str] May be either:
   • A sequence (cx, cy) where cx and cy range from 0 to 1, where 0
     is left or bottom and 1 is right or top
   • a string: - 'C' for centered - 'S' for bottom-center - 'SE' for bottom-
     left - 'E' for left - etc.
   container [Bbox, optional] The box within which the Bbox is positioned; it defaults to the initial Bbox.

bounds
   Return (x0, y0, width, height).

coeffs = {'C': (0.5, 0.5), 'E': (1.0, 0.5), 'N': (0.5, 1.0), 'NE': (1.0, 1.0), 'NW': (0, 1.0), 'S':
contains(self, x, y)
   Return whether (x, y) is in the bounding box or on its edge.

containsx(self, x)
   Return whether x is in the closed (x0, x1) interval.

containsy(self, y)
   Return whether y is in the closed (y0, y1) interval.

corners(self)
   Return the corners of this rectangle as an array of points.
Specifically, this returns the array $[[x_0, y_0], [x_0, y_1], [x_1, y_0], [x_1, y_1]]$.

count_contains(self, vertices)
Count the number of vertices contained in the Bbox. Any vertices with a non-finite x or y value are ignored.

Parameters

vertices [Nx2 Numpy array.]

count_overlaps(self, bboxes)
Count the number of bounding boxes that overlap this one.

Parameters

bboxes [sequence of BboxBase objects]

expanded(self, sw, sh)
Construct a Bbox by expanding this one around its center by the factors sw and sh.

extents
Return $(x_0, y_0, x_1, y_1)$.

frozen(self)
TransformNode is the base class for anything that participates in the transform tree and needs to invalidate its parents or be invalidated. This includes classes that are not really transforms, such as bounding boxes, since some transforms depend on bounding boxes to compute their values.

fully_contains(self, x, y)
Return whether $x$, $y$ is in the bounding box, but not on its edge.

fully_containsx(self, x)
Return whether $x$ is in the open $(x_0, x_1)$ interval.

fully_containsy(self, y)
Return whether $y$ is in the open $(y_0, y_1)$ interval.

fully_overlaps(self, other)
Return whether this bounding box overlaps with the other bounding box, not including the edges.

Parameters

other [BboxBase]

get_points(self)
height
The (signed) height of the bounding box.

static intersection(bbox1, bbox2)
Return the intersection of bbox1 and bbox2 if they intersect, or None if they don’t.

intervalx
The pair of x coordinates that define the bounding box.
This is not guaranteed to be sorted from left to right.

intervaly
The pair of y coordinates that define the bounding box.
This is not guaranteed to be sorted from bottom to top.
inverse_transformed(self, transform)
    Construct a $Bbox$ by statically transforming this one by the inverse of $transform$.

is_affine = True
is_bbox = True
is_unit(self)
    Return whether this is the unit box (from (0, 0) to (1, 1)).

max
    The top-right corner of the bounding box.

min
    The bottom-left corner of the bounding box.

overlaps(self, other)
    Return whether this bounding box overlaps with the other bounding box.

    Parameters
    other [BboxBase]

p0
    The first pair of ($x$, $y$) coordinates that define the bounding box.
    This is not guaranteed to be the bottom-left corner (for that, use $min$).

p1
    The second pair of ($x$, $y$) coordinates that define the bounding box.
    This is not guaranteed to be the top-right corner (for that, use $max$).

padded(self, p)
    Construct a $Bbox$ by padding this one on all four sides by $p$.

rotated(self, radians)
    Return a new bounding box that bounds a rotated version of this bounding box by
    the given radians. The new bounding box is still aligned with the axes, of course.

shrunk(self, mx, my)
    Return a copy of the $Bbox$, shrunk by the factor $mx$ in the $x$ direction and the factor
    $my$ in the $y$ direction. The lower left corner of the box remains unchanged. Normally
    $mx$ and $my$ will be less than 1, but this is not enforced.

shrunk_to_aspect(self, box_aspect, container=None, fig_aspect=1.0)
    Return a copy of the $Bbox$, shrunk so that it is as large as it can be while having
    the desired aspect ratio, $box_aspect$. If the box coordinates are relative—that is,
    fractions of a larger box such as a figure—then the physical aspect ratio of that
    figure is specified with $fig_aspect$, so that $box_aspect$ can also be given as a ratio of
    the absolute dimensions, not the relative dimensions.

size
    The (signed) width and height of the bounding box.

splitx(self, *args)
    Return a list of new $Bbox$ objects formed by splitting the original one with vertical
    lines at fractional positions given by $args$.

splity(self, *args)
    Return a list of new $Bbox$ objects formed by splitting the original one with horizontal
    lines at fractional positions given by $args$. 
transformed(self, transform)
    Construct a Bbox by statically transforming this one by transform.

translated(self, tx, ty)
    Construct a Bbox by translating this one by tx and ty.

static union(bboxes)
    Return a Bbox that contains all of the given bboxes.

width
    The (signed) width of the bounding box.

x0
    The first of the pair of x coordinates that define the bounding box.
    This is not guaranteed to be less than x1 (for that, use xmin).

x1
    The second of the pair of x coordinates that define the bounding box.
    This is not guaranteed to be greater than x0 (for that, use xmax).

xmax
    The right edge of the bounding box.

xmin
    The left edge of the bounding box.

y0
    The first of the pair of y coordinates that define the bounding box.
    This is not guaranteed to be less than y1 (for that, use ymin).

y1
    The second of the pair of y coordinates that define the bounding box.
    This is not guaranteed to be greater than y0 (for that, use ymax).

ymax
    The top edge of the bounding box.

ymin
    The bottom edge of the bounding box.
class matplotlib.transforms.BboxTransformTo(boxout, **kwargs)
    Bases: matplotlib.transforms.Affine2DBase

BboxTransformTo is a transformation that linearly transforms points from the unit bounding box to a given Bbox.

Create a new BboxTransformTo that linearly transforms points from the unit bounding box to boxout.

get_matrix(self)
    Get the Affine transformation array for the affine part of this transform.

is_separable = True

class matplotlib.transforms.BboxTransformToMaxOnly(boxout, **kwargs)
    Bases: matplotlib.transforms.BboxTransformTo

BboxTransformTo is a transformation that linearly transforms points from the unit bounding box to a given Bbox with a fixed upper left of (0, 0).

Create a new BboxTransformTo that linearly transforms points from the unit bounding box to boxout.

get_matrix(self)
    Get the Affine transformation array for the affine part of this transform.

class matplotlib.transforms.BlendedAffine2D(x_transform, y_transform, **kwargs)
    Bases: matplotlib.transforms.Affine2DBase

A "blended" transform uses one transform for the x-direction, and another transform for the y-direction.

This version is an optimization for the case where both child transforms are of type Affine2DBase.

Create a new "blended" transform using x_transform to transform the x-axis and y_transform to transform the y-axis.

Both x_transform and y_transform must be 2D affine transforms.

You will generally not call this constructor directly but use the blended_transform_factory() function instead, which can determine automatically which kind of blended transform to create.

contains_branch_seperately(self, transform)
    Returns whether the given branch is a sub-tree of this transform on each separate dimension.

    A common use for this method is to identify if a transform is a blended transform containing an axes' data transform. e.g.:

    x_isdata, y_isdata = trans.contains_branch_seperately(ax.transData)

get_matrix(self)
    Get the Affine transformation array for the affine part of this transform.

is_separable = True

class matplotlib.transforms.BlendedGenericTransform(x_transform, y_transform, **kwargs)
    Bases: matplotlib.transforms.Transform

A "blended" transform uses one transform for the x-direction, and another transform for the y-direction.
This “generic” version can handle any given child transform in the x- and y-directions.

Create a new “blended” transform using `x_transform` to transform the x-axis and `y_transform` to transform the y-axis.

You will generally not call this constructor directly but use the `blended_transform_factory()` function instead, which can determine automatically which kind of blended transform to create.

```python
contains_branch(self, other)
```

Return whether the given transform is a sub-tree of this transform.

This routine uses transform equality to identify sub-trees, therefore in many situations it is object id which will be used.

For the case where the given transform represents the whole of this transform, returns True.

```python
contains_branch_seperately(self, transform)
```

Returns whether the given branch is a sub-tree of this transform on each separate dimension.

A common use for this method is to identify if a transform is a blended transform containing an axes’ data transform. e.g.:

```python
x_isdata, y_isdata = trans.contains_branch_seperately(ax.transData)
```

```python
depth
```

Returns the number of transforms which have been chained together to form this Transform instance.

**Note:** For the special case of a Composite transform, the maximum depth of the two is returned.

```python
frozen(self)
```

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where `copy.deepcopy()` might normally be used.

```python
get_affine(self)
```

Get the affine part of this transform.

```python
has_inverse
```

```python
input_dims = 2
```

```python
inverted(self)
```

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to `self` does not cause a corresponding update to its inverted copy.

```python
x == self.inverted().transform(self.transform(x))
```

```python
is_affine
```

```python
is_separable = True
```

```python
output_dims = 2
```

```python
pass_through = True
```
transform_non_affine(self, points)

Performs only the non-affine part of the transformation.

transform(values) is always equivalent to transform_affine(transform_non_affine(values)).

In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.

Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).

Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

class matplotlib.transforms.CompositeAffine2D(a, b, **kwargs)

Bases: matplotlib.transforms.Affine2DBase

A composite transform formed by applying transform a then transform b.

This version is an optimization that handles the case where both a and b are 2D affines.

Create a new composite transform that is the result of applying transform a then transform b.

Both a and b must be instances of Affine2DBase.

You will generally not call this constructor directly but use the composite_transform_factory() function instead, which can automatically choose the best kind of composite transform instance to create.

def depth(self)

Returns the number of transforms which have been chained together to form this Transform instance.

**Note:** For the special case of a Composite transform, the maximum depth of the two is returned.

class matplotlib.transforms.CompositeGenericTransform(a, b, **kwargs)

Bases: matplotlib.transforms.Transform

A composite transform formed by applying transform a then transform b.

This "generic" version can handle any two arbitrary transformations.

Create a new composite transform that is the result of applying transform a then transform b.

You will generally not call this constructor directly but use the composite_transform_factory() function instead, which can automatically choose the best kind of composite transform instance to create.

def depth(self)

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where copy.deepcopy() might normally be used.
get_affine(self)
Get the affine part of this transform.

has_inverse
inverted(self)
Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.

\[ x \rightarrow self.inversed().transform(self.transform(x)) \]

is_affine
is_separable
pass_through = True

transform_affine(self, points)
Performs only the affine part of this transformation on the given array of values.

\[ \text{transform(values)} \text{ is always equivalent to transform_affine(transform_non_affine(values))}. \]

In non-affine transformations, this is generally a no-op. In affine transformations,
this is equivalent to \( \text{transform(values)} \).

Accepts a numpy array of shape \((N \times \text{input_dims})\) and returns a numpy array of shape
\((N \times \text{output_dims})\).

Alternatively, accepts a numpy array of length \(\text{input_dims}\) and returns a numpy array
of length \(\text{output_dims}\).

transform_non_affine(self, points)
Performs only the non-affine part of the transformation.

\[ \text{transform(values)} \text{ is always equivalent to transform_affine(transform_non_affine(values))}. \]

In non-affine transformations, this is generally equivalent to \(\text{transform(values)}\). In
affine transformations, this is always a no-op.

Accepts a numpy array of shape \((N \times \text{input_dims})\) and returns a numpy array of shape
\((N \times \text{output_dims})\).

Alternatively, accepts a numpy array of length \(\text{input_dims}\) and returns a numpy array
of length \(\text{output_dims}\).

transform_path_non_affine(self, path)
Returns a path, transformed only by the non-affine part of this transform.

\[ \text{path: a Path instance}. \]

\[ \text{transform_path(path)} \text{ is equivalent to transform_path_affine(transform_path_non_affine(values))}. \]

class matplotlib.transforms.IdentityTransform(*args, **kwargs)
Bases: matplotlib.transforms.Affine2DBase

A special class that does one thing, the identity transform, in a fast way.

frozen(self)
Returns a frozen copy of this transform node. The frozen copy will not update when
its children change. Useful for storing a previously known state of a transform
where copy.deepcopy() might normally be used.

gt_affine(self)
Get the affine part of this transform.
get_matrix(self)
    Get the Affine transformation array for the affine part of this transform.

inverted(self)
    Return the corresponding inverse transformation.
    The return value of this method should be treated as temporary. An update to self
does not cause a corresponding update to its inverted copy.
    
x === self.inverted().transform(self.transform(x))

transform(self, points)
    Performs the transformation on the given array of values.
    Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape
    (N x output_dims).
    Alternatively, accepts a numpy array of length input_dims and returns a numpy array
    of length output_dims.

transform_affine(self, points)
    Performs only the affine part of this transformation on the given array of values.
    transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
    In non-affine transformations, this is generally a no-op. In affine transformations,
    this is equivalent to transform(values).
    Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape
    (N x output_dims).
    Alternatively, accepts a numpy array of length input_dims and returns a numpy array
    of length output_dims.

transform_non_affine(self, points)
    Performs only the non-affine part of the transformation.
    transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
    In non-affine transformations, this is generally equivalent to transform(values). In
    affine transformations, this is always a no-op.
    Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape
    (N x output_dims).
    Alternatively, accepts a numpy array of length input_dims and returns a numpy array
    of length output_dims.

transform_path(self, path)
    Returns a transformed path.
    path: a Path instance.
    In some cases, this transform may insert curves into the path that began as line
    segments.

transform_path_affine(self, path)
    Returns a path, transformed only by the affine part of this transform.
    path: a Path instance.
    transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).

transform_path_non_affine(self, path)
    Returns a path, transformed only by the non-affine part of this transform.
**path**: a `Path` instance.

`transform_path(path)` is equivalent to `transform_path_affine(transform_path_non_affine(values))`.

class `matplotlib.transforms.LockableBbox(bbox, x0=None, y0=None, x1=None, y1=None, **kwargs)`

Bases: `matplotlib.transforms.BboxBase`

A `Bbox` where some elements may be locked at certain values.

When the child bounding box changes, the bounds of this bbox will update accordingly with the exception of the locked elements.

**Parameters**

- `bbox` [Bbox] The child bounding box to wrap.
- `x0` [float or None] The locked value for x0, or None to leave unlocked.
- `y0` [float or None] The locked value for y0, or None to leave unlocked.
- `x1` [float or None] The locked value for x1, or None to leave unlocked.
- `y1` [float or None] The locked value for y1, or None to leave unlocked.

get_points(self)

locked_x0
  float or None: The value used for the locked x0.

locked_x1
  float or None: The value used for the locked x1.

locked_y0
  float or None: The value used for the locked y0.

locked_y1
  float or None: The value used for the locked y1.

class `matplotlib.transforms.ScaledTranslation(xt, yt, scale_trans, **kwargs)`

Bases: `matplotlib.transforms.Affine2DBase`

A transformation that translates by `xt` and `yt`, after `xt` and `yt` have been transformed by `scale_trans`.

get_matrix(self)

  Get the Affine transformation array for the affine part of this transform.

class `matplotlib.transforms.Transform(shorthand_name=None)`

Bases: `matplotlib.transforms.TransformNode`

The base class of all `TransformNode` instances that actually perform a transformation.

All non-affine transformations should be subclasses of this class. New affine transformations should be subclasses of `Affine2D`.

Subclasses of this class should override the following members (at minimum):

- `input_dims`
- `output_dims`
- `transform()`
- `is_separable`
- `has_inverse`
• `inverted()` (if `has_inverse` is True)

If the transform needs to do something non-standard with `matplotlib.path.Path` objects, such as adding curves where there were once line segments, it should override:

• `transform_path()`

Creates a new `TransformNode`.

**Parameters**

`shorthand_name` [str] A string representing the “name” of the transform. The name carries no significance other than to improve the readability of `str(transform)` when `DEBUG=True`.

`contains_branch(self, other)`

Return whether the given transform is a sub-tree of this transform.

This routine uses transform equality to identify sub-trees, therefore in many situations it is object id which will be used.

For the case where the given transform represents the whole of this transform, returns True.

`contains_branch_seperately(self, other_transform)`

Returns whether the given branch is a sub-tree of this transform on each separate dimension.

A common use for this method is to identify if a transform is a blended transform containing an axes’ data transform. e.g.:

```python
x_isdata, y_isdata = trans.contains_branch_seperately(ax.transData)
```

`depth`  

Returns the number of transforms which have been chained together to form this Transform instance.

**Note:** For the special case of a Composite transform, the maximum depth of the two is returned.

`get_affine(self)`

Get the affine part of this transform.

`get_matrix(self)`

Get the Affine transformation array for the affine part of this transform.

`has_inverse = False`

True if this transform has a corresponding inverse transform.

`input_dims = None`

The number of input dimensions of this transform. Must be overridden (with integers) in the subclass.

`inverted(self)`

Return the corresponding inverse transformation.

The return value of this method should be treated as temporary. An update to `self` does not cause a corresponding update to its inverted copy.

```python
x == self.inverted().transform(self.transform(x))
```
is_separable = False
    True if this transform is separable in the x- and y- dimensions.

output_dims = None
    The number of output dimensions of this transform. Must be overridden (with integers) in the subclass.

transform(self, values)
    Performs the transformation on the given array of values.
    Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).
    Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_affine(self, values)
    Performs only the affine part of this transformation on the given array of values.
    transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
    In non-affine transformations, this is generally a no-op. In affine transformations, this is equivalent to transform(values).
    Accepts a numpy array of shape (N x input_dims) and returns a numpy array of shape (N x output_dims).
    Alternatively, accepts a numpy array of length input_dims and returns a numpy array of length output_dims.

transform_angles(self, angles, pts, radians=False, pushoff=1e-05)
    Transforms a set of angles anchored at specific locations.

    Parameters
    angles [(N,) array-like] The angles to transform.
    pts [(N, 2) array-like] The points where the angles are anchored.
    radians [bool, default: False] Whether angles are radians or degrees.
    pushoff [float] For each point in pts and angle in angles, the transformed angle is computed by transforming a segment of length pushoff starting at that point and making that angle relative to the horizontal axis, and measuring the angle between the horizontal axis and the transformed segment.

    Returns
    transformed_angles [(N,) array]

transform_bbox(self, bbox)
    Transform the given bounding box.
    Note, for smarter transforms including caching (a common requirement for matplotlib figures), see TransformedBbox.

transform_non_affine(self, values)
    Performs only the non-affine part of the transformation.
    transform(values) is always equivalent to transform_affine(transform_non_affine(values)).
    In non-affine transformations, this is generally equivalent to transform(values). In affine transformations, this is always a no-op.
Accepts a numpy array of shape \((N \times \text{input_dims})\) and returns a numpy array of shape \((N \times \text{output_dims})\).
Alternatively, accepts a numpy array of length \(\text{input_dims}\) and returns a numpy array of length \(\text{output_dims}\).

\[
\text{transform_path}(\text{self, path})
\]
Returns a transformed path.
\[
\text{path: a Path instance.}
\]
In some cases, this transform may insert curves into the path that began as line segments.

\[
\text{transform_path_affine}(\text{self, path})
\]
Returns a path, transformed only by the affine part of this transform.
\[
\text{path: a Path instance.}
\]
\[
\text{transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).}
\]

\[
\text{transform_path_non_affine}(\text{self, path})
\]
Returns a path, transformed only by the non-affine part of this transform.
\[
\text{path: a Path instance.}
\]
\[
\text{transform_path(path) is equivalent to transform_path_affine(transform_path_non_affine(values)).}
\]

\[
\text{transform_point}(\text{self, point})
\]
A convenience function that returns the transformed copy of a single point.
The point is given as a sequence of length \(\text{input_dims}\). The transformed point is returned as a sequence of length \(\text{output_dims}\).

\[
\text{class matplotlib.transforms.TransformNode(\text{shorthand_name=None})}
\]
\[
\text{Bases: object}
\]

\[
\text{TransformNode is the base class for anything that participates in the transform tree and needs to invalidate its parents or be invalidated. This includes classes that are not really transforms, such as bounding boxes, since some transforms depend on bounding boxes to compute their values.}
\]

\[
\text{Creates a new TransformNode.}
\]

**Parameters**

\[
\text{shorthand_name [str] A string representing the “name” of the transform. The name carries no significance other than to improve the readability of str(transform) when DEBUG=True.}
\]

\[
\text{INVALID = 3}
\]

\[
\text{INVALID_AFFINE = 2}
\]

\[
\text{INVALID_NON_AFFINE = 1}
\]

\[
\text{frozen(self)}
\]
Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where \text{copy.deepcopy()} might normally be used.

\[
\text{invalidate(self)}
\]
Invalidates this TransformNode and triggers an invalidation of its ancestors. Should be called any time the transform changes.
is_affine = False

is_bbox = False

pass_through = False

If pass_through is True, all ancestors will always be invalidated, even if ‘self’ is already invalid.

set_children(self, *children)

Set the children of the transform, to let the invalidation system know which transforms can invalidate this transform. Should be called from the constructor of any transforms that depend on other transforms.

class matplotlib.transforms.TransformWrapper(child)

Bases: matplotlib.transforms.Transform

A helper class that holds a single child transform and acts equivalently to it.

This is useful if a node of the transform tree must be replaced at run time with a transform of a different type. This class allows that replacement to correctly trigger invalidation.

Note that TransformWrapper instances must have the same input and output dimensions during their entire lifetime, so the child transform may only be replaced with another child transform of the same dimensions.

child: A class:Transform instance. This child may later be replaced with set().

frozen(self)

Returns a frozen copy of this transform node. The frozen copy will not update when its children change. Useful for storing a previously known state of a transform where copy.deepcopy() might normally be used.

has_inverse

is_affine

is_separable

pass_through = True

set(self, child)

Replace the current child of this transform with another one.

The new child must have the same number of input and output dimensions as the current child.

class matplotlib.transforms.TransformedBbox(bbox, transform, **kwargs)

Bases: matplotlib.transforms.BboxBase

A Bbox that is automatically transformed by a given transform. When either the child bounding box or transform changes, the bounds of this bbox will update accordingly.

Parameters

bbox [Bbox]

transform [Transform]

g get_points(self)

class matplotlib.transforms.TransformedPatchPath(patch)

Bases: matplotlib.transforms.TransformedPath
A `TransformedPatchPath` caches a non-affine transformed copy of the `Path`. This cached copy is automatically updated when the non-affine part of the transform or the patch changes.

Create a new `TransformedPatchPath` from the given `Path`.

```python
class matplotlib.transforms.TransformedPath(path, transform)
```

Bases: `matplotlib.transforms.TransformNode`

A `TransformedPath` caches a non-affine transformed copy of the `Path`. This cached copy is automatically updated when the non-affine part of the transform changes.

**Note:** Paths are considered immutable by this class. Any update to the path’s vertices/codes will not trigger a transform recomputation.

Create a new `TransformedPath` from the given `Path` and `Transform`.

```python
def get_affine(self)
def get_fully_transformed_path(self)
    Return a fully-transformed copy of the child path.

def get_transformed_path_and_affine(self)
    Return a copy of the child path, with the non-affine part of the transform already applied, along with the affine part of the path necessary to complete the transformation.

def get_transformed_points_and_affine(self)
    Return a copy of the child path, with the non-affine part of the transform already applied, along with the affine part of the path necessary to complete the transformation. Unlike `get_transformed_path_and_affine()`, no interpolation will be performed.
```

```python
matplotlib.transforms.blended_transform_factory(x_transform, y_transform)
```

Create a new “blended” transform using `x_transform` to transform the x-axis and `y_transform` to transform the y-axis.

A faster version of the blended transform is returned for the case where both child transforms are affine.

```python
matplotlib.transforms.composite_transform_factory(a, b)
```

Create a new composite transform that is the result of applying transform `a` then transform `b`.

Shortcut versions of the blended transform are provided for the case where both child transforms are affine, or one or the other is the identity transform.

Composite transforms may also be created using the ‘+’ operator, e.g.:

```python
c = a + b
```

```python
matplotlib.transforms.interval_contains(interval, val)
```

Check, inclusively, whether an interval includes a given value.

**Parameters**

- `interval` [sequence of scalar] A 2-length sequence, endpoints that define the interval.
- `val` [scalar] Value to check is within interval.

**Returns**
bool Returns True if given val is within the interval.

matplotlib.transforms.interval_contains_open(interval, val)
  Check, excluding endpoints, whether an interval includes a given value.

Parameters
interval [sequence of scalar] A 2-length sequence, endpoints that define the interval.
val [scalar] Value to check is within interval.

Returns
bool Returns true if given val is within the interval.

matplotlib.transforms.nonsingular(vmin, vmax, expander=0.001, tiny=1e-15, increasing=True)
  Modify the endpoints of a range as needed to avoid singularities.

Parameters
vmin, vmax [float] The initial endpoints.
expander [float, optional, default: 0.001] Fractional amount by which vmin and vmax are expanded if the original interval is too small, based on tiny.
tiny [float, optional, default: 1e-15] Threshold for the ratio of the interval to the maximum absolute value of its endpoints. If the interval is smaller than this, it will be expanded. This value should be around 1e-15 or larger; otherwise the interval will be approaching the double precision resolution limit.
increasing [bool, optional, default: True] If True, swap vmin, vmax if vmin > vmax.

Returns
vmin, vmax [float] Endpoints, expanded and/or swapped if necessary. If either input is inf or NaN, or if both inputs are 0 or very close to zero, it returns -expander, expander.

matplotlib.transforms.offset_copy(trans, fig=None, x=0.0, y=0.0, units='inches')
  Return a new transform with an added offset.

Parameters
trans [Transform instance] Any transform, to which offset will be applied.
fig [Figure, optional, default: None] Current figure. It can be None if units are 'dots'.
x, y [float, optional, default: 0.0] Specifies the offset to apply.
units [{‘inches’, ‘points’, ‘dots’}, optional] Units of the offset.

Returns
trans [Transform instance] Transform with applied offset.
Unstructured triangular grid functions.

```python
class matplotlib.tri.Triangulation(x, y, triangles=None, mask=None)
```

An unstructured triangular grid consisting of npoints points and ntri triangles. The triangles can either be specified by the user or automatically generated using a Delaunay triangulation.

**Parameters**

- `x, y` [array-like of shape (npoints)] Coordinates of grid points.
- `triangles` [integer array_like of shape (ntri, 3), optional] For each triangle, the indices of the three points that make up the triangle, ordered in an anticlockwise manner. If not specified, the Delaunay triangulation is calculated.
- `mask` [boolean array-like of shape (ntri), optional] Which triangles are masked out.

**Notes**

For a Triangulation to be valid it must not have duplicate points, triangles formed from colinear points, or overlapping triangles.

**Attributes**

- `edges` [int array of shape (nedges, 2)] Return integer array of shape (nedges, 2) containing all edges of non-masked triangles.
- `neighbors` [int array of shape (ntri, 3)] Return integer array of shape (ntri, 3) containing neighbor triangles.
- `mask` [bool array of shape (ntri, 3)] Masked out triangles.
- `is_delaunay` [bool] Whether the Triangulation is a calculated Delaunay triangulation (where triangles was not specified) or not.

**calculate_plane_coefficients(self, z)**

Calculate plane equation coefficients for all unmasked triangles from the point (x, y) coordinates and specified z-array of shape (npoints). The returned array has shape (npoints, 3) and allows z-value at (x, y) position in triangle tri to be calculated using $z = array[tri, 0] \times x + array[tri, 1] \times y + array[tri, 2]$.

**edges**

Return integer array of shape (nedges, 2) containing all edges of non-masked triangles.

Each row defines an edge by it’s start point index and end point index. Each edge appears only once, i.e. for an edge between points $i$ and $j$, there will only be either $(i, j)$ or $(j, i)$.

**get_cpp_triangulation(self)**

Return the underlying C++ Triangulation object, creating it if necessary.

**static get_from_args_and_kwargs(*args, **kwargs)**

Return a Triangulation object from the args and kwargs, and the remaining args and kwargs with the consumed values removed.
There are two alternatives: either the first argument is a Triangulation object, in which case it is returned, or the args and kwargs are sufficient to create a new Triangulation to return. In the latter case, see Triangulation.__init__ for the possible args and kwargs.

get_masked_triangles(self)
Return an array of triangles that are not masked.

get_trifinder(self)
Return the default matplotlib.tri.TriFinder of this triangulation, creating it if necessary. This allows the same TriFinder object to be easily shared.

neighbors
Return integer array of shape (ntri, 3) containing neighbor triangles.
For each triangle, the indices of the three triangles that share the same edges, or -1 if there is no such neighboring triangle. neighbors[i,j] is the triangle that is the neighbor to the edge from point index triangles[i,j] to point index triangles[i,(j+1)%3].

set_mask(self, mask)
Set or clear the mask array. This is either None, or a boolean array of shape (ntri).

class matplotlib.tri.TriFinder(triangulation)
Abstract base class for classes used to find the triangles of a Triangulation in which (x,y) points lie.
Rather than instantiate an object of a class derived from TriFinder, it is usually better to use the function matplotlib.tri.Triangulation.get_trifinder().
Derived classes implement __call__(x,y) where x,y are array_like point coordinates of the same shape.

class matplotlib.tri.TrapezoidMapTriFinder(triangulation)
Bases: matplotlib.tri.trifinder.TriFinder
The triangulation must be valid, i.e. it must not have duplicate points, triangles formed from colinear points, or overlapping triangles. The algorithm has some tolerance to triangles formed from colinear points, but this should not be relied upon.

class matplotlib.tri.TriInterpolator(triangulation, z, trifinder=None)
Abstract base class for classes used to perform interpolation on triangular grids.
Derived classes implement the following methods:
• __call__(x, y), where x, y are array_like point coordinates of the same shape, and that returns a masked array of the same shape containing the interpolated z-values.
• gradient(x, y), where x, y are array_like point coordinates of the same shape, and that returns a list of 2 masked arrays of the same shape containing the 2 derivatives of the interpolator (derivatives of interpolated z values with respect to x and y).

class matplotlib.tri.LinearTriInterpolator(triangulation, z, trifinder=None)
Bases: matplotlib.tri.triinterpolate.TriInterpolator
A LinearTriInterpolator performs linear interpolation on a triangular grid.
Each triangle is represented by a plane so that an interpolated value at point (x,y) lies on the plane of the triangle containing (x,y). Interpolated values are therefore continuous.
across the triangulation, but their first derivatives are discontinuous at edges between triangles.

**Parameters**

- **triangulation** [Triangulation object] The triangulation to interpolate over.
- **z** [array_like of shape (npoints,)] Array of values, defined at grid points, to interpolate between.
- **trifinder** [TriFinder object, optional] If this is not specified, the Triangulation’s default TriFinder will be used by calling `matplotlib.tri.Triangulation.get_trifinder()`.

**Methods**

- **`__call__`(x, y)** (Returns interpolated values at x,y points)
- **`gradient`(x, y)** (Returns interpolated derivatives at x,y points)

`gradient(self, x, y)`

Returns a list of 2 masked arrays containing interpolated derivatives at the specified x,y points.

**Parameters**

- **x, y** [array-like] x and y coordinates of the same shape and any number of dimensions.

**Returns**

- **dzdx, dzdy** [np.ma.array] 2 masked arrays of the same shape as x and y; values corresponding to (x,y) points outside of the triangulation are masked out. The first returned array contains the values of $\frac{\partial z}{\partial x}$ and the second those of $\frac{\partial z}{\partial y}$.

**class** `matplotlib.tri.CubicTriInterpolator(triangulation, z, kind='min_E', trifinder=None, dz=None)`

Bases: `matplotlib.tri.triinterpolate.TriInterpolator`

A CubicTriInterpolator performs cubic interpolation on triangular grids.

In one-dimension - on a segment - a cubic interpolating function is defined by the values of the function and its derivative at both ends. This is almost the same in 2-d inside a triangle, except that the values of the function and its 2 derivatives have to be defined at each triangle node.

The CubicTriInterpolator takes the value of the function at each node - provided by the user - and internally computes the value of the derivatives, resulting in a smooth interpolation. (As a special feature, the user can also impose the value of the derivatives at each node, but this is not supposed to be the common usage.)

**Parameters**

- **triangulation** [Triangulation object] The triangulation to interpolate over.
- **z** [array_like of shape (npoints,)] Array of values, defined at grid points, to interpolate between.
kind [{‘min_E’, ‘geom’, ‘user’}, optional] Choice of the smoothing algorithm, in order to compute the interpolant derivatives (defaults to ‘min_E’):

- if ‘min_E’: (default) The derivatives at each node is computed to minimize a bending energy.
- if ‘geom’: The derivatives at each node is computed as a weighted average of relevant triangle normals. To be used for speed optimization (large grids).
- if ‘user’: The user provides the argument dz, no computation is hence needed.

 trifinder [TriFinder object, optional] If not specified, the Triangulation’s default TriFinder will be used by calling matplotlib.tri.Triangulation.get_trifinder().

dz [tuple of array_likes (dzdx, dzdy), optional] Used only if kind = ‘user’. In this case dz must be provided as (dzdx, dzdy) where dzdx, dzdy are arrays of the same shape as z and are the interpolant first derivatives at the triangulation points.

Notes

This note is a bit technical and details the way a CubicTriInterpolator computes a cubic interpolation.

The interpolation is based on a Clough-Tocher subdivision scheme of the triangulation mesh (to make it clearer, each triangle of the grid will be divided in 3 child-triangles, and on each child triangle the interpolated function is a cubic polynomial of the 2 coordinates). This technique originates from FEM (Finite Element Method) analysis; the element used is a reduced Hsieh-Clough-Tocher (HCT) element. Its shape functions are described in [1]. The assembled function is guaranteed to be C1-smooth, i.e. it is continuous and its first derivatives are also continuous (this is easy to show inside the triangles but is also true when crossing the edges).

In the default case (kind = ‘min_E’), the interpolant minimizes a curvature energy on the functional space generated by the HCT element shape functions - with imposed values but arbitrary derivatives at each node. The minimized functional is the integral of the so-called total curvature (implementation based on an algorithm from [2] - PCG sparse solver):

\[
E(z) = \frac{1}{2} \int_{\Omega} \left( \left( \frac{\partial^2 z}{\partial x^2} \right)^2 + \left( \frac{\partial^2 z}{\partial y^2} \right)^2 + 2 \left( \frac{\partial^2 z}{\partial y \partial x} \right)^2 \right) dx dy
\]

If the case kind = ‘geom’ is chosen by the user, a simple geometric approximation is used (weighted average of the triangle normal vectors), which could improve speed on very large grids.

References

[1], [2]
Methods

| '__call__' (x, y) | (Returns interpolated values at x, y points) |
| 'gradient' (x, y) | (Returns interpolated derivatives at x, y points) |

`gradient(self, x, y)`

Returns a list of 2 masked arrays containing interpolated derivatives at the specified x, y points.

Parameters

- `x, y` [array-like] x and y coordinates of the same shape and any number of dimensions.

Returns

- `dzdx, dzdy` [np.ma.array] 2 masked arrays of the same shape as x and y; values corresponding to (x, y) points outside of the triangulation are masked out. The first returned array contains the values of $\frac{\partial z}{\partial x}$ and the second those of $\frac{\partial z}{\partial y}$.

class matplotlib.tri.TriRefiner(triangulation)

Abstract base class for classes implementing mesh refinement.

A TriRefiner encapsulates a Triangulation object and provides tools for mesh refinement and interpolation.

Derived classes must implements:

- `refine_triangulation(return_tri_index=False, **kwargs)` , where the optional keyword arguments `kwargs` are defined in each TriRefiner concrete implementation, and which returns:
  - a refined triangulation
  - optionally (depending on `return_tri_index`), for each point of the refined triangulation: the index of the initial triangulation triangle to which it belongs.

- `refine_field(z, triinterpolator=None, **kwargs)` , where:
  - `z` array of field values (to refine) defined at the base triangulation nodes
  - `triinterpolator` is a `TriInterpolator` (optional)
  - the other optional keyword arguments `kwargs` are defined in each TriRefiner concrete implementation

  and which returns (as a tuple) a refined triangular mesh and the interpolated values of the field at the refined triangulation nodes.

class matplotlib.tri.UniformTriRefiner(triangulation)

Bases: matplotlib.tri.trirefine.TriRefiner

Uniform mesh refinement by recursive subdivisions.

Parameters

- `triangulation` [Triangulation] The encapsulated triangulation (to be refined)

- `refine_field(self, z, triinterpolator=None, subdiv=3)`
  Refines a field defined on the encapsulated triangulation.
Returns `refi_tri` (refined triangulation), `refi_z` (interpolated values of the field at the node of the refined triangulation).

**Parameters**

- `z` [1d-array-like of length `n_points`] Values of the field to refine, defined at the nodes of the encapsulated triangulation. (`n_points` is the number of points in the initial triangulation)

- `tr interpolator` [TriInterpolator, optional] Interpolator used for field interpolation. If not specified, a CubicTriInterpolator will be used.

- `subdiv` [integer, optional] Recursion level for the subdivision. Defaults to 3. Each triangle will be divided into $4^{\text{subdiv}}$ child triangles.

**Returns**

- `refi_tri` [Triangulation object] The returned refined triangulation
- `refi_z` [1d array of length: `refi_tri` node count.] The returned interpolated field (at `refi_tri` nodes)

`refine_triangulation(self, return_tri_index=False, subdiv=3)`

Computes an uniformly refined triangulation `refi_triangulation` of the encapsulated triangulation.

This function refines the encapsulated triangulation by splitting each father triangle into 4 child sub-triangles built on the edges midside nodes, recursively (level of recursion `subdiv`). In the end, each triangle is hence divided into $4^{\text{subdiv}}$ child triangles. The default value for `subdiv` is 3 resulting in 64 refined subtriangles for each triangle of the initial triangulation.

**Parameters**

- `return_tri_index` [boolean, optional] Boolean indicating whether an index table indicating the father triangle index of each point will be returned. Default value False.

- `subdiv` [integer, optional] Recursion level for the subdivision. Defaults value 3. Each triangle will be divided into $4^{\text{subdiv}}$ child triangles.

**Returns**

- `refi_triangulation` [Triangulation] The returned refined triangulation
- `found_index` [array-like of integers] Index of the initial triangulation containing triangle, for each point of `refi_triangulation`. Returned only if `return_tri_index` is set to True.

`class matplotlib.tri.TriAnalyzer(triangulation)`

Define basic tools for triangular mesh analysis and improvement.

A TriAnalyzer encapsulates a Triangulation object and provides basic tools for mesh analysis and mesh improvement.

**Parameters**

- `triangulation` [Triangulation object] The encapsulated triangulation to analyze.

**Attributes**

- `scale_factors`
circle_ratios(self, rescale=True)

Returns a measure of the triangulation triangles flatness.

The ratio of the incircle radius over the circumcircle radius is a widely used indicator of a triangle flatness. It is always <= 0.5 and == 0.5 only for equilateral triangles. Circle ratios below 0.01 denote very flat triangles.

To avoid unduly low values due to a difference of scale between the 2 axis, the triangular mesh can first be rescaled to fit inside a unit square with scale_factors (Only if rescale is True, which is its default value).

Parameters

rescale [boolean, optional] If True, a rescaling will be internally performed (based on scale_factors, so that the (unmasked) triangles fit exactly inside a unit square mesh. Default is True.

Returns

circle_ratios [masked array] Ratio of the incircle radius over the circumcircle radius, for each `rescaled` triangle of the encapsulated triangulation. Values corresponding to masked triangles are masked out.

get_flat_tri_mask(self, min_circle_ratio=0.01, rescale=True)

Eliminates excessively flat border triangles from the triangulation.

Returns a mask new_mask which allows to clean the encapsulated triangulation from its border-located flat triangles (according to their circle_ratios()). This mask is meant to be subsequently applied to the triangulation using matplotlib.tri.Triangulation.set_mask(). new_mask is an extension of the initial triangulation mask in the sense that an initially masked triangle will remain masked.

The new_mask array is computed recursively; at each step flat triangles are removed only if they share a side with the current mesh border. Thus no new holes in the triangulated domain will be created.

Parameters

min_circle_ratio [float, optional] Border triangles with incircle/circumcircle radii ratio r/R will be removed if r/R < min_circle_ratio. Default value: 0.01

rescale [boolean, optional] If True, a rescaling will first be internally performed (based on scale_factors), so that the (unmasked) triangles fit exactly inside a unit square mesh. This rescaling accounts for the difference of scale which might exist between the 2 axis. Default (and recommended) value is True.

Returns

new_mask [array-like of booleans] Mask to apply to encapsulated triangulation. All the initially masked triangles remain masked in the new_mask.

Notes

The rationale behind this function is that a Delaunay triangulation - of an unstructured set of points - sometimes contains almost flat triangles at its border, leading
to artifacts in plots (especially for high-resolution contouring). Masked with computed new mask, the encapsulated triangulation would contain no more unmasked border triangles with a circle ratio below min_circle_ratio, thus improving the mesh quality for subsequent plots or interpolation.

scale_factors
Factors to rescale the triangulation into a unit square.

Returns

- **k**: Tuple of 2 scale factors.

**Returns**

k [tuple of 2 floats (kx, ky)] Tuple of floats that would rescale the triangulation: [triangulation.x * kx, triangulation.y * ky] fits exactly inside a unit square.

17.53 matplotlib.type1font

This module contains a class representing a Type 1 font.

This version reads pfa and pfb files and splits them for embedding in pdf files. It also supports SlantFont and ExtendFont transformations, similarly to pdfTeX and friends. There is no support yet for subsetting.

Usage:

```python
>>> font = Type1Font(filename)
>>> clear_part, encrypted_part, finale = font.parts
>>> slanted_font = font.transform({'slant': 0.167})
>>> extended_font = font.transform({'extend': 1.2})
```

Sources:

- Adobe Technical Note #5040, Supporting Downloadable PostScript Language Fonts.

class matplotlib.type1font.Type1Font(input)

Bases: object

A class representing a Type-1 font, for use by backends.

**Attributes**

- **parts**: A 3-tuple of the cleartext part, the encrypted part, and the finale of zeros.
- **prop**: A dictionary of font properties.

Initialize a Type-1 font. *input* can be either the file name of a pfb file or a 3-tuple of already-decoded Type-1 font parts.

```python
>>> parts
>>> prop
```

**transform(self, effects)**

Transform the font by slanting or extending. *effects* should be a dict where effects['slant'] is the tangent of the angle that the font is to be slanted to the
right (so negative values slant to the left) and `effects['extend']` is the multiplier by which the font is to be extended (so values less than 1.0 condense). Returns a new `Type1Font` object.

## 17.54 `matplotlib.units`

The classes here provide support for using custom classes with Matplotlib, e.g., those that do not expose the array interface but know how to convert themselves to arrays. It also supports classes with units and units conversion. Use cases include converters for custom objects, e.g., a list of datetime objects, as well as for objects that are unit aware. We don’t assume any particular units implementation; rather a units implementation must provide the register with the Registry converter dictionary and a `ConversionInterface`. For example, here is a complete implementation which supports plotting with native datetime objects:

```python
import matplotlib.units as units
import matplotlib.dates as dates
import matplotlib.ticker as ticker
import datetime

class DateConverter(units.ConversionInterface):
    @staticmethod
    def convert(value, unit, axis):
        'Convert a datetime value to a scalar or array'
        return dates.date2num(value)

    @staticmethod
    def axisinfo(unit, axis):
        'Return major and minor tick locators and formatters'
        if unit != 'date': return None
        majloc = dates.AutoDateLocator()
        majfmt = dates.AutoDateFormatter(majloc)
        return AxisInfo(majloc=majloc,
                        majfmt=majfmt,
                        label='date')

    @staticmethod
    def default_units(x, axis):
        'Return the default unit for x or None'
        return 'date'

# Finally we register our object type with the Matplotlib units registry.
units.registry[datetime.date] = DateConverter()
```

class `matplotlib.units.AxisInfo`

Bases: `object`

Information to support default axis labeling, tick labeling, and limits.

An instance of this class must be returned by `ConversionInterface.axisinfo`.

### Parameters
**majloc, minloc** [Locator, optional] Tick locators for the major and minor ticks.

**majfmt, minfmt** [Formatter, optional] Tick formatters for the major and minor ticks.

**label** [str, optional] The default axis label.

**default_limits** [optional] The default min and max limits of the axis if no data has been plotted.

**Notes**

If any of the above are `None`, the axis will simply use the default value.

**exception** `matplotlib.units.ConversionError`

**Bases:** `TypeError`

**class** `matplotlib.units.ConversionInterface`

**Bases:** `object`

The minimal interface for a converter to take custom data types (or sequences) and convert them to values Matplotlib can use.

**static axisinfo(**`unit`, `axis`)**

Return an `AxisInfo` for the axis with the specified units.

**static convert(**`obj`, `unit`, `axis`)**

Convert `obj` using `unit` for the specified `axis`.

If `obj` is a sequence, return the converted sequence. The output must be a sequence of scalars that can be used by the `numpy` array layer.

**static default_units(**`x`, `axis`)**

Return the default unit for `x` or `None` for the given axis.

**static is_numlike(**`x`)**

The Matplotlib datalim, autoscaling, locators etc work with scalars which are the units converted to floats given the current unit. The converter may be passed these floats, or arrays of them, even when units are set.

**class** `matplotlib.units.Registry`

**Bases:** `dict`

Register types with conversion interface.

**get_converter(**`self`, `x`)**

Get the converter interface instance for `x`, or None.
17.55 matplotlib.widgets

GUI neutral widgets

Widgets that are designed to work for any of the GUI backends. All of these widgets require you to predefine a `matplotlib.axes.Axes` instance and pass that as the first arg. matplotlib doesn't try to be too smart with respect to layout - you will have to figure out how wide and tall you want your Axes to be to accommodate your widget.

```python
class matplotlib.widgets.AxesWidget(ax)
    Bases: matplotlib.widgets.Widget

    Widget that is connected to a single Axes.

    To guarantee that the widget remains responsive and not garbage-collected, a reference to the object should be maintained by the user.
```
This is necessary because the callback registry maintains only weak.refs to the functions, which are member functions of the widget. If there are no references to the widget object it may be garbage collected which will disconnect the callbacks.

Attributes:

- **ax** [Axes] The parent axes for the widget
- **canvas** [FigureCanvasBase subclass] The parent figure canvas for the widget.
- **active** [bool] If False, the widget does not respond to events.

```python
connect_event(self, event, callback)
```

Connect callback with an event. This should be used in lieu of `figure.canvas.mpl_connect` since this function stores callback ids for later cleanup.

```python
disconnect_events(self)
```

Disconnect all events created by this widget.

```python
class matplotlib.widgets.Button(ax, label, image=None, color='0.85', hovercolor='0.95')
```

Bases: `matplotlib.widgets.AxesWidget`

A GUI neutral button.

For the button to remain responsive you must keep a reference to it. Call `on_clicked()` to connect to the button.

**Attributes**

- **ax** The `matplotlib.axes.Axes` the button renders into.
- **label** A `matplotlib.text.Text` instance.
- **color** The color of the button when not hovering.
- **hovercolor** The color of the button when hovering.

**Parameters**

- **ax** [matplotlib.axes.Axes] The `matplotlib.axes.Axes` instance the button will be placed into.
- **label** [str] The button text. Accepts string.
- **image** [array, mpl image, Pillow Image] The image to place in the button, if not `None`. Can be any legal arg to imshow (numpy array, matplotlib Image instance, or Pillow Image).
- **color** [color] The color of the button when not activated
- **hovercolor** [color] The color of the button when the mouse is over it

```python
disconnect(self, cid)
```

Remove the callback function with connection id `cid`.

```python
on_clicked(self, func)
```

Connect the callback function `func` to button click events.

Returns a connection id, which can be used to disconnect the callback.

```python
class matplotlib.widgets.CheckButtons(ax, labels, actives=None)
```

Bases: `matplotlib.widgets.AxesWidget`

---

17.55. `matplotlib.widgets`
A GUI neutral set of check buttons. For the check buttons to remain responsive you must keep a reference to this object. The following attributes are exposed

- **ax** The `matplotlib.axes.Axes` instance the buttons are located in
- **labels** List of `matplotlib.text.Text` instances
- **lines** List of (line1, line2) tuples for the x's in the check boxes. These lines exist for each box, but have `set_visible(False)` when its box is not checked.
- **rectangles** List of `matplotlib.patches.Rectangle` instances

Connect to the CheckButtons with the `on_clicked()` method

Add check buttons to `matplotlib.axes.Axes` instance `ax`

### Parameters

- **ax** [`Axes`] The parent axes for the widget.
- **labels** [List[`str`]] The labels of the check buttons.
- **actives** [List[bool], optional] The initial check states of the buttons. The list must have the same length as `labels`. If not given, all buttons are unchecked.

#### disconnect

`remove the observer with connection id cid`

#### get_status

`Return a tuple of the status (True/False) of all of the check buttons.`

#### on_clicked

`Connect the callback function `func` to button click events. Returns a connection id, which can be used to disconnect the callback.`

#### set_active

Directly (de)activate a check button by index.

**index is an index into the original label list** that this object was constructed with. Raises ValueError if `index` is invalid.

Callbacks will be triggered if `eventson` is True.

### class `matplotlib.widgets.Cursor(ax, horizOn=True, vertOn=True, useblit=False, **lineprops)`

**Bases:** `matplotlib.widgets.AxesWidget`

A crosshair cursor that spans the axes and moves with mouse cursor. For the cursor to remain responsive you must keep a reference to it.

### Parameters

- **ax** [`matplotlib.axes.Axes`] The `Axes` to attach the cursor to.
- **horizOn** [bool, optional, default: True] Whether to draw the horizontal line.
- **vertOn** [bool, optional, default: True] Whether to draw the vertical line.
- **useblit** [bool, optional, default: False] Use blitting for faster drawing if supported by the backend.
**lineprops** Line2D properties that control the appearance of the lines. See also `axhline`.

Examples

See /gallery/widgets/cursor.

```python
clear(self, event)
Internal event handler to clear the cursor.

onmove(self, event)
Internal event handler to draw the cursor when the mouse moves.
```

```python
class matplotlib.widgets.EllipseSelector(ax, onselect, drawtype='box',
    minspanx=None, minspany=None,
    useblit=False, lineprops=None, rectprops=None, spancoords='data',
    button=None, maxdist=10,
    marker_props=None, interactive=False,
    state_modifier_keys=None)
```

Bases: `matplotlib.widgets.RectangleSelector`

Select an elliptical region of an axes.

For the cursor to remain responsive you must keep a reference to it.

Example usage:

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.widgets import EllipseSelector

def onselect(eclick, erelease):
    "eclick and erelease are matplotlib events at press and release."
    print('startposition: (%f, %f)' % (eclick.xdata, eclick.ydata))
    print('endposition: (%f, %f)' % (erelease.xdata, erelease.ydata))
    print('used button : ', eclick.button)

def toggle_selector(event):
    print('Key pressed.')
    if event.key in ['Q', 'q'] and toggle_selector.ES.active:
        print('EllipseSelector deactivated.')
        toggle_selector.RS.set_active(False)
    if event.key in ['A', 'a'] and not toggle_selector.ES.active:
        print('EllipseSelector activated.')
        toggle_selector.ES.set_active(True)

x = np.arange(100.) / 99
y = np.sin(x)
fig, ax = plt.subplots()
ax.plot(x, y)
toggle_selector.ES = EllipseSelector(ax, onselect, drawtype='line')
```

(continues on next page)
fig.canvas.mpl_connect('key_press_event', toggle_selector)
plt.show()

Create a selector in ax. When a selection is made, clear the span and call onselect with:

onselect(pos_1, pos_2)

and clear the drawn box/line. The pos_1 and pos_2 are arrays of length 2 containing the x- and y-coordinate.

If minspanx is not None then events smaller than minspanx in x direction are ignored (it’s the same for y).

The rectangle is drawn with rectprops; default:

rectprops = dict(facecolor='red', edgecolor = 'black',
                 alpha=0.2, fill=True)

The line is drawn with lineprops; default:

lineprops = dict(color='black', linestyle='-',
                 linewidth = 2, alpha=0.5)

Use drawtype if you want the mouse to draw a line, a box or nothing between click and actual position by setting

drawtype = 'line', drawtype='box' or drawtype = 'none'. Drawing a line would result in a line from vertex A to vertex C in a rectangle ABCD.

spancoords is one of ‘data’ or ‘pixels’. If ‘data’, minspanx and minspanx will be interpreted in the same coordinates as the x and y axis. If ‘pixels’, they are in pixels.

button is a list of integers indicating which mouse buttons should be used for rectangle selection. You can also specify a single integer if only a single button is desired. Default is None, which does not limit which button can be used.

Note, typically: 1 = left mouse button 2 = center mouse button (scroll wheel) 3 = right mouse button

interactive will draw a set of handles and allow you interact with the widget after it is drawn.

state_modifier_keys are keyboard modifiers that affect the behavior of the widget.

The defaults are: dict(move=' ', clear='escape', square='shift', center='ctrl')

Keyboard modifiers, which: 'move': Move the existing shape. 'clear': Clear the current shape. 'square': Makes the shape square. 'center': Make the initial point the center of the shape. 'square' and 'center' can be combined.

draw_shape(self, extents)

class matplotlib.widgets.Lasso(ax, xy, callback=None, useblit=True)

Selection curve of an arbitrary shape.

The selected path can be used in conjunction with contains_point() to select data points from an image.
Unlike LassoSelector, this must be initialized with a starting point \( xy \), and the Lasso events are destroyed upon release.

**Parameters**

- **ax** [Axes] The parent axes for the widget.
- **xy** [(float, float)] Coordinates of the start of the lasso.
- **callback** [callable] Whenever the lasso is released, the callback function is called and passed the vertices of the selected path.

```python
onmove(self, event)
onrelease(self, event)
```

```python
class matplotlib.widgets.LassoSelector(ax, onselect=None, useblit=True, lineprops=None, button=None)
```

Bases: matplotlib.widgets._SelectorWidget

Selection curve of an arbitrary shape.

For the selector to remain responsive you must keep a reference to it.

The selected path can be used in conjunction with contains_point to select data points from an image.

In contrast to Lasso, LassoSelector is written with an interface similar to RectangleSelector and SpanSelector, and will continue to interact with the axes until disconnected.

Example usage:

```python
ax = subplot(111)
ax.plot(x, y)

def onselect(verts):
    print(verts)
lasso = LassoSelector(ax, onselect)
```

**Parameters**

- **ax** [Axes] The parent axes for the widget.
- **onselect** [function] Whenever the lasso is released, the onselect function is called and passed the vertices of the selected path.
- **button** [List[Int], optional] A list of integers indicating which mouse buttons should be used for rectangle selection. You can also specify a single integer if only a single button is desired. Default is None, which does not limit which button can be used.

Note, typically:

- 1 = left mouse button
- 2 = center mouse button (scroll wheel)
- 3 = right mouse button

```python
onpress(self, event)
onrelease(self, event)
```
class matplotlib.widgets.LockDraw
    Bases: object
    
    Some widgets, like the cursor, draw onto the canvas, and this is not desirable under all circumstances, like when the toolbar is in zoom-to-rect mode and drawing a rectangle. To avoid this, a widget can acquire a canvas’ lock with canvas.widgetlock(widget) before drawing on the canvas; this will prevent other widgets from doing so at the same time (if they also try to acquire the lock first).

    available(self, o)
        Return whether drawing is available to o.

    isowner(self, o)
        Return whether o owns this lock.

    locked(self)
        Return whether the lock is currently held by an owner.

    release(self, o)
        Release the lock from o.

class matplotlib.widgets.MultiCursor(canvas, axes, useblit=True, horizOn=False, vertOn=True, **lineprops)
    Bases: matplotlib.widgets.Widget
    
    Provide a vertical (default) and/or horizontal line cursor shared between multiple axes. For the cursor to remain responsive you must keep a reference to it.

    Example usage:

    ```python
    from matplotlib.widgets import MultiCursor
    import matplotlib.pyplot as plt
    import numpy as np

    fig, (ax1, ax2) = plt.subplots(nrows=2, sharex=True)
    t = np.arange(0.0, 2.0, 0.01)
    ax1.plot(t, np.sin(2*np.pi*t))
    ax2.plot(t, np.sin(4*np.pi*t))

    multi = MultiCursor(fig.canvas, (ax1, ax2), color='r', lw=1,
                        horizOn=False, vertOn=True)

    plt.show()
    ```

    clear(self, event)
        clear the cursor

    connect(self)
        connect events

    disconnect(self)
        disconnect events

    onmove(self, event)

class matplotlib.widgets.PolygonSelector(ax, onselect, useblit=False, lineprops=None, markerprops=None, vertex_select_radius=15)
    Bases: matplotlib.widgets._SelectorWidget
    
    Select a polygon region of an axes.
Place vertices with each mouse click, and make the selection by completing the polygon (clicking on the first vertex). Hold the `ctrl` key and click and drag a vertex to reposition it (the `ctrl` key is not necessary if the polygon has already been completed). Hold the `shift` key and click and drag anywhere in the axes to move all vertices. Press the `esc` key to start a new polygon.

For the selector to remain responsive you must keep a reference to it.

**Parameters**

- **ax** (*Axes*) The parent axes for the widget.
- **onselect** (*function*) When a polygon is completed or modified after completion, the `onselect` function is called and passed a list of the vertices as `(xdata, ydata)` tuples.
- **useblit** (*bool, optional*)
- **lineprops** (*dict, optional*) The line for the sides of the polygon is drawn with the properties given by `lineprops`. The default is `dict(color='k', linestyle='-', linewidth=2, alpha=0.5)`.
- **markerprops** (*dict, optional*) The markers for the vertices of the polygon are drawn with the properties given by `markerprops`. The default is `dict(marker='o', markersize=7, mec='k', mfc='k', alpha=0.5)`.
- **vertex_select_radius** (*float, optional*) A vertex is selected (to complete the polygon or to move a vertex) if the mouse click is within `vertex_select_radius` pixels of the vertex. The default radius is 15 pixels.

**Examples**

```
/gallery/widgets/polygon_selector_demo
```

**Returns**

- **list** A list of the vertices of the polygon as `(xdata, ydata)` tuples.

**class** `matplotlib.widgets.RadioButtons(ax, labels, active=0, activecolor='blue')`

*Bases:* `matplotlib.widgets.AxesWidget`

A GUI neutral radio button.

For the buttons to remain responsive you must keep a reference to this object.

Connect to the RadioButtons with the `on_clicked()` method.

**Attributes**

- **ax** The containing `Axes` instance.
- **activecolor** The color of the selected button.
- **labels** A list of `Text` instances containing the button labels.
- **circles** A list of `Circle` instances defining the buttons.
value_selected [str] The label text of the currently selected button.

Add radio buttons to an Axes.

Parameters

ax [Axes] The axes to add the buttons to.
labels [list of str] The button labels.
active [int] The index of the initially selected button.
activecolor [color] The color of the selected button.

disconnect(self, cid)
Remove the observer with connection id cid.

on_clicked(self, func)
Connect the callback function func to button click events.
Returns a connection id, which can be used to disconnect the callback.

set_active(self, index)
Select button with number index.
Callbacks will be triggered if eventson is True.

class matplotlib.widgets.RectangleSelector(ax, onselect, drawtype='box',
                                           minspanx=None, minspany=None,
                                           useblit=False, lineprops=None, rectprops=None,
                                           spancoords='data', button=None, maxdist=10,
                                           marker_props=None, interactive=False,
                                           state_modifier_keys=None)

Bases: matplotlib.widgets._SelectorWidget

Select a rectangular region of an axes.
For the cursor to remain responsive you must keep a reference to it.
Example usage:

import numpy as np
import matplotlib.pyplot as plt
from matplotlib.widgets import RectangleSelector

def onselect(eclick, erelease):
    "eclick and erelease are matplotlib events at press and release."
    print('startposition: (%f, %f) ' % (eclick.xdata, eclick.ydata))
    print('endposition : (%f, %f) ' % (erelease.xdata, erelease.ydata))
    print('used button : ', eclick.button)

def toggle_selector(event):
    print('Key pressed.
    if event.key in ['Q', 'q'] and toggle_selector.RS.active:
        print('RectangleSelector deactivated.')
        toggle_selector.RS.set_active(False)
    if event.key in ['A', 'a'] and not toggle_selector.RS.active:
        print('RectangleSelector activated.')
        toggle_selector.RS.set_active(True)

(continues on next page)
x = np.arange(100.) / 99
y = np.sin(x)
fig, ax = plt.subplots()
ax.plot(x, y)
toggle_selector.RS = RectangleSelector(ax, onselect, drawtype='line')
fig.canvas.mpl_connect('key_press_event', toggle_selector)
plt.show()

Create a selector in `ax`. When a selection is made, clear the span and call `onselect` with:

```python
donselect(pos_1, pos_2)
```

and clear the drawn box/line. The `pos_1` and `pos_2` are arrays of length 2 containing the x- and y-coordinate.

If `minspanx` is not `None` then events smaller than `minspanx` in x direction are ignored (it's the same for y).

The rectangle is drawn with `rectprops`; default:

```python
rectprops = dict(facecolor='red', edgecolor='black',
                  alpha=0.2, fill=True)
```

The line is drawn with `lineprops`; default:

```python
lineprops = dict(color='black', linestyle='-',
                  linewidth=2, alpha=0.5)
```

Use `drawtype` if you want the mouse to draw a line, a box or nothing between click and actual position by setting

```python
drawtype = 'line', drawtype='box' or drawtype = 'none'. Drawing a line would result in a line from vertex A to vertex C in a rectangle ABCD.
```

`spancoords` is one of 'data' or 'pixels'. If 'data', `minspanx` and `minspanx` will be interpreted in the same coordinates as the x and y axis. If 'pixels', they are in pixels.

`button` is a list of integers indicating which mouse buttons should be used for rectangle selection. You can also specify a single integer if only a single button is desired. Default is `None`, which does not limit which button can be used.

**Note, typically:** 1 = left mouse button 2 = center mouse button (scroll wheel) 3 = right mouse button

`interactive` will draw a set of handles and allow you interact with the widget after it is drawn.

`state_modifier_keys` are keyboard modifiers that affect the behavior of the widget.

The defaults are: `dict(move=' ', clear='escape', square='shift', center='ctrl')`

Keyboard modifiers, which: 'move': Move the existing shape. 'clear': Clear the current shape. 'square': Makes the shape square. 'center': Make the initial point the center of the shape. 'square' and 'center' can be combined.

`center` Center of rectangle
corners
Corners of rectangle from lower left, moving clockwise.

draw_shape(self, extents)

edge_centers
Midpoint of rectangle edges from left, moving clockwise.

extents
Return (xmin, xmax, ymin, ymax).

geometry
Returns numpy.ndarray of shape (2,5) containing x (RectangleSelector.geometry[1, :]) and y (RectangleSelector.geometry[0,:]) coordinates of the four corners of the rectangle starting and ending in the top left corner.

class matplotlib.widgets.Slider(ax, label, valmin, valmax, valinit=0.5, valfmt='%1.2f',
    closedmin=True, closedmax=True, slidermin=None,
    slidermax=None, dragging=True, valstep=None,
    orientation='horizontal', **kwargs)

Bases: matplotlib.widgets.AxesWidget

A slider representing a floating point range.

Create a slider from valmin to valmax in axes ax. For the slider to remain responsive you must maintain a reference to it. Call on_changed() to connect to the slider event.

Attributes
val [float] Slider value.

Parameters
ax [Axes] The Axes to put the slider in.
label [str] Slider label.
valmin [float] The minimum value of the slider.
valmax [float] The maximum value of the slider.
valinit [float, optional, default: 0.5] The slider initial position.
valfmt [str, optional, default: "%1.2f"] Used to format the slider value, fprint format string.
closedmin [bool, optional, default: True] Indicate whether the slider interval is closed on the bottom.
closedmax [bool, optional, default: True] Indicate whether the slider interval is closed on the top.
slidermin [Slider, optional, default: None] Do not allow the current slider to have a value less than the value of the Slider slidermin.
slidermax [Slider, optional, default: None] Do not allow the current slider to have a value greater than the value of the Slider slidermax.
dragging [bool, optional, default: True] If True the slider can be dragged by the mouse.
valstep [float, optional, default: None] If given, the slider will snap to multiples of valstep.
**orientation** [str; 'horizontal' or 'vertical', default: 'horizontal'] The orientation of the slider.

**Notes**

Additional kwargs are passed on to `self.poly` which is the `Rectangle` that draws the slider knob. See the `Rectangle` documentation for valid property names (e.g., `facecolor`, `edgecolor`, `alpha`).

```python
disconnect(self, cid)
    Remove the observer with connection id `cid`
```

**Parameters**

```python
cid [int] Connection id of the observer to be removed
```

```python
on_changed(self, func)
    When the slider value is changed call `func` with the new slider value
```

**Parameters**

```python
func [callable] Function to call when slider is changed. The function must accept a single float as its arguments.
```

**Returns**

```python
cid [int] Connection id (which can be used to disconnect `func`)
```

```python
reset(self)
    Reset the slider to the initial value
```

```python
set_val(self, val)
    Set slider value to `val`
```

**Parameters**

```python
val [float]
```

```python
class matplotlib.widgets.SpanSelector(ax, onselect, direction, minspan=None, useblit=False, rectprops=None, onmove_callback=None, span_stays=False, button=None)
```

**Bases:** `matplotlib.widgets._SelectorWidget`

Visually select a min/max range on a single axis and call a function with those values.

To guarantee that the selector remains responsive, keep a reference to it.

In order to turn off the SpanSelector, set `span_selector.active=False`. To turn it back on, set `span_selector.active=True`.

**Parameters**

```python
ax [matplotlib.axes.Axes object]
onselect [func(min, max), min/max are floats]
direction ['horizontal' or 'vertical'] The axis along which to draw the span selector
minspan [float, default is None] If selection is less than `minspan`, do not call `onselect`
```
**useblit** [bool, default is False] If True, use the backend-dependent blitting features for faster canvas updates.

**rectprops** [dict, default is None] Dictionary of :mod:`matplotlib.patches.Patch` properties

**onmove_callback** [func(min, max), min/max are floats, default is None] Called on mouse move while the span is being selected

**span_stays** [bool, default is False] If True, the span stays visible after the mouse is released

**button** [int or list of ints]

**Determines which mouse buttons activate the span selector**
- 1 = left mouse button
- 2 = center mouse button (scroll wheel)
- 3 = right mouse button

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> import matplotlib.widgets as mwidgets
>>> fig, ax = plt.subplots()
>>> ax.plot([1, 2, 3], [10, 50, 100])
>>> def onselect(vmin, vmax):
...     print(vmin, vmax)
>>> rectprops = dict(facecolor='blue', alpha=0.5)
>>> span = mwidgets.SpanSelector(ax, onselect, 'horizontal',
...                               rectprops=rectprops)
>>> fig.show()
```

See also: /gallery/widgets/span_selector

**buttonDown**

```python
ignore(self, event)
    return True if event should be ignored
```

**new_axes**

```python
Set SpanSelector to operate on a new Axes
```

class `matplotlib.widgets.SubplotTool`

```
Bases: matplotlib.widgets.Widget
A tool to adjust the subplot params of a matplotlib.figure.Figure.
```

**targetfig** The figure instance to adjust.

**toolfig** The figure instance to embed the subplot tool into. If None, a default figure will be created. If you are using this from the GUI

```python
funcbottom(self, val)
funcspace(self, val)
funcleft(self, val)
funcright(self, val)
```
functop(self, val)
funcwspace(self, val)

```python
class matplotlib.widgets.TextBox(ax, label, initial='', color='.95', hovercolor='1', label_pad=0.01)
Bases: matplotlib.widgets.AxesWidget
```

A GUI neutral text input box.

For the text box to remain responsive you must keep a reference to it.

The following attributes are accessible:

- **ax** The `matplotlib.axes.Axes` the button renders into.
- **label** A `matplotlib.text.Text` instance.
- **color** The color of the text box when not hovering.
- **hovercolor** The color of the text box when hovering.

Call `on_text_change()` to be updated whenever the text changes.

Call `on_submit()` to be updated whenever the user hits enter or leaves the text entry field.

**Parameters**

- **ax** [`matplotlib.axes.Axes`] The `matplotlib.axes.Axes` instance the button will be placed into.
- **label** [str] Label for this text box. Accepts string.
- **initial** [str] Initial value in the text box
- **color** [color] The color of the box
- **hovercolor** [color] The color of the box when the mouse is over it
- **label_pad** [float] the distance between the label and the right side of the textbox

```python
begin_typing(self, x)
disconnect(self, cid)
    Remove the observer with connection id `cid`.
on_submit(self, func)
    When the user hits enter or leaves the submission box, call this `func` with event.
    A connection id is returned which can be used to disconnect.
on_text_change(self, func)
    When the text changes, call this `func` with event.
    A connection id is returned which can be used to disconnect.
position_cursor(self, x)
set_val(self, val)
stop_typing(self)
```

```python
class matplotlib.widgets.ToolHandles(ax, x, y, marker='o', marker_props=None, useblit=True)
Bases: object
```

Control handles for canvas tools.
**Parameters**

- **ax** ([`matplotlib.axes.Axes`]) Matplotlib axes where tool handles are displayed.
- **x, y** ([1D arrays]) Coordinates of control handles.
- **marker** ([str]) Shape of marker used to display handle. See `matplotlib.pyplot.plot`.
- **marker_props** ([dict]) Additional marker properties. See `matplotlib.lines.Line2D`.

```python
closest(self, x, y)
    Return index and pixel distance to closest index.

set_animated(self, val)

set_data(self, pts, y=None)
    Set x and y positions of handles

set_visible(self, val)

x

y
```

class matplotlib.widgets.Widget
    Bases: object

    Abstract base class for GUI neutral widgets

    active
        Is the widget active?

    drawn = True

    eventson = True

    get_active(self)
        Get whether the widget is active.

    ignore(self, event)
        Return True if event should be ignored.
        This method (or a version of it) should be called at the beginning of any event callback.

    set_active(self, active)
        Set whether the widget is active.
Toolkits are collections of application-specific functions that extend Matplotlib. The following toolkits are included:

## 18.1 Toolkits

Toolkits are collections of application-specific functions that extend Matplotlib.

### 18.1.1 mplot3d

`mpl_toolkits.mplot3d` provides some basic 3D plotting (scatter, surf, line, mesh) tools. Not the fastest or most feature complete 3D library out there, but it ships with Matplotlib and thus may be a lighter weight solution for some use cases. Check out the `mplot3d tutorial` for more information.

![Fig. 1: Contourf3d 2](image)

mplot3d
Matplotlib mplot3d toolkit

The mplot3d toolkit adds simple 3D plotting capabilities to matplotlib by supplying an axes object that can create a 2D projection of a 3D scene. The resulting graph will have the same look and feel as regular 2D plots.

See the mplot3d tutorial for more information on how to use this toolkit.

The interactive backends also provide the ability to rotate and zoom the 3D scene. One can rotate the 3D scene by simply clicking-and-dragging the scene. Zooming is done by right-clicking the scene and dragging the mouse up and down. Note that one does not use the zoom button like one would use for regular 2D plots.

mplot3d FAQ

How is mplot3d different from MayaVi?

MayaVi2 is a very powerful and featureful 3D graphing library. For advanced 3D scenes and excellent rendering capabilities, it is highly recommended to use MayaVi2.

mplot3d was intended to allow users to create simple 3D graphs with the same "look-and-feel" as matplotlib’s 2D plots. Furthermore, users can use the same toolkit that they are already familiar with to generate both their 2D and 3D plots.
My 3D plot doesn’t look right at certain viewing angles

This is probably the most commonly reported issue with mplot3d. The problem is that – from some viewing angles – a 3D object would appear in front of another object, even though it is physically behind it. This can result in plots that do not look “physically correct.”

Unfortunately, while some work is being done to reduce the occurrence of this artifact, it is currently an intractable problem, and can not be fully solved until matplotlib supports 3D graphics rendering at its core.

The problem occurs due to the reduction of 3D data down to 2D + z-order scalar. A single value represents the 3rd dimension for all parts of 3D objects in a collection. Therefore, when the bounding boxes of two collections intersect, it becomes possible for this artifact to occur. Furthermore, the intersection of two 3D objects (such as polygons or patches) can not be rendered properly in matplotlib’s 2D rendering engine.

This problem will likely not be solved until OpenGL support is added to all of the backends (patches are greatly welcomed). Until then, if you need complex 3D scenes, we recommend using MayaVi.

I don’t like how the 3D plot is laid out, how do I change that?

Historically, mplot3d has suffered from a hard-coding of parameters used to control visuals such as label spacing, tick length, and grid line width. Work is being done to eliminate this issue. For matplotlib v1.1.0, there is a semi-official manner to modify these parameters. See the note in the axis3d section of the mplot3d API documentation for more information.

18.1.2 Matplotlib axes_grid1 Toolkit

The matplotlib mpl_toolkits.axes_grid1 toolkit is a collection of helper classes to ease displaying multiple images in matplotlib. While the aspect parameter in matplotlib adjust the position of the single axes, axes_grid1 toolkit provides a framework to adjust the position of multiple axes according to their aspects.

See What is axes_grid1 toolkit? for a guide on the usage of axes_grid1.

The submodules of the axes_grid1 API are:
The axes_divider module provides helper classes to adjust the positions of multiple axes at drawing time.

Provides classes of simple units that will be used with AxesDivider class (or others) to determine the size of each axes.

Colorbar toolkit with two classes and a function:

A collection of functions and objects for creating or placing inset axes.

An anchored container with transformed coordinates.

Draw two perpendicular arrows to indicate directions.

An anchored container with a fixed size and fillable DrawingArea.

Draw an anchored ellipse of a given size.

Draw a horizontal scale bar with a center-aligned label underneath.

An anchored container with transformed coordinates.

Artists added to the drawing_area are scaled according to the coordinates of the transformation used. The dimensions of this artist will scale to contain the artists added.

Parameters

transform : [matplotlib.transforms.Transform] The transformation object for the coordinate system in use, i.e., matplotlib.axes.Axes.transData.
loc [int] Location of this artist. Valid location codes are:

<table>
<thead>
<tr>
<th>Location Code</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>

pad [int or float, optional] Padding around the child objects, in fraction of the font size. Defaults to 0.4.

borderpad [int or float, optional] Border padding, in fraction of the font size. Defaults to 0.5.

frameon [bool, optional] If True, draw a box around this artists. Defaults to True.

**kwargs Keyworded arguments to pass to matplotlib.offsetbox.AnchoredOffsetbox.

Examples

To display an ellipse in the upper left, with a width of 0.1 and height of 0.4 in data coordinates:

```python
>>> box = AnchoredAuxTransformBox(ax.transData, loc='upper left')
>>> el = Ellipse((0,0), width=0.1, height=0.4, angle=30)
>>> box.drawing_area.add_artist(el)
>>> ax.add_artist(box)
```

Attributes

- drawing_area [matplotlib.offsetbox.AuxTransformBox] A container for artists to display.

Examples using mpl_toolkits.axes_grid1.anchored_artists.AnchoredAuxTransformBox

- sphx_glr_gallery_userdemo_anchored_box03.py
mpl_toolkits.axes_grid1.anchored_artists.AnchoredDirectionArrows

class mpl_toolkits.axes_grid1.anchored_artists.AnchoredDirectionArrows(transform, label_x, label_y, length=0.15, fontsize=0.08, loc=2, angle=0, aspect_ratio=1, pad=0.4, borderpad=0.4, frameon=False, color='w', alpha=1, sep_x=0.01, sep_y=0, fontproperties=None, back_length=0.15, head_width=10, head_length=15, tail_width=2, textProps=None, arrowprops=None, **kwargs)

Bases: matplotlib.offsetbox.AnchoredOffsetbox

Draw two perpendicular arrows to indicate directions.

Parameters

label_x, label_y [string] Label text for the x and y arrows

length [int or float, optional] Length of the arrow, given in coordinates of transform. Defaults to 0.15.

fontsize [int, optional] Size of label strings, given in coordinates of transform. Defaults to 0.08.

loc [int, optional] Location of the direction arrows. Valid location codes are:

<table>
<thead>
<tr>
<th>Location Code</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
<tr>
<td>'upper center'</td>
<td>9</td>
</tr>
<tr>
<td>'center'</td>
<td>10</td>
</tr>
</tbody>
</table>
Defaults to 2.

**angle** [int or float, optional] The angle of the arrows in degrees. Defaults to 0.

**aspect_ratio** [int or float, optional] The ratio of the length of arrow_x and arrow_y. Negative numbers can be used to change the direction. Defaults to 1.

**pad** [int or float, optional] Padding around the labels and arrows, in fraction of the font size. Defaults to 0.4.

**borderpad** [int or float, optional] Border padding, in fraction of the font size. Defaults to 0.4.

**frameon** [bool, optional] If True, draw a box around the arrows and labels. Defaults to False.

**color** [str, optional] Color for the arrows and labels. Defaults to white.

**alpha** [int or float, optional] Alpha values of the arrows and labels. Defaults to 1.

**sep_x, sep_y** [int or float, optional] Separation between the arrows and labels in coordinates of transform. Defaults to 0.01 and 0.

**fontproperties** [matplotlib.font_manager.FontProperties, optional] Font properties for the label text.

**back_length** [float, optional] Fraction of the arrow behind the arrow crossing. Defaults to 0.15.

**head_width** [int or float, optional] Width of arrow head, sent to ArrowStyle. Defaults to 10.

**head_length** [int or float, optional] Length of arrow head, sent to ArrowStyle. Defaults to 15.

**tail_width** [int or float, optional] Width of arrow tail, sent to ArrowStyle. Defaults to 2.

**text_props, arrow_props** [dict] Properties of the text and arrows, passed to matplotlib.text.TextPath and matplotlib.patches.FancyArrowPatch.

**kwargs** Keyworded arguments to pass to matplotlib.offsetbox.AnchoredOffsetbox.

**Notes**

If *prop* is passed as a keyword argument, but *fontproperties* is not, then *prop* is be assumed to be the intended *fontproperties*. Using both *prop* and *fontproperties* is not supported.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from mpl_toolkits.axes_grid1.anchored_artists import (  
```
(continues on next page)
AnchoredDirectionArrows)

```python
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.random.random((10,10)))
>>> arrows = AnchoredDirectionArrows(ax.transAxes, '111', '110')
>>> ax.add_artist(arrows)
>>> fig.show()
```

Using several of the optional parameters, creating downward pointing arrow and high contrast text labels.

```python
>>> import matplotlib.font_manager as fm
>>> fontprops = fm.FontProperties(family='monospace')
>>> arrows = AnchoredDirectionArrows(ax.transAxes, 'East', 'South',
... loc='lower left', color='k',
... aspect_ratio=-1, sep_x=0.02,
... sep_y=-0.01,
... text_props={'ec':w', 'fc':k'},
... fontproperties=fontprops)
```

**Attributes**

- `arrow_x, arrow_y` [matplotlib.patches.FancyArrowPatch] Arrow x and y
- `text_path_x, text_path_y` [matplotlib.text.TextPath] Path for arrow labels
- `p_x, p_y` [matplotlib.patches.PathPatch] Patch for arrow labels
- `box` [matplotlib.offsetbox.AuxTransformBox] Container for the arrows and labels.

**Examples using** mpl_toolkits.axes_grid1.anchored_artists.AnchoredDirectionArrows

- sphx_glr_gallery_axes_grid1_demo_anchored_direction_arrows.py

**mpl_toolkits.axes_grid1.anchored_artists.AnchoredDrawingArea**

```python
class mpl_toolkits.axes_grid1.anchored_artists.AnchoredDrawingArea(
    width, height, xdescent, ydescent, loc, pad=0.4, borderpad=0.5,
    prop=None, frameon=True, **kwargs)
```

**Bases:** matplotlib.offsetbox.AuxTransformBox

An anchored container with a fixed size and fillable DrawingArea.

Artists added to the `drawing_area` will have their coordinates interpreted as pixels. Any transformations set on the artists will be overridden.

**Parameters**
width, height [int or float] width and height of the container, in pixels.

xdescent, ydescent [int or float] descent of the container in the x- and y-direction, in pixels.

loc [int] Location of this artist. Valid location codes are:

```python
{'upper right': 1,  
'upper left': 2,  
'lower left': 3,  
'lower right': 4,  
'right': 5,  
'center left': 6,  
'center right': 7,  
'lower center': 8,  
'upper center': 9,  
'center': 10}
```

pad [int or float, optional] Padding around the child objects, in fraction of the font size. Defaults to 0.4.

borderpad [int or float, optional] Border padding, in fraction of the font size. Defaults to 0.5.

frameon [bool, optional] If True, draw a box around this artists. Defaults to True.

**kwargs Keyworded arguments to pass to `matplotlib.offsetbox.AnchoredOffsetbox`.

Examples

To display blue and red circles of different sizes in the upper right of an axes `ax`:

```python
>>> ada = AnchoredDrawingArea(20, 20, 0, 0,  
...                        loc='upper right', frameon=False)  
>>> ada.drawing_area.add_artist(Circle((10, 10), 10, fc="b"))  
>>> ada.drawing_area.add_artist(Circle((30, 10), 5, fc="r"))  
>>> ax.add_artist(ada)
```

Attributes

drawing_area [matplotlib.offsetbox.DrawingArea] A container for artists to display.

Examples using mpl_toolkits.axes_grid1.anchored_artists.AnchoredDrawingArea

- sphx_glr_gallery_axes_grid1_simple_anchored_artists.py
- sphx_glr_gallery_userdemo_anchored_box02.py
mpl_toolkits.axes_grid1.anchored_artists.AnchoredEllipse

class mpl_toolkits.axes_grid1.anchored_artists.AnchoredEllipse(transform, width, height, angle, loc, pad=0.1, borderpad=0.1, prop=None, frameon=True, **kwargs)

Bases: matplotlib.offsetbox.AnchoredOffsetbox

Draw an anchored ellipse of a given size.

Parameters

- **transform** [matplotlib.transforms.Transform] The transformation object for the coordinate system in use, i.e., matplotlib.axes.Axes.transData.
- **width, height** [int or float] Width and height of the ellipse, given in coordinates of transform.
- **angle** [int or float] Rotation of the ellipse, in degrees, anti-clockwise.
- **loc** [int] Location of this size bar. Valid location codes are:

```
'upper right' : 1,
'upper left'  : 2,
'lower left'  : 3,
'lower right' : 4,
'right'      : 5,
'center left' : 6,
'center right': 7,
'lower center': 8,
'upper center': 9,
'center'     : 10
```

- **pad** [int or float, optional] Padding around the ellipse, in fraction of the font size. Defaults to 0.1.
- **borderpad** [int or float, optional] Border padding, in fraction of the font size. Defaults to 0.1.
- **frameon** [bool, optional] If True, draw a box around the ellipse. Defaults to True.
- **prop** [matplotlib.font_manager.FontProperties, optional] Font property used as a reference for paddings.
- **kwargs** Keyworded arguments to pass to matplotlib.offsetbox.AnchoredOffsetbox.

Attributes

- **ellipse** [matplotlib.patches.Ellipse] Ellipse patch drawn.

Examples using mpl_toolkits.axes_grid1.anchored_artists.AnchoredEllipse

- sphx_glr_gallery_axes_grid1_simple_anchored_artists.py
mpl_toolkits.axes_grid1.anchored_artists.AnchoredSizeBar

class mpl_toolkits.axes_grid1.anchored_artists.AnchoredSizeBar(transform, size, label, loc, pad=0.1, borderpad=0.1, sep=2, frameon=True, size_vertical=0, color='black', label_top=False, fontproperties=None, fill_bar=None, **kwargs)

Bases: matplotlib.offsetbox.AnchoredOffsetbox

Draw a horizontal scale bar with a center-aligned label underneath.

Parameters

- size [int or float] Horizontal length of the size bar, given in coordinates of transform.
- label [str] Label to display.
- loc [int] Location of this size bar. Valid location codes are:

  ```
  'upper right' : 1,
  'upper left'  : 2,
  'lower left' : 3,
  'lower right' : 4,
  'right' : 5,
  'center left' : 6,
  'center right': 7,
  'lower center': 8,
  'upper center': 9,
  'center' : 10
  ```

- pad [int or float, optional] Padding around the label and size bar, in fraction of the font size. Defaults to 0.1.
- borderpad [int or float, optional] Border padding, in fraction of the font size. Defaults to 0.1.
- sep [int or float, optional] Separation between the label and the size bar, in points. Defaults to 2.
- frameon [bool, optional] If True, draw a box around the horizontal bar and label. Defaults to True.
- size_vertical [int or float, optional] Vertical length of the size bar, given in coordinates of transform. Defaults to 0.
- color [str, optional] Color for the size bar and label. Defaults to black.
- label_top [bool, optional] If True, the label will be over the size bar. Defaults to False.
**fontproperties** [matplotlib.font_manager.FontProperties, optional] Font properties for the label text.

**fill_bar** [bool, optional] If True and if size_vertical is nonzero, the size bar will be filled in with the color specified by the size bar. Defaults to True if size_vertical is greater than zero and False otherwise.

**kwargs** Keyworded arguments to pass to matplotlib.offsetbox.AnchoredOffsetbox.

**Notes**

If **prop** is passed as a keyworded argument, but **fontproperties** is not, then **prop** is be assumed to be the intended **fontproperties**. Using both **prop** and **fontproperties** is not supported.

**Examples**

```python
def main():
    from mpl_toolkits.axes_grid1.anchored_artists import AnchoredSizeBar
    import matplotlib.pyplot as plt
    import numpy as np

    fig, ax = plt.subplots()
    ax.imshow(np.random.random((10,10)))
    bar = AnchoredSizeBar(ax.transData, 3, '3 data units', 4,
                          sep=5, borderpad=0.5, frameon=False,
                          size_vertical=0.5, color='white',
                          fontproperties=fontprops)
    ax.add_artist(bar)
    fig.show()
```

Using all the optional parameters

```python
def main():
    from mpl_toolkits.axes_grid1.anchored_artists import AnchoredSizeBar
    import matplotlib.pyplot as plt
    import numpy as np

    fig, ax = plt.subplots()
    ax.imshow(np.random.random((10,10)))
    bar = AnchoredSizeBar(ax.transData, 3, '3 units', 4, pad=0.5,
                          sep=5, borderpad=0.5, frameon=False,
                          size_vertical=0.5, color='white',
                          fontproperties=fontprops)
    ax.add_artist(bar)
    fig.show()
```

**Attributes**

- **size_bar** [matplotlib.offsetbox.AuxTransformBox] Container for the size bar.
- **txt_label** [matplotlib.offsetbox.TextArea] Container for the label of the size bar.

**Examples using mpl_toolkits.axes_grid1.anchored_artists.AnchoredSizeBar**

- sphx_glr_gallery_axes_grid1_inset_locator_demo2.py
- sphx_glr_gallery_axes_grid1_simple_anchored_artists.py
The axes divider module provides helper classes to adjust the positions of multiple axes at drawing time.

**Divider:** this is the class that is used to calculate the axes position. It divides the given rectangular area into several sub rectangles. You initialize the divider by setting the horizontal and vertical lists of sizes that the division will be based on. You then use the new_locator method, whose return value is a callable object that can be used to set the axes_locator of the axes.

### Classes

<table>
<thead>
<tr>
<th><strong>Class</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axes(**kwargs)</td>
<td>[Deprecated]</td>
</tr>
<tr>
<td>AxesDivider(axes[, xref, yref])</td>
<td>Divider based on the pre-existing axes.</td>
</tr>
<tr>
<td>AxesLocator(axes_divider, nx, ny[, nx1, ny1])</td>
<td>A simple callable object, initialized with AxesDivider class, returns the position and size of the given cell.</td>
</tr>
<tr>
<td>Divider(fig, pos, horizontal, vertical[, ...])</td>
<td>This class calculates the axes position.</td>
</tr>
<tr>
<td>HBoxDivider(fig, *args, **kwargs)</td>
<td></td>

<tr>
<td>LocatableAxesBase(**kwargs)</td>
<td>[Deprecated]</td>
</tr>
<tr>
<td>SubplotDivider(fig, *args[, horizontal, ...])</td>
<td>The Divider class whose rectangle area is specified as a subplot geometry.</td>
</tr>
<tr>
<td>VBoxDivider(fig, *args, **kwargs)</td>
<td>The Divider class whose rectangle area is specified as a subplot geometry.</td>
</tr>
</tbody>
</table>

### mpl_toolkits.axes_grid1.axes_divider.Axes

```python
class mpl_toolkits.axes_grid1.axes_divider.Axes(**kwargs)
    Bases: mpl_toolkits.axes_grid1.mpl_axes.Axes
          [Deprecated]

    Notes
    Deprecated since version 3.0:
```

### mpl_toolkits.axes_grid1.axes_divider.AxesDivider

```python
class mpl_toolkits.axes_grid1.axes_divider.AxesDivider(axes, xref=None, yref=None)
    Bases: mpl_toolkits.axes_grid1.axes_divider.Divider

    Divider based on the pre-existing axes.

    Parameters
    axes [Axes]
    xref
    yref
```
append_axes(self, position, size, pad=None, add_to_figure=True, **kwargs)
Create an axes at the given position with the same height (or width) of the main axes.

**position** [“left”|“right”|“bottom”|“top”]
size and pad should be axes_grid.axes_size compatible.

get_anchor(self)
return the anchor

get_aspect(self)
return aspect

get_position(self)
return the position of the rectangle.

get_subplotspec(self)

new_horizontal(self, size, pad=None, pack_start=False, **kwargs)
Add a new axes on the right (or left) side of the main axes.

Parameters

**size** [axes_size or float or string] A width of the axes. If float or string is given, from_any function is used to create the size, with ref_size set to AxesX instance of the current axes.

**pad** [axes_size or float or string] Pad between the axes. It takes same argument as size.

**pack_start** [bool] If False, the new axes is appended at the end of the list, i.e., it became the right-most axes. If True, it is inserted at the start of the list, and becomes the left-most axes.

**kwargs** All extra keywords arguments are passed to the created axes. If axes_class is given, the new axes will be created as an instance of the given class. Otherwise, the same class of the main axes will be used.

new_vertical(self, size, pad=None, pack_start=False, **kwargs)
Add a new axes on the top (or bottom) side of the main axes.

Parameters

**size** [axes_size or float or string] A height of the axes. If float or string is given, from_any function is used to create the size, with ref_size set to AxesX instance of the current axes.

**pad** [axes_size or float or string] Pad between the axes. It takes same argument as size.

**pack_start** [bool] If False, the new axes is appended at the end of the list, i.e., it became the right-most axes. If True, it is inserted at the start of the list, and becomes the left-most axes.

**kwargs** All extra keywords arguments are passed to the created axes. If axes_class is given, the new axes will be created as an instance of the given class. Otherwise, the same class of the main axes will be used.
mpl_toolkits.axes_grid1.axes_divider.AxesLocator

class mpl_toolkits.axes_grid1.axes_divider.AxesLocator(axes_divider, nx, ny, nx1=None, ny1=None)
    Bases: object

A simple callable object, initialized with AxesDivider class, returns the position and size of the given cell.

Parameters

axes_divider [AxesDivider]

nx, nx1 [int] Integers specifying the column-position of the cell. When nx1 is None, a single nx-th column is specified. Otherwise location of columns spanning between nx to nx1 (but excluding nx1-th column) is specified.

ny, ny1 [int] Same as nx and nx1, but for row positions.

get_subplotspec(self)

mpl_toolkits.axes_grid1.axes_divider.Divider

class mpl_toolkits.axes_grid1.axes_divider.Divider(fig, pos, horizontal, vertical, aspect=None, anchor='C')
    Bases: object

This class calculates the axes position. It divides the given rectangular area into several sub-rectangles. You initialize the divider by setting the horizontal and vertical lists of sizes (mpl_toolkits.axes_grid1.axes_size) that the division will be based on. You then use the new_locator method to create a callable object that can be used as the axes locator of the axes.

Parameters

fig [Figure]

pos [tuple of 4 floats] position of the rectangle that will be divided

horizontal [list of axes_size] sizes for horizontal division

vertical [list of axes_size] sizes for vertical division

aspect [bool] if True, the overall rectangular area is reduced so that the relative part of the horizontal and vertical scales have the same scale.

anchor [{'C', 'SW', 'S', 'SE', 'E', 'NE', 'N', 'NW', 'W'}] placement of the reduced rectangle when aspect is True

add_auto_adjustable_area(self, use_axes, pad=0.1, adjust_dirs=None)

append_size(self, position, size)

get_anchor(self)
    return the anchor

get_aspect(self)
    return aspect

get_horizontal(self)
    return horizontal sizes
get_horizontal_sizes(self, renderer)
get_locator(self)
get_position(self)
    return the position of the rectangle.
get_position_runtime(self, ax, renderer)
get_vertical(self)
    return vertical sizes
get_vertical_sizes(self, renderer)
get_vsize_hsize(self)

locate(self, nx, ny, nx1=None, ny1=None, axes=None, renderer=None)

Parameters

nx, nx1  [int] Integers specifying the column-position of the cell. When
        nx1 is None, a single nx-th column is specified. Otherwise location
        of columns spanning between nx to nx1 (but excluding nx1-th col-
        umn) is specified.

ny, ny1  [int] Same as nx and nx1, but for row positions.

axes

renderer

new_locator(self, nx, ny, nx1=None, ny1=None)
    Returns a new locator (mpl_toolkits.axes_grid.axes_divider.AxesLocator) for speci-
    fied cell.

Parameters

nx, nx1  [int] Integers specifying the column-position of the cell. When
        nx1 is None, a single nx-th column is specified. Otherwise location
        of columns spanning between nx to nx1 (but excluding nx1-th col-
        umn) is specified.

ny, ny1  [int] Same as nx and nx1, but for row positions.

set_anchor(self, anchor)

Parameters

    anchor position

<table>
<thead>
<tr>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘C’</td>
<td>Center</td>
</tr>
<tr>
<td>‘SW’</td>
<td>bottom left</td>
</tr>
<tr>
<td>‘S’</td>
<td>bottom</td>
</tr>
<tr>
<td>‘SE’</td>
<td>bottom right</td>
</tr>
<tr>
<td>‘E’</td>

<tr>
<td>‘N’</td>
<td>top</td>
</tr>
<tr>
<td>‘NW’</td>
<td>top left</td>
</tr>
<tr>
<td>‘W’</td>
<td>left</td>
</tr>
</tbody>
</table>
set_aspect(self, aspect=False)

Parameters
aspect [bool]

set_horizontal(self, h)

Parameters
h [list of axes_size] sizes for horizontal division

set_locator(self, _locator)

set_position(self, pos)
set the position of the rectangle.

Parameters
pos [tuple of 4 floats] position of the rectangle that will be divided

set_vertical(self, v)

Parameters
v [list of axes_size] sizes for vertical division

mpl_toolkits.axes_grid1.axes_divider.HBoxDivider

class mpl_toolkits.axes_grid1.axes_divider.HBoxDivider(fig, *args, **kwargs)
Bases: mpl_toolkits.axes_grid1.axes_divider.SubplotDivider

locate(self, nx, ny, nx1=None, ny1=None, axes=None, renderer=None)

Parameters
axes_divider [AxesDivider]
x, nx1 [int] Integers specifying the column-position of the cell. When

nx1 is None, a single nx-th column is specified. Otherwise location

of columns spanning between nx to nx1 (but excluding nx1-th col-

umn) is specified.

ny, ny1 [int] Same as nx and nx1, but for row positions.

axes
renderer

new_locator(self, nx, nx1=None)
Create a new AxesLocator for the specified cell.

Parameters
nx, nx1 [int] Integers specifying the column-position of the cell. When

nx1 is None, a single nx-th column is specified. Otherwise location

of columns spanning between nx to nx1 (but excluding nx1-th col-

umn) is specified.

ny, ny1 [int] Same as nx and nx1, but for row positions.
Examples using `mpl_toolkits.axes_grid1.axes_divider.HBoxDivider`

- `sphx_glr_gallery_axes_grid1_demo_axes_hbox_divider.py`

`mpl_toolkits.axes_grid1.axes_divider.LocatableAxes`

class `mpl_toolkits.axes_grid1.axes_divider.LocatableAxes(**kwargs)`

    Bases: `mpl_toolkits.axes_grid1.mpl_axes.Axes`

    [Deprecated]

    Notes

    Deprecated since version 3.0:

`mpl_toolkits.axes_grid1.axes_divider.LocatableAxesBase`

class `mpl_toolkits.axes_grid1.axes_divider.LocatableAxesBase(**kwargs)`

    Bases: `object`

    [Deprecated]

    Notes

    Deprecated since version 3.0:

`mpl_toolkits.axes_grid1.axes_divider.SubplotDivider`

class `mpl_toolkits.axes_grid1.axes_divider.SubplotDivider(fig, *args, horizontal=None, vertical=None, aspect=None, anchor='C')`

    Bases: `mpl_toolkits.axes_grid1.axes_divider.Divider`

    The Divider class whose rectangle area is specified as a subplot geometry.

    Parameters

    * `fig` [matplotlib.figure.Figure]
    * `args` [tuple (numRows, numCols, plotNum)] The array of subplots in the
      figure has dimensions numRows, numCols, and plotNum is the number
      of the subplot being created. plotNum starts at 1 in the upper left
      corner and increases to the right.

      If numRows <= numCols <= plotNum < 10, args can be the decimal
      integer numRows * 100 + numCols * 10 + plotNum.

    `change_geometry(self, numrows, numcols, num)`
      change subplot geometry, e.g., from 1,1,1 to 2,2,3

    `get_geometry(self)`
      get the subplot geometry, e.g., 2,2,3
get_position(self)  
return the bounds of the subplot box

get_subplotspec(self)  
get the SubplotSpec instance

set_subplotspec(self, subplotspec)  
set the SubplotSpec instance

update_params(self)  
update the subplot position from fig.subplotpars

mpl_toolkits.axes_grid1.axes_divider.VBoxDivider

class mpl_toolkits.axes_grid1.axes_divider.VBoxDivider(fig, *args, **kwargs)
    Bases: mpl_toolkits.axes_grid1.axes_divider.HBoxDivider

    The Divider class whose rectangle area is specified as a subplot geometry.

    locate(self, nx, ny, nx1=None, ny1=None, axes=None, renderer=None)

        Parameters

        axes_divider [AxesDivider]

        nx, nx1 [int] Integers specifying the column-position of the cell. When
        nx1 is None, a single nx-th column is specified. Otherwise location
        of columns spanning between nx to nx1 (but excluding nx1-th col-
        umn) is specified.

        ny, ny1 [int] Same as nx and nx1, but for row positions.

        axes

        renderer

        new_locator(self, ny, ny1=None)

        Create a new AxesLocator for the specified cell.

        Parameters

        ny, ny1 [int] Integers specifying the row-position of the cell. When ny1
        is None, a single ny-th row is specified. Otherwise location of rows
        spanning between ny to ny1 (but excluding ny1-th row) is specified.

    Functions

    locatable_axes_factory(axes_class) [Deprecated]

    make_axes_area_auto_adjustable(ax[, ...])

    make_axes_locatable(axes)

mpl_toolkits.axes_grid1.axes_divider.locatable_axes_factory

mpl_toolkits.axes_grid1.axes_divider.locatable_axes_factory(axes_class)
    [Deprecated]
Notes

Deprecated since version 3.0:

mpl_toolkits.axes_grid1.axes_divider.make_axes_area_auto_adjustable

mpl_toolkits.axes_grid1.axes_grid1.AxesGrid

mpl_toolkits.axes_grid1.axes_grid.CbarAxes

class mpl_toolkits.axes_grid1.axes_grid.CbarAxes(*args, orientation, **kwargs)

cla(self)

Clear the current axes.
mpl_toolkits.axes_grid1.axes_grid.CbarAxesBase

class mpl_toolkits.axes_grid1.axes_grid.CbarAxesBase
    Bases: object

    colorbar(self, mappable, *, locator=None, **kwargs)
    toggle_label(self, b)

mpl_toolkits.axes_grid1.axes_grid.Grid

class mpl_toolkits.axes_grid1.axes_grid.Grid(fig, rect, nrows_ncols, ngrids=None, direction='row', axes_pad=0.02, add_all=True, share_all=False, share_x=True, share_y=True, label_mode='L', axes_class=None)
    Bases: object

A class that creates a grid of Axes. In matplotlib, the axes location (and size) is specified in the normalized figure coordinates. This may not be ideal for images that needs to be displayed with a given aspect ratio. For example, displaying images of a same size with some fixed padding between them cannot be easily done in matplotlib. AxesGrid is used in such case.

Parameters

- **fig** [Figure] The parent figure.
- **rect** [(float, float, float, float) or int] The axes position, as a (left, bottom, width, height) tuple or as a three-digit subplot position code (e.g., "121").
- **direction** ["row", "column"], default: "row"
- **axes_pad** [float or (float, float), default: 0.02] Padding or (horizontal padding, vertical padding) between axes, in inches.
- **add_all** [bool, default: True]
- **share_all** [bool, default: False]
- **share_x** [bool, default: True]
- **share_y** [bool, default: True]
- **label_mode** ["L", "1", "all"], default: "L"] Determines which axes will get tick labels:
  - "L": All axes on the left column get vertical tick labels; all axes on the bottom row get horizontal tick labels.
  - "1": Only the bottom left axes is labelled.
  - "all": all axes are labelled.
- **axes_class** [a type that is a subclass of matplotlib.axes.Axes, default: None]

get_aspect(self)
    Return the aspect of the SubplotDivider.

get_axes_locator(self)
get_axes_pad(self)
    Return the axes padding.

    Returns
    
    hpad, vpad  Padding (horizontal pad, vertical pad) in inches.

get_divider(self)

get_geometry(self)
    Return the number of rows and columns of the grid as (nrows, ncols).

get_vsize_hsize(self)

set_aspect(self, aspect)
    Set the aspect of the SubplotDivider.

set_axes_locator(self, locator)

set_axes_pad(self, axes_pad)
    Set the padding between the axes.

Parameters

    axes_pad  [(float, float)] The padding (horizontal pad, vertical pad) in inches.

set_label_mode(self, mode)
    Define which axes have tick labels.

Parameters

    mode  [{“L”, “1”, “all”}] The label mode:
    • “L”: All axes on the left column get vertical tick labels; all axes on the bottom row get horizontal tick labels.
    • “1”: Only the bottom left axes is labelled.
    • “all”: all axes are labelled.

mpl_toolkits.axes_grid1.axes_grid.ImageGrid

class mpl_toolkits.axes_grid1.axes_grid.ImageGrid(fig, rect, nrows_ncols, 
ngrids=None, direction='row', 
axes_pad=0.02, add_all=True, 
share_all=False, aspect=True, label_mode='L', cbar_mode=None, 
cbar_location='right', 
cbar_pad=None, cbar_size='5%', 
cbar_set_cax=True, 
axes_class=None)

Bases: mpl_toolkits.axes_grid1.axes_grid.Grid

A class that creates a grid of Axes. In matplotlib, the axes location (and size) is specified in the normalized figure coordinates. This may not be ideal for images that needs to be displayed with a given aspect ratio. For example, displaying images of a same size with some fixed padding between them cannot be easily done in matplotlib. ImageGrid is used in such case.

Parameters
**fig** [Figure] The parent figure.

**rect** [(float, float, float, float) or int] The axes position, as a (left, bottom, width, height) tuple or as a three-digit subplot position code (e.g., “121”).

**direction** [{“row”, “column”}, default: “row”]

**axes_pad** [float or (float, float), default: 0.02] Padding or (horizontal padding, vertical padding) between axes, in inches.

**add_all** [bool, default: True]

**share_all** [bool, default: False]

**aspect** [bool, default: True]

**label_mode** [{“L”, “1”, “all”}, default: “L”] Determines which axes will get tick labels:
- “L”: All axes on the left column get vertical tick labels; all axes on the bottom row get horizontal tick labels.
- “1”: Only the bottom left axes is labelled.
- “all”: all axes are labelled.

**cbar_mode** [{“each”, “single”, “edge”, None }, default: None]

**cbar_location** [{“left”, “right”, “bottom”, “top”}, default: “right”]

**cbar_pad** [float, default: None]

**cbar_size** [size specification (see `Size.from_any`), default: “5%”]

**cbar_set_cax** [bool, default: True] If True, each axes in the grid has a cax attribute that is bound to associated cbar_axes.

**axes_class** [a type that is a subclass of `matplotlib.axes.Axes`, default: None]

---

**mpl_toolkits.axes_grid1.axes_rgb**

**Classes**

`RGBAxes(*args[, pad, add_all])`

**Parameters**

`RGBAxesBase(*args[, pad, add_all])` base class for a 4-panel imshow (RGB, R, G, B)

---

**mpl_toolkits.axes_grid1.axes_rgb.RGBAxes**

**class** `mpl_toolkits.axes_grid1.axes_rgb.RGBAxes(*args, pad=0, add_all=True, **kwargs)`

**Bases:** `mpl_toolkits.axes_grid1.axes_rgb.RGBAxesBase`

**Parameters**

- **pad** [float] fraction of the axes height to put as padding. defaults to 0.0
- **add_all** [bool] True: Add the {rgb, r, g, b} axes to the figure defaults to

---

18.1. **Toolkits**
True.

**axes_class** [matplotlib.axes.Axes]

*args Unpacked into axes_class() init for RGB

**kwargs Unpacked into axes_class() init for RGB, R, G, B axes

Examples using mpl_toolkits.axes_grid1.axes_rgb.RGBAxes

- sphx_glr_gallery_pyplots_whats_new_99_axes_grid.py
- sphx_glr_gallery_axes_grid1_demo_axes_rgb.py
- sphx_glr_gallery_axes_grid1_simple_rgb.py

mpl_toolkits.axes_grid1.axes_rgb.RGBAxesBase

class mpl_toolkits.axes_grid1.axes_rgb.RGBAxesBase(*args, pad=0, add_all=True, **kwargs)

Bases: object

base class for a 4-panel imshow (RGB, R, G, B)

Layout: +———-+—–+ | | R | + ——-+ | RGB | G | + ——+ | | B | +———-+—–+

Attributes

 defiantAxesClass [matplotlib.axes.Axes] defaults to ‘Axes’ in RGBAxes child class. No default in abstract base class

RGB [defaultAxesClass] The axes object for the three-channel imshow

R [defaultAxesClass] The axes object for the red channel imshow

G [defaultAxesClass] The axes object for the green channel imshow

B [defaultAxesClass] The axes object for the blue channel imshow

Parameters

pad [float] fraction of the axes height to put as padding. defaults to 0.0

add_all [bool] True: Add the {rgb, r, g, b} axes to the figure defaults to True.

axes_class [matplotlib.axes.Axes]

*args Unpacked into axes_class() init for RGB

**kwargs Unpacked into axes_class() init for RGB, R, G, B axes

add_RGB_to_figure(self)

Add the red, green and blue axes to the RGB composite’s axes figure

imshow_rgb(self, r, g, b, **kwargs)

Create the four images {rgb, r, g, b}

Parameters

r [array-like] The red array

g [array-like] The green array
b [array-like] The blue array

kwargs [imshow kwargs] kwargs get unpacked into the imshow calls for the four images

Returns

rgb [matplotlib.image.AxesImage]  
r [matplotlib.image.AxesImage]  
g [matplotlib.image.AxesImage]  
 b [matplotlib.image.AxesImage]

Functions

imshow_rgb(ax, r, g, b, **kwargs)

make_rgb_axes(ax[, pad, axes_class, add_all])

Parameters

mpl_toolkits.axes_grid1.axes_rgb.imshow_rgb

mpl_toolkits.axes_grid1.axes_rgb.imshow_rgb(ax, r, g, b, **kwargs)

mpl_toolkits.axes_grid1.axes_rgb.make_rgb_axes

mpl_toolkits.axes_grid1.axes_rgb.make_rgb_axes(ax, pad=0.01, axes_class=None, add_all=True)

Parameters

pad [float] Fraction of the axes height.

Examples using mpl_toolkits.axes_grid1.axes_rgb.make_rgb_axes

• sphx_glr_gallery_axes_grid1_demo_axes_rgb.py

mpl_toolkits.axes_grid1.axes_size

Provides classes of simple units that will be used with AxesDivider class (or others) to determine the size of each axes. The unit classes define get_size method that returns a tuple of two floats, meaning relative and absolute sizes, respectively.

Note that this class is nothing more than a simple tuple of two floats. Take a look at the Divider class to see how these two values are used.

Classes

### mpl_toolkits.axes_grid1.axes_size.Add

```python
class mpl_toolkits.axes_grid1.axes_size.Add:
    Bases: mpl_toolkits.axes_grid1.axes_size._Base
    get_size(self, renderer)
```

### mpl_toolkits.axes_grid1.axes_size.AddList

```python
class mpl_toolkits.axes_grid1.axes_size.AddList:
    Bases: mpl_toolkits.axes_grid1.axes_size._Base
    get_size(self, renderer)
```

### mpl_toolkits.axes_grid1.axes_size.AxesX

```python
class mpl_toolkits.axes_grid1.axes_size.AxesX:
    Bases: mpl_toolkits.axes_grid1.axes_size._Base
    Scaled size whose relative part corresponds to the data width of the `axes` multiplied by the `aspect`.
    get_size(self, renderer)
```
Examples using `mpl_toolkits.axes_grid1.axes_sizeAxesX`

- `sphx_glr_gallery_axes_grid1_demo_axes_hbox_divider.py`
- `sphx_glr_gallery_axes_grid1_simple_axes_divider3.py`

`mpl_toolkits.axes_grid1.axes_sizeAxesY`

class `mpl_toolkits.axes_grid1.axes_sizeAxesY(axes, aspect=1.0, ref_ax=None)`

Bases: `mpl_toolkits.axes_grid1.axes_size._Base`

Scaled size whose relative part corresponds to the data height of the `axes` multiplied by the `aspect`.

```python
get_size(self, renderer)
```

Examples using `mpl_toolkits.axes_grid1.axes_sizeAxesY`

- `sphx_glr_gallery_axes_grid1_demo_axes_hbox_divider.py`
- `sphx_glr_gallery_axes_grid1_simple_axes_divider3.py`

`mpl_toolkits.axes_grid1.axes_sizeFixed`

class `mpl_toolkits.axes_grid1.axes_sizeFixed(fixed_size)`

Bases: `mpl_toolkits.axes_grid1.axes_size._Base`

Simple fixed size with absolute part = `fixed_size` and relative part = 0.

```python
get_size(self, renderer)
```

Examples using `mpl_toolkits.axes_grid1.axes_sizeFixed`

- `sphx_glr_gallery_axes_grid1_demo_axes_hbox_divider.py`
- `sphx_glr_gallery_axes_grid1_simple_axes_divider2.py`
- `sphx_glr_gallery_axes_grid1_simple_axes_divider3.py`

`mpl_toolkits.axes_grid1.axes_sizeFraction`

class `mpl_toolkits.axes_grid1.axes_sizeFraction(fraction, ref_size)`

Bases: `mpl_toolkits.axes_grid1.axes_size._Base`

An instance whose size is a `fraction` of the `ref_size`.

```python
>>> s = Fraction(0.3, AxesX(ax))

get_size(self, renderer)
```
mpl_toolkits.axes_grid1.axes_size.GetExtentHelper

class mpl_toolkits.axes_grid1.axes_size.GetExtentHelper(ax, direction)
    Bases: object

mpl_toolkits.axes_grid1.axes_size.MaxExtent

class mpl_toolkits.axes_grid1.axes_size.MaxExtent(artist_list, w_or_h)
    Bases: mpl_toolkits.axes_grid1.axes_size._Base
    Size whose absolute part is the largest width (or height) of the given artist_list.
    add_artist(self, a)
    get_size(self, renderer)

mpl_toolkits.axes_grid1.axes_size.MaxHeight

class mpl_toolkits.axes_grid1.axes_size.MaxHeight(artist_list)
    Bases: mpl_toolkits.axes_grid1.axes_size._Base
    Size whose absolute part is the largest height of the given artist_list.
    add_artist(self, a)
    get_size(self, renderer)

mpl_toolkits.axes_grid1.axes_size.MaxWidth

class mpl_toolkits.axes_grid1.axes_size.MaxWidth(artist_list)
    Bases: mpl_toolkits.axes_grid1.axes_size._Base
    Size whose absolute part is the largest width of the given artist_list.
    add_artist(self, a)
    get_size(self, renderer)

mpl_toolkits.axes_grid1.axes_size.Padded

class mpl_toolkits.axes_grid1.axes_size.Padded(size, pad)
    Bases: mpl_toolkits.axes_grid1.axes_size._Base
    Return a instance where the absolute part of size is increase by the amount of pad.
    get_size(self, renderer)

mpl_toolkits.axes_grid1.axes_size.Scalable

mpl_toolkits.axes_grid1.axes_size.Scalable
    alias of mpl_toolkits.axes_grid1.axes_size.Scaled
mpl_toolkits.axes_grid1.axes_size.Scaled

class mpl_toolkits.axes_grid1.axes_size.Scaled(scalable_size)
    Bases: mpl_toolkits.axes_grid1.axes_size._Base

    Simple scaled(?) size with absolute part = 0 and relative part = scalable_size.
    get_size(self, renderer)

Examples using mpl_toolkits.axes_grid1.axes_size.Scaled

- sphx_glr_gallery_axes_grid1_demo_axes_hbox_divider.py
- sphx_glr_gallery_axes_grid1_simple_axes_divider2.py

mpl_toolkits.axes_grid1.axes_size.SizeFromFunc

class mpl_toolkits.axes_grid1.axes_size.SizeFromFunc(func)
    Bases: mpl_toolkits.axes_grid1.axes_size._Base

    get_size(self, renderer)

Functions

from_any(size[, fraction_ref]) Creates Fixed unit when the first argument
    is a float, or a Fraction unit if that is a string
    that ends with %.

mpl_toolkits.axes_grid1.axes_size.from_any

mpl_toolkits.axes_grid1.axes_size.from_any(size, fraction_ref=None)
    Creates Fixed unit when the first argument is a float, or a Fraction unit if that is a string
    that ends with %. The second argument is only meaningful when Fraction unit is cre-
    ated.: 

    >>> a = Size.from_any(1.2) # => Size.Fixed(1.2)
    >>> Size.from_any("50%", a) # => Size.Fraction(0.5, a)

mpl_toolkits.axes_grid1.colorbar

Colorbar toolkit with two classes and a function:

    ColorbarBase the base class with full colorbar drawing functionality. It can be used
    as-is to make a colorbar for a given colormap; a mappable object (e.g., image)
    is not needed.

    Colorbar the derived class for use with images or contour plots.

    make_axes() a function for resizing an axes and adding a second axes suitable for a
    colorbar
The `colorbar()` method uses `make_axes()` and `Colorbar`; the `colorbar()` function is a thin wrapper over `colorbar()`.

```python
class mpl_toolkits.axes_grid1.colorbar.CbarAxesLocator(locator=None, extend='neither', orientation='vertical')
```

`CbarAxesLocator` is a axes_locator for colorbar axes. It adjust the position of the axes to make a room for extended ends, i.e., the extended ends are located outside the axes area.

**locator** [the bbox returned from the locator is used as a] initial axes location. If None, axes.bbox is used.

**extend** : same as in `ColorbarBase`

**orientation** : same as in `ColorbarBase`

```python
def get_end_vertices(self):
    return a tuple of two vertices for the colorbar extended ends. The first vertices is for the minimum end, and the second is for the maximum end.
```

```python
def get_original_position(self, axes, renderer):
    get the original position of the axes.
```

```python
def get_path_ends(self):
    get the paths for extended ends
```

```python
def get_path_patch(self):
    get the path for axes patch
```

```python
class mpl_toolkits.axes_grid1.colorbar.Colorbar(ax, mappable, **kw)
```

```python
add_lines(self, CS)
    Add the lines from a non-filled `ContourSet` to the colorbar.
```

```python
update_bruteforce(self, mappable)
    Update the colorbar artists to reflect the change of the associated mappable.
```

```python
class mpl_toolkits.axes_grid1.colorbar.ColorbarBase(ax, cmap=None, norm=None, alpha=1.0, values=None, boundaries=None, orientation='vertical', extend='neither', spacing='uniform', ticks=None, format=None, drawedges=False, filled=True)
```

Draw a colorbar in an existing axes.

This is a base class for the `Colorbar` class, which is the basis for the `colorbar()` method and `pyplot` function.

It is also useful by itself for showing a colormap. If the `cmap` kwarg is given but `boundaries` and `values` are left as None, then the colormap will be displayed on a 0-1 scale. To show the under- and over-value colors, specify the `norm` as:

```python
colors.Normalize(clip=False)
```

To show the colors versus index instead of on the 0-1 scale, use:

```python
norm=colors.NoNorm.
```

Useful attributes:

- `ax` the Axes instance in which the colorbar is drawn
lines a LineCollection if lines were drawn, otherwise None

dividers a LineCollection if drawedges is True, otherwise None

Useful public methods are set_label() and add_lines().

add_lines(self, levels, colors, linewidhts)
  Draw lines on the colorbar. It deletes preexisting lines.

set_alpha(self, alpha)
  set alpha value.

set_label_text(self, label, **kw)
  Label the long axis of the colorbar

update_artists(self)
  Update the colorbar associated artists, filled and ends. Note that lines are not updated. This needs to be called whenever clim of associated image changes.

mpl_toolkits.axes_grid1.colorbar.colorbar(mappable, cax=None, ax=None, **kw)

  Create a colorbar for a ScalarMappable instance.

  Documentation for the pyplot thin wrapper:

  Add a colorbar to a plot.

  Function signatures for the pyplot interface; all but the first are also method signatures for the colorbar() method:

  colorbar(**kwargs)
  colorbar(mappable, **kwargs)
  colorbar(mappable, cax=cax, **kwargs)
  colorbar(mappable, ax=ax, **kwargs)

arguments:

  mappable the Image, ContourSet, etc. to which the colorbar applies; this argument is mandatory for the colorbar() method but optional for the colorbar() function, which sets the default to the current image.

keyword arguments:

  cax None | axes object into which the colorbar will be drawn
  ax None | parent axes object from which space for a new colorbar axes will be stolen

Additional keyword arguments are of two kinds:

  axes properties:
colorbar properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extend</td>
<td>['neither'</td>
</tr>
<tr>
<td>spacing</td>
<td>['uniform'</td>
</tr>
<tr>
<td>ticks</td>
<td>None</td>
</tr>
<tr>
<td>format</td>
<td>None</td>
</tr>
<tr>
<td>drawedges</td>
<td>Whether to draw lines at color boundaries.</td>
</tr>
</tbody>
</table>

The following will probably be useful only in the context of indexed colors (that is, when the mappable has norm=NoNorm()), or other unusual circumstances.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boundaries</td>
<td>None or a sequence</td>
</tr>
<tr>
<td>values</td>
<td>None or a sequence which must be of length 1 less than the sequence of boundaries. For each region delimited by adjacent entries in boundaries, the color mapped to the corresponding value in values will be used.</td>
</tr>
</tbody>
</table>

If mappable is a ContourSet, its extend kwarg is included automatically.

Note that the shrink kwarg provides a simple way to keep a vertical colorbar, for example, from being taller than the axes of the mappable to which the colorbar is attached; but it is a manual method requiring some trial and error. If the colorbar is too tall (or a horizontal colorbar is too wide) use a smaller value of shrink.

For more precise control, you can manually specify the positions of the axes objects in which the mappable and the colorbar are drawn. In this case, do not use any of the axes.
properties kwargs.

It is known that some vector graphics viewer (svg and pdf) renders white gaps between segments of the colorbar. This is due to bugs in the viewers not matplotlib. As a workaround the colorbar can be rendered with overlapping segments:

```python
cbar = colorbar()
cbar.solids.set_edgecolor("face")
draw()
```

However this has negative consequences in other circumstances. Particularly with semi transparent images (alpha < 1) and colorbar extensions and is not enabled by default see (issue #1188).

**returns:** `Colorbar` instance; see also its base class, `ColorbarBase`. Call the `set_label()` method to label the colorbar.

The transData of the `cax` is adjusted so that the limits in the longest axis actually corresponds to the limits in colorbar range. On the other hand, the shortest axis has a data limits of [1,2], whose unconventional value is to prevent underflow when log scale is used.

```python
mpl_toolkits.axes_grid1.colorbar.make_axes(parent, *, fraction=0.15, shrink=1.0, aspect=20, **kw)
```

Resize and reposition a parent axes, and return a child axes suitable for a colorbar

```python
cax, kw = make_axes(parent, **kw)
```

Keyword arguments may include the following (with defaults):

**orientation** ‘vertical’ or ‘horizontal’

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orientation</td>
<td>vertical or horizontal</td>
</tr>
<tr>
<td>fraction</td>
<td>0.15; fraction of original axes to use for colorbar</td>
</tr>
<tr>
<td>pad</td>
<td>0.05 if vertical, 0.15 if horizontal; fraction of original axes between colorbar and new image axes</td>
</tr>
<tr>
<td>shrink</td>
<td>1.0; fraction by which to shrink the colorbar</td>
</tr>
<tr>
<td>aspect</td>
<td>20; ratio of long to short dimensions</td>
</tr>
</tbody>
</table>

All but the first of these are stripped from the input kw set.

Returns (cax, kw), the child axes and the reduced kw dictionary.

**mpl_toolkits.axes_grid1.inset_locator**

A collection of functions and objects for creating or placing inset axes.

**Classes**
AnchoredLocatorBase(bbox_to_anchor, ...)  
AnchoredSizeLocator(bbox_to_anchor, x_size, ...)  
AnchoredZoomLocator(parent_axes, zoom, loc)  
BboxConnector(bbox1, bbox2, loc1[, loc2]) Connect two bboxes with a straight line.  
BboxConnectorPatch(bbox1, bbox2, loc1a, ...) Connect two bboxes with a quadrilateral.  
BboxPatch(bbox, **kwargs) Patch showing the shape bounded by a Bbox.  
InsetPosition(parent, lbwh) An object for positioning an inset axes.

mpl_toolkits.axes_grid1.inset_locator.AnchoredLocatorBase

class mpl_toolkits.axes_grid1.inset_locator.AnchoredLocatorBase(bbox_to_anchor,
offsetbox, loc,
borderpad=0.5,
bbox_transform=None)

Bases: matplotlib.offsetbox.AnchoredOffsetbox
draw(self, renderer)  
draw the artist

mpl_toolkits.axes_grid1.inset_locator.AnchoredSizeLocator

class mpl_toolkits.axes_grid1.inset_locator.AnchoredSizeLocator(bbox_to_anchor,
x_size, y_size, loc,
borderpad=0.5,
bbox_transform=None)

Bases: mpl_toolkits.axes_grid1.inset_locator.AnchoredLocatorBase
get_extent(self, renderer)  
return the extent of the artist. The extent of the child added with the pad is returned

mpl_toolkits.axes_grid1.inset_locator.AnchoredZoomLocator

class mpl_toolkits.axes_grid1.inset_locator.AnchoredZoomLocator(parent_axes, zoom,
loc, borderpad=0.5,
bbox_to_anchor=None,
bbox_transform=None)

Bases: mpl_toolkits.axes_grid1.inset_locator.AnchoredLocatorBase
get_extent(self, renderer)  
return the extent of the artist. The extent of the child added with the pad is returned

mpl_toolkits.axes_grid1.inset_locator.BboxConnector

class mpl_toolkits.axes_grid1.inset_locator.BboxConnector(bbox1, bbox2, loc1,
loc2=None, **kwargs)

Bases: matplotlib.patches.Patch  
Connect two bboxes with a straight line.  

Parameters
bbox1, bbox2 [matplotlib.transforms.Bbox] Bounding boxes to connect.

loc1 [{1, 2, 3, 4}] Corner of bbox1 to draw the line. Valid values are:

<table>
<thead>
<tr>
<th>Location</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
</tbody>
</table>

loc2 [{1, 2, 3, 4}, optional] Corner of bbox2 to draw the line. If None, defaults to loc1. Valid values are:

<table>
<thead>
<tr>
<th>Location</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
</tbody>
</table>

**kwargs Patch properties for the line drawn. Valid arguments include:

<table>
<thead>
<tr>
<th>Property</th>

</tbody>
</table>

static connect_bbox(bbox1, bbox2, loc1, loc2=None)
Helper function to obtain a Path from one bbox to another.
Parameters
bbox1, bbox2 [matplotlib.transforms.Bbox] Bounding boxes to connect.
loc1 [{1, 2, 3, 4}] Corner of bbox1 to use. Valid values are:

<table>
<thead>
<tr>
<th>Corner</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
</tbody>
</table>

loc2 [{1, 2, 3, 4}, optional] Corner of bbox2 to use. If None, defaults to loc1. Valid values are:

<table>
<thead>
<tr>
<th>Corner</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
</tbody>
</table>

Returns
path [matplotlib.path.Path] A line segment from the loc1 corner of bbox1 to the loc2 corner of bbox2.

static get_bbox_edge_pos(bbox, loc)
Helper function to obtain the location of a corner of a bbox

Parameters
bbox [matplotlib.transforms.Bbox]
loc [{1, 2, 3, 4}] Corner of bbox. Valid values are:

<table>
<thead>
<tr>
<th>Corner</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
</tbody>
</table>

Returns
x, y [float] Coordinates of the corner specified by loc.

get_path(self)
Return the path of this patch

Examples using mpl_toolkits.axes_grid1.inset_locator.BboxConnector

- sphx_glr_gallery_subplots_axes_and_figures_axes_zoom_effect.py

mpl_toolkits.axes_grid1.inset_locator.BboxConnectorPatch

class mpl_toolkits.axes_grid1.inset_locator.BboxConnectorPatch(bbox1, bbox2, loc1a, loc2a, loc1b, loc2b, **kwargs)

Bases: mpl_toolkits.axes_grid1.inset_locator.BboxConnector
Connect two bboxes with a quadrilateral.

The quadrilateral is specified by two lines that start and end at corners of the bboxes. The four sides of the quadrilateral are defined by the two lines given, the line between the two corners specified in `bbox1` and the line between the two corners specified in `bbox2`.

**Parameters**

- **bbox1, bbox2** ([`matplotlib.transforms.Bbox`]) Bounding boxes to connect.
- **loc1a, loc2a** ([1, 2, 3, 4]) Corners of `bbox1` and `bbox2` to draw the first line. Valid values are:
  
<table>
<thead>
<tr>
<th>Value</th>
<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
</tbody>
</table>

- **loc1b, loc2b** ([1, 2, 3, 4]) Corners of `bbox1` and `bbox2` to draw the second line. Valid values are:
  
<table>
<thead>
<tr>
<th>Value</th>
<th>Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
</tbody>
</table>

**kwargs** Patch properties for the line drawn:

- `agg_filter` a filter function, which takes a (m, n, 3) float array and a dpi value, and returns a (m, n, 3) array
- `alpha` float or None
- `animated` bool
- `antialiased` or `aa` unknown
- `capstyle` {'butt', 'round', 'projecting'}
- `clip_box` `Bbox`
- `clip_on` bool
- `clip_path` `[(Path, Transform) | Patch | None]`
- `color` color
- `contains` callable
- `edgecolor` or `ec` color or None or `auto`
- `facecolor` or `fc` color or None
- `figure` `Figure`
- `fill` bool
- `gid` str
- `hatch` {'/', '\', '|', '-', '+', 'x', 'o', 'O', '.', '*'}
- `in_layout` bool
- `joinstyle` {'miter', 'round', 'bevel'}
- `label` object
- `linestyle` or `ls` {'-', '-', '..', 'o', 'O', '.', '*', '...'}
- `linewidth` or `lw` float or None
- `path_effects` `AbstractPathEffect`
- `picker` None or bool or float or callable
- `rasterized` None or bool or float or callable

#### `mpl_toolkits.axes_grid1.inset_locator.BboxPatch`

**class** `mpl_toolkits.axes_grid1.inset_locator.BboxPatch(bbox, **kwargs)`

Bases: `matplotlib.patches.Patch`

Patch showing the shape bounded by a Bbox.

**Parameters**

- `bbox` `[matplotlib.transforms.Bbox]` Bbox to use for the extents of this patch.

- `**kwargs` Patch properties. Valid arguments include:

<table>

```python
def get_path(self):
    Return the path of this patch
```

**Examples using** `mpl_toolkits.axes_grid1.inset_locator.BboxPatch`

- sphx_glr_gallery_subplots_axes_and_figures_axes_zoom_effect.py

**mpl_toolkits.axes_grid1.inset_locator.InsetPosition**

```python
class mpl_toolkits.axes_grid1.inset_locator.InsetPosition(parent, lbwh):
    Bases: object

    An object for positioning an inset axes.

    This is created by specifying the normalized coordinates in the axes, instead of the figure.

    **Parameters**

    - **parent** [``matplotlib.axes.Axes``] Axes to use for normalizing coordinates.
    - **lbwh** [iterable of four floats] The left edge, bottom edge, width, and height of the inset axes, in units of the normalized coordinate of the parent axes.

    **See also:**

    - matplotlib.axes.Axes.set_axes_locator()
```

**Examples**

The following bounds the inset axes to a box with 20% of the parent axes’s height and 40% of the width. The size of the axes specified ([0, 0, 1, 1]) ensures that the axes completely fills the bounding box:

```python
>>> parent_axes = plt.gca()
>>> ax_ins = plt.axes([0, 0, 1, 1])
>>> ip = InsetPosition(ax, [0.5, 0.1, 0.4, 0.2])
>>> ax_ins.set_axes_locator(ip)
```
**Functions**

- `inset_axes(parent_axes, width, height[, ...])` Create an inset axes with a given width and height.
- `mark_inset(parent_axes, inset_axes, loc1, ...)` Draw a box to mark the location of an area represented by an inset axes.
- `zoomed_inset_axes(parent_axes, zoom[, loc, ...])` Create an anchored inset axes by scaling a parent axes.

```python
mpl_toolkits.axes_grid1.inset_locator.inset_axes

mpl_toolkits.axes_grid1.inset_locator.inset_axes

Create an inset axes with a given width and height.
Both sizes used can be specified either in inches or percentage. For example:

```python
inset_axes(parent_axes, width='40%', height='30%', loc=3)
```

creates an inset axes in the lower left corner of `parent_axes` which spans over 30% in height and 40% in width of the `parent_axes`. Since the usage of `inset_axes` may become slightly tricky when exceeding such standard cases, it is recommended to read the examples.

**Parameters**

- `width, height` [float or str] Size of the inset axes to create. If a float is provided, it is the size in inches, e.g. `width=1.3`. If a string is provided, it is the size in relative units, e.g. `width='40%'`. By default, i.e. if neither `bbox_to_anchor` nor `bbox_transform` are specified, those are relative to the `parent_axes`. Otherwise they are to be understood relative to the bounding box provided via `bbox_to_anchor`.
- `loc` [int or string, optional, default to 1] Location to place the inset axes. The valid locations are:

```python
"upper right" : 1,
"upper left"  : 2,
"lower left"  : 3,
"lower right" : 4,
"right"      : 5,
"center left" : 6,
"center right": 7,
"lower center": 8,
"upper center": 9,
"center"     : 10
```
bbox_to_anchor [tuple or matplotlib.transforms.BboxBase, optional] Bbox that the inset axes will be anchored to. If None, a tuple of (0, 0, 1, 1) is used if bbox_transform is set to parent_axes.transAxes or parent_axes.figure.transFigure. Otherwise, parent_axes.bbox is used. If a tuple, can be either [left, bottom, width, height], or [left, bottom]. If the kwargs width and/or height are specified in relative units, the 2-tuple [left, bottom] cannot be used. Note that, unless bbox_transform is set, the units of the bounding box are interpreted in the pixel coordinate. When using bbox_to_anchor with tuple, it almost always makes sense to also specify a bbox_transform. This might often be the axes transform parent_axes.transAxes.

bbox_transform [matplotlib.transforms.Transform, optional] Transformation for the bbox that contains the inset axes. If None, a transforms.IdentityTransform is used. The value of bbox_to_anchor (or the return value of its get_points method) is transformed by the bbox_transform and then interpreted as points in the pixel coordinate (which is dpi dependent). You may provide bbox_to_anchor in some normalized coordinate, and give an appropriate transform (e.g., parent_axes.transAxes).

axes_class [matplotlib.axes.Axes type, optional] If specified, the inset axes created will be created with this class’s constructor.

axes_kwarg [dict, optional] Keyworded arguments to pass to the constructor of the inset axes. Valid arguments include:

</table>

**borderpad** [float, optional] Padding between inset axes and the bbox_to_anchor. Defaults to 0.5. The units are axes font size, i.e. for a default font size of 10 points borderpad = 0.5 is equivalent to a padding of 5 points.

**Returns**

inset_axes [axes_class] Inset axes object created.

**Notes**

The meaning of bbox_to_anchor and bbox_to_transform is interpreted differently from that of legend. The value of bbox_to_anchor (or the return value of its get_points method; the default is parent_axes.bbox) is transformed by the bbox_transform (the default is Identity transform) and then interpreted as points in the pixel coordinate (which is dpi dependent).

Thus, following three calls are identical and creates an inset axes with respect to the parent_axes:

```python
axins = inset_axes(parent_axes, "30\%", "40\%")
axins = inset_axes(parent_axes, "30\%", "40\%",
                   bbox_to_anchor=parent_axes.bbox)
axins = inset_axes(parent_axes, "30\%", "40\%",
                   bbox_to_anchor=(0, 0, 1, 1),
                   bbox_transform=parent_axes.transAxes)
```

- Overview of axes_grid1 toolkit

`mpl_toolkits.axes_grid1.inset_locator.mark_inset`

`mpl_toolkits.axes_grid1.inset_locator.mark_inset(parent_axes, inset_axes, loc1, loc2, **kwargs)`

Draw a box to mark the location of an area represented by an inset axes.

This function draws a box in `parent_axes` at the bounding box of `inset_axes`, and shows a connection with the inset axes by drawing lines at the corners, giving a “zoomed in” effect.

**Parameters**

- `loc1, loc2` [{1, 2, 3, 4}] Corners to use for connecting the inset axes and the area in the parent axes.
- **kwargs** Patch properties for the lines and box drawn:

</table>

Continued on next page
## Returns

- **pp** [``matplotlib.patches.Patch``] The patch drawn to represent the area of the inset axes.
- **p1, p2** [``matplotlib.patches.Patch``] The patches connecting two corners of the inset axes and its area.

### Examples using mpl_toolkits.axes_grid1.inset_locator.mark_inset

- sphx_glr_gallery_axes_grid1_inset_locator_demo2.py

### Examples using mpl_toolkits.axes_grid1.inset_locator.zoomed_inset_axes

```python
mpl_toolkits.axes_grid1.inset_locator.zoomed_inset_axes
```

Create an anchored inset axes by scaling a parent axes. For usage, also see the examples.

### Parameters

- **parent_axes** [``matplotlib.axes.Axes``] Axes to place the inset axes.
- **zoom** [``float``] Scaling factor of the data axes. **zoom** > 1 will enlarge the coordinates (i.e., "zoomed in"), while **zoom** < 1 will shrink the coordinates (i.e., "zoomed out").
- **loc** [``int`` or string, optional, default to 1] Location to place the inset axes. The valid locations are:

<table>
<thead>
<tr>
<th>Location</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'upper right'</td>
<td>1</td>
</tr>
<tr>
<td>'upper left'</td>
<td>2</td>
</tr>
<tr>
<td>'lower left'</td>
<td>3</td>
</tr>
<tr>
<td>'lower right'</td>
<td>4</td>
</tr>
<tr>
<td>'right'</td>
<td>5</td>
</tr>
<tr>
<td>'center left'</td>
<td>6</td>
</tr>
<tr>
<td>'center right'</td>
<td>7</td>
</tr>
<tr>
<td>'lower center'</td>
<td>8</td>
</tr>
</tbody>
</table>

(continues on next page)
bbox_to_anchor [tuple or matplotlib.transforms.BboxBase, optional] Bbox that the inset axes will be anchored to. If None, parent_axes.bbox is used. If a tuple, can be either [left, bottom, width, height], or [left, bottom]. If the kwargs width and/or height are specified in relative units, the 2-tuple [left, bottom] cannot be used. Note that the units of the bounding box are determined through the transform in use. When using bbox_to_anchor it almost always makes sense to also specify a bbox_transform. This might often be the axes transform parent_axes.transAxes.

bbox_transform [matplotlib.transforms.Transform, optional] Transformation for the bbox that contains the inset axes. If None, a transforms.IdentityTransform is used (i.e. pixel coordinates). This is useful when not providing any argument to bbox_to_anchor. When using bbox_to_anchor it almost always makes sense to also specify a bbox_transform. This might often be the axes transform parent_axes.transAxes. Inversely, when specifying the axes- or figure-transform here, be aware that not specifying bbox_to_anchor will use parent_axes.bbox, the units of which are in display (pixel) coordinates.

axes_class [matplotlib.axes.Axes type, optional] If specified, the inset axes created will be created with this class's constructor.

axes_kwargs [dict, optional] Keyworded arguments to pass to the constructor of the inset axes. Valid arguments include:

<table>

</tbody>
</table>

**borderpad** [float, optional] Padding between inset axes and the bbox_to_anchor. Defaults to 0.5. The units are axes font size, i.e. for a default font size of 10 points borderpad = 0.5 is equivalent to a padding of 5 points.

**Returns**

**inset_axes** [axes_class] Inset axes object created.

**Examples using** mpl_toolkits.axes_grid1.inset_locator.zoomed_inset_axes

- sphx_glr_gallery_axes_grid1_demo_colorbar_of_inset_axes.py
- sphx_glr_gallery_axes_grid1_inset_locator_demo2.py

**mpl_toolkits.axes_grid1.mpl_axes**

**Classes**
Axes(fig, rect[, facecolor, frameon, ...]) Build an axes in a figure.

SimpleAxisArtist(axis, axisnum, spine)
SimpleChainedObjects(objects)

mpl_toolkits.axes_grid1.mpl_axes.Axes

**class** mpl_toolkits.axes_grid1.mpl_axes.Axes(fig, rect=color, facecolor=None, frameon=True, sharex=None, sharey=None, label='', xscale=None, yscale=None, **kwargs)

Bases: matplotlib.axes._axes.Axes

Build an axes in a figure.

**Parameters**

- **fig** [Figure] The axes is build in the Figure fig.
- **rect** [[left, bottom, width, height]] The axes is build in the rectangle rect. rect is in Figure coordinates.
- **sharex, sharey** [Axes, optional] The x or y axis is shared with the x or y axis in the input Axes.
- **frameon** [bool, optional] True means that the axes frame is visible.
- ****kwargs Other optional keyword arguments:

Returns

class AxisDict() -> new empty dictionary
dict(mapping) -> new dictionary initialized from a mapping object's (key, value) pairs
dict(iterable) -> new dictionary initialized as if via: d = {} for k, v in iterable: d[k] = v
dict(**kwargs) -> new dictionary initialized with the name=value pairs in the keyword argument list. For example: dict(one=1, two=2)

Bases: dict

axis

Convenience method to get or set some axis properties.

Call signatures:

```python
xmin, xmax, ymin, ymax = axis()
xmin, xmax, ymin, ymax = axis([xmin, xmax, ymin, ymax])
xmin, xmax, ymin, ymax = axis(option)
xmin, xmax, ymin, ymax = axis(**kwargs)
```

Parameters

- **xmin, xmax, ymin, ymax** [float, optional] The axis limits to be set.
  - Either none or all of the limits must be given. This can also be achieved using
ax.set(xlim=(xmin, xmax), ylim=(ymin, ymax))

**option** [bool or str] If a bool, turns axis lines and labels on or off. If a string, possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'on'</td>
<td>Turn on axis lines and labels. Same as True.</td>
</tr>
<tr>
<td>'off'</td>
<td>Turn off axis lines and labels. Same as False.</td>
</tr>
<tr>
<td>'equal'</td>
<td>Set equal scaling (i.e., make circles circular) by changing axis limits.</td>
</tr>
<tr>
<td>'scaled'</td>
<td>Set equal scaling (i.e., make circles circular) by changing dimensions</td>
</tr>
<tr>
<td></td>
<td>of the plot box.</td>
</tr>
<tr>
<td>'tight'</td>
<td>Set limits just large enough to show all data.</td>
</tr>
<tr>
<td>'auto'</td>
<td>Automatic scaling (fill plot box with data).</td>
</tr>
<tr>
<td>'normal'</td>
<td>Same as 'auto'; deprecated.</td>
</tr>
<tr>
<td>'image'</td>
<td>'scaled' with axis limits equal to data limits.</td>
</tr>
<tr>
<td>'square'</td>
<td>'Square plot; similar to 'scaled', but initially forcing xmax-xmin =</td>
</tr>
<tr>
<td></td>
<td>ymax-ymin.</td>
</tr>
</tbody>
</table>

**emit** [bool, optional, default True] Whether observers are notified of the axis limit change. This option is passed on to `set_xlim` and `set_ylim`.

**Returns**

**xmin, xmax, ymin, ymax** [float] The axis limits.

**See also:**

- `matplotlib.axes.Axes.set_xlim`
- `matplotlib.axes.Axes.set_ylim`

```python
cla(self)
```

Clear the current axes.

**Examples using** `mpl_toolkits.axes_grid1.mpl_axes.Axes`

- sphx_glr_gallery_axes_grid1_demo_axes_divider.py
- sphx_glr_gallery_axes_grid1_demo_fixed_size_axes.py

**mpl_toolkits.axes_grid1.mpl_axes.SimpleAxisArtist**

```python
class mpl_toolkits.axes_grid1.mpl_axes.SimpleAxisArtist(axis, axisnum, spine)
```

Bases: `matplotlib.artist.Artist`

- `label`
- `major_ticklabels`
- `major_ticks`

18.1. Toolkits
set_label(self, txt)
    Set a label that will be displayed in the legend.

Parameters
    s [object] s will be converted to a string by calling str.

set_visible(self, b)
    Set the artist’s visibility.

Parameters
    b [bool]

toggle(self, all=None, ticks=None, ticklabels=None, label=None)

mpl_toolkits.axes_grid1.mpl_axes.SimpleChainedObjects

class mpl_toolkits.axes_grid1.mpl_axes.SimpleChainedObjects(objects)
    Bases: object

mpl_toolkits.axes_grid1.parasite_axes

Classes

```python
class HostAxes(HostAxesBase(*args, **kwargs))
    alias of mpl_toolkits.axes_grid1.parasite_axes.AxesHostAxes

class ParasiteAxes(ParasiteAxesBase(*args, **kwargs))
    alias of mpl_toolkits.axes_grid1.parasite_axes.AxesParasite

class ParasiteAxesAuxTrans(ParasiteAxesAuxTransBase(parent_axes, ...[, ...]))
    alias of mpl_toolkits.axes_grid1.parasite_axes.AxesParasiteParasiteAuxTrans

class ParasiteAxesBase(ParasiteAxesBase(parent_axes, **kwargs))
```

mpl_toolkits.axes_grid1.parasite_axes.HostAxes

mpl_toolkits.axes_grid1.parasite_axes.HostAxes
    alias of mpl_toolkits.axes_grid1.parasite_axes.AxesHostAxes

mpl_toolkits.axes_grid1.parasite_axes.HostAxesBase

class mpl_toolkits.axes_grid1.parasite_axes.HostAxesBase(*args, **kwargs)
    Bases: object
    cla(self)
    draw(self, renderer)
    get_aux_axes(self, tr, viewlim_mode='equal', axes_class=None)
    get_tightbbox(self, renderer, call_axes_locator=True, bbox_extra_artists=None)
pick(self, mouseevent)

twin(self, aux_trans=None, axes_class=None)
    Create a twin of Axes with no shared axis.
    While self will have ticks on the left and bottom axis, the returned axes will have
    ticks on the top and right axis.

twinx(self, axes_class=None)
    Create a twin of Axes with a shared x-axis but independent y-axis.
    The y-axis of self will have ticks on the left and the returned axes will have ticks on
    the right.

twiny(self, axes_class=None)
    Create a twin of Axes with a shared y-axis but independent x-axis.
    The x-axis of self will have ticks on the bottom and the returned axes will have ticks
    on the top.

mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxes

mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxes
    alias of mpl_toolkits.axes_grid1.parasite_axes.AxesParasite

mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxesAuxTrans

mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxesAuxTrans
    alias of mpl_toolkits.axes_grid1.parasite_axes.AxesParasiteParasiteAuxTrans

mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxesAuxTransBase

class mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxesAuxTransBase(parent_axes,
aux_transform,
viewlim_mode=None,
**kwargs)

    Bases: object

    contour(self, *XYCL, **kwargs)
    contourf(self, *XYCL, **kwargs)
    get_viewlim_mode(self)
    pcolor(self, *XYC, **kwargs)
    pcolormesh(self, *XYC, **kwargs)
    set_viewlim_mode(self, mode)
    update_viewlim(self)
mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxesBase

class mpl_toolkits.axes_grid1.parasite_axes.ParasiteAxesBase(parent_axes, **kwargs)
    Bases: object
    cla(self)
    get_images_artists(self)
    pick(self, mouseevent)

Functions

host_axes(*args[, axes_class, figure]) Create axes that can act as a hosts to parasitic axes.

host_subplot(*args[, axes_class, figure]) Create a subplot that can act as a host to parasitic axes.

d_factory(axes_class)

mpl_toolkits.axes_grid1.parasite_axes.host_axes

mpl_toolkits.axes_grid1.parasite_axes.host_axes(*args, axes_class=None, figure=None, **kwargs)
Create axes that can act as a hosts to parasitic axes.

Parameters

figure [matplotlib.figure.Figure] Figure to which the axes will be added. Defaults to the current figure pyplot.gcf().

*args, **kwargs Will be passed on to the underlying Axes object creation.

mpl_toolkits.axes_grid1.parasite_axes.host_subplot

mpl_toolkits.axes_grid1.parasite_axes.host_subplot(*args, axes_class=None, figure=None, **kwargs)
Create a subplot that can act as a host to parasitic axes.

Parameters

figure [matplotlib.figure.Figure] Figure to which the subplot will be added. Defaults to the current figure pyplot.gcf().

*args, **kwargs Will be passed on to the underlying Axes object creation.

mpl_toolkits.axes_grid1.parasite_axes.host_subplot_class_factory

mpl_toolkits.axes_grid1.parasite_axes.host_subplot_class_factory(axes_class)
18.1.3 Matplotlib axisartist Toolkit

The `axisartist` namespace includes a derived Axes implementation (`mpl_toolkits.axisartist.Axes`). The biggest difference is that the artists that are responsible for drawing axis lines, ticks, ticklabels, and axis labels are separated out from the mpl’s Axis class. This change was strongly motivated to support curvilinear grid.

You can find a tutorial describing usage of axisartist at the `axisartist` user guide.

![Curvilinear Grid Example](image)

The submodules of the axisartist API are:

- `axisartist.angle_helper`
- `axisartist.axes_divider`
- `axisartist.axes_grid`
- `axisartist.axes_rgb`
- `axisartist.axis_artist`
  - `axis_artist.py` module provides axis-related artists.
- `axisartist.axisline_style`
- `axisartist.axislines`
  - Axislines includes modified implementation of the Axes class.
- `axisartist.clip_path`
- `axisartist.floating_axes`
  - An experimental support for curvilinear grid.
- `axisartist.grid_finder`
- `axisartist.grid_helper_curvelinear`
  - An experimental support for curvilinear grid.
- `axisartist.parasite_axes`

`mpl_toolkits.axisartist.angle_helper`

Classes

- `ExtremeFinderCycle(nx, ny[, lon_cycle, ...])` When there is a cycle, e.g., longitude goes from 0-360.
- `FormatterDMS`
- `FormatterHMS`
- `LocatorBase(den[, include_last])` Continued on next page
Table 23 – continued from previous page

```
LocatorD(den[, include_last])
LocatorDM(den[, include_last])
LocatorDMS(den[, include_last])
LocatorH(den[, include_last])
LocatorHM(den[, include_last])
LocatorHMS(den[, include_last])
```

```
mpl_toolkits.axisartist.angle_helper.ExtremeFinderCycle

class mpl_toolkits.axisartist.angle_helper.ExtremeFinderCycle(nx, ny,
                                            lon_cycle=360.0,
                                            lat_cycle=None,
                                            lon_minmax=None,
                                            lat_minmax=(-90, 90))

    Bases: mpl_toolkits.axisartist.grid_finder.ExtremeFinderSimple

    When there is a cycle, e.g., longitude goes from 0-360.

Examples using mpl_toolkits.axisartist.angle_helper.ExtremeFinderCycle

- sphx_glr_gallery_axisartist_demo_axis_direction.py
- sphx_glr_gallery_axisartist_demo_curvelinear_grid.py
- sphx_glr_gallery_axisartist_demo_curvelinear_grid2.py
- sphx_glr_gallery_axisartist_demo_floating_axis.py
- sphx_glr_gallery_axisartist_simple_axis_pad.py

mpl_toolkits.axisartist.angle_helper.FormatterDMS

class mpl_toolkits.axisartist.angle_helper.FormatterDMS

mpl_toolkits.axisartist.axes_grid

Classes

AxesGrid alias of mpl_toolkits.axisartist.axes_grid.ImageGrid

CbarAxes(*args, orientation, **kwargs)

Grid(fig, rect, nrows_ncols[, ngrids, ...])

Parameters

ImageGrid(fig, rect, nrows_ncols[, ngrids, ...])

Parameters

mpl_toolkits.axisartist.axes_grid.AxesGrid

mpl_toolkits.axisartist.axes_grid.AxesGrid

   alias of mpl_toolkits.axisartist.axes_grid.ImageGrid

mpl_toolkits.axisartist.axislines.CbarAxes

class mpl_toolkits.axisartist.axes_grid.CbarAxes(*args, orientation, **kwargs)

   cla(self)

   Clear the current axes.
**mpl_toolkits.axisartist.axes_grid.Grid**

class mpl_toolkits.axisartist.axes_grid.Grid(fig, rect, nrows_ncols, ngrids=None, direction='row', axes_pad=0.02, add_all=True, share_all=False, share_x=True, share_y=True, label_mode='L', axes_class=None)

Bases: mpl_toolkits.axes_grid1.axes_grid.Grid

**Parameters**

- **fig** [Figure] The parent figure.
- **rect** ([float, float, float, float] or int) The axes position, as a (left, bottom, width, height) tuple or as a three-digit subplot position code (e.g., "121").
- **direction** [{"row", "column"}, default: "row"]
- **axes_pad** [float or (float, float), default: 0.02] Padding or (horizontal padding, vertical padding) between axes, in inches.
- **add_all** [bool, default: True]
- **share_all** [bool, default: False]
- **share_x** [bool, default: True]
- **share_y** [bool, default: True]
- **label_mode** [{"L", "1", "all"}, default: "L"] Determines which axes will get tick labels:
  - "L": All axes on the left column get vertical tick labels; all axes on the bottom row get horizontal tick labels.
  - "1": Only the bottom left axes is labelled.
  - "all": all axes are labelled.
- **axes_class** [a type that is a subclass of matplotlib.axes.Axes, default: None]

**mpl_toolkits.axisartist.axes_grid.ImageGrid**

class mpl_toolkits.axisartist.axes_grid.ImageGrid(fig, rect, nrows_ncols, ngrids=None, direction='row', axes_pad=0.02, add_all=True, share_all=False, aspect=True, label_mode='L', cbar_mode=None, cbar_location='right', cbar_pad=None, cbar_size='5%', cbar_set_cax=True, axes_class=None)

Bases: mpl_toolkits.axes_grid1.axes_grid.ImageGrid

**Parameters**

- **fig** [Figure] The parent figure.
rect [(float, float, float, float) or int] The axes position, as a (left, bottom, width, height) tuple or as a three-digit subplot position code (e.g., "121").

direction [{"row", "column"}, default: "row"]

axes_pad [float or (float, float), default: 0.02] Padding or (horizontal padding, vertical padding) between axes, in inches.

add_all [bool, default: True]

share_all [bool, default: False]

aspect [bool, default: True]

label_mode [{"L", "1", "all"}, default: "L"] Determines which axes will get tick labels:

- "L": All axes on the left column get vertical tick labels; all axes on the bottom row get horizontal tick labels.
- "1": Only the bottom left axes is labelled.
- "all": all axes are labelled.

cbar_mode [{“each”, “single”, “edge”, None }, default: None]

cbar_location [{“left”, “right”, “bottom”, “top"}, default: “right”]

cbar_pad [float, default: None]

cbar_size [size specification (see Size.from_any), default: “5%”]

cbar_set_cax [bool, default: True] If True, each axes in the grid has a cax attribute that is bound to associated cbar_axes.

axes_class [a type that is a subclass of matplotlib.axes.Axes, default: None]

mpl_toolkits.axisartist.**RGBAxes**

**Classes**

- RGBAaxes(*args[, pad, add_all])

**Parameters**

mpl_toolkits.axisartist.**RGBAxes**

**class** mpl_toolkits.axisartist.**axes_rgb**.RGBAxes(*args, pad=0, add_all=True, **kwargs)  
Bases: mpl_toolkits.axes_grid1.axes_rgb.RGBAxesBase

**Parameters**

- pad [float] fraction of the axes height to put as padding. defaults to 0.0
- add_all [bool] True: Add the {rgb, r, g, b} axes to the figure defaults to True.
- axes_class [matplotlib.axes.Axes]
*args Unpacked into axes_class() init for RGB

**kwargs Unpacked into axes_class() init for RGB, R, G, B axes

mpl_toolkits.axisartist.axis_artist

axis_artist.py module provides axis-related artists. They are

• axis line
• tick lines
• tick labels
• axis label
• grid lines

The main artist classes are AxisArtist and GridlinesCollection. While GridlinesCollection is responsible for drawing grid lines, AxisArtist is responsible for all other artists. AxisArtist has attributes that are associated with each type of artists:

• line: axis line
• major_ticks: major tick lines
• major_ticklabels: major tick labels
• minor_ticks: minor tick lines
• minor_ticklabels: minor tick labels
• label: axis label

Typically, the AxisArtist associated with an axes will be accessed with the axis dictionary of the axes, i.e., the AxisArtist for the bottom axis is

```python
ax.axis["bottom"]
```

where `ax` is an instance of mpl_toolkits.axislines.Axes. Thus, `ax.axis["bottom"]`.line is an artist associated with the axis line, and `ax.axis["bottom"]`.major_ticks is an artist associated with the major tick lines.

You can change the colors, fonts, line widths, etc. of these artists by calling suitable set method. For example, to change the color of the major ticks of the bottom axis to red, use

```python
ax.axis["bottom"] .major_ticks .set_color("r")
```

However, things like the locations of ticks, and their ticklabels need to be changed from the side of the grid_helper.

axis_direction

AxisArtist, AxisLabel, TickLabels have an axis_direction attribute, which adjusts the location, angle, etc.,. The axis_direction must be one of “left”, “right”, “bottom”, “top”, and follows the Matplotlib convention for rectangular axis.

For example, for the bottom axis (the left and right is relative to the direction of the increasing coordinate),

• ticklabels and axislabel are on the right
• ticklabels and axislabel have text angle of 0
• ticklabels are baseline, center-aligned
• axislabel is top, center-aligned

The text angles are actually relative to (90 + angle of the direction to the ticklabel), which gives 0 for bottom axis.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticklabels location</td>
<td>left</td>
<td>right</td>
<td>right</td>
<td>left</td>
</tr>
<tr>
<td>axislabel location</td>
<td>left</td>
<td>right</td>
<td>right</td>
<td>left</td>
</tr>
<tr>
<td>ticklabels angle</td>
<td>90</td>
<td>0</td>
<td>-90</td>
<td>180</td>
</tr>
<tr>
<td>axislabel angle</td>
<td>180</td>
<td>0</td>
<td>0</td>
<td>180</td>
</tr>
<tr>
<td>ticklabel va</td>
<td>center</td>
<td>baseline</td>
<td>center</td>
<td>baseline</td>
</tr>
<tr>
<td>axislabel va</td>
<td>center</td>
<td>top</td>
<td>center</td>
<td>bottom</td>
</tr>
<tr>
<td>ticklabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
<tr>
<td>axislabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
</tbody>
</table>

Ticks are by default direct opposite side of the ticklabels. To make ticks to the same side of the ticklabels,

```python
ax.axis["bottom"].major_ticks.set_ticks_out(True)
```

The following attributes can be customized (use the `set_xxx` methods):

• **Ticks**: ticksize, tick_out
• **TickLabels**: pad
• **AxisLabel**: pad

**Classes**

```python
AttributeCopier(ref_artist[, klass])
```

**AxisArtist**(axes, helper[, offset, ...]) An artist which draws axis (a line along which the n-th axes coord is constant) line, ticks, ticklabels, and axis label.

**AxisLabel**(*args[, axis_direction, axis]) Axis Label.

**BezierPath**(path, *args, **kwargs)

**GridlinesCollection**(*args[, which, axis]) which: "major" or "minor" axis: "both", "x" or "y"

**LabelBase**(*args, **kwargs) A base class for AxisLabel and TickLabels.

**Ticks**(ticksize[, tick_out, axis]) Tick Labels.

**mpl_toolkits.axisartist.axis_artist.AttributeCopier**

```python
class mpl_toolkits.axisartist.axis_artist.AttributeCopier(ref_artist, klass=class 'matplotlib.artist.Artist')
```

**Bases**: `object`

```python
get_attribute_from_ref_artist(self, attr_name, default_value)
```
get_ref_artist(self)
set_ref_artist(self, artist)

mpl_toolkits.axisartist.axis_artist.AxisArtist

class mpl_toolkits.axisartist.axis_artist.AxisArtist(axes, helper, offset=None,
axis_direction='bottom', **kwargs)

Bases: matplotlib.artist.Artist

An artist which draws axis (a line along which the n-th axes coord is constant) line, ticks,
ticklabels, and axis label.
axes : axes
helper : an AxisArtistHelper instance.

LABELPAD
ZORDER = 2.5
draw(self, renderer)
    Draw the axis lines, tick lines and labels
get_axisline_style(self)
    return the current axisline style.
get_helper(self)
    Return axis artist helper instance.
get_tightbbox(self, renderer)
    Like Artist.get_window_extent, but includes any clipping.

Parameters
    renderer [RendererBase instance] renderer that will be used to draw
    the figures (i.e. fig.canvas.get_renderer())

Returns
    bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

get_transform(self)
    Return the Transform instance used by this artist.
invert_ticklabel_direction(self)
set_axis_direction(self, axis_direction)
    Adjust the direction, text angle, text alignment of ticklabels, labels following the
    matplotlib convention for the rectangle axes.

    The axis_direction must be one of [left, right, bottom, top].

<table>
<thead>
<tr>
<th>property</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticklabels location</td>
<td>&quot;-&quot;</td>
<td>&quot;+&quot;</td>
<td>&quot;+&quot;</td>
<td>&quot;-&quot;</td>
</tr>
<tr>
<td>axislabel location</td>
<td>&quot;-&quot;</td>
<td>&quot;+&quot;</td>
<td>&quot;+&quot;</td>
<td>&quot;-&quot;</td>
</tr>
<tr>
<td>ticklabels angle</td>
<td>90</td>
<td>0</td>
<td>-90</td>
<td>180</td>
</tr>
<tr>
<td>ticklabel va</td>
<td>center</td>
<td>baseline</td>
<td>center</td>
<td>baseline</td>
</tr>
<tr>
<td>ticklabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
<tr>
<td>axislabel angle</td>
<td>180</td>
<td>0</td>
<td>0</td>
<td>180</td>
</tr>
<tr>
<td>axislabel va</td>
<td>center</td>
<td>top</td>
<td>center</td>
<td>bottom</td>
</tr>
<tr>
<td>axislabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
</tbody>
</table>
Note that the direction "+" and "-" are relative to the direction of the increasing coordinate. Also, the text angles are actually relative to (90 + angle of the direction to the ticklabel), which gives 0 for bottom axis.

```python
set_axislabel_direction(self, label_direction)
```
Adjust the direction of the axislabel.

Note that the `label_direction` s ‘+’ and ‘-’ are relative to the direction of the increasing coordinate.

**Parameters**

- **tick_direction** [{"+", "-"}]

```python
set_axisline_style(self, axisline_style=None, **kwargs)
```
Set the axisline style.

*axisline_style can be a string with axisline style name with optional* comma-separated attributes. Alternatively, the attrs can be provided as keywords.

```python
set_axisline_style("->,size=1.5")
```

Old attrs simply are forgotten.

Without argument (or with arrowstyle=None), return available styles as a list of strings.

```python
set_label(self, s)
```
Set a label that will be displayed in the legend.

**Parameters**

- **s** [object] s will be converted to a string by calling `str`.

```python
set_ticklabel_direction(self, tick_direction)
```
Adjust the direction of the ticklabel.

Note that the `label_direction` s ‘+’ and ‘-’ are relative to the direction of the increasing coordinate.

**Parameters**

- **tick_direction** [{"+", "-"}]

```python
toggle(self, all=None, ticks=None, ticklabels=None, label=None)
```
Toggle visibility of ticks, ticklabels, and (axis) label. To turn all off,

```python
axis.toggle(all=False)
```

To turn all off but ticks on

```python
axis.toggle(all=False, ticks=True)
```

To turn all on but (axis) label off

```python
axis.toggle(all=True, label=False))
```
mpl_toolkits.axisartist.axis_artist.AxisLabel

class mpl_toolkits.axisartist.axis_artist.AxisLabel(*args, axis_direction='bottom', axis=None, **kwargs)

Bases: mpl_toolkits.axisartist.axis_artist.LabelBase, mpl_toolkits.axisartist.axis_artist.AttributeCopier

Axis Label. Derived from Text. The position of the text is updated in the fly, so changing text position has no effect. Otherwise, the properties can be changed as a normal Text.

To change the pad between ticklabels and axis label, use set_pad.

draw(self, renderer)
   Draws the Text object to the given renderer.

get_color(self)
   Return the color of the text

get_pad(self)
   return pad in points. See set_pad for more details.

get_ref_artist(self)

get_text(self)
   Get the text as string

get_window_extent(self, renderer)
   Return the Bbox bounding the text, in display units.

   In addition to being used internally, this is useful for specifying clickable regions in a png file on a web page.

Parameters

   renderer [Renderer, optional] A renderer is needed to compute the bounding box. If the artist has already been drawn, the renderer is cached; thus, it is only necessary to pass this argument when calling get_window_extent before the first draw. In practice, it is usually easier to trigger a draw first (e.g. by saving the figure).

   dpi [float, optional] The dpi value for computing the bbox, defaults to self.figure.dpi (not the renderer dpi); should be set e.g. if to match regions with a figure saved with a custom dpi value.

set_axis_direction(self, d)
   Adjust the text angle and text alignment of axis label according to the matplotlib convention.

<table>
<thead>
<tr>
<th>property</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>axislabel angle</td>
<td>180</td>
<td>0</td>
<td>0</td>
<td>180</td>
</tr>
<tr>
<td>axislabel va</td>
<td>center</td>
<td>top</td>
<td>center</td>
<td>bottom</td>
</tr>
<tr>
<td>axislabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
</tbody>
</table>

   Note that the text angles are actually relative to (90 + angle of the direction to the ticklabel), which gives 0 for bottom axis.

set_default_alignment(self, d)

set_default_angle(self, d)
set_pad(self, pad)
   Set the pad in points. Note that the actual pad will be the sum of the internal pad
   and the external pad (that are set automatically by the AxisArtist), and it only set
   the internal pad

mpl_toolkits.axisartist.axis_artist.BezierPath

class mpl_toolkits.axisartist.axis_artist.BezierPath(path, *args, **kwargs)
   Bases: matplotlib.lines.Line2D
draw(self, renderer)
   Draw the Artist using the given renderer.
   This method will be overridden in the Artist subclasses. Typically, it is implemented
   to not have any effect if the Artist is not visible (Artist.get_visible is False).

   Parameters
   renderer [RendererBase subclass.]

recache(self)
set_path(self, path)

mpl_toolkits.axisartist.axis_artist.GridlinesCollection

class mpl_toolkits.axisartist.axis_artist.GridlinesCollection(*args, which='major',
   axis='both', **kwargs)
   Bases: matplotlib.collections.LineCollection
   which : "major" or "minor" axis : "both", "x" or "y"
draw(self, renderer)
   Draw the Artist using the given renderer.
   This method will be overridden in the Artist subclasses. Typically, it is implemented
   to not have any effect if the Artist is not visible (Artist.get_visible is False).

   Parameters
   renderer [RendererBase subclass.]

set_axis(self, axis)
set_grid_helper(self, grid_helper)
set_which(self, which)

mpl_toolkits.axisartist.axis_artist.LabelBase

class mpl_toolkits.axisartist.axis_artist.LabelBase(*args, **kwargs)
   Bases: matplotlib.text.Text
   A base class for AxisLabel and TickLabels. The position and angle of the text are calcu-
   lated by to offset_ref_angle, text_ref_angle, and offset_radius attributes.
draw(self, renderer)
   Draws the Text object to the given renderer.
get_window_extent(self, renderer)
Return the Bbox bounding the text, in display units.

In addition to being used internally, this is useful for specifying clickable regions in a png file on a web page.

Parameters

 renderer [Renderer, optional] A renderer is needed to compute the bounding box. If the artist has already been drawn, the renderer is cached; thus, it is only necessary to pass this argument when calling get_window_extent before the first draw. In practice, it is usually easier to trigger a draw first (e.g. by saving the figure).

dpi [float, optional] The dpi value for computing the bbox, defaults to self.figure.dpi (not the renderer dpi); should be set e.g. if to match regions with a figure saved with a custom dpi value.

mpl_toolkits.axisartist.axis_artist.TickLabels

class mpl_toolkits.axisartist.axis_artist.TickLabels(*, axis_direction='bottom', **kwargs)

Tick Labels. While derived from Text, this single artist draws all ticklabels. As in AxisLabel, the position of the text is updated in the fly, so changing text position has no effect. Otherwise, the properties can be changed as a normal Text. Unlike the ticklabels of the mainline matplotlib, properties of single ticklabel alone cannot modified.

To change the pad between ticks and ticklabels, use set_pad.

draw(self, renderer)
Draws the Text object to the given renderer.

get_ref_artist(self)

get_texts_widths_heights_descents(self, renderer)
return a list of width, height, descent for ticklabels.

get_window_extents(self, renderer)

invert_axis_direction(self)

set_axis_direction(self, label_direction)
Adjust the text angle and text alignment of ticklabels according to the matplotlib convention.

The label_direction must be one of [left, right, bottom, top].

<table>
<thead>
<tr>
<th>property</th>
<th>left</th>
<th>bottom</th>
<th>right</th>
<th>top</th>
</tr>
</thead>
<tbody>
<tr>
<td>ticklabels angle</td>
<td>90</td>
<td>0</td>
<td>-90</td>
<td>180</td>
</tr>
<tr>
<td>ticklabel va</td>
<td>center</td>
<td>baseline</td>
<td>center</td>
<td>baseline</td>
</tr>
<tr>
<td>ticklabel ha</td>
<td>right</td>
<td>center</td>
<td>right</td>
<td>center</td>
</tr>
</tbody>
</table>

Note that the text angles are actually relative to (90 + angle of the direction to the ticklabel), which gives 0 for bottom axis.

set_locs_angles_labels(self, locs_angles_labels)
class mpl_toolkits.axisartist.axis_artist.Ticks(ticksize, tick_out=False, *, axis=None, **kwargs)

Bases: matplotlib.lines.Line2D, mpl_toolkits.axisartist.axis_artist.AttributeCopier

Ticks are derived from Line2D, and note that ticks themselves are markers. Thus, you should use set_mec, set_mew, etc.

To change the tick size (length), you need to use set_ticksize. To change the direction of the ticks (ticks are in opposite direction of ticklabels by default), use set_tick_out(False).

draw(self, renderer)
    Draw the Artist using the given renderer.

    This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (Artist.get_visible is False).

    Parameters
        renderer [RendererBase subclass.]

get_color(self)
    Return the line color.

    See also set_color.

get_markeredgecolor(self)
    Return the marker edge color.

    See also set_markeredgecolor.

get_markeredgewidth(self)
    Return the marker edge width in points.

    See also set_markeredgewidth.

get_ref_artist(self)

get_tick_out(self)
    Return True if the tick will be rotated by 180 degree.

get_ticksize(self)
    Return length of the ticks in points.

set_locs_angles(self, locs_angles)

set_tick_out(self, b)
    set True if tick need to be rotated by 180 degree.

set_ticksize(self, ticksize)
    set length of the ticks in points.
AxislineStyle

AxislineStyle is a container class which defines style classes for AxisArtists.

mpl_toolkits.axisartist.axisline_style.AxislineStyle

class mpl_toolkits.axisartist.axisline_style.AxislineStyle
    Bases: matplotlib.patches._Style

    AxislineStyle is a container class which defines style classes for AxisArtists.
    An instance of any axisline style class is an callable object, whose call signature is
    __call__(self, axis_artist, path, transform)

    When called, this should return a mpl artist with following methods implemented.

        def set_path(self, path):
            # set the path for axisline.
        def set_line_mutation_scale(self, scale):
            # set the scale
        def draw(self, renderer):
            # draw

    return the instance of the subclass with the given style name.

class FilledArrow(size=1)
    Bases: mpl_toolkits.axisartist.axisline_style.SimpleArrow

    size  size of the arrow as a fraction of the ticklabel size.

    ArrowAxisClass
        alias of _FancyAxislineStyle.FilledArrow

class SimpleArrow(size=1)
    Bases: mpl_toolkits.axisartist.axisline_style._Base

    A simple arrow.

    size  size of the arrow as a fraction of the ticklabel size.

    ArrowAxisClass
        alias of _FancyAxislineStyle.SimpleArrow

    new_line(self, axis_artist, transform)

mpl_toolkits.axisartist.axislines

Axislines includes modified implementation of the Axes class. The biggest difference is that
the artists responsible for drawing the axis spine, ticks, ticklabels and axis labels are sepa-
rated out from mpl’s Axis class. Originally, this change was motivated to support curvilinear
grid. Here are a few reasons that I came up with a new axes class:

- “top” and “bottom” x-axis (or “left” and “right” y-axis) can have different ticks (tick lo-
cations and labels). This is not possible with the current mpl, although some twin axes
trick can help.
• Curvilinear grid.
• angled ticks.

In the new axes class, xaxis and yaxis is set to not visible by default, and new set of artist (AxisArtist) are defined to draw axis line, ticks, ticklabels and axis label. Axes.axis attribute serves as a dictionary of these artists, i.e., ax.axis["left"] is a AxisArtist instance responsible to draw left y-axis. The default Axes.axis contains "bottom", "left", "top" and "right".

AxisArtist can be considered as a container artist and has following children artists which will draw ticks, labels, etc.

• line
• major_ticks, major_ticklabels
• minor_ticks, minor_ticklabels
• offsetText
• label

Note that these are separate artists from Axis class of the original mpl, thus most of tick-related command in the original mpl won't work, although some effort has made to work with. For example, color and markerwidth of the ax.axis["bottom"].major_ticks will follow those of Axes.xaxis unless explicitly specified.

In addition to AxisArtist, the Axes will have gridlines attribute, which obviously draws grid lines. The gridlines needs to be separated from the axis as some gridlines can never pass any axis.

Classes

_axes(*args[, grid_helper])
AxesZero(*args[, grid_helper])
AxisArtistHelper
AxisArtistHelper should define following method with given APIs.
AxisArtistHelperRectlinear
GridHelperBase()
GridHelperRectlinear(axes)
SimpleChainedObjects(**kwargs) [Deprecated]

mpl_toolkits.axisartist.axislines.Axes

class mpl_toolkits.axisartist.axislines.Axes(*args, grid_helper=None, **kwargs)
Bases: matplotlib.axes._axes.Axes

class AxisDict(**kwargs)
Bases: dict

[Deprecated]

Notes

Deprecated since version 3.1:
axis

Convenience method to get or set some axis properties.

Call signatures:

\[
\begin{align*}
x_{min}, x_{max}, y_{min}, y_{max} &= \text{axis()} \\
x_{min}, x_{max}, y_{min}, y_{max} &= \text{axis}([x_{min}, x_{max}, y_{min}, y_{max}]) \\
x_{min}, x_{max}, y_{min}, y_{max} &= \text{axis}('\text{option}') \\
x_{min}, x_{max}, y_{min}, y_{max} &= \text{axis}(**\text{kwargs})
\end{align*}
\]

Parameters

- **xmin, xmax, ymin, ymax** [float, optional] The axis limits to be set. Either none or all of the limits must be given. This can also be achieved using

\[
\text{ax.set(xlim}=(\text{xmin, xmax}), \text{ylim}=(\text{ymin, ymax})
\]

- **option** [bool or str] If a bool, turns axis lines and labels on or off. If a string, possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'on'</td>
<td>Turn on axis lines and labels. Same as True.</td>
</tr>
<tr>
<td>'off'</td>
<td>Turn off axis lines and labels. Same as False.</td>
</tr>
<tr>
<td>'equal'</td>
<td>Set equal scaling (i.e., make circles circular) by changing axis limits.</td>
</tr>
<tr>
<td>'scaled'</td>
<td>Set equal scaling (i.e., make circles circular) by changing dimensions of the plot box.</td>
</tr>
<tr>
<td>'tight'</td>
<td>Set limits just large enough to show all data.</td>
</tr>
<tr>
<td>'auto'</td>
<td>Automatic scaling (fill plot box with data).</td>
</tr>
<tr>
<td>'normal'</td>
<td>Same as 'auto'; deprecated.</td>
</tr>
<tr>
<td>'image'</td>
<td>'scaled' with axis limits equal to data limits.</td>
</tr>
<tr>
<td>'square'</td>
<td>Square plot; similar to 'scaled', but initially forcing (x_{max}-x_{min} = y_{max}-y_{min}).</td>
</tr>
</tbody>
</table>

- **emit** [bool, optional, default True] Whether observers are notified of the axis limit change. This option is passed on to \text{set_xlim} and \text{set_ylim}.

Returns

- **xmin, xmax, ymin, ymax** [float] The axis limits.

See also:

- \text{matplotlib.axes.Axes.set_xlim}
- \text{matplotlib.axes.Axes.set_ylim}

- \text{cla(self)}
  
  Clear the current axes.

- \text{get_children(self)}

  Return a list of the child \text{Artists} of this \text{Artist}.
Matplotlib, Release 3.1.1

get_grid_helper(self)

grid(self, b=None, which='major', axis='both', **kwargs)
Toggle the gridlines, and optionally set the properties of the lines.

invalidate_grid_helper(self)

new_fixed_axis(self, loc, offset=None)

new_floating_axis(self, nth_coord, value, axis_direction='bottom')

new_gridlines(self, grid_helper=None)
Create and return a new GridlineCollection instance.

mpl_toolkits.axisartist.parasite_axes

18.1.4 Matplotlib axes_grid Toolkit

Note: AxesGrid toolkit has been a part of matplotlib since v 0.99. Originally, the toolkit had a single namespace of axes_grid. In more recent version, the toolkit has divided into two separate namespace (axes_grid1 and axisartist). While axes_grid namespace is maintained for the backward compatibility, use of axes_grid1 and axisartist is recommended. For the documentation on axes_grid, see the previous version of the docs.

Matplotlib axes_grid1 Toolkit

The matplotlib mpl_toolkits.axes_grid1 toolkit is a collection of helper classes to ease displaying multiple images in matplotlib. While the aspect parameter in matplotlib adjust the position of the single axes, axes_grid1 toolkit provides a framework to adjust the position of multiple axes according to their aspects.

See What is axes_grid1 toolkit? for a guide on the usage of axes_grid1.

The submodules of the axes_grid1 API are:
The axes_divider module provides helper classes to adjust the positions of multiple axes at drawing time.

Provides classes of simple units that will be used with AxesDivider class (or others) to determine the size of each axes.

Colorbar toolkit with two classes and a function:

A collection of functions and objects for creating or placing inset axes.

Matplotlib axisartist Toolkit

The axisartist namespace includes a derived Axes implementation (mpl_toolkits.axisartist.Axes). The biggest difference is that the artists that are responsible for drawing axis lines, ticks, ticklabels, and axis labels are separated out from the mpl’s Axis class. This change was strongly motivated to support curvilinear grid.

You can find a tutorial describing usage of axisartist at the axisartist user guide.

The submodules of the axisartist API are:

axis_artist.py module provides axis-related artists.

Axislines includes modified implementation of the Axes class.

18.2 mplot3d API

Contents

- mplot3d API
  - `axes3d`
  - `axis3d`
  - `art3d`
  - `Art3D Utility Functions`
  - `proj3d`

18.2.1 axes3d

**Note:** Significant effort went into bringing axes3d to feature-parity with regular axes objects for version 1.1.0. However, more work remains. Please report any functions that do not behave as expected as a bug. In addition, help and patches would be greatly appreciated!

```python
axes3d.Axes3D(fig[, rect, azim, elev, ...]) 3D axes object.
```

```python
mpl_toolkits.mplot3d.axes3d.Axes3D
```

class `mpl_toolkits.mplot3d.axes3d.Axes3D(fig, rect=None, *args, azim=-60, elev=30, zscale=None, sharez=None, proj_type='persp', **kwargs)`

Bases: `matplotlib.axes._axes.Axes`

3D axes object.

**Parameters**

- `fig` [Figure] The parent figure.
- `rect` [(float, float, float, float)] The (left, bottom, width, height) axes position.
- `azim` [float, optional] Azimuthal viewing angle, defaults to -60.
**elev** [float, optional] Elevation viewing angle, defaults to 30.

**zs** [‘function’ | ‘functionlog’ | ‘linear’ | ‘log’ | ‘logit’ | ‘symlog’], optional] The z scale. Note that currently, only a linear scale is supported.

**sharez** [Axes3D, optional] Other axes to share z-limits with.

**proj_type** [{‘persp’, ‘ortho’}] The projection type, default ‘persp’.

### Notes

New in version 1.2.1: The sharez parameter.

```
add_collection3d(self, col, zs=0, zdir='z')
```

Add a 3D collection object to the plot.

2D collection types are converted to a 3D version by modifying the object and adding z coordinate information.

**Supported are:**

- PolyCollection
- LineCollection
- PatchCollection

```
add_contour_set(self, cset, extend3d=False, stride=5, zdir='z', offset=None)
add_contourf_set(self, cset, zdir='z', offset=None)
auto_scale_xyz(self, X, Y, Z=None, had_data=None)
autoscale(self, enable=True, axis='both', tight=None)
```

Auto-scale the view limits using the data limits. See **autoscale**.autoscale() for documentation. Note that this function applies to the 3D axes, and as such adds the scalez to the function arguments.

```
autoscale_view(self, tight=None, scalex=True, scaley=True, scalez=True)
```

Autoscale the view limits using the data limits. See **autoscale_view** for documentation. Note that this function applies to the 3D axes, and as such adds the scalez to the function arguments.

```
bar(self, left, height, zs=0, zdir='z', *args, **kwargs)
```

Add 2D bar(s).

### Parameters

- **left** [1D array-like] The x coordinates of the left sides of the bars.
- **height** [1D array-like] The height of the bars.
- **zs** [scalar or 1D array-like] Z coordinate of bars; if a single value is specified, it will be used for all bars.
zdir [{‘x’, ‘y’, ‘z’}] When plotting 2D data, the direction to use as z (‘x’, ‘y’ or ‘z’); defaults to ‘z’.

**kwargs Other arguments are forwarded to matplotlib.axes.Axes.bar.

Returns

mpl_toolkits.mplot3d.art3d.Patch3DCollection

bar3d(self, x, y, z, dx, dy, dz, color=None, zsort=’average’, shade=True, *args, **kwargs)

Generate a 3D barplot.

This method creates three dimensional barplot where the width, depth, height, and color of the bars can all be uniquely set.

Parameters

x, y, z [array-like] The coordinates of the anchor point of the bars.

dx, dy, dz [scalar or array-like] The width, depth, and height of the bars, respectively.

color [sequence of valid color specifications, optional] The color of the bars can be specified globally or individually. This parameter can be:

• A single color value, to color all bars the same color.
• An array of colors of length N bars, to color each bar independently.
• An array of colors of length 6, to color the faces of the bars similarly.
• An array of colors of length 6 * N bars, to color each face independently.

When coloring the faces of the boxes specifically, this is the order of the coloring:

1. -Z (bottom of box)
2. +Z (top of box)
3. -Y
4. +Y
5. -X
6. +X

zsort [str, optional] The z-axis sorting scheme passed onto Poly3DCollection

shade [bool, optional (default = True)] When true, this shades the dark sides of the bars (relative to the plot’s source of light).

**kwargs Any additional keyword arguments are passed onto Poly3DCollection.

Returns
**collection** [Poly3DCollection] A collection of three dimensional polygons representing the bars.

```python
can_pan(self)
    Return True if this axes supports the pan/zoom button functionality.
    3D axes objects do not use the pan/zoom button.

can_zoom(self)
    Return True if this axes supports the zoom box button functionality.
    3D axes objects do not use the zoom box button.
```

cla(self)
    Clear axes

clabel(self, *args, **kwargs)
    This function is currently not implemented for 3D axes. Returns None.

```python
contour(self, X, Y, Z, *args, extend3d=False, stride=5, zdir='z', offset=None, **kwargs)
    Create a 3D contour plot.
```

**Parameters**

- **X, Y, Z** [array-likes] Input data.
- **extend3d** [bool] Whether to extend contour in 3D; defaults to False.
- **stride** [int] Step size for extending contour.
- **zdir** [{‘x’, ‘y’, ‘z’}] The direction to use; defaults to ‘z’.
- **offset** [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to zdir
- ***args, **kwargs** Other arguments are forwarded to matplotlib.axes.Axes.contour.

**Returns**

- **matplotlib.contour.QuadContourSet**

```python
contour3D(self, X, Y, Z, *args, extend3d=False, stride=5, zdir='z', offset=None, **kwargs)
    Create a 3D contour plot.
```

**Parameters**

- **X, Y, Z** [array-likes] Input data.
- **extend3d** [bool] Whether to extend contour in 3D; defaults to False.
- **stride** [int] Step size for extending contour.
- **zdir** [{‘x’, ‘y’, ‘z’}] The direction to use; defaults to ‘z’.
- **offset** [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to zdir
- ***args, **kwargs** Other arguments are forwarded to matplotlib.axes.Axes.contour.

**Returns**

- **matplotlib.contour.QuadContourSet**
contourf(self, X, Y, Z, *args, zdir='z', offset=None, **kwargs)
Create a 3D filled contour plot.

Parameters

X, Y, Z [array-likes] Input data.

zdir [{'x', 'y', 'z'}] The direction to use; defaults to 'z'.

offset [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to zdir

*args, **kwargs Other arguments are forwarded to matplotlib.axes.Axes.contourf.

Returns

matplotlib.contour.QuadContourSet

Notes

New in version 1.1.0: The zdir and offset parameters.

contourf3D(self, X, Y, Z, *args, zdir='z', offset=None, **kwargs)
Create a 3D filled contour plot.

Parameters

X, Y, Z [array-likes] Input data.

zdir [{'x', 'y', 'z'}] The direction to use; defaults to 'z'.

offset [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to zdir

*args, **kwargs Other arguments are forwarded to matplotlib.axes.Axes.contourf.

Returns

matplotlib.contour.QuadContourSet

Notes

New in version 1.1.0: The zdir and offset parameters.

calculate_zunits(self, z)
For artists in an axes, if the zaxis has units support, convert z using zaxis unit type

New in version 1.2.1.

calculate_z_units

disable_mouse_rotation(self)
Disable mouse button callbacks.

draw(self, renderer)
Draw everything (plot lines, axes, labels)

format_coord(self, xd, yd)
Given the 2D view coordinates attempt to guess a 3D coordinate. Looks for the nearest edge to the point and then assumes that the point is at the same z location as the nearest point on the edge.
format_zdata(self, z)
    Return z string formatted. This function will use the fmt_zdata attribute if it is
callable, else will fall back on the zaxis major formatter

get_autoscale_on(self)
    Get whether autoscaling is applied for all axes on plot commands
    New in version 1.1.0: This function was added, but not tested. Please report any
    bugs.

get_autoscalez_on(self)
    Get whether autoscaling for the z-axis is applied on plot commands
    New in version 1.1.0: This function was added, but not tested. Please report any
    bugs.

get_axis_position(self)

get_frame_on(self)
    Get whether the 3D axes panels are drawn.
    New in version 1.1.0.

get_proj(self)
    Create the projection matrix from the current viewing position.
    elev stores the elevation angle in the z plane azim stores the azimuth angle in the
    x,y plane
    dist is the distance of the eye viewing point from the object point.

get_w_lims(self)
    Get 3D world limits.

get_xlim(self)
    Return the x-axis view limits.

    Returns
        left, right [(float, float)] The current x-axis limits in data coordinates.

    See also:
        set_xlim
        set_xbound, get_xbound
        invert_xaxis, xaxis_inverted

    Notes
    The x-axis may be inverted, in which case the left value will be greater than the
    right value.
    Changed in version 1.1.0: This function now correctly refers to the 3D x-limits

get_xlim3d(self)
    Return the x-axis view limits.

    Returns
        left, right [(float, float)] The current x-axis limits in data coordinates.

    See also:
set_xlim
set_xbound, get_xbound
invert_xaxis, xaxis_inverted

Notes

The x-axis may be inverted, in which case the left value will be greater than the right value.

Changed in version 1.1.0: This function now correctly refers to the 3D x-limits

get_ylim(self)
Return the y-axis view limits.

Returns

bottom, top [(float, float)] The current y-axis limits in data coordinates.

See also:

set_ylim
set_ybound, get_ybound
invert_yaxis, yaxis_inverted

Notes

The y-axis may be inverted, in which case the bottom value will be greater than the top value.

Changed in version 1.1.0: This function now correctly refers to the 3D y-limits.

get_ylim3d(self)
Return the y-axis view limits.

Returns

bottom, top [(float, float)] The current y-axis limits in data coordinates.

See also:

set_ylim
set_ybound, get_ybound
invert_yaxis, yaxis_inverted

Notes

The y-axis may be inverted, in which case the bottom value will be greater than the top value.

Changed in version 1.1.0: This function now correctly refers to the 3D y-limits.
get_zaxis(self)
Return the ZAxis (Axis) instance.

get_zbound(self)
Returns the z-axis numerical bounds where:

```
lowerBound < upperBound
```

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

get_zlabel(self)
Get the z-label text string.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

get_zlim(self)
Get 3D z limits.

get_zlim3d(self)
Get 3D z limits.

get_zmajorticklabels(self)
Get the ztick labels as a list of Text instances

New in version 1.1.0.

get_zminorticklabels(self)
Get the ztick labels as a list of Text instances

Note: Minor ticks are not supported. This function was added only for completeness.

New in version 1.1.0.

get_zscale(self)

get_zticklabels(self, minor=False)
Get ztick labels as a list of Text instances. See `matplotlib.axes.Axes.get_yticklabels()` for more details.

Note: Minor ticks are not supported.

New in version 1.1.0.

get_zticklines(self)
Get ztick lines as a list of Line2D instances. Note that this function is provided merely for completeness. These lines are re-calculated as the display changes.

New in version 1.1.0.

get_zticks(self, minor=False)
Return the z ticks as a list of locations See `matplotlib.axes.Axes.get_yticks()` for more details.

Note: Minor ticks are not supported.
New in version 1.1.0.

```python
grid(self, b=True, **kwargs)
```
Set / unset 3D grid.

**Note:** Currently, this function does not behave the same as `matplotlib.axes.Axes.grid()`, but it is intended to eventually support that behavior.

Changed in version 1.1.0: This function was changed, but not tested. Please report any bugs.

```python
have_units(self)
```
Return True if units are set on the x, y, or z axes

```python
invert_zaxis(self)
```
Invert the z-axis.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
locator_params(self, axis='both', tight=None, **kwargs)
```
Convenience method for controlling tick locators.

See `matplotlib.axes.Axes.locator_params()` for full documentation. Note that this is for Axes3D objects, therefore, setting `axis` to 'both' will result in the parameters being set for all three axes. Also, `axis` can also take a value of 'z' to apply parameters to the z axis.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
margins(self, *margins, x=None, y=None, z=None, tight=True)
```
Convenience method to set or retrieve autoscaling margins.

**signatures:**
margins()

returns xmargin, ymargin, zmargin

```python
margins(margin)
margins(xmargin, ymargin, zmargin)
margins(x=xmargin, y=ymargin, z=zmargin)
margins(..., tight=False)
```

All forms above set the xmargin, ymargin and zmargin parameters. All keyword parameters are optional. A single positional argument specifies xmargin, ymargin and zmargin. Passing both positional and keyword arguments for xmargin, ymargin, and/or zmargin is invalid.

The `tight` parameter is passed to `autoscale_view()`, which is executed after a margin is changed; the default here is True, on the assumption that when margins are specified, no additional padding to match tick marks is usually desired. Setting `tight` to None will preserve the previous setting.

Specifying any margin changes only the autoscaling; for example, if `xmargin` is not None, then `xmargin` times the X data interval will be added to each end of that interval before it is used in autoscaling.
New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
mouse_init(self, rotate_btn=1, zoom_btn=3)
```
Initializes mouse button callbacks to enable 3D rotation of the axes. Also optionally sets the mouse buttons for 3D rotation and zooming.

**Parameters**

- `rotate_btn` [int or list of int] The mouse button or buttons to use for 3D rotation of the axes; defaults to 1.
- `zoom_btn` [int or list of int] The mouse button or buttons to use to zoom the 3D axes; defaults to 3.

```python
name = '3d'
```

```python
plot(self, xs, ys, *args, zdir='z', **kwargs)
```
Plot 2D or 3D data.

**Parameters**

- `xs` [1D array-like] x coordinates of vertices.
- `ys` [1D array-like] y coordinates of vertices.
- `zs` [scalar or 1D array-like] z coordinates of vertices; either one for all points or one for each point.
- `zdir` [{‘x’, ‘y’, ‘z’}] When plotting 2D data, the direction to use as z (‘x’, ‘y’ or ‘z’); defaults to ‘z’.
- `**kwargs` Other arguments are forwarded to `matplotlib.axes.Axes.plot`.

```python
plot3D(self, xs, ys, *args, zdir='z', **kwargs)
```
Plot 2D or 3D data.

**Parameters**

- `xs` [1D array-like] x coordinates of vertices.
- `ys` [1D array-like] y coordinates of vertices.
- `zs` [scalar or 1D array-like] z coordinates of vertices; either one for all points or one for each point.
- `zdir` [{‘x’, ‘y’, ‘z’}] When plotting 2D data, the direction to use as z (‘x’, ‘y’ or ‘z’); defaults to ‘z’.
- `**kwargs` Other arguments are forwarded to `matplotlib.axes.Axes.plot`.

```python
plot_surface(self, X, Y, Z, *args, norm=None, vmin=None, vmax=None, light-source=None, **kwargs)
```
Create a surface plot.

By default it will be colored in shades of a solid color, but it also supports color mapping by supplying the `cmap` argument.

**Note:** The `rcount` and `ccount` kwargs, which both default to 50, determine the maximum number of samples used in each direction. If the input data is larger, it will be downsampled (by slicing) to these numbers of points.
Parameters

**X, Y, Z** [2d arrays] Data values.

**rcount, ccount** [int] Maximum number of samples used in each direction. If the input data is larger, it will be downsampled (by slicing) to these numbers of points. Defaults to 50.

New in version 2.0.

**rstride, cstride** [int] Downsampling stride in each direction. These arguments are mutually exclusive with **rcount** and **ccount**. If only one of **rstride** or **cstride** is set, the other defaults to 10.

‘classic’ mode uses a default of rstride = cstride = 10 instead of the new default of rcount = ccount = 50.

**color** [color-like] Color of the surface patches.

**cmap** [Colormap] Colormap of the surface patches.

**facecolors** [array-like of colors.] Colors of each individual patch.

**norm** [Normalize] Normalization for the colormap.

**vmin, vmax** [float] Bounds for the normalization.

**shade** [bool] Whether to shade the facecolors. Defaults to True. Shading is always disabled when **cmap** is specified.

**lightsource** [LightSource] The lightsource to use when **shade** is True.

****kwargs** Other arguments are forwarded to **Poly3DCollection**.

**plot_trisurf**

```python
plot_trisurf(self, *args, color=None, norm=None, vmin=None, vmax=None, lightsource=None, **kwargs)
```

Plot a triangulated surface.

The (optional) triangulation can be specified in one of two ways; either:

```python
plot_trisurf(triangulation, ...)
```

where triangulation is a **Triangulation** object, or:

```python
plot_trisurf(X, Y, ...)
plot_trisurf(X, Y, triangles, ...)
plot_trisurf(X, Y, triangles=triangles, ...)
```

in which case a Triangulation object will be created. See **Triangulation** for a explanation of these possibilities.

The remaining arguments are:

```python
plot_trisurf(..., Z)
```

where **Z** is the array of values to contour, one per point in the triangulation.

**Parameters**

**X, Y, Z** [array-like] Data values as 1D arrays.

**color** Color of the surface patches.

**cmap** A colormap for the surface patches.
**norm** [Normalize] An instance of Normalize to map values to colors.

**vmin, vmax** [scalar, optional, default: None] Minimum and maximum value to map.

**shade** [bool] Whether to shade the facecolors. Defaults to True. Shading is always disabled when **cmap** is specified.

**lightsource** [LightSource] The lightsource to use when **shade** is True.

****kwargs** All other arguments are passed on to Poly3DCollection

Examples

![3D wireframe plot](image)

New in version 1.2.0: This plotting function was added for the v1.2.0 release.

```python
plot_wireframe(self, X, Y, Z, *args, **kwargs)
```

Plot a 3D wireframe.

**Note:** The **rcount** and **ccount** **kwargs**, which both default to 50, determine the maximum number of samples used in each direction. If the input data is larger, it will be downsampled (by slicing) to these numbers of points.

**Parameters**

**X, Y, Z** [2d arrays] Data values.
**rcount, ccount** [int] Maximum number of samples used in each direction. If the input data is larger, it will be downsampled (by slicing) to these numbers of points. Setting a count to zero causes the data to be not sampled in the corresponding direction, producing a 3D line plot rather than a wireframe plot. Defaults to 50.

New in version 2.0.

**rstride, cstride** [int] Downsampling stride in each direction. These arguments are mutually exclusive with rcount and ccount. If only one of rstride or cstride is set, the other defaults to 1. Setting a stride to zero causes the data to be not sampled in the corresponding direction, producing a 3D line plot rather than a wireframe plot.

'classic' mode uses a default of rstride = cstride = 1 instead of the new default of rcount = ccount = 50.

**kwargs** Other arguments are forwarded to Line3DCollection.

**quiver**(*X*, *Y*, *Z*, *U*, *V*, *W*, *, length=1, arrow_length_ratio=.3, pivot='tail', normalize=False, **kwargs)

Plot a 3D field of arrows.

The arguments could be array-like or scalars, so long as they can be broadcast together. The arguments can also be masked arrays. If an element in any of argument is masked, then that corresponding quiver element will not be plotted.

**Parameters**

*X, Y, Z* [array-like] The x, y and z coordinates of the arrow locations (default is tail of arrow; see pivot kwarg)

*U, V, W* [array-like] The x, y and z components of the arrow vectors

*length* [float] The length of each quiver, default to 1.0, the unit is the same with the axes
**arrow_length_ratio** [float] The ratio of the arrow head with respect to the quiver, default to 0.3

**pivot** [{'tail', 'middle', 'tip'}] The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name pivot. Default is 'tail'

**normalize** [bool] When True, all of the arrows will be the same length. This defaults to False, where the arrows will be different lengths depending on the values of u,v,w.

**kwargs** Any additional keyword arguments are delegated to LineCollection

`quiver3D(X, Y, Z, U, V, W, /, length=1, arrow_length_ratio=.3, pivot='tail', normalize=False, **kwargs)`

Plot a 3D field of arrows.

The arguments could be array-like or scalars, so long as they can be broadcast together. The arguments can also be masked arrays. If an element in any of argument is masked, then that corresponding quiver element will not be plotted.

**Parameters**

**X, Y, Z** [array-like] The x, y and z coordinates of the arrow locations (default is tail of arrow; see **pivot** kwarg)

**U, V, W** [array-like] The x, y and z components of the arrow vectors

**length** [float] The length of each quiver, default to 1.0, the unit is the same with the axes

**arrow_length_ratio** [float] The ratio of the arrow head with respect to the quiver, default to 0.3

**pivot** [{'tail', 'middle', 'tip'}] The part of the arrow that is at the grid point; the arrow rotates about this point, hence the name pivot. Default is 'tail'

**normalize** [bool] When True, all of the arrows will be the same length. This defaults to False, where the arrows will be different lengths depending on the values of u,v,w.

**kwargs** Any additional keyword arguments are delegated to LineCollection

`scatter(self, xs, ys, zs=0, zdir='z', s=20, c=None, depthshade=True, *args, **kwargs)`

Create a scatter plot.

**Parameters**

**xs, ys** [array-like] The data positions.

**zs** [float or array-like, optional, default: 0] The z-positions. Either an array of the same length as xs and ys or a single value to place all points in the same plane.

**zdir** [{'x', 'y', 'z', '-x', '-y', '-z'}, optional, default: 'z'] The axis direction for the zs. This is useful when plotting 2D data on a 3D Axes. The data must be passed as xs, ys. Setting zdir to 'y' then plots the data to the x-z-plane.

See also /gallery/mplot3d/2dcollections3d.
Parameters

xs, ys [array-like] The data positions.

zs [float or array-like, optional, default: 0] The z-positions. Either an array of the same length as xs and ys or a single value to place all points in the same plane.

zdir [{'x', 'y', 'z', '-x', '-y', '-z'}, optional, default: 'z'] The axis direction for the zs. This is useful when plotting 2D data on a 3D Axes. The data must be passed as xs, ys. Setting zdir to 'y' then plots the data to the x-z-plane.

See also /gallery/mplot3d/2dcollections3d.

s [scalar or array-like, optional, default: 20] The marker size in points**2. Either an array of the same length as xs and ys or a single value to make all markers the same size.

c [color, sequence, or sequence of color, optional] The marker color. Possible values:

- A single color format string.
- A sequence of color specifications of length n.
- A sequence of n numbers to be mapped to colors using cmap and norm.
- A 2-D array in which the rows are RGB or RGBA.

For more details see the c argument of scatter.

depthshade [bool, optional, default: True] Whether to shade the scatter markers to give the appearance of depth.

**kwargs All other arguments are passed on to scatter.

Returns

paths [PathCollection]

scatter3D(self, xs, ys, zs=0, zdir='z', s=20, c=None, depthshade=True, *args, **kwargs)

Create a scatter plot.
**kwargs All other arguments are passed on to `scatter`.

**Returns**

paths [PathCollection]

set_autoscale_on(self, b)
Set whether autoscaling is applied on plot commands

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

**Parameters**

b [bool]

set_autoscalez_on(self, b)
Set whether autoscaling for the z-axis is applied on plot commands

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

**Parameters**

b [bool]

set_axis_off(self)
Turn the x- and y-axis off.

This affects the axis lines, ticks, ticklabels, grid and axis labels.

set_axis_on(self)
Turn the x- and y-axis on.

This affects the axis lines, ticks, ticklabels, grid and axis labels.

set_frame_on(self, b)
Set whether the 3D axes panels are drawn.

New in version 1.1.0.

**Parameters**

b [bool]

set_proj_type(self, proj_type)
Set the projection type.

**Parameters**

proj_type [str] Type of projection, accepts 'persp' and 'ortho'.

set_title(self, label, fontdict=None, loc='center', **kwargs)
Set a title for the axes.

Set one of the three available axes titles. The available titles are positioned above the axes in the center, flush with the left edge, and flush with the right edge.

**Parameters**

label [str] Text to use for the title

fontdict [dict] A dictionary controlling the appearance of the title text, the default fontdict is:
loc [{‘center’, ‘left’, ‘right’}, str, optional] Which title to set, defaults to ‘center’

pad [float] The offset of the title from the top of the axes, in points. Default is None to use rcParams[‘axes.titlepad’].

**Returns**

- text [Text] The matplotlib text instance representing the title

**Other Parameters**

****kwargs [Text properties] Other keyword arguments are text properties, see Text for a list of valid text properties.

---

18.2. mplot3d API

---
set_ylim(self, bottom=None, top=None, emit=True, auto=False, *, ymin=None, ymax=None)
Set 3D y limits.

See matplotlib.axes.Axes.set_ylim() for full documentation.

set_ylim3d(self, bottom=None, top=None, emit=True, auto=False, *, ymin=None, ymax=None)
Set 3D y limits.

See matplotlib.axes.Axes.set_ylim() for full documentation.

set_yscale(self, value, **kwargs)
Set the y-axis scale.

Parameters

value [{“linear”, “log”, “symlog”, “logit”, ...}] The axis scale type to apply.

**kwargs Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:

• matplotlib.scale.LinearScale
• matplotlib.scale.LogScale
• matplotlib.scale.SymmetricalLogScale
• matplotlib.scale.LogitScale

Notes

By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using matplotlib.scale.register_scale. These scales can then also be used here.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

set_zbound(self, lower=None, upper=None)
Set the lower and upper numerical bounds of the z-axis. This method will honor axes inversion regardless of parameter order. It will not change the _autoscaleZon attribute.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

set_zlabel(self, zlabel, fontdict=None, labelpad=None, **kwargs)
Set zlabel. See doc for set_ylabel() for description.

set_zlim(self, bottom=None, top=None, emit=True, auto=False, *, zmin=None, zmax=None)
Set 3D z limits.

See matplotlib.axes.Axes.set_ylim() for full documentation

set_zlim3d(self, bottom=None, top=None, emit=True, auto=False, *, zmin=None, zmax=None)
Set 3D z limits.

See matplotlib.axes.Axes.set_ylim() for full documentation
set_zmargin(self, m)
Set padding of Z data limits prior to autoscaling.
m times the data interval will be added to each end of that interval before it is used in autoscaling.
accepts: float in range 0 to 1
New in version 1.1.0: This function was added, but not tested. Please report any bugs.

set_zscale(self, value, **kwargs)
Set the z-axis scale.

Parameters
value [{"linear", "log", "symlog", "logit", ...}] The axis scale type to apply.

**kwargs Different keyword arguments are accepted, depending on the scale. See the respective class keyword arguments:
• matplotlib.scale.LinearScale
• matplotlib.scale.LogScale
• matplotlib.scale.SymmetricalLogScale
• matplotlib.scale.LogitScale

Notes
Currently, Axes3D objects only supports linear scales. Other scales may or may not work, and support for these is improving with each release.
By default, Matplotlib supports the above mentioned scales. Additionally, custom scales may be registered using matplotlib.scale.register_scale. These scales may then also be used here as support is added.

set_zticklabels(self, *args, **kwargs)
Set z-axis tick labels. See matplotlib.axes.Axes.set_yticklabels() for more details.

Note: Minor ticks are not supported by Axes3D objects.

New in version 1.1.0.

set_zticks(self, *args, **kwargs)
Set z-axis tick locations. See matplotlib.axes.Axes.set_yticks() for more details.

Note: Minor ticks are not supported.

New in version 1.1.0.

text(self, x, y, z, s, zdir=None, **kwargs)
Add text to the plot. kwargs will be passed on to Axes.text, except for the zdir keyword, which sets the direction to be used as the z direction.
text2D(self, x, y, s, fontdict=None, withdash=<deprecated parameter>, **kwargs)
Add text to the axes.
Add the text s to the axes at location x, y in data coordinates.

Parameters
x, y [scalars] The position to place the text. By default, this is in data coordinates. The coordinate system can be changed using the transform parameter.
s [str] The text.
fontdict [dictionary, optional, default: None] A dictionary to override the default text properties. If fontdict is None, the defaults are determined by your rc parameters.

Returns
text [Text] The created Text instance.

Other Parameters
**kwargs [Text properties.] Other miscellaneous text parameters.

Examples
Individual keyword arguments can be used to override any given parameter:

```python
>>> text(x, y, s, fontsize=12)
```

The default transform specifies that text is in data coords, alternatively, you can specify text in axis coords (0,0 is lower-left and 1,1 is upper-right). The example below places text in the center of the axes:

```python
>>> text(0.5, 0.5, 'matplotlib', horizontalalignment='center',
...       verticalalignment='center', transform=ax.transAxes)
```

You can put a rectangular box around the text instance (e.g., to set a background color) by using the keyword bbox. bbox is a dictionary of Rectangle properties. For example:

```python
>>> text(x, y, s, bbox=dict(facecolor='red', alpha=0.5))
```

text3D(self, x, y, z, s, zdir=None, **kwargs)
Add text to the plot. kwargs will be passed on to Axes.text, except for the zdir keyword, which sets the direction to be used as the z direction.

tick_params(self, axis='both', **kwargs)
Convenience method for changing the appearance of ticks and tick labels.
See matplotlib.axes.Axes.tick_params() for more complete documentation.
The only difference is that setting axis to 'both' will mean that the settings are applied to all three axes. Also, the axis parameter also accepts a value of 'z', which would mean to apply to only the z-axis.
Also, because of how Axes3D objects are drawn very differently from regular 2D axes, some of these settings may have ambiguous meaning. For simplicity, the ‘z’ axis will accept settings as if it was like the ‘y’ axis.

**Note:** While this function is currently implemented, the core part of the Axes3D object may ignore some of these settings. Future releases will fix this. Priority will be given to those who file bugs.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
ticklabel_format(self, *, style="", scilimits=None, useOffset=None, axis='both')
```

Convenience method for manipulating the ScalarFormatter used by default for linear axes in Axes3D objects.

See `matplotlib.axes.Axes.ticklabel_format()` for full documentation. Note that this version applies to all three axes of the Axes3D object. Therefore, the `axis` argument will also accept a value of ‘z’ and the value of ‘both’ will apply to all three axes.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.

```python
tricontour(self, *args, extend3d=False, stride=5, zdir='z', offset=None, **kwargs)
```

Create a 3D contour plot.

Changed in version 1.3.0: Added support for custom triangulations

**Note:** This method currently produces incorrect output due to a longstanding bug in 3D PolyCollection rendering.

**Parameters**

- **X, Y, Z** [array-likes] Input data.
- **extend3d** [bool] Whether to extend contour in 3D; defaults to False.
- **stride** [int] Step size for extending contour.
- **zdir** [‘x’, ‘y’, ‘z’] The direction to use; defaults to ‘z’.
- **offset** [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to `zdir`
- ***args, **kwargs** Other arguments are forwarded to `matplotlib.axes.Axes.tricontour`.

**Returns**

- `matplotlib.tri.tricontour.TriContourSet`

```python
tricontourf(self, *args, zdir='z', offset=None, **kwargs)
```

Create a 3D filled contour plot.

**Note:** This method currently produces incorrect output due to a longstanding bug in 3D PolyCollection rendering.
Parameters

**X, Y, Z** [array-likes] Input data.

**zdir** [{‘x’, ‘y’, ‘z’}] The direction to use; defaults to ‘z’.

**offset** [scalar] If specified, plot a projection of the contour lines at this position in a plane normal to zdir

***args, **kwargs** Other arguments are forwarded to matplotlib.axes.Axes.tricontourf.

Returns

matplotlib.tri.tricontour.TriContourSet

Notes

New in version 1.1.0: The *zdir* and *offset* parameters.

Changed in version 1.3.0: Added support for custom triangulations

**tunit_cube**(*self*, *vals=None, M=None)

**tunit_edges**(*self*, *vals=None, M=None)

**unit_cube**(*self*, *vals=None, M=None)

**update_datalim**(*self*, *xys, **kwargs*)

- Extend the dataLim BBox to include the given points.
  - If no data is set currently, the BBox will ignore its limits and set the bound to be the bounds of the xydata (*xys*). Otherwise, it will compute the bounds of the union of its current data and the data in *xys*.

Parameters

**xys** [2D array-like] The points to include in the data limits BBox. This can be either a list of (x, y) tuples or a N×2 array.

**update_x, update_y** [bool, optional, default *True*] Whether to update the x/y limits.

**view_init**(*self*, *elev=None, azim=None*)

- Set the elevation and azimuth of the axes in degrees (not radians).
  - This can be used to rotate the axes programmatically.
  - ’elev’ stores the elevation angle in the z plane (in degrees). ’azim’ stores the azimuth angle in the x,y plane (in degrees).
  - If elev or azim are None (default), then the initial value is used which was specified in the Axes3D constructor.

**voxels**([*x, y, z*], *, filled, facecolors=None, edgecolors=None, **kwargs*)

- Plot a set of filled voxels
  - All voxels are plotted as 1x1x1 cubes on the axis, with filled[0,0,0] placed with its lower corner at the origin. Occluded faces are not plotted.

New in version 2.1.

Parameters
filled [3D np.array of bool] A 3d array of values, with truthy values indicating which voxels to fill

x, y, z [3D np.array, optional] The coordinates of the corners of the voxels. This should broadcast to a shape one larger in every dimension than the shape of filled. These can be used to plot non-cubic voxels.

If not specified, defaults to increasing integers along each axis, like those returned by `indices()`. As indicated by the / in the function signature, these arguments can only be passed positionally.

facecolors, edgecolors [array_like, optional] The color to draw the faces and edges of the voxels. Can only be passed as keyword arguments. This parameter can be:

• A single color value, to color all voxels the same color. This can be either a string, or a 1D rgb/rgba array

• None, the default, to use a single color for the faces, and the style default for the edges.

• A 3D ndarray of color names, with each item the color for the corresponding voxel. The size must match the voxels.

• A 4D ndarray of rgb/rgba data, with the components along the last axis.

shade [bool] Whether to shade the facecolors. Defaults to True. Shading is always disabled when cmap is specified.

New in version 3.1.

lightsource [LightSource] The lightsource to use when shade is True.

New in version 3.1.

**kwargs Additional keyword arguments to pass onto `Poly3DCollection()`

Returns

faces [dict] A dictionary indexed by coordinate, where faces[i,j,k] is a Poly3DCollection of the faces drawn for the voxel filled[i,j,k]. If no faces were drawn for a given voxel, either because it was not asked to be drawn, or it is fully occluded, then (i,j,k) not in faces.

Examples

zaxis_date(self, tz=None)

Sets up z-axis ticks and labels that treat the z data as dates.

tz is a timezone string or tzinfo instance. Defaults to rc value.

Note: This function is merely provided for completeness. Axes3D objects do not officially support dates for ticks, and so this may or may not work as expected.

New in version 1.1.0: This function was added, but not tested. Please report any bugs.
zaxis_inverted(self)
    Returns True if the z-axis is inverted.

    New in version 1.1.0: This function was added, but not tested. Please report any bugs.

18.2.2 axis3d

Note: See mpl_toolkits.mplot3d.axis3d._axinfo for a dictionary containing constants that may be modified for controlling the look and feel of mplot3d axes (e.g., label spacing, font colors and panel colors). Historically, axis3d has suffered from having hard-coded constants that precluded user adjustments, and this dictionary was implemented in version 1.1 as a stop-gap measure.

axis3d.Axis(adir, v_intervalx, d_intervalx, ...)

mpl_toolkits.mplot3d.axis3d.Axis

class mpl_toolkits.mplot3d.axis3d.Axis(adir, v_intervalx, d_intervalx, axes, *args, rotate_label=None, **kwargs)

    An Axis class for the 3D plots.

...
set_rotate_label(self, val)
    Whether to rotate the axis label: True, False or None. If set to None the label will
    be rotated if longer than 4 chars.

v_interval

18.2.3 art3d

art3d.Line3D(xs, ys, zs, *args, **kwargs)    3D line object.
art3d.Line3DCollection(segments[, ...])    A collection of 3D lines.
art3d.Patch3D(*args[, zs, zdir])            3D patch object.
art3d.Patch3DCollection(*args[, zs, zdir, ...])    A collection of 3D patches.
art3d.Path3DCollection(*args[, zs, zdir, ...])    A collection of 3D paths.
art3d.PathPatch3D(path, *[, zs, zdir])        3D PathPatch object.
art3d.Text3D([x, y, z, text, zdir])          Text object with 3D position and direction.

mpl_toolkits.mplot3d.art3d.Line3D

class mpl_toolkits.mplot3d.art3d.Line3D(xs, ys, zs, *args, **kwargs)
    Bases: matplotlib.lines.Line2D
    3D line object.
    Keyword arguments are passed onto Line2D().
    draw(self, renderer)

18.2. mpl_toolkits.mplot3d Axes

    The Artist using the given renderer.

This method will be overridden in the Artist subclasses. Typically, it is implemented
to not have any effect if the Artist is not visible (Artist.get_visible is False).
Notes

Accepts x, y, z arguments or a single array_like (x, y, z)

mpl_toolkits.mplot3d.art3d.Line3DCollection

class mpl_toolkits.mplot3d.art3d.Line3DCollection(segments, linewidths=None, colors=None, antialiaseds=None, linestyles='solid', offsets=None, transOffset=None, norm=None, cmap=None, pickradius=5, zorder=2, facecolors='none', **kwargs)

Bases: matplotlib.collections.LineCollection

A collection of 3D lines.

Parameters

segments A sequence of (line0, line1, line2), where:

    linen = (x0, y0), (x1, y1), ... (xm, ym)

    or the equivalent numpy array with two columns. Each line can be a different length.
colors [sequence, optional] A sequence of RGBA tuples (e.g., arbitrary color strings, etc, not allowed).

antialiaseds [sequence, optional] A sequence of ones or zeros.

linestyles [string, tuple, optional] Either one of [ 'solid' | 'dashed' | 'dashdot' | 'dotted' ], or a dash tuple. The dash tuple is:

```
(offset, onoffseq)
```

where onoffseq is an even length tuple of on and off ink in points.

norm [Normalize, optional] Normalize instance.

cmap [string or Colormap, optional] Colormap name or Colormap instance.

pickradius [float, optional] The tolerance in points for mouse clicks picking a line. Default is 5 pt.

facecolors [optional] The facecolors of the LineCollection. Default is ‘none’. Setting to a value other than ‘none’ will lead to a filled polygon being drawn between points on each line.
Notes

If `lineweights`, `colors`, or `antialiaseds` is None, they default to their rcParams setting, in sequence form.

If `offsets` and `transOffset` are not None, then `offsets` are transformed by `transOffset` and applied after the segments have been transformed to display coordinates.

If `offsets` is not None but `transOffset` is None, then the `offsets` are added to the segments before any transformation. In this case, a single offset can be specified as:

```
offsets=(xo,yo)
```

and this value will be added cumulatively to each successive segment, so as to produce a set of successively offset curves.

The use of `ScalarMappable` is optional. If the `ScalarMappable` array `_A` is not None (i.e., a call to `set_array()` has been made), at draw time a call to scalar mappable will be made to set the colors.

do_3d_projection(self, renderer)
    Project the points according to renderer matrix.

draw(self, renderer, project=False)
    Draw the Artist using the given renderer.
    This method will be overridden in the Artist subclasses. Typically, it is implemented to not have any effect if the Artist is not visible (`Artist.get_visible` is False).

    Parameters
    ----------
    renderer \[RendererBase subclass.\]

set_segments(self, segments)
    Set 3D segments.

set_sort_zpos(self, val)
    Set the position to use for z-sorting.

mpl_toolkits.mplot3d.art3d.Patch3D

class mpl_toolkits.mplot3d.art3d.Patch3D(*args, zs=(), zdir='z', **kwargs)
    Bases: matplotlib.patches.Patch
    3D patch object.

do_3d_projection(self, renderer)

get_facecolor(self)
    Return the face color of the Patch.

get_path(self)
    Return the path of this patch

set_3d_properties(self, verts, zs=0, zdir='z')
A collection of 3D patches.
Create a collection of flat 3D patches with its normal vector pointed in `zdir` direction, and located at `zs` on the `zdir` axis. `zs` can be a scalar or an array-like of the same length as the number of patches in the collection.

Constructor arguments are the same as for `PatchCollection`. In addition, keywords `zs=0` and `zdir='z'` are available.

Also, the keyword argument "depthshade" is available to indicate whether or not to shade the patches in order to give the appearance of depth (default is `True`). This is typically desired in scatter plots.

```python
mpl_toolkits.mplot3d.art3d.Patch3DCollection
```

A collection of 3D paths.
Create a collection of flat 3D paths with its normal vector pointed in `zdir` direction, and located at `zs` on the `zdir` axis. `zs` can be a scalar or an array-like of the same length as the number of paths in the collection.

Constructor arguments are the same as for `PathCollection`. In addition, keywords `zs=0` and `zdir='z'` are available.

Also, the keyword argument "depthshade" is available to indicate whether or not to shade the patches in order to give the appearance of depth (default is `True`). This is typically desired in scatter plots.

```python
mpl_toolkits.mplot3d.art3d.Path3DCollection
```

A 3D PathPatch object.

```python
mpl_toolkits.mplot3d.art3d.PathPatch3D
```
set_3d_properties(self, path, zs=0, zdir='z')

mpl_toolkits.mplot3d.art3d.Poly3DCollection

class mpl_toolkits.mplot3d.art3d.Poly3DCollection(verts, *args, zsort='average', **kwargs)
Bases: matplotlib.collections.PolyCollection
A collection of 3D polygons.
Create a Poly3DCollection.
verts should contain 3D coordinates.
Keyword arguments: zsort, see set_zsort for options.
Note that this class does a bit of magic with the _facecolors and _edgecolors properties.

do_3d_projection(self, renderer)
    Perform the 3D projection for this object.
get_edgecolor(self)
get_facecolor(self)
get_vector(self, segments3d)
    Optimize points for projection.
set_3d_properties(self)
set_alpha(self, alpha)
    Set the alpha transparencies of the collection.

Parameters

    alpha [float or None]

set_edgecolor(self, colors)
    Set the edgecolor(s) of the collection.

Parameters

    c [color or sequence of colors or 'face'] The collection edgecolor(s).
    If a sequence, the patches cycle through it. If 'face', match the
    facecolor.

set_facecolor(self, colors)
    Set the facecolor(s) of the collection. c can be a matplotlib color spec (all patches
    have same color), or a sequence of specs; if it is a sequence the patches will cycle
    through the sequence.

    If c is 'none', the patch will not be filled.

Parameters

    c [color or sequence of colors]

set_sort_zpos(self, val)
    Set the position to use for z-sorting.

set_verts(self, verts, closed=True)
    Set 3D vertices.
set_verts_and_codes(self, verts, codes)
Sets 3D vertices with path codes.

set_zsort(self, zsort)
Sets the calculation method for the z-order.

**Parameters**

zsort [{‘average’, ‘min’, ‘max’}] The function applied on the z-coordinates of the vertices in the viewer’s coordinate system, to determine the z-order. True is deprecated and equivalent to ‘average’.

mpl_toolkits.mplot3d.art3d.Text3D

class mpl_toolkits.mplot3d.art3d.Text3D

```
(x=0, y=0, z=0, text='', zdir='z', **kwargs)
```

Text object with 3D position and direction.

**Parameters**

x, y, z The position of the text.

text [str] The text string to display.

zdir [{‘x’, ‘y’, ‘z’, None, 3-tuple}] The direction of the text. See get_dir_vector for a description of the values.

**Other Parameters**

**kwargs All other parameters are passed on to Text.

draw(self, renderer)

Draws the Text object to the given renderer.

get_tightbbox(self, renderer)

Like Artist.get_window_extent, but includes any clipping.

**Parameters**

renderer [RendererBase instance] renderer that will be used to draw the figures (i.e. fig.canvas.get_renderer())

**Returns**

bbox [BBox] The enclosing bounding box (in figure pixel co-ordinates).

set_3d_properties(self, z=0, zdir='z')

**Notes**

Deprecation since version 3.1.

### mpl_toolkits.mplot3d.art3d.get_colors

`mpl_toolkits.mplot3d.art3d.get_colors(c, num)`

[Deprecated] Stretch the color argument to provide the required number `num`.

### mpl_toolkits.mplot3d.art3d.get_dir_vector

Return a direction vector.

**Parameters**

- **zdir** ([‘x’, ‘y’, ‘z’, None, 3-tuple]) The direction. Possible values are: - ‘x’: equivalent to (1, 0, 0) - ‘y’: equivalent to (0, 1, 0) - ‘z’: equivalent to (0, 0, 1)
(0, 0, 1) - None: equivalent to (0, 0, 0) - an iterable (x, y, z) is returned unchanged.

**Returns**

x, y, z [array-like] The direction vector. This is either a numpy.array or zdir itself if zdir is already a length-3 iterable.

`mpl_toolkits.mplot3d.art3d.get_patch_verts`

`mpl_toolkits.mplot3d.art3d.get_patch_verts(patch)`  
**[Deprecated]** Return a list of vertices for the path of a patch.

**Notes**

Deprecated since version 3.1.

`mpl_toolkits.mplot3d.art3d.juggle_axes`

`mpl_toolkits.mplot3d.art3d.juggle_axes(xs, ys, zs, zdir)`  
Reorder coordinates so that 2D xs, ys can be plotted in the plane orthogonal to zdir. zdir is normally x, y or z. However, if zdir starts with a '-' it is interpreted as a compensation for rotate_axes.

`mpl_toolkits.mplot3d.art3d.line_2d_to_3d`

`mpl_toolkits.mplot3d.art3d.line_2d_to_3d(line, zs=0, zdir='z')`  
Convert a 2D line to 3D.

`mpl_toolkits.mplot3d.art3d.line_collection_2d_to_3d`

`mpl_toolkits.mplot3d.art3d.line_collection_2d_to_3d(col, zs=0, zdir='z')`  
Convert a LineCollection to a Line3DCollection object.

`mpl_toolkits.mplot3d.art3d.norm_angle`

`mpl_toolkits.mplot3d.art3d.norm_angle(a)`  
**[Deprecated]** Return the given angle normalized to -180 < a <= 180 degrees.

**Notes**

Deprecated since version 3.1.

`mpl_toolkits.mplot3d.art3d.norm_text_angle`

`mpl_toolkits.mplot3d.art3d.norm_text_angle(a)`  
**[Deprecated]** Return the given angle normalized to -90 < a <= 90 degrees.
Notes

Deprecated since version 3.1.

mpl_toolkits.mplot3d.art3d.patch_2d_to_3d

mpl_toolkits.mplot3d.art3d.patch_2d_to_3d(patch, z=0, zdir='z')

Convert a Patch to a Patch3D object.

mpl_toolkits.mplot3d.art3d.patch_collection_2d_to_3d

mpl_toolkits.mplot3d.art3d.patch_collection_2d_to_3d(col, zs=0, zdir='z',
depthshade=True)

Convert a PatchCollection into a Patch3DCollection object (or a
PathCollection into a
Path3DCollection object).

Parameters

za The location or locations to place the patches in the collection along
the zdir axis. Default: 0.

zdir The axis in which to place the patches. Default: “z”.

depthshade Whether to shade the patches to give a sense of depth. De-
default: True.

mpl_toolkits.mplot3d.art3d.path_to_3d_segment

mpl_toolkits.mplot3d.art3d.path_to_3d_segment(path, zs=0, zdir='z')

[Deprecated] Convert a path to a 3D segment.

Notes

Deprecated since version 3.1.

mpl_toolkits.mplot3d.art3d.path_to_3d_segment_with_codes

mpl_toolkits.mplot3d.art3d.path_to_3d_segment_with_codes(path, zs=0, zdir='z')

[Deprecated] Convert a path to a 3D segment with path codes.

Notes

Deprecated since version 3.1.

mpl_toolkits.mplot3d.art3d.pathpatch_2d_to_3d

mpl_toolkits.mplot3d.art3d.pathpatch_2d_to_3d(pathpatch, z=0, zdir='z')

Convert a PathPatch to a PathPatch3D object.
Examples using mpl_toolkits.mplot3d.art3d.pathpatch_2d_to_3d

- sphx_glr_gallery_mplot3d_pathpatch3d.py

mpl_toolkits.mplot3d.art3d.paths_to_3d_segments

mpl_toolkits.mplot3d.art3d.paths_to_3d_segments(paths, zs=0, zdir='z')

[Deprecated] Convert paths from a collection object to 3D segments.

Notes

Deprecated since version 3.1.

mpl_toolkits.mplot3d.art3d.paths_to_3d_segments_with_codes

mpl_toolkits.mplot3d.art3d.paths_to_3d_segments_with_codes(paths, zs=0, zdir='z')

[Deprecated] Convert paths from a collection object to 3D segments with path codes.

Notes

Deprecated since version 3.1.

mpl_toolkits.mplot3d.art3d.poly_collection_2d_to_3d

mpl_toolkits.mplot3d.art3d.poly_collection_2d_to_3d(col, zs=0, zdir='z')

Convert a PolyCollection to a Poly3DCollection object.

mpl_toolkits.mplot3d.art3d.rotate_axes

mpl_toolkits.mplot3d.art3d.rotate_axes(xs, ys, zs, zdir)

Reorder coordinates so that the axes are rotated with zdir along the original z axis. Prepending the axis with a '-' does the inverse transform, so zdir can be x, -x, y, -y, z or -z

mpl_toolkits.mplot3d.art3d.text_2d_to_3d

mpl_toolkits.mplot3d.art3d.text_2d_to_3d(obj, z=0, zdir='z')

Convert a Text to a Text3D object.

mpl_toolkits.mplot3d.art3d.zalpha

mpl_toolkits.mplot3d.art3d.zalpha(colors, zs)

[Deprecated] Modify the alphas of the color list according to depth.
Notes

Deprecated since version 3.1.

### 18.2.5 proj3d

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>

`mpl_toolkits.mplot3d.proj3d.inv_transform` is deprecated.
matplotlib.mplot3d.proj3d.line2d_dist

matplotlib.mplot3d.proj3d.line2d_dist(l, p)

[Deprecated] Distance from line to point

Notes

Deprecated since version 3.1.

matplotlib.mplot3d.proj3d.line2d_seg_dist

matplotlib.mplot3d.proj3d.line2d_seg_dist(p1, p2, p0)

[Deprecated] distance(s) from line defined by p1 - p2 to point(s) p0

p0[0] = x(s) p0[1] = y(s)

intersection point p = p1 + u*(p2-p1) and intersection point lies within segment if u is between 0 and 1

Notes

Deprecated since version 3.1.

matplotlib.mplot3d.proj3d.mod

matplotlib.mplot3d.proj3d.mod(v)

[Deprecated] 3d vector length

Notes

Deprecated since version 3.1.

matplotlib.mplot3d.proj3d.persp_transformation

matplotlib.mplot3d.proj3d.persp_transformation(zfront, zback)

matplotlib.mplot3d.proj3d.proj_points

matplotlib.mplot3d.proj3d.proj_points(points, M)

matplotlib.mplot3d.proj3d.proj_trans_clip_points

matplotlib.mplot3d.proj3d.proj_trans_clip_points(points, M)

[Deprecated]
Notes

Deprecated since version 3.1:

mpl_toolkits.mplot3d.proj3d.proj_trans_points

mpl_toolkits.mplot3d.proj3d.proj_trans_points(points, M)

mpl_toolkits.mplot3d.proj3d.proj_transform

mpl_toolkits.mplot3d.proj3d.proj_transform(xs, ys, zs, M)
    Transform the points by the projection matrix

mpl_toolkits.mplot3d.proj3d.proj_transform_clip

mpl_toolkits.mplot3d.proj3d.proj_transform_clip(xs, ys, zs, M)
    Transform the points by the projection matrix and return the clipping result returns txs,tys,tzs,tis

mpl_toolkits.mplot3d.proj3d.proj_transform_vec

mpl_toolkits.mplot3d.proj3d.proj_transform_vec(vec, M)
    [Deprecated]

Notes

Deprecated since version 3.1:

mpl_toolkits.mplot3d.proj3d.proj_transform_vec_clip

mpl_toolkits.mplot3d.proj3d.proj_transform_vec_clip(vec, M)
    [Deprecated]

Notes

Deprecated since version 3.1:

mpl_toolkits.mplot3d.proj3d.rot_x

mpl_toolkits.mplot3d.proj3d.rot_x(V, alpha)

mpl_toolkits.mplot3d.proj3d.transform

mpl_toolkits.mplot3d.proj3d.transform(xs, ys, zs, M)
    Transform the points by the projection matrix
mpl_toolkits.mplot3d.proj3d.vec_pad_ones

mpl_toolkits.mplot3d.proj3d.vec_pad_ones(xs, ys, zs)
[Deprecated]

Notes

Deprecated since version 3.1:

mpl_toolkits.mplot3d.proj3d.view_transformation

mpl_toolkits.mplot3d.proj3d.view_transformation(E, R, V)

mpl_toolkits.mplot3d.proj3d.world_transformation

mpl_toolkits.mplot3d.proj3d.world_transformation(xmin, xmax, ymin, ymax, zmin, zmax)

18.3 Matplotlib axes_grid Toolkit

Note: AxesGrid toolkit has been a part of matplotlib since v 0.99. Originally, the toolkit had a single namespace of axes_grid. In more recent version, the toolkit has divided into two separate namespace (axes_grid1 and axisartist). While axes_grid namespace is maintained for the backward compatibility, use of axes_grid1 and axisartist is recommended. For the documentation on axes_grid, see the previous version of the docs.

Third party packages
Several external packages that extend or build on Matplotlib functionality are listed below. They are maintained and distributed separately from Matplotlib and thus need to be installed individually.

Please submit an issue or pull request on Github if you have created a package that you would like to have included. We are also happy to host third party packages within the Matplotlib Github Organization.
CHAPTER
TWENTYTWO

MAPPING TOOLKITS

22.1 Basemap

Basemap plots data on map projections, with continental and political boundaries.

contour lines over filled continent background

22.2 Cartopy

Cartopy builds on top of Matplotlib to provide object oriented map projection definitions and close integration with Shapely for powerful yet easy-to-use vector data processing tools. An example plot from the Cartopy gallery:
22.3 Ridge Map

ridge_map uses Matplotlib, SRTM.py, NumPy, and scikit-image to make ridge plots of your favorite ridges.
THE WHITE MOUNTAINS
23.1 ggplot

ggplot is a port of the R ggplot2 package to python based on Matplotlib.

23.2 holoviews

holoviews makes it easier to visualize data interactively, especially in a Jupyter notebook, by providing a set of declarative plotting objects that store your data and associated meta-data. Your data is then immediately visualizable alongside or overlaid with other data, either statically or with automatically provided widgets for parameter exploration.
import numpy as np
import holoviews as hv
hv.notebook_extension('matplotlib')
fractal = hv.Image(np.load('mandelbrot.npy'))
((fractal * hv.HLine(y=0)).hist() + fractal.sample(y=0))

23.3 plotnine

plotnine implements a grammar of graphics, similar to R’s ggplot2. The grammar allows users to compose plots by explicitly mapping data to the visual objects that make up the plot.
24.1 Broken Axes

`brokenaxes` supplies an axes class that can have a visual break to indicate a discontinuous range.

![Broken Axes Example](image)

24.2 DeCiDa

`DeCiDa` is a library of functions and classes for electron device characterization, electronic circuit design and general data visualization and analysis.

24.3 Matplotlib-Venn

`Matplotlib-Venn` provides a set of functions for plotting 2- and 3-set area-weighted (or unweighted) Venn diagrams.

24.4 mpl-probscale

`mpl-probscale` is a small extension that allows Matplotlib users to specify probability scales.
Simply importing the `probscale` module registers the scale with Matplotlib, making it accessible via e.g., `ax.set_xscale('prob')` or `plt.yscale('prob')`.

### 24.5 mpl-scatter-density

`mpl-scatter-density` is a small package that makes it easy to make scatter plots of large numbers of points using a density map. The following example contains around 13 million points and the plotting (excluding reading in the data) took less than a second on an average laptop:
When used in interactive mode, the density map is downsampled on-the-fly while panning/zooming in order to provide a smooth interactive experience.

### 24.6 mplstereonet

`mplstereonet` provides stereonets for plotting and analyzing orientation data in Matplotlib.

### 24.7 Natgrid

`mpl_toolkits.natgrid` is an interface to the natgrid C library for gridding irregularly spaced data.

### 24.8 pyUpSet

`pyUpSet` is a static Python implementation of the UpSet suite by Lex et al. to explore complex intersections of sets and data frames.

### 24.9 seaborn

`seaborn` is a high level interface for drawing statistical graphics with Matplotlib. It aims to
make visualization a central part of exploring and understanding complex datasets.

24.10 WCSAxes

The Astropy core package includes a submodule called WCSAxes (available at astropy.visualization.wcsaxes) which adds Matplotlib projections for Astronomical image data. The following is an example of a plot made with WCSAxes which includes the original coordinate system of the image and an overlay of a different coordinate system:

![Galactic Coordinate System](image)

24.11 Windrose

Windrose is a Python Matplotlib, Numpy library to manage wind data, draw windroses (also known as polar rose plots), draw probability density functions and fit Weibull distributions.
24.12 Yellowbrick

Yellowbrick is a suite of visual diagnostic tools for machine learning that enables human steering of the model selection process. Yellowbrick combines scikit-learn with matplotlib using an estimator-based API called the Visualizer, which wraps both sklearn models and matplotlib Axes. Visualizer objects fit neatly into the machine learning workflow allowing data scientists to integrate visual diagnostic and model interpretation tools into experimentation without extra steps.
25.1 mplcursors

`mplcursors` provides interactive data cursors for Matplotlib.

25.2 MplDataCursor

`MplDataCursor` is a toolkit written by Joe Kington to provide interactive “data cursors” (clickable annotation boxes) for Matplotlib.

25.3 animatplot

`animatplot` is a library for producing interactive animated plots with the goal of making production of animated plots almost as easy as static ones.
For an animated version of the above picture and more examples, see the animatplot gallery.
26.1 adjustText

adjustText is a small library for automatically adjusting text position in Matplotlib plots to minimize overlaps between them, specified points and other objects.
26.2 iTerm2 terminal backend

`matplotlib_iterm2` is an external Matplotlib backend using the iTerm2 nightly build inline image display feature.
26.3 mplcairo

mplcairo is a cairo backend for Matplotlib, with faster and more accurate marker drawing, support for a wider selection of font formats and complex text layout, and various other features.

26.4 mpl-template

mpl-template provides a customizable way to add engineering figure elements such as a title block, border, and logo.
26.5 numpngw

numpngw provides functions for writing NumPy arrays to PNG and animated PNG files. It also includes the class AnimatedPNGWriter that can be used to save a Matplotlib animation as an animated PNG file. See the example on the PyPI page or at the numpngw github repository.
Part VI

The Matplotlib Developers’ Guide
This project is a community effort, and everyone is welcome to contribute. The project is hosted on https://github.com/matplotlib/matplotlib

27.1 Submitting a bug report

If you find a bug in the code or documentation, do not hesitate to submit a ticket to the Bug Tracker. You are also welcome to post feature requests or pull requests.

If you are reporting a bug, please do your best to include the following:

1. A short, top-level summary of the bug. In most cases, this should be 1-2 sentences.
2. A short, self-contained code snippet to reproduce the bug, ideally allowing a simple copy and paste to reproduce. Please do your best to reduce the code snippet to the minimum required.
3. The actual outcome of the code snippet.
4. The expected outcome of the code snippet.
5. The Matplotlib version, Python version and platform that you are using. You can grab the version with the following commands:

```python
>>> import matplotlib
>>> matplotlib.__version__
'1.5.3'
>>> import platform
>>> platform.python_version()
'2.7.12'
```

We have preloaded the issue creation page with a Markdown template that you can use to organize this information.

Thank you for your help in keeping bug reports complete, targeted and descriptive.

27.2 Retrieving and installing the latest version of the code

When developing Matplotlib, sources must be downloaded, built, and installed into a local environment on your machine.
Follow the instructions detailed here to set up your environment to build Matplotlib from source.

**Warning:** When working on Matplotlib sources, having multiple versions installed by different methods into the same environment may not always work as expected.

To work on Matplotlib sources, it is strongly recommended to set up an alternative development environment, using the something like virtual environments in python, or a conda environment.

If you choose to use an already existing environment, and not a clean virtual or conda environment, uninstall the current version of Matplotlib in that environment using the same method used to install it.

If working on Matplotlib documentation only, the above steps are not absolutely necessary.

We use Git for version control and GitHub for hosting our main repository.

You can check out the latest sources with the command (see Set up your fork for more details):

```
    git clone https://github.com/matplotlib/matplotlib.git
```

and navigate to the matplotlib directory. If you have the proper privileges, you can use git@ instead of https://, which works through the ssh protocol and might be easier to use if you are using 2-factor authentication.

### 27.2.1 Building Matplotlib for image comparison tests

Matplotlib’s test suite makes heavy use of image comparison tests, meaning the result of a plot is compared against a known good result. Unfortunately, different versions of FreeType produce differently formed characters, causing these image comparisons to fail. To make them reproducible, Matplotlib can be built with a special local copy of FreeType. This is recommended for all Matplotlib developers.

Copy `setup.cfg.template` to `setup.cfg` and edit it to contain:

```ini
[test]
local_freetype = True
tests = True
```

or set the MPLLOCALFREETYPE environmental variable to any true value.

### 27.2.2 Installing Matplotlib in developer mode

To install Matplotlib (and compile the C-extensions) run the following command from the top-level directory

```
    python -mpip install -ve .
```

This installs Matplotlib in ‘editable/develop mode’, i.e., builds everything and places the correct link entries in the install directory so that python will be able to import Matplotlib from the source directory. Thus, any changes to the `*.py` files will be reflected the next time you
import the library. If you change the C-extension source (which might happen if you change branches) you will need to run

```
python setup.py build
```

or re-run `python -mpip install -ve ..`

Alternatively, if you do

```
python -mpip install -v .
```

all of the files will be copied to the installation directory however, you will have to rerun this command every time the source is changed. Additionally you will need to copy `setup.cfg.template` to `setup.cfg` and edit it to contain

```
[test]
local_freetype = True
tests = True
```

In either case you can then run the tests to check your work environment is set up properly:

```
pytest
```

**Note:** Additional dependencies for testing: pytest (version 3.6 or later), Ghostscript, Inkscape

# 27.3 Contributing code

## 27.3.1 How to contribute

The preferred way to contribute to Matplotlib is to fork the main repository on GitHub, then submit a “pull request” (PR).

The best practices for using GitHub to make PRs to Matplotlib are documented in the Development workflow section.

A brief overview is:

1. Create an account on GitHub if you do not already have one.

2. Fork the project repository: click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub server.

3. Clone this copy to your local disk:

   ```
   $ git clone https://github.com/YourLogin/matplotlib.git
   ```

4. Create a branch to hold your changes:

   ```
   $ git checkout -b my-feature origin/master
   ```
and start making changes. Never work in the master branch!

5. Work on this copy, on your computer, using Git to do the version control. When you’re done editing e.g., `lib/matplotlib/collections.py`, do:

```
$ git add lib/matplotlib/collections.py
$ git commit
```

to record your changes in Git, then push them to GitHub with:

```
$ git push -u origin my-feature
```

Finally, go to the web page of your fork of the Matplotlib repo, and click ‘Pull request’ to send your changes to the maintainers for review. You may want to consider sending an email to the mailing list for more visibility.

- Development workflow.
- Working with Matplotlib source code

### 27.3.2 Contributing pull requests

It is recommended to check that your contribution complies with the following rules before submitting a pull request:

- If your pull request addresses an issue, please use the title to describe the issue and mention the issue number in the pull request description to ensure that a link is created to the original issue.

- All public methods should have informative docstrings with sample usage when appropriate. Use the numpy docstring standard.

- Formatting should follow the recommendations of PEP8. You should consider installing/enabling automatic PEP8 checking in your editor. Part of the test suite is checking PEP8 compliance, things go smoother if the code is mostly PEP8 compliant to begin with.

- Each high-level plotting function should have a simple example in the Example section of the docstring. This should be as simple as possible to demonstrate the method. More complex examples should go in the examples tree.

- Changes (both new features and bugfixes) should be tested. See Developer’s tips for testing for more details.

- Import the following modules using the standard scipy conventions:

```
import numpy as np
import numpy.ma as ma
import matplotlib as mpl
import matplotlib.pyplot as plt
```

(continues on next page)
• If your change is a major new feature, add an entry to the What's new section by adding a new file in doc/users/next Whats_new (see doc/users/next Whats_new/README.rst for more information).

• If you change the API in a backward-incompatible way, please document it in doc/api/api_changes, by adding a new file describing your changes (see doc/api/api_changes/README.rst for more information)

• See below for additional points about Keyword argument processing, if applicable for your pull request.

In addition, you can check for common programming errors with the following tools:

• Code with a good unittest coverage (at least 70%, better 100%), check with:

```python
python -mpip install coverage
pytest --cov=matplotlib --showlocals -v
```

• No pyflakes warnings, check with:

```python
python -mpip install pyflakes
pyflakes path/to/module.py
```

**Note:** The current state of the Matplotlib code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will move the overall code base quality in the right direction.

**See also:**

• Coding guidelines

• Developer’s tips for testing

• Writing documentation

### 27.3.3 Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle issues labeled good first issue as they are easy, well documented issues, that do not require an understanding of the different submodules of Matplotlib. This helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!

### 27.4 Other ways to contribute

Code is not the only way to contribute to Matplotlib. For instance, documentation is also a very important part of the project and often doesn’t get as much attention as it deserves. If you find a typo in the documentation, or have made improvements, do not hesitate to send an
email to the mailing list or submit a GitHub pull request. Full documentation can be found under the doc/ directory.

It also helps us if you spread the word: reference the project from your blog and articles or link to it from your website!

## 27.5 Coding guidelines

### 27.5.1 New modules and files: installation

- If you have added new files or directories, or reorganized existing ones, make sure the new files are included in the match patterns in MANIFEST.in, and/or in package_data in setup.py.

### 27.5.2 C/C++ extensions

- Extensions may be written in C or C++.
- Code style should conform to PEP7 (understanding that PEP7 doesn’t address C++, but most of its admonitions still apply).
- Python/C interface code should be kept separate from the core C/C++ code. The interface code should be named FOO_wrap.cpp or FOO_wrapper.cpp.
- Header file documentation (aka docstrings) should be in Numpydoc format. We don’t plan on using automated tools for these docstrings, and the Numpydoc format is well understood in the scientific Python community.

### 27.5.3 Keyword argument processing

Matplotlib makes extensive use of **kwargs for pass-through customizations from one function to another. A typical example is in matplotlib.pyplot.text(). The definition of the pylab text function is a simple pass-through to matplotlib.axes.Axes.text():

```python
# in pylab.py
def text(*args, **kwargs):
    ret = gca().text(*args, **kwargs)
    draw_if_interactive()
    return ret
text()
```

In simplified form looks like this, i.e., it just passes all args and kwargs on to matplotlib.text.Text.__init__():

```python
# in axes/_axes.py
def text(self, x, y, s, fontdict=None, withdash=False, **kwargs):
    t = Text(x=x, y=y, text=s, **kwargs)
```

and __init__() (again with liberties for illustration) just passes them on to the matplotlib.artist.Artist.update() method:
# in text.py

def __init__(self, x=0, y=0, text='', **kwargs):
    Artist.__init__(self)
    self.update(kwargs)

update does the work looking for methods named like set_property if property is a keyword argument. i.e., no one looks at the keywords, they just get passed through the API to the artist constructor which looks for suitably named methods and calls them with the value.

As a general rule, the use of **kwargs should be reserved for pass-through keyword arguments, as in the example above. If all the keyword args are to be used in the function, and not passed on, use the key/value keyword args in the function definition rather than the **kwargs idiom.

In some cases, you may want to consume some keys in the local function, and let others pass through. Instead of poping arguments to use off **kwargs, specify them as keyword-only arguments to the local function. This makes it obvious at a glance which arguments will be consumed in the function. For example, in plot(), scalex and scaley are local arguments and the rest are passed on as Line2D() keyword arguments:

# in axes/_axes.py

def plot(self, *args, scalex=True, scaley=True, **kwargs):
    lines = []
    for line in self._get_lines(*args, **kwargs):
        self.add_line(line)
    lines.append(line)

27.5.4 Using logging for debug messages

Matplotlib uses the standard python logging library to write verbose warnings, information, and debug messages. Please use it! In all those places you write print() statements to do your debugging, try using log.debug() instead!

To include logging in your module, at the top of the module, you need to import logging. Then calls in your code like:

```python
_log = logging.getLogger(__name__)  # right after the imports

# code
# more code
_log.info('Here is some information')
_log.debug('Here is some more detailed information')
```

will log to a logger named matplotlib.yourmodulename.

If an end-user of Matplotlib sets up logging to display at levels more verbose than logger. WARNING in their code with the Matplotlib-provided helper:

```python
plt.set_loglevel("debug")
```

or manually with

```python
import logging
logging.basicConfig(level=logging.DEBUG)
import matplotlib.pyplot as plt
```
Then they will receive messages like:

```
DEBUG:matplotlib.backends.backend MacOSX version unknown
DEBUG:matplotlib.yourmodulename:Here is some information
DEBUG:matplotlib.yourmodulename:Here is some more detailed information
```

**Which logging level to use?**

There are five levels at which you can emit messages.

- `logging.critical` and `logging.error` are really only there for errors that will end the use of the library but not kill the interpreter.
- `logging.warning` and `cbook._warn_external` are used to warn the user, see below.
- `logging.info` is for information that the user may want to know if the program behaves oddly. They are not displayed by default. For instance, if an object isn't drawn because its position is NaN, that can usually be ignored, but a mystified user could call `logging.basicConfig(level=logging.INFO)` and get an error message that says why.
- `logging.debug` is the least likely to be displayed, and hence can be the most verbose. “Expected” code paths (e.g., reporting normal intermediate steps of layouting or rendering) should only log at this level.

By default, `logging` displays all log messages at levels higher than `logging.WARNING` to `sys.stderr`.

The logging tutorial suggests that the difference between `logging.warning` and `cbook._warn_external` (which uses `warnings.warn`) is that `cbook._warn_external` should be used for things the user must change to stop the warning (typically in the source), whereas `logging.warning` can be more persistent. Moreover, note that `cbook._warn_external` will by default only emit a given warning *once* for each line of user code, whereas `logging.warning` will display the message every time it is called.

By default, `warnings.warn` displays the line of code that has the `warn` call. This usually isn’t more informative than the warning message itself. Therefore, Matplotlib uses `cbook._warn_external` which uses `warnings.warn`, but goes up the stack and displays the first line of code outside of Matplotlib. For example, for the module:

```
# in my_matplotlib_module.py
import warnings

def set_range(bottom, top):
    if bottom == top:
        warnings.warn('Attempting to set identical bottom==top')
```

running the script:

```
from matplotlib import my_matplotlib_module
my_matplotlib_module.set_range(0, 0) # set range
```

will display:

```
UserWarning: Attempting to set identical bottom==top
warnings.warn('Attempting to set identical bottom==top')
```

Modifying the module to use `cbook._warn_external`:
from matplotlib import cbook

def set_range(bottom, top):
    if bottom == top:
        cbook._warn_external('Attempting to set identical bottom==top')

and running the same script will display:

UserWarning: Attempting to set identical bottom==top
my_matplotlib_module.set_range(0, 0)  # set range

27.5.5 Developing a new backend

If you are working on a custom backend, the backend setting in matplotlibrc (Customizing Matplotlib with style sheets and rcParams) supports an external backend via the module directive. If my_backend.py is a Matplotlib backend in your PYTHONPATH, you can set it on one of several ways

• in matplotlibrc:

backend : module://my_backend

• with the MPLBACKEND environment variable:

  > export MPLBACKEND="module://my_backend"
  > python simple_plot.py

• with the use directive in your script:

import matplotlib
matplotlib.use('module://my_backend')

27.5.6 Writing examples

We have hundreds of examples in subdirectories of matplotlib/examples, and these are automatically generated when the website is built to show up in the examples section of the website.

Any sample data that the example uses should be kept small and distributed with Matplotlib in the lib/matplotlib/mpl-data/sample_data/ directory. Then in your example code you can load it into a file handle with:

import matplotlib.cbook as cbook
fh = cbook.get_sample_data('mydata.dat')
DEVELOPER’S TIPS FOR TESTING

Matplotlib’s testing infrastructure depends on pytest. The tests are in lib/matplotlib/tests, and customizations to the pytest testing infrastructure are in matplotlib.testing.

28.1 Requirements

Install the latest version of Matplotlib as documented in Retrieving and installing the latest version of the code. In particular, follow the instructions to use a local FreeType build.

The following software is required to run the tests:

- pytest (>=3.6)
- Ghostscript (>= 9.0, to render PDF files)
- Inkscape (to render SVG files)

Optionally you can install:

- pytest-cov (>=2.3.1) to collect coverage information
- pytest-pep8 to test coding standards
- pytest-timeout to limit runtime in case of stuck tests
- pytest-xdist to run tests in parallel

28.2 Running the tests

Running the tests is simple. Make sure you have pytest installed and run:

```
pytest
```

or:

```
pytest .
```

in the root directory of the distribution. The script takes a set of commands, such as:

```
--pep8 Perform pep8 checks (requires pytest-pep8)
-m "not network" Disable tests that require network access
```
Additional arguments are passed on to pytest. See the pytest documentation for supported arguments. Some of the more important ones are given here:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--verbose</td>
<td>Be more verbose</td>
</tr>
<tr>
<td>--n NUM</td>
<td>Run tests in parallel over NUM processes (requires pytest-xdist)</td>
</tr>
<tr>
<td>--timeout=SECONDS</td>
<td>Set timeout for results from each test process (requires pytest-timeout)</td>
</tr>
<tr>
<td>--capture=no or -s</td>
<td>Do not capture stdout</td>
</tr>
</tbody>
</table>

To run a single test from the command line, you can provide a file path, optionally followed by the function separated by two colons, e.g., (tests do not need to be installed, but Matplotlib should be):

```bash
pytest lib/matplotlib/tests/test_simplification.py::test_clipping
```

or, if tests are installed, a dot-separated path to the module, optionally followed by the function separated by two colons, such as:

```bash
pytest --pyargs matplotlib.tests.test_simplification::test_clipping
```

If you want to run the full test suite, but want to save wall time try running the tests in parallel:

```bash
pytest --verbose -n 5
```

Depending on your version of Python and pytest-xdist, you may need to set PYTHONHASHSEED to a fixed value when running in parallel:

```bash
PYTHONHASHSEED=0 pytest --verbose -n 5
```

An alternative implementation that does not look at command line arguments and works from within Python is to run the tests from the Matplotlib library function `matplotlib.test()`:

```python
import matplotlib
matplotlib.test()
```

## 28.3 Writing a simple test

Many elements of Matplotlib can be tested using standard tests. For example, here is a test from `matplotlib.tests.test_basic`:

```python
def test_simple():
    
    very simple example test

    assert 1 + 1 == 2
```

Pytest determines which functions are tests by searching for files whose names begin with "test_" and then within those files for functions beginning with "test" or classes beginning with "Test".

Some tests have internal side effects that need to be cleaned up after their execution (such as created figures or modified rc params). The pytest fixture `mpl_test_settings()` will automatically clean these up; there is no need to do anything further.
28.4 Random data in tests

Random data is a very convenient way to generate data for examples, however the randomness is problematic for testing (as the tests must be deterministic!). To work around this set the seed in each test. For numpy use:

```python
import numpy as np
def seed(19680801)
```

and Python’s random number generator:

```python
import random
random.seed(19680801)
```

The seed is John Hunter’s birthday.

28.5 Writing an image comparison test

Writing an image-based test is only slightly more difficult than a simple test. The main consideration is that you must specify the “baseline”, or expected, images in the `image_comparison` decorator. For example, this test generates a single image and automatically tests it:

```python
from matplotlib.testing.decorators import image_comparison
import matplotlib.pyplot as plt

def test_line_dashes():
    fig, ax = plt.subplots()
    ax.plot(range(10), linestyle=(0, (3, 3)), lw=5)
```

The first time this test is run, there will be no baseline image to compare against, so the test will fail. Copy the output images (in this case `result_images/test_lines/test_line_dashes.png`) to the correct subdirectory of the `lib/mpltest/baseline_images` tree in the source directory (in this case `lib/matplotlib/tests/baseline_images/test_lines`). Put this new file under source code revision control (with `git add`). When rerunning the tests, they should now pass.

Baseline images take a lot of space in the Matplotlib repository. An alternative approach for image comparison tests is to use the `check_figures_equal` decorator, which should be used to decorate a function taking two `Figure` parameters and draws the same images on the figures using two different methods (the tested method and the baseline method). The decorator will arrange for setting up the figures and then collect the drawn results and compare them.

See the documentation of `image_comparison` and `check_figures_equal` for additional information about their use.

28.6 Known failing tests

If you’re writing a test, you may mark it as a known failing test with the `pytest.mark.xfail()` decorator. This allows the test to be added to the test suite and run on the buildbots without
causing undue alarm. For example, although the following test will fail, it is an expected failure:

```python
import pytest

@pytest.mark.xfail
def test_simple_fail():
    '''very simple example test that should fail'''
    assert 1 + 1 == 3
```

Note that the first argument to the `xfail()` decorator is a fail condition, which can be a value such as True, False, or may be a dynamically evaluated expression. If a condition is supplied, then a reason must also be supplied with the `reason='message'` keyword argument.

### 28.7 Creating a new module in matplotlib.tests

We try to keep the tests categorized by the primary module they are testing. For example, the tests related to the `mathtext.py` module are in `test_mathtext.py`.

### 28.8 Using Travis CI

Travis CI is a hosted CI system “in the cloud”.

Travis is configured to receive notifications of new commits to GitHub repos (via GitHub “service hooks”) and to run builds or tests when it sees these new commits. It looks for a YAML file called `.travis.yml` in the root of the repository to see how to test the project.

Travis CI is already enabled for the main matplotlib GitHub repository – for example, see its Travis page.

If you want to enable Travis CI for your personal Matplotlib GitHub repo, simply enable the repo to use Travis CI in either the Travis CI UI or the GitHub UI (Admin | Service Hooks). For details, see the Travis CI Getting Started page. This generally isn’t necessary, since any pull request submitted against the main Matplotlib repository will be tested.

Once this is configured, you can see the Travis CI results at `https://travis-ci.org/your_GitHub_user_name/matplotlib` – here’s an example.

### 28.9 Using tox

Tox is a tool for running tests against multiple Python environments, including multiple versions of Python (e.g., 3.6, 3.7) and even different Python implementations altogether (e.g., CPython, PyPy, Jython, etc.), as long as all these versions are available on your system’s `PATH` (consider using your system package manager, e.g. apt-get, yum, or Homebrew, to install them).

Tox makes it easy to determine if your working copy introduced any regressions before submitting a pull request. Here’s how to use it:
Matplotlib, Release 3.1.1

```bash
$ pip install tox
$ tox
```

You can also run tox on a subset of environments:

```bash
$ tox -e py36,py37
```

Tox processes everything serially so it can take a long time to test several environments. To speed it up, you might try using a new, parallelized version of tox called detox. Give this a try:

```bash
$ pip install -U -i http://pypi.testrun.org detox
$ detox
```

Tox is configured using a file called `tox.ini`. You may need to edit this file if you want to add new environments to test (e.g., `py33`) or if you want to tweak the dependencies or the way the tests are run. For more info on the `tox.ini` file, see the Tox Configuration Specification.

### 28.10 Building old versions of Matplotlib

When running a `git bisect` to see which commit introduced a certain bug, you may (rarely) need to build very old versions of Matplotlib. The following constraints need to be taken into account:

- Matplotlib 1.3 (or earlier) requires numpy 1.8 (or earlier).

29.1 Getting started

29.1.1 General file structure

All documentation is built from the doc/ directory. This directory contains both reStructured-Text (ReST; .rst) files that contain pages in the documentation and configuration files for Sphinx.

The .rst files are kept in doc/users, doc/devel, doc/api and doc/faq. The main entry point is doc/index.rst, which pulls in the index.rst file for the users guide, developers guide, api reference, and FAQs. The documentation suite is built as a single document in order to make the most effective use of cross referencing.

Sphinx also creates .rst files that are staged in doc/api from the docstrings of the classes in the Matplotlib library. Except for doc/api/api_changes/, these .rst files are created when the documentation is built.

Similarly, the contents of doc/gallery and doc/tutorials are generated by the Sphinx Gallery from the sources in examples and tutorials. These sources consist of python scripts that have ReST documentation built into their comments. Don’t directly edit the .rst files in doc/gallery and doc/tutorials as they are regenerated when the documentation are built.

29.1.2 Installing dependencies

The documentation for Matplotlib is generated from reStructuredText (ReST) using the Sphinx documentation generation tool. There are several extra requirements that are needed to build the documentation. They are listed in doc-requirements.txt, which is shown below:

```
# Requirements for building docs
#
# You will first need a matching Matplotlib installation
# e.g (from the Matplotlib root directory)
#    pip install -e .
#
# Install the documentation requirements with:
#    pip install -r requirements/doc/doc-requirements.txt
#
sphinx>=1.3,!=1.5.0,!=1.6.4,!=1.7.3,!=1.8.0,<2.0.0
# colors spacious
```

(continues on next page)
Note:

- You’ll need a minimal working LaTeX distribution for many examples to run.
- Graphviz is not a Python package, and needs to be installed separately.

29.1.3 Building the docs

The documentation sources are found in the `doc/` directory in the trunk. The configuration file for Sphinx is `doc/conf.py`. It controls which directories Sphinx parses, how the docs are built, and how the extensions are used. To build the documentation in html format, cd into `doc/` and run:

```
make html
```

Other useful invocations include

```
# Delete built files. May help if you get errors about missing paths or
# broken links.
make clean

# Build pdf docs.
make latexpdf
```

The `SPHINXOPTS` variable is set to `-W` by default to turn warnings into errors. To unset it, use

```
make SPHINXOPTS= html
```

You can use the `O` variable to set additional options:

- make `O=-j4` html runs a parallel build with 4 processes.
- make `O=-Dplot_formats=png:100` html saves figures in low resolution.
- make `O=-Dplot_gallery=0` html skips the gallery build.

Multiple options can be combined using e.g. make `O=-j4 -Dplot_gallery=0` html.

On Windows, options needs to be set as environment variables, e.g. set `O=-W -j4` & make html.

29.2 Writing ReST pages

Most documentation is either in the docstring of individual classes and methods, in explicit `.rst` files, or in examples and tutorials. All of these use the ReST syntax. Users should look
at the ReST documentation for a full description. But some specific hints and conventions Matplotlib uses are useful for creating documentation.

### 29.2.1 Formatting and style conventions

It is useful to strive for consistency in the Matplotlib documentation. Here are some formatting and style conventions that are used.

#### Section name formatting

For everything but top-level chapters, use **Upper lower** for section titles, e.g., Possible hangups rather than Possible Hangups

#### Function arguments

Function arguments and keywords within docstrings should be referred to using the *emphasis* role. This will keep Matplotlib’s documentation consistent with Python’s documentation:

Here is a description of *argument*  

Do not use the `default role`:

Do not describe `argument` like this. As per the next section, this syntax will (unsuccessfully) attempt to resolve the argument as a link to a class or method in the library.

nor the ``literal`` role:

Do not describe ```argument``` like this.

### 29.2.2 Referring to other documents and sections

Sphinx allows internal references between documents. Documents can be linked with the :doc: directive:

See the :doc:`/faq/installing_faq`

See the tutorial :doc:`/tutorials/introductory/sample_plots`

See the example :doc:`/gallery/lines_bars_and_markers/simple_plot`

will render as:

See the Installation  
See the tutorial Sample plots in Matplotlib  
See the example /gallery/lines_bars_and_markers/simple_plot

Sections can also be given reference names. For instance from the Installation link:
How to completely remove Matplotlib

Occasionally, problems with Matplotlib can be solved with a clean...

and refer to it using the standard reference syntax:

See :ref:`clean-install`

will give the following link: *How to completely remove Matplotlib*

To maximize internal consistency in section labeling and references, use hyphen separated, descriptive labels for section references. Keep in mind that contents may be reorganized later, so avoid top level names in references like `user` or `devel` or `faq` unless necessary, because for example the FAQ “what is a backend?” could later become part of the users guide, so the label:

```
.. _what-is-a-backend:
```

is better than:

```
.. _faq-backend:
```

In addition, since underscores are widely used by Sphinx itself, use hyphens to separate words.

**29.2.3 Referring to other code**

To link to other methods, classes, or modules in Matplotlib you can use back ticks, for example:

```
`matplotlib.collections.LineCollection`
```

generates a link like this: *matplotlib.collections.LineCollection*.

*Note:* We use the sphinx setting `default_role = 'obj'` so that you don’t have to use qualifiers like :class:, :func:, :meth: and the likes.

Often, you don’t want to show the full package and module name. As long as the target is unambiguous you can simply leave them out:

```
`.LineCollection`
```

and the link still works: *LineCollection*.

If there are multiple code elements with the same name (e.g. `plot()` is a method in multiple classes), you’ll have to extend the definition:

```
`.pyplot.plot` or `.Axes.plot`
```

These will show up as `pyplot.plot` or `Axes.plot`. To still show only the last segment you can add a tilde as prefix:
`.pyplot.plot` or `~.Axes.plot` will render as `plot` or `plot`.

Other packages can also be linked via `intersphinx`:

```
numpy.mean
```

will return this link: `numpy.mean`. This works for Python, Numpy, Scipy, and Pandas (full list is in `doc/conf.py`). Sometimes it is tricky to get external Sphinx linking to work; to check that something exists to link to the following shell command outputs a list of all objects that can be referenced (in this case for Numpy):

```shell
python -m sphinx.ext.intersphinx 'https://docs.scipy.org/doc/numpy/objects.inv'
```

### 29.2.4 Including figures and files

Image files can directly included in pages with the `image::` directive. e.g., `users/navigation_toolbar.rst` displays the toolbar icons with a call to a static image:

```
.. image:: ../_static/toolbar.png
```

as rendered on the page: *Interactive navigation*.

Files can be included verbatim. For instance the `matplotlibrc` file is important for customizing Matplotlib, and is included verbatim in the tutorial in `Customizing Matplotlib with style sheets and rcParams`:

```
.. literalinclude:: ../_static/matplotlibrc
```

This is rendered at the bottom of `Customizing Matplotlib with style sheets and rcParams`. Note that this is in a tutorial; see `Writing examples and tutorials` below.

The examples directory is also copied to `doc/gallery` by `sphinx-gallery`, so plots from the examples directory can be included using

```
.. plot:: gallery/lines_bars_and_markers/simple_plot.py
```

Note that the python script that generates the plot is referred to, rather than any plot that is created. Sphinx-gallery will provide the correct reference when the documentation is built.

### 29.3 Writing docstrings

Most of the API documentation is written in docstrings. These are comment blocks in source code that explain how the code works.

**Note:** Some parts of the documentation do not yet conform to the current documentation style. If in doubt, follow the rules given here and not what you may see in the source code. Pull requests updating docstrings to the current style are very welcome.
All new or edited docstrings should conform to the numpydoc docstring guide. Much of the ReST syntax discussed above (Writing ReST pages) can be used for links and references. These docstrings eventually populate the doc/api directory and form the reference documentation for the library.

29.3.1 Example docstring

An example docstring looks like:

```python
def hlines(self, y, xmin, xmax, colors='k', linestyles='solid',
           label='', **kwargs):
    """
    Plot horizontal lines at each *y* from *xmin* to *xmax*.

    Parameters
    ----------
    y : float or array-like
        y-indexes where to plot the lines.
    xmin, xmax : float or array-like
        Respective beginning and end of each line. If scalars are provided, all lines will have the same length.
    colors : array-like of colors, optional, default: 'k'
    linestyles : {'solid', 'dashed', 'dashdot', 'dotted'}, optional
    label : string, optional, default: ''

    Returns
    -------
    lines : `~matplotlib.collections.LineCollection`

    Other Parameters
    ----------------
    **kwargs : `~matplotlib.collections.LineCollection` properties.

    See also
    --------
    vlines : vertical lines
    axhline: horizontal line across the axes
    """
```

See the hlines documentation for how this renders.

The Sphinx website also contains plenty of documentation concerning ReST markup and working with Sphinx in general.

29.3.2 Formatting conventions

The basic docstring conventions are covered in the numpydoc docstring guide and the Sphinx documentation. Some Matplotlib-specific formatting conventions to keep in mind:
### Function arguments

Function arguments and keywords within docstrings should be referred to using the *emphasis* role. This will keep Matplotlib’s documentation consistent with Python’s documentation:

```
If *linestyles* is *None*, the 'solid' is used.
```

Do not use the `default role` or the ```literal``` role:

```
Neither `argument` nor `argument` should be used.
```

### Quotes for strings

Matplotlib does not have a convention whether to use single-quotes or double-quotes. There is a mixture of both in the current code.

Use simple single or double quotes when giving string values, e.g.

```
If 'tight', try to figure out the tight bbox of the figure.
```

### Parameter type descriptions

The main goal for parameter type descriptions is to be readable and understandable by humans. If the possible types are too complex use a simplification for the type description and explain the type more precisely in the text.

Generally, the numpydoc docstring guide conventions apply. The following rules expand on them where the numpydoc conventions are not specific.

Use `float` for a type that can be any number.

Use `(float, float)` to describe a 2D position.

Use `array-like` for homogeneous numeric sequences, which could typically be a numpy.array. Dimensionality may be specified using `2D`, `3D`, `n-dimensional`. If you need to have variables denoting the sizes of the dimensions, use capital letters in brackets (`array-like (M, N)`). When referring to them in the text they are easier read and no special formatting is needed.

`float` is the implicit default dtype for array-likes. For other dtypes use `array-like of int`.

Some possible uses:

```
2D array-like
array-like (N)
array-like (M, N)
array-like (M, N, 3)
array-like of int
```

Non-numeric homogeneous sequences are described as lists, e.g.:

```
list of str
list of `.Artist`
```
**Referencing types**

Generally, the rules from *referring-to-other-code* apply. More specifically:

Use full references `~matplotlib.colors.Normalize` with an abbreviation tilde in parameter types. While the full name helps the reader of plain text docstrings, the HTML does not need to show the full name as it links to it. Hence, the `~`-shortening keeps it more readable.

Use abbreviated links `.Normalize` in the text.

```
norm : `~matplotlib.colors.Normalize`, optional
    A `.Normalize` instance is used to scale luminance data to 0, 1.
```

**See also sections**

Sphinx automatically links code elements in the definition blocks of *See also* sections. No need to use backticks there:

```
See also
-----------
vlines : vertical lines
axhline: horizontal line across the axes
```

**Wrapping parameter lists**

Long parameter lists should be wrapped using a \ for continuation and starting on the new line without any indent (no indent because pydoc will parse the docstring and strip the line continuation so that indent would result in a lot of whitespace within the line):

```
def add_axes(self, *args, **kwargs):
    """
    ...

    Parameters
    -----------
    projection : {'aitoff', 'hammer', 'lambert', 'mollweide', 'polar', \n    'rectilinear'}, optional
        The projection type of the axes.
    ...
    """
```

Alternatively, you can describe the valid parameter values in a dedicated section of the docstring.

**rcParams**

rcParams can be referenced with the custom :rc: role: :rc:`foo` yields `rcParams["foo"]`. Use `=` [default-val] to indicate the default value of the parameter. The default value should be literal, i.e. enclosed in double backticks. For simplicity these may be omitted for string default values.
If not provided, defaults to `rc: `figure.figsize` = `[6.4, 4.8]``.
If not provided, defaults to `rc: `figure.facecolor` = 'w'.

29.3.3 Deprecated formatting conventions

Formerly, we have used square brackets for explicit parameter lists `['solid' | 'dashed' | 'dotted']`. With numpydoc we have switched to their standard using curly braces `{ 'solid', 'dashed', 'dotted' }`.

29.3.4 Setters and getters

Artist properties are implemented using setter and getter methods (because Matplotlib pre-dates the introductions of the `property` decorator in Python). By convention, these setters and getters are named `set_PROPERTYNAME` and `get_PROPERTYNAME`; the list of properties thusly defined on an artist and their values can be listed by the `setp` and `getp` functions.

**Note:** ACCEPTS blocks have recently become optional. You may now use a numpydoc `Parameters` block because the accepted values can now be read from the type description of the first parameter.

Property setter methods should indicate the values they accept using a (legacy) special block in the docstring, starting with ACCEPTS, as follows:

```python
# in lines.py
def set_linestyle(self, linestyle):
    """
    Set the linestyle of the line
    ACCEPTS: [ '-' | '--' | '-.' | ':' | 'steps' | 'None' | ' ' | '' ]
    """
```

The ACCEPTS block is used to render a table of all properties and their acceptable values in the docs; it can also be displayed using, e.g., `plt.setp(Line2D)` (all properties) or `plt.setp(Line2D, 'linestyle')` (just one property).

There are cases in which the ACCEPTS string is not useful in the generated Sphinx documentation, e.g. if the valid parameters are already defined in the numpydoc parameter list. You can hide the ACCEPTS string from Sphinx by making it a ReST comment (i.e. use `.. ACCEPTS:`):

```python
def set_linestyle(self, linestyle):
    """
    An ACCEPTS string invisible to Sphinx.
    .. ACCEPTS: [ '-' | '--' | '-.' | ':' | 'steps' | 'None' | ' ' | '' ]
    """
```

29.3.5 Keyword arguments
**Note:** The information in this section is being actively discussed by the development team, so use the docstring interpolation only if necessary. This section has been left in place for now because this interpolation is part of the existing documentation.

Since Matplotlib uses a lot of pass-through `**kwargs`, e.g., in every function that creates a line (`plot`, `semilogx`, `semilogy`, etc...), it can be difficult for the new user to know which `kwargs` are supported. Matplotlib uses a docstring interpolation scheme to support documentation of every function that takes a `**kwargs`. The requirements are:

1. single point of configuration so changes to the properties don’t require multiple doc-string edits.
2. as automated as possible so that as properties change, the docs are updated automatically.

The function `matplotlib.artist.kwdoc` and the decorator `matplotlib.docstring.dedent_interpd` facilitate this. They combine Python string interpolation in the docstring with the Matplotlib artist introspection facility that underlies `setp` and `getp`. The `kwdoc` function gives the list of properties as a docstring. In order to use this in another docstring, first update the `matplotlib.docstring.interpd` object, as seen in this example from `matplotlib.lines`:

```python
# in lines.py
docstring.interpd.update(Line2D=artist.kwdoc(Line2D))
```

Then in any function accepting `Line2D` pass-through `**kwargs`, e.g., `matplotlib.axes.Axes.plot`:

```python
# in axes.py
@docstring.dedent_interpd
def plot(self, *args, **kwargs):
    ""
    Some stuff omitted

    The kwargs are Line2D properties:
    %(_Line2D_docstr)s

    kwargs scalex and scaley, if defined, are passed on
to autoscale_view to determine whether the x and y axes are
autoscaled; default True. See Axes.autoscale_view for more
information
    ""
```

Note there is a problem for `Artist __init__` methods, e.g., `matplotlib.patches.Patch.__init__`, which supports Patch `kwargs`, since the artist inspector cannot work until the class is fully defined and we can’t modify the `Patch.__init__.__doc__` docstring outside the class definition. There are some some manual hacks in this case, violating the "single entry point" requirement above – see the `docstring.interpd.update` calls in `matplotlib.patches`.

### 29.3.6 Inheriting docstrings

If a subclass overrides a method but does not change the semantics, we can reuse the parent docstring for the method of the child class. Python does this automatically, if the subclass method does not have a docstring.
Use a plain comment # docstring inherited to denote the intention to reuse the parent docstring. That way we do not accidentally create a docstring in the future:

```python
class A:
    def foo():
        """The parent docstring."""
        pass

class B(A):
    def foo():
        # docstring inherited
        pass
```

### 29.3.7 Adding figures

As above (see *Including figures and files*), figures in the examples gallery can be referenced with a :plot: directive pointing to the python script that created the figure. For instance the `legend` docstring references the file `examples/text_labels_and_annotations/legend.py`:

```python
"""
...

Examples
--------
.. plot:: gallery/text_labels_and_annotations/legend.py
"""

Note that `examples/text_labels_and_annotations/legend.py` has been mapped to `gallery/text_labels_and_annotations/legend.py`, a redirection that may be fixed in future reorganization of the docs.

Plots can also be directly placed inside docstrings. Details are in *Plot directive documentation*. A short example is:

```python
"""
...

Examples
--------

.. plot::
    :matplotlib:
    :py:func: matplotlib.image as mpimg
    img = mpimg.imread('_static/stinkbug.png')
    imgplot = plt.imshow(img)
"""

An advantage of this style over referencing an example script is that the code will also appear in interactive docstrings.
29.4 Writing examples and tutorials

Examples and tutorials are Python scripts that are run by Sphinx Gallery to create a gallery of images in the `/doc/gallery` and `/doc/tutorials` directories respectively. To exclude an example from having a plot generated insert "sgskip" somewhere in the filename.

The format of these files is relatively straightforward. Properly formatted comment blocks are treated as ReST text, the code is displayed, and figures are put into the built page.

For instance the example `/gallery/lines_bars_and_markers/simple_plot` example is generated from `/examples/lines_bars_and_markers/simple_plot.py`, which looks like:

```python
""
===========
Simple Plot
===========

Create a simple plot.
""
import matplotlib.pyplot as plt
import numpy as np

# Data for plotting
t = np.arange(0.0, 2.0, 0.01)
s = 1 + np.sin(2 * np.pi * t)

# Note that using plt.subplots below is equivalent to using
# fig = plt.figure and then ax = fig.add_subplot(111)
fig, ax = plt.subplots()
ax.plot(t, s)
ax.set(xlabel='time (s)', ylabel='voltage (mV)',
      title='About as simple as it gets, folks')
ax.grid()
plt.show()
```

The first comment block is treated as ReST text. The other comment blocks render as comments in `/gallery/lines_bars_and_markers/simple_plot`.

Tutorials are made with the exact same mechanism, except they are longer, and typically have more than one comment block (i.e. Usage Guide). The first comment block can be the same as the example above. Subsequent blocks of ReST text are delimited by a line of "###" characters:

```python
""
===========
Simple Plot
===========

Create a simple plot.
""
...
ax.grid()
plt.show()
```

(continues on next page)
In this way text, code, and figures are output in a “notebook” style.

### 29.4.1 Order of examples in the gallery

The order of the sections of the *Tutorials* and the gallery, as well as the order of the examples within each section are determined in a two step process from within the `doc/sphinxext/gallery_order.py`:

- **Explicit order**: This file contains a list of folders for the section order and a list of examples for the subsection order. The order of the items shown in the doc pages is the order those items appear in those lists.
- **Implicit order**: If a folder or example is not in those lists, it will be appended after the explicitly ordered items and all of those additional items will be ordered by pathname (for the sections) or by filename (for the subsections).

As a consequence, if you want to let your example appear in a certain position in the gallery, extend those lists with your example. In case no explicit order is desired or necessary, still make sure to name your example consistently, i.e. use the main function or subject of the example as first word in the filename; e.g. an image example should ideally be named similar to `imshow_mynewexample.py`.

### 29.5 Miscellaneous

#### 29.5.1 Adding animations

There is a Matplotlib Google/Gmail account with username `mplgithub` which was used to setup the github account but can be used for other purposes, like hosting Google docs or Youtube videos. You can embed a Matplotlib animation in the docs by first saving the animation as a movie using `matplotlib.animation.Animation.save()`, and then uploading to Matplotlib’s Youtube channel and inserting the embedding string youtube provides like:

```
.. raw:: html

    <iframe width="420" height="315"
        src="http://www.youtube.com/embed/32cjc6V0OZY"
        frameborder="0" allowfullscreen>
    </iframe>
```

An example save command to generate a movie looks like this
ani = animation.FuncAnimation(fig, animate, np.arange(1, len(y)),
    interval=25, blit=True, init_func=init)

ani.save('double_pendulum.mp4', fps=15)

Contact Michael Droettboom for the login password to upload youtube videos of google docs to the mplgithub account.

### 29.5.2 Generating inheritance diagrams

Class inheritance diagrams can be generated with the `inheritance-diagram` directive. To use it, provide the directive with a number of class or module names (separated by whitespace). If a module name is provided, all classes in that module will be used. All of the ancestors of these classes will be included in the inheritance diagram.

A single option is available: `parts` controls how many of parts in the path to the class are shown. For example, if `parts == 1`, the class `matplotlib.patches.Patch` is shown as `Patch`. If `parts == 2`, it is shown as `patches.Patch`. If `parts == 0`, the full path is shown.

Example:

```python
.. inheritance-diagram:: matplotlib.patches matplotlib.lines matplotlib.text
   :parts: 2
```
29.5.3 Emacs helpers

There is an emacs mode `rst.el` which automates many important ReST tasks like building and updating table-of-contents, and promoting or demoting section headings. Here is the basic `.emacs` configuration:

```lisp
(require 'rst)
(setq auto-mode-alist
  (append '(("\.txt$" . rst-mode)
           ("\.rst$" . rst-mode)
           ("\.rest$" . rst-mode)) auto-mode-alist))
```

Some helpful functions:

```
C-c TAB - rst-toc-insert
  Insert table of contents at point
C-c C-u - rst-toc-update
```

(continues on next page)
Update the table of contents at point

C-c C-l rst-shift-region-left

Shift region to the left

C-c C-r rst-shift-region-right

Shift region to the right
A directive for including a matplotlib plot in a Sphinx document.

By default, in HTML output, plot will include a .png file with a link to a high-res .png and .pdf. In LaTeX output, it will include a .pdf.

The source code for the plot may be included in one of three ways:

1. **A path to a source file** as the argument to the directive:

   ```
   .. plot:: path/to/plot.py
   ```

   When a path to a source file is given, the content of the directive may optionally contain a caption for the plot:

   ```
   .. plot:: path/to/plot.py

   This is the caption for the plot
   ```

   Additionally, one may specify the name of a function to call (with no arguments) immediately after importing the module:

   ```
   .. plot:: path/to/plot.py plot_function1
   ```

2. Included as **inline content** to the directive:

   ```
   .. plot::

       import matplotlib.pyplot as plt
       import matplotlib.image as mpimg
       import numpy as np
       img = mpimg.imread('_static/stinkbug.png')
       imgplot = plt.imshow(img)
   ```

3. Using **doctest** syntax:

   ```
   .. plot::

       A plotting example:
       >>> import matplotlib.pyplot as plt
       >>> plt.plot([1,2,3], [4,5,6])
   ```
30.1 Options

The plot directive supports the following options:

- **format** [{‘python’, ‘doctest’}] Specify the format of the input
- **include-source** [bool] Whether to display the source code. The default can be changed using the plot_include_source variable in conf.py
- **encoding** [str] If this source file is in a non-UTF8 or non-ASCII encoding, the encoding must be specified using the :encoding: option. The encoding will not be inferred using the -*- coding -*- metacomment.
- **context** [bool or str] If provided, the code will be run in the context of all previous plot directives for which the :context: option was specified. This only applies to inline code plot directives, not those run from files. If the :context: reset option is specified, the context is reset for this and future plots, and previous figures are closed prior to running the code. :context:close-figs keeps the context but closes previous figures before running the code.
- **nofigs** [bool] If specified, the code block will be run, but no figures will be inserted. This is usually useful with the :context: option.

Additionally, this directive supports all of the options of the image directive, except for target (since plot will add its own target). These include alt, height, width, scale, align and class.

30.2 Configuration options

The plot directive has the following configuration options:

- **plot_include_source** Default value for the include-source option
- **plot_html_show_source_link** Whether to show a link to the source in HTML.
- **plot_pre_code** Code that should be executed before each plot. If not specified or None it will default to a string containing:

  ```
  import numpy as np
  from matplotlib import pyplot as plt
  ```

- **plot_basedir** Base directory, to which plot:: file names are relative to. (If None or empty, file names are relative to the directory where the file containing the directive is.)
- **plot_formats** File formats to generate. List of tuples or strings:

  ```
  [(suffix, dpi), suffix, ...]
  ```

  that determine the file format and the DPI. For entries whose DPI was omitted, sensible defaults are chosen. When passing from the command line through sphinx_build the list should be passed as suffix:dpi,suffix:dpi, ....

- **plot_html_show_formats** Whether to show links to the files in HTML.
- **plot_rcparams** A dictionary containing any non-standard rcParams that should be applied before each plot.
**plot_apply_rccparams** By default, rcParams are applied when context option is not used in a plot directive. This configuration option overrides this behavior and applies rcParams before each plot.

**plot_working_directory** By default, the working directory will be changed to the directory of the example, so the code can get at its data files, if any. Also its path will be added to sys.path so it can import any helper modules sitting beside it. This configuration option can be used to specify a central directory (also added to sys.path) where data files and helper modules for all code are located.

**plot_template** Provide a customized template for preparing restructured text.

```python
class matplotlib.sphinxext.plot_directive.PlotDirective(name, arguments, options, content, content_offset, block_text, state, state_machine)
```

Implementation of the .. plot:: directive.

See the module docstring for details.

```python
run(self)
    Run the plot directive.
```

**exception** matplotlib.sphinxext.plot_directive.PlotError

```python
matplotlib.sphinxext.plot_directive.mark_plot_labels(app, document)
```

To make plots referenceable, we need to move the reference from the “htmlonly” (or “latexonly”) node to the actual figure node itself.

```python
matplotlib.sphinxext.plot_directive.out_of_date(original, derived)
```

Return whether derived is out-of-date relative to original, both of which are full file paths.

```python
matplotlib.sphinxext.plot_directive.plot_directive(name, arguments, options, content, lineno, content_offset, block_text, state, state_machine)
```

**[Deprecated]** Implementation of the .. plot:: directive.

See the module docstring for details.

**Notes**

Deprecated since version 3.1.

```python
matplotlib.sphinxext.plot_directive.remove_coding(text)
```

Remove the coding comment, which six.exec_ doesn’t like.

```python
matplotlib.sphinxext.plot_directive.render_figures(code, code_path, output_dir, output_base, context, function_name, config, context_reset=False, close_figs=False)
```

Run a pyplot script and save the images in output_dir.

Save the images under output_dir with file names derived from output_base

```python
matplotlib.sphinxext.plot_directive.run_code(code, code_path, ns=None, function_name=None)
```

Import a Python module from a path, and run the function given by name, if function_name is not None.
matplotlib.sphinxext.plot_directive.split_code_at_show(text)
    Split code at plt.show().

matplotlib.sphinxext.plot_directive.unescape_doctest(text)
    Extract code from a piece of text, which contains either Python code or doctests.
Matplotlib supports the addition of custom procedures that transform the data before it is displayed.

There is an important distinction between two kinds of transformations. Separable transformations, working on a single dimension, are called “scales”, and non-separable transformations, that handle data in two or more dimensions at a time, are called “projections”.

From the user’s perspective, the scale of a plot can be set with `set_xscale()` and `set_yscale()`. Projections can be chosen using the `projection` keyword argument to the `plot()` or `subplot()` functions, e.g.:

```python
plot(x, y, projection="custom")
```

This document is intended for developers and advanced users who need to create new scales and projections for matplotlib. The necessary code for scales and projections can be included anywhere: directly within a plot script, in third-party code, or in the matplotlib source tree itself.

### 31.1 Creating a new scale

Adding a new scale consists of defining a subclass of `matplotlib.scale.ScaleBase`, that includes the following elements:

- A transformation from data coordinates into display coordinates.
- An inverse of that transformation. This is used, for example, to convert mouse positions from screen space back into data space.
- A function to limit the range of the axis to acceptable values (`limit_range_for_scale()`). A log scale, for instance, would prevent the range from including values less than or equal to zero.
- Locators (major and minor) that determine where to place ticks in the plot, and optionally, how to adjust the limits of the plot to some “good” values. Unlike `limit_range_for_scale()`, which is always enforced, the range setting here is only used when automatically setting the range of the plot.
- Formatters (major and minor) that specify how the tick labels should be drawn.

Once the class is defined, it must be registered with matplotlib so that the user can select it.
A full-fledged and heavily annotated example is in /gallery/scales/custom_scale. There are also some classes in `matplotlib.scale` that may be used as starting points.

### 31.2 Creating a new projection

Adding a new projection consists of defining a projection axes which subclasses `matplotlib.axes.Axes` and includes the following elements:

- A transformation from data coordinates into display coordinates.
- An inverse of that transformation. This is used, for example, to convert mouse positions from screen space back into data space.
- Transformations for the gridlines, ticks and ticklabels. Custom projections will often need to place these elements in special locations, and matplotlib has a facility to help with doing so.
- Setting up default values (overriding `cla()`), since the defaults for a rectilinear axes may not be appropriate.
- Defining the shape of the axes, for example, an elliptical axes, that will be used to draw the background of the plot and for clipping any data elements.
- Defining custom locators and formatters for the projection. For example, in a geographic projection, it may be more convenient to display the grid in degrees, even if the data is in radians.
- Set up interactive panning and zooming. This is left as an “advanced” feature left to the reader, but there is an example of this for polar plots in `matplotlib.projections.polar`.
- Any additional methods for additional convenience or features.

Once the projection axes is defined, it can be used in one of two ways:

- By defining the class attribute `name`, the projection axes can be registered with `matplotlib.projections.register_projection()` and subsequently simply invoked by name:

  ```python
gplt.axes(projection='my_proj_name')
```

- For more complex, parameterisable projections, a generic “projection” object may be defined which includes the method `_as_mpl_axes`. `_as_mpl_axes` should take no arguments and return the projection’s axes subclass and a dictionary of additional arguments to pass to the subclass’ `_init__` method. Subsequently a parameterised projection can be initialised with:

  ```python
gplt.axes(projection=MyProjection(param1=param1_value))
```

  where `MyProjection` is an object which implements a `_as_mpl_axes` method.

A full-fledged and heavily annotated example is in /gallery/misc/custom_projection. The polar plot functionality in `matplotlib.projections.polar` may also be of interest.

### 31.3 API documentation

- `matplotlib.scale`
- `matplotlib.projections`
- `matplotlib.projections.polar`
CHAPTER
THIRTYTWO

WORKING WITH MATPLOTLIB SOURCE CODE

Contents:

32.1 Introduction

These pages describe a git and github workflow for the Matplotlib project. There are several different workflows here, for different ways of working with Matplotlib. This is not a comprehensive git reference, it’s just a workflow for our own project. It’s tailored to the github hosting service. You may well find better or quicker ways of getting stuff done with git, but these should get you started.

For general resources for learning git, see git resources.

32.2 Install git

32.2.1 Overview

<table>
<thead>
<tr>
<th>OS</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian / Ubuntu</td>
<td><code>sudo apt-get install git</code></td>
</tr>
<tr>
<td>Fedora</td>
<td><code>sudo yum install git</code></td>
</tr>
<tr>
<td>Windows</td>
<td>Download and install msysGit</td>
</tr>
<tr>
<td>OS X</td>
<td>Use the <code>git-osx-installer</code></td>
</tr>
</tbody>
</table>

32.2.2 In detail

See the git page for the most recent information.

Have a look at the github install help pages available from github help

There are good instructions here: https://git-scm.com/book/en/v2/Getting-Started-Installing-Git
32.3 Following the latest source

These are the instructions if you just want to follow the latest Matplotlib source, but you don’t need to do any development for now.

The steps are:

- *Install git*
- get local copy of the Matplotlib github git repository
- update local copy from time to time

32.3.1 Get the local copy of the code

From the command line:

```
git clone git://github.com/matplotlib/matplotlib.git
```

You now have a copy of the code tree in the new matplotlib directory.

32.3.2 Updating the code

From time to time you may want to pull down the latest code. Do this with:

```
cd matplotlib
git pull
```

The tree in matplotlib will now have the latest changes from the initial repository.

32.4 Making a patch

You’ve discovered a bug or something else you want to change in Matplotlib .. — excellent!
You’ve worked out a way to fix it — even better!
You want to tell us about it — best of all!

The easiest way is to make a patch or set of patches. Here we explain how. Making a patch is the simplest and quickest, but if you’re going to be doing anything more than simple quick things, please consider following the *Git for development* model instead.

32.4.1 Making patches

**Overview**

```
# tell git who you are
git config --global user.email you@yourdomain.example.com
git config --global user.name "Your Name Comes Here"
# get the repository if you don't have it
```

(continues on next page)
In detail

1. Tell git who you are so it can label the commits you’ve made:

```
    git config --global user.email you@yourdomain.example.com
    git config --global user.name "Your Name Comes Here"
```

2. If you don’t already have one, clone a copy of the Matplotlib repository:

```
    git clone git://github.com/matplotlib/matplotlib.git
    cd matplotlib
```

3. Make a ‘feature branch’. This will be where you work on your bug fix. It’s nice and safe and leaves you with access to an unmodified copy of the code in the main branch:

```
    git branch the-fix-im-thinking-of
    git checkout the-fix-im-thinking-of
```

4. Do some edits, and commit them as you go:

```
# hack, hack, hack
# Tell git about any new files you've made
    git add somewhere/tests/test_my_bug.py
# commit work in progress as you go
    git commit -am 'BF - added tests for Funny bug'
# hack hack, hack
    git commit -am 'BF - added fix for Funny bug'
# make the patch files
    git format-patch -M -C master
```

Note the -am options to commit. The m flag just signals that you’re going to type a message on the command line. The a flag — you can just take on faith — or see why the -a flag?

5. When you have finished, check you have committed all your changes:

```
    git status
```
6. Finally, make your commits into patches. You want all the commits since you branched from the master branch:

```bash
git format-patch -M -C master
```

You will now have several files named for the commits:

- 0001-BF-added-tests-for-Funny-bug.patch
- 0002-BF-added-fix-for-Funny-bug.patch

Send these files to the Matplotlib mailing list.

When you are done, to switch back to the main copy of the code, just return to the master branch:

```bash
git checkout master
```

### 32.4.2 Moving from patching to development

If you find you have done some patches, and you have one or more feature branches, you will probably want to switch to development mode. You can do this with the repository you have. Fork the Matplotlib repository on github — *Making your own copy (fork) of Matplotlib*. Then:

```bash
# checkout and refresh master branch from main repo
git checkout master
git pull origin master
# rename pointer to main repository to 'upstream'
git remote rename origin upstream
# point your repo to default read / write to your fork on github
git remote add origin git@github.com:your-user-name/matplotlib.git
# push up any branches you've made and want to keep
git push origin the-fix-im-thinking-of
```

Then you can, if you want, follow the *Development workflow*.

### 32.5 Git for development

Contents:

#### 32.5.1 Making your own copy (fork) of Matplotlib

You need to do this only once. The instructions here are very similar to the instructions at [https://help.github.com/forking/](https://help.github.com/forking/) — please see that page for more detail. We’re repeating some of it here just to give the specifics for the Matplotlib project, and to suggest some default names.
Set up and configure a github account

If you don’t have a github account, go to the github page, and make one. You then need to configure your account to allow write access — see the generating SSH keys help on github help.

Create your own forked copy of Matplotlib

1. Log into your github account.
2. Go to the Matplotlib github home at Matplotlib github.
3. Click on the fork button:

Now, after a short pause, you should find yourself at the home page for your own forked copy of Matplotlib.

32.5.2 Set up your fork

First you follow the instructions for Making your own copy (fork) of Matplotlib.

Overview

```
git clone https://github.com/your-user-name/matplotlib.git
cd matplotlib
git remote add upstream git://github.com/matplotlib/matplotlib.git
```

In detail

Clone your fork

1. Clone your fork to the local computer with git clone https://github.com/your-user-name/matplotlib.git
2. Investigate. Change directory to your new repo: cd matplotlib. Then git branch -a to show you all branches. You’ll get something like:

```
* master
remotes/origin/master
```
This tells you that you are currently on the master branch, and that you also have a remote connection to origin/master. What remote repository is remote/origin? Try `git remote -v` to see the URLs for the remote. They will point to your github fork.

Now you want to connect to the upstream Matplotlib github repository, so you can merge in changes from trunk.

**Linking your repository to the upstream repo**

```bash
cd matplotlib
git remote add upstream git://github.com/matplotlib/matplotlib.git
```

**upstream** here is just the arbitrary name we’re using to refer to the main Matplotlib repository at Matplotlib github.

Note that we’ve used `git://` for the URL rather than `https://` or `git@`. The `git://` URL is read only. This means that we can’t accidentally (or deliberately) write to the upstream repo, and we are only going to use it to merge into our own code.

Just for your own satisfaction, show yourself that you now have a new ‘remote’, with `git remote -v show`, giving you something like:

```
upstream  git://github.com/matplotlib/matplotlib.git (fetch)
upstream  git://github.com/matplotlib/matplotlib.git (push)
origin    https://github.com/your-user-name/matplotlib.git (fetch)
origin    https://github.com/your-user-name/matplotlib.git (push)
```

### 32.5.3 Configure git

**Overview**

Your personal git configurations are saved in the `.gitconfig` file in your home directory.

Here is an example `.gitconfig` file:

```plaintext
[user]
    name = Your Name
    email = you@yourdomain.example.com

[alias]
    ci = commit -a
    co = checkout
    st = status
    stat = status
    br = branch
    wdiff = diff --color-words

[core]
    editor = vim

[merge]
    summary = true
```
You can edit this file directly or you can use the `git config --global` command:

```bash
git config --global user.name "Your Name"
git config --global user.email you@yourdomain.example.com
git config --global alias.ci "commit -a"
git config --global alias.co checkout
git config --global alias.st "status -a"
git config --global alias.stat "status -a"
git config --global alias.br branch
git config --global alias.wdiff "diff --color-words"
git config --global core.editor vim
git config --global merge.summary true
```

To set up on another computer, you can copy your `~/.gitconfig` file, or run the commands above.

### In detail

**user.name and user.email**

It is good practice to tell `git` who you are, for labeling any changes you make to the code. The simplest way to do this is from the command line:

```bash
git config --global user.name "Your Name"
git config --global user.email you@yourdomain.example.com
```

This will write the settings into your git configuration file, which should now contain a user section with your name and email:

```ini
[user]
  name = Your Name
  email = you@yourdomain.example.com
```

Of course you’ll need to replace `Your Name` and `you@yourdomain.example.com` with your actual name and email address.

**Aliases**

You might well benefit from some aliases to common commands.

For example, you might well want to be able to shorten `git checkout` to `git co`. Or you may want to alias `git diff --color-words` (which gives a nicely formatted output of the diff) to `git wdiff`

The following `git config --global` commands:

```bash
git config --global alias.ci "commit -a"
git config --global alias.co checkout
git config --global alias.st "status -a"
git config --global alias.stat "status -a"
git config --global alias.br branch
git config --global alias.wdiff "diff --color-words"
```
will create an alias section in your .gitconfig file with contents like this:

```
[alias]
   ci = commit -a
   co = checkout
   st = status -a
   stat = status -a
   br = branch
   wdiff = diff --color-words
```

**Editor**

You may also want to make sure that your editor of choice is used

```
git config --global core.editor vim
```

**Merging**

To enforce summaries when doing merges (-/_.gitconfig file again):

```
[merge]
   log = true
```

Or from the command line:

```
git config --global merge.log true
```

**Fancy log output**

This is a very nice alias to get a fancy log output; it should go in the alias section of your .gitconfig file:

```
lg = log --graph --pretty=format:'%Cred%h%Creset -%C(yellow)%d%Creset %s %Cgreen(%cr)
   %C(bold blue)(%an)%Creset' --abbrev-commit --date=relative
```

You use the alias with:

```
git lg
```

and it gives graph / text output something like this (but with color!):

```
* 6d8e1ee - (HEAD, origin/my-fancy-feature, my-fancy-feature) NF - a fancy file (45 min ago) [Matthew Brett]
* d304a73 - (origin/placeholder, placeholder) Merge pull request #48 from hhuuggoo/master (2 weeks ago) [Jonathan Terhorst]
|\ *
| * 4aff2a8 - fixed bug 35, and added a test in test_bugfixes (2 weeks ago) [Hugo]
|/
* a7ff2e5 - Added notes on discussion/proposal made during Data Array Summit. (2 weeks ago) [Corran Webster]
```

(continues on next page)
* 68f6752 - Initial implementation of AxisIndexer - uses \texttt{index\_by} which needs to be changed to a call on an Axes object - this is all very sketchy right now. (2 weeks ago) [Corr]
* 376adbd - Merge pull request \#46 from terhorst/master (2 weeks ago) [Jonathan Terhorst]
| * b605216 - updated joshu example to current api (3 weeks ago) [Jonathan Terhorst]
| * 2e991e8 - add testing for outer ufunc (3 weeks ago) [Jonathan Terhorst]
| * 7beda5a - prevent axis from throwing an exception if testing equality with non-axis object (3 weeks ago) [Jonathan Terhorst]
| * 65af65e - convert unit testing code to assertions (3 weeks ago) [Jonathan Terhorst]
| * 956fbab - Merge remote-tracking branch 'upstream/master' (3 weeks ago) [Jonathan Terhorst]

Thanks to Yury V. Zaytsev for posting it.

### 32.5.4 Development workflow

You already have your own forked copy of the Matplotlib repository, by following \textit{Making your own copy (fork) of Matplotlib}. You have \textit{Set up your fork}. You have configured git by following \textit{Configure git}. Now you are ready for some real work.

**Workflow summary**

In what follows we’ll refer to the upstream Matplotlib master branch, as “trunk”.

- Don’t use your \texttt{master} branch for anything. Consider deleting it.
- When you are starting a new set of changes, fetch any changes from trunk, and start a new \texttt{feature branch} from that.
- Make a new branch for each separable set of changes — “one task, one branch” (ipython git workflow).
- Name your branch for the purpose of the changes - e.g. \texttt{bugfix-for-issue-14} or \texttt{refactor-database-code}.
- If you can possibly avoid it, avoid merging trunk or any other branches into your feature branch while you are working.
- If you do find yourself merging from trunk, consider \texttt{Rebasing on trunk}
- Ask on the Matplotlib mailing list if you get stuck.
- Ask for code review!

This way of working helps to keep work well organized, with readable history. This in turn makes it easier for project maintainers (that might be you) to see what you’ve done, and why you did it.

See \textit{linux git workflow} and \textit{ipython git workflow} for some explanation.
Consider deleting your master branch

It may sound strange, but deleting your own master branch can help reduce confusion about which branch you are on. See deleting master on github for details.

Update the mirror of trunk

First make sure you have done Linking your repository to the upstream repo. From time to time you should fetch the upstream (trunk) changes from github:

```
git fetch upstream
```

This will pull down any commits you don’t have, and set the remote branches to point to the right commit. For example, ‘trunk’ is the branch referred to by (remote/branchname) upstream/master - and if there have been commits since you last checked, upstream/master will change after you do the fetch.

Make a new feature branch

When you are ready to make some changes to the code, you should start a new branch. Branches that are for a collection of related edits are often called ‘feature branches’.

Making an new branch for each set of related changes will make it easier for someone reviewing your branch to see what you are doing.

Choose an informative name for the branch to remind yourself and the rest of us what the changes in the branch are for. For example add-ability-to-fly, or buxfix-for-issue-42.

```
# Update the mirror of trunk
git fetch upstream
# Make new feature branch starting at current trunk
git branch my-new-feature upstream/master
git checkout my-new-feature
```

Generally, you will want to keep your feature branches on your public github fork of Matplotlib. To do this, you git push this new branch up to your github repo. Generally (if you followed the instructions in these pages, and by default), git will have a link to your github repo, called origin. You push up to your own repo on github with:

```
git push origin my-new-feature
```

In git >= 1.7 you can ensure that the link is correctly set by using the --set-upstream option:

```
git push --set-upstream origin my-new-feature
```

From now on git will know that my-new-feature is related to the my-new-feature branch in the github repo.

The editing workflow
# hack hack

git add my_new_file

git commit -am 'NF - some message'

git push

## In more detail

1. Make some changes

2. See which files have changed with `git status` (see [git status](#git-status)). You'll see a listing like this one:

   ```
   # On branch ny-new-feature
   # Changed but not updated:
   # (use "git add <file>..." to update what will be committed)
   # (use "git checkout -- <file>..." to discard changes in working directory)
   #
   # modified: README
   #
   # Untracked files:
   # (use "git add <file>..." to include in what will be committed)
   #
   # INSTALL
   no changes added to commit (use "git add" and/or "git commit -a")
   ```

3. Check what the actual changes are with `git diff` ([git diff](#git-diff)).

4. Add any new files to version control `git add new_file_name` (see [git add](#git-add)).

5. To commit all modified files into the local copy of your repo, do `git commit -am 'A commit message'`. Note the `-am` options to `commit`. The `m` flag just signals that you're going to type a message on the command line. The `a` flag — you can just take on faith — or see why the `-a` flag? — and the helpful use-case description in the tangled working copy problem. The `git commit` manual page might also be useful.

6. To push the changes up to your forked repo on github, do a `git push` (see [git push](#git-push)).

## Ask for your changes to be reviewed or merged

When you are ready to ask for someone to review your code and consider a merge:

1. Go to the URL of your forked repo, say `https://github.com/your-user-name/matplotlib`.

2. Use the ‘Switch Branches’ dropdown menu near the top left of the page to select the branch with your changes:
3. Click on the 'Pull request' button:

Enter a title for the set of changes, and some explanation of what you’ve done. Say if there is anything you’d like particular attention for - like a complicated change or some code you are not happy with.

If you don’t think your request is ready to be merged, just say so in your pull request message. This is still a good way of getting some preliminary code review.

**Some other things you might want to do**

Delete a branch on github

```
git checkout master
# delete branch locally
git branch -D my-unwanted-branch
# delete branch on github
git push origin :my-unwanted-branch
```

Note the colon : before my-unwanted-branch. See also: https://help.github.com/articles/pushing-to-a-remote/#deleting-a-remote-branch-or-tag

**Several people sharing a single repository**

If you want to work on some stuff with other people, where you are all committing into the same repository, or even the same branch, then just share it via github.

First fork Matplotlib into your account, as from *Making your own copy (fork) of Matplotlib*. Then, go to your forked repository github page, say https://github.com/your-user-name/matplotlib
Click on the ‘Admin’ button, and add anyone else to the repo as a collaborator:

Now all those people can do:

```
git clone https://github.com/your-user-name/matplotlib.git
```

Remember that links starting with https or git@ are read-write, and that git@ uses the ssh protocol; links starting with git:// are read-only.

Your collaborators can then commit directly into that repo with the usual:

```
git commit -am 'ENH - much better code'
git push origin master # pushes directly into your repo
```

**Explore your repository**

To see a graphical representation of the repository branches and commits:

```
gitk --all
```

To see a linear list of commits for this branch:

```
git log
```

You can also look at the network graph visualizer for your github repo.

Finally the *Fancy log output* `lg` alias will give you a reasonable text-based graph of the repository.

**Rebasing on trunk**

Let’s say you thought of some work you’d like to do. You *Update the mirror of trunk* and *Make a new feature branch* called `cool-feature`. At this stage trunk is at some commit, let’s call it E. Now you make some new commits on your `cool-feature` branch, let’s call them A, B, C. Maybe your changes take a while, or you come back to them after a while. In the meantime, trunk has progressed from commit E to commit (say) G:

```
A---B---C cool-feature
|
D---E---F---G trunk
```

At this stage you consider merging trunk into your feature branch, and you remember that this here page sternly advises you not to do that, because the history will get messy. Most of the time you can just ask for a review, and not worry that trunk has got a little ahead. But
sometimes, the changes in trunk might affect your changes, and you need to harmonize them. In this situation you may prefer to do a rebase.

rebase takes your changes (A, B, C) and replays them as if they had been made to the current state of trunk. In other words, in this case, it takes the changes represented by A, B, C and replays them on top of G. After the rebase, your history will look like this:

```
A'--B'--C' cool-feature
  /
D---E---F---G trunk
```

See rebase without tears for more detail.

To do a rebase on trunk:

```
# Update the mirror of trunk
git fetch upstream
# go to the feature branch
git checkout cool-feature
# make a backup in case you mess up
git branch tmp cool-feature
# rebase cool-feature onto trunk
git rebase --onto upstream/master upstream/master cool-feature
```

In this situation, where you are already on branch cool-feature, the last command can be written more succinctly as:

```
git rebase upstream/master
```

When all looks good you can delete your backup branch:

```
git branch -D tmp
```

If it doesn’t look good you may need to have a look at Recovering from mess-ups.

If you have made changes to files that have also changed in trunk, this may generate merge conflicts that you need to resolve - see the git rebase man page for some instructions at the end of the “Description” section. There is some related help on merging in the git user manual - see resolving a merge.

**Recovering from mess-ups**

Sometimes, you mess up merges or rebases. Luckily, in git it is relatively straightforward to recover from such mistakes.

If you mess up during a rebase:

```
git rebase --abort
```

If you notice you messed up after the rebase:

```
# reset branch back to the saved point
git reset --hard tmp
```

If you forgot to make a backup branch:
```
# look at the reflog of the branch
git reflog show cool-feature

8630830 cool-feature@{0}: commit: BUG: io: close file handles immediately
278dd2a cool-feature@{1}: rebase finished: refs/heads/my-feature-branch onto ...
26aa21a cool-feature@{2}: commit: BUG: lib: make seek_gzip_factory not leak gzip obj ...

# reset the branch to where it was before the botched rebase
git reset --hard cool-feature@{2}
```

### Rewriting commit history

**Note:** Do this only for your own feature branches.

There’s an embarrassing typo in a commit you made? Or perhaps the you made several false starts you would like the posterity not to see.

This can be done via **interactive rebasing**.

Suppose that the commit history looks like this:

```
git log --oneline
eadc391 Fix some remaining bugs
a815645 Modify it so that it works
2dec1ac Fix a few bugs + disable
13d7934 First implementation
6ad92e5 * masked is now an instance of a new object, MaskedConstant
29001ed Add pre-nep for a copule of structured_array_extensions.
...
```

and **6ad92e5** is the last commit in the **cool-feature** branch. Suppose we want to make the following changes:

- Rewrite the commit message for **13d7934** to something more sensible.
- Combine the commits **2dec1ac**, **a815645**, **eadc391** into a single one.

We do as follows:

```
# make a backup of the current state
git branch tmp HEAD
# interactive rebase
git rebase -i 6ad92e5
```

This will open an editor with the following text in it:

```
pick 13d7934 First implementation
pick 2dec1ac Fix a few bugs + disable
pick a815645 Modify it so that it works
pick eadc391 Fix some remaining bugs
```

(continues on next page)
To achieve what we want, we will make the following changes to it:

```
r 13d7934 First implementation
pick 2dec1ac Fix a few bugs + disable
f a815645 Modify it so that it works
f eadc391 Fix some remaining bugs
```

This means that (i) we want to edit the commit message for 13d7934, and (ii) collapse the last three commits into one. Now we save and quit the editor.

Git will then immediately bring up an editor for editing the commit message. After revising it, we get the output:

```
[detached HEAD 721fc64] FOO: First implementation
  2 files changed, 199 insertions(+), 66 deletions(−)
[detached HEAD 0f22701] Fix a few bugs + disable
  1 files changed, 79 insertions(+), 61 deletions(−)
Successfully rebased and updated refs/heads/my-feature-branch.
```

and the history looks now like this:

```
0f22701 Fix a few bugs + disable
721fc64 ENH: Sophisticated feature
6ad92e5 * masked is now an instance of a new object, MaskedConstant
```

If it went wrong, recovery is again possible as explained above.

### 32.5.5 Maintainer workflow

This page is for maintainers — those of us who merge our own or other peoples’ changes into the upstream repository.

Being as how you’re a maintainer, you are completely on top of the basic stuff in Development workflow.

The instructions in Linking your repository to the upstream repo add a remote that has read-only access to the upstream repo. Being a maintainer, you’ve got read-write access.

It’s good to have your upstream remote have a scary name, to remind you that it’s a read-write remote:
Integrating changes

Let’s say you have some changes that need to go into trunk (upstream-rw/master).
The changes are in some branch that you are currently on. For example, you are looking at
someone’s changes like this:

```
git remote add someone git://github.com/someone/matplotlib.git
git fetch someone
git branch cool-feature --track someone/cool-feature
git checkout cool-feature
```

So now you are on the branch with the changes to be incorporated upstream. The rest of this
section assumes you are on this branch.

A few commits

If there are only a few commits, consider rebasing to upstream:

```
# Fetch upstream changes
git fetch upstream-rw
# rebase
git rebase upstream-rw/master
```

Remember that, if you do a rebase, and push that, you’ll have to close any github pull requests
manually, because github will not be able to detect the changes have already been merged.

A long series of commits

If there are a longer series of related commits, consider a merge instead:

```
git fetch upstream-rw
git merge --no-ff upstream-rw/master
```

The merge will be detected by github, and should close any related pull requests automati-
cally.

Note the --no-ff above. This forces git to make a merge commit, rather than doing a fast-
forward, so that these set of commits branch off trunk then rejoin the main history with a
merge, rather than appearing to have been made directly on top of trunk.

Check the history

Now, in either case, you should check that the history is sensible and you have the right
commits:
The first line above just shows the history in a compact way, with a text representation of the history graph. The second line shows the log of commits excluding those that can be reached from trunk (upstream-rw/master), and including those that can be reached from current HEAD (implied with the .. at the end). So, it shows the commits unique to this branch compared to trunk. The -p option shows the diff for these commits in patch form.

Push to trunk

This pushes the my-new-feature branch in this repository to the master branch in the upstream-rw repository.

32.6 git resources

32.6.1 Tutorials and summaries

- [github help](https://help.github.com) has an excellent series of how-to guides.
- The [pro git book](https://git-scm.com/book) is a good in-depth book on git.
- A [git cheat sheet](https://www.kernel.org/pub/software/scm/git/docs/cheatsheet) is a page giving summaries of common commands.
- The [git user manual](https://git-scm.com/docs)  
- The [git tutorial](https://git-scm.com/docs)  
- The [git community book](https://git-scm.com/docs)  
- [git ready](https://git-scm.com/docs) — a nice series of tutorials  
- [git magic](https://git-scm.com/docs) — extended introduction with intermediate detail  
- The [git parable](https://git-scm.com/docs) is an easy read explaining the concepts behind git.  
- [git foundation](https://git-scm.com/docs) expands on the git parable.  
- Fernando Perez’ git page — [Fernando’s git page](https://git-scm.com/docs) — many links and tips  
- A good but technical page on [git concepts](https://git-scm.com/docs)  
- [git svn crash course](https://git-scm.com/docs): git for those of us used to subversion

32.6.2 Advanced git workflow

There are many ways of working with git; here are some posts on the rules of thumb that other projects have come up with:  
- Linus Torvalds on [git management](https://git-scm.com/docs)
• Linus Torvalds on linux git workflow. Summary; use the git tools to make the history of your edits as clean as possible; merge from upstream edits as little as possible in branches where you are doing active development.

32.6.3 Manual pages online

You can get these on your own machine with (e.g) git help push or (same thing) git push --help, but, for convenience, here are the online manual pages for some common commands:

• git add
• git branch
• git checkout
• git clone
• git commit
• git config
• git diff
• git log
• git pull
• git push
• git remote
• git status

32.7 Two and three dots in difference specs

Thanks to Yarik Halchenko for this explanation.

Imagine a series of commits A, B, C, D... Imagine that there are two branches, topic and master. You branched topic off master when master was at commit ‘E’. The graph of the commits looks like this:

```
A---B---C topic
/  
D---E---F---G master
```

Then:

```
git diff master..topic
```

will output the difference from G to C (i.e. with effects of F and G), while:

```
git diff master...topic
```

would output just differences in the topic branch (i.e. only A, B, and C).
33.1 Pull request checklist

33.1.1 Branch selection

In general target the master branch for all new features and bug-fixes. PRs may target maintenance or doc branches on a case-by-case basis.

33.1.2 Documentation

• Every new feature should be documented. If it’s a new module, don’t forget to add a new rst file to the API docs.

• Each high-level plotting function should have a small example in the Example section of the docstring. This should be as simple as possible to demonstrate the method. More complex examples should go in the examples section of the documentation.

• Build the docs and make sure all formatting warnings are addressed.

• See Writing documentation for our documentation style guide.

• If your change is a major new feature, add an entry to doc/users/whats_new.rst.

• If you change the API in a backward-incompatible way, please document it in doc/api/api_changes.rst.

33.2 PR Review guidelines

• Be patient and kind with contributors.

• If you have commit rights, then you are trusted to use them. Please help review and merge PRs!

• Documentation and examples may be merged by the first reviewer. Use the threshold “is this better than it was?” as the review criteria.

• For code changes (anything in src or lib) at least two developers (those with commit rights) should review all pull requests. If you are the first to review a PR and approve of the changes use the github ‘approve review’ tool to mark it as such. If you are a subsequent reviewer please approve the review and if you think no more review is needed, merge the PR.
Ensure that all API changes are documented in doc/api/api_changes and significant new features have and entry in doc/user/whats_new.

- Make sure the Travis, Appveyor, circle, and codecov tests are passing before merging.
  - Whenever a pull request is created or updated, Travis and Appveyor automatically runs the test suite on all versions of Python supported by Matplotlib. The tox support in Matplotlib may be useful for testing locally.

- Do not self merge, except for 'small' patches to un-break the CI or when another reviewer explicitly allows it (ex, "Approve modulo CI passing, may self merge when green")

- Squashing is case-by-case. The balance is between burden on the contributor, keeping a relatively clean history, and keeping a history usable for bisecting. The only time we are really strict about it is to eliminate binary files (ex multiple test image re-generations) and to remove upstream merges.

- Do not let perfect be the enemy of the good, particularly for documentation or example PRs. If you find yourself making many small suggestions, either open a PR against the original branch, push changes to the contributor branch, or merge the PR and then open a new PR against upstream.

- If you push to a contributor branch leave a comment explaining what you did, ex “I took the liberty of pushing a small clean-up PR to your branch, thanks for your work.” If you are going to make substantial changes to the code or intent of the PR please check with the contributor first.

### 33.3 Branches and Backports

The current active branches are

- **master** This will be Matplotlib 3.0. Supports Python 3.5+.
- **v2.2.x** Maintenance branch for Matplotlib 2.2 LTS. Supports Python 2.7, 3.4+

**v2.2.N-doc** Documentation for the current release. On a patch release, this will be replaced by a properly named branch for the new release.

We always will backport to 2.2.x

- critical bug fixes (segfault, failure to import, things that the user can not work around)
- fixes for regressions against 2.0 or 2.1

Everything else (regressions against 1.x versions, bugs/api inconsistencies the user can work around in their code) are on a case-by-case basis, should be low-risk, and need someone to advocate for and shepherd through the backport.

The only changes to be backported to 2.2.N-doc are changes to doc, examples, or tutorials. Any changes to lib or src should not be backported to this branch.

### 33.3.1 Automated backports

We use meeseeksdev bot to automatically backport merges to the correct maintenance branch base on the milestone. To work properly the milestone must be set before merging. If you have commit rights, the bot can also be manually triggered after a merge by leaving a message @meeseeksdev backport to BRANCH on the PR. If there are conflicts meeseekdevs will inform you that the backport needs to be done manually.
The target branch is configured by putting `on-merge: backport` to `TARGETBRANCH` in the milestone description on it's own line.

If the bot is not working as expected, please report issues to Meeseeksdev.

### 33.3.2 Manual backports

When doing backports please copy the form used by meeseekdev, **Backport PR #XXXX: TITLE OF PR**. If you need to manually resolve conflicts make note of them and how you resolved them in the commit message.

We do a backport from master to v2.2.x assuming:

- matplotlib is a read-only remote branch of the matplotlib/matplotlib repo

The `TARGET_SHA` is the hash of the merge commit you would like to backport. This can be read off of the github PR page (in the UI with the merge notification) or through the git CLI tools.

Assuming that you already have a local branch v2.2.x (if not, then `git checkout -b v2.2.x`), and that your remote pointing to `https://github.com/matplotlib/matplotlib` is called `upstream`:

```
git fetch upstream
git checkout v2.2.x  # or include -b if you don't already have this.
git reset --hard upstream/v2.2.x
git cherry-pick -m 1 TARGET_SHA
# resolve conflicts and commit if required
```

Files with conflicts can be listed by `git status`, and will have to be fixed by hand (search on `>>>>>>`). Once the conflict is resolved, you will have to re-add the file(s) to the branch and then continue the cherry pick:

```
git add lib/matplotlib/conflicted_file.py
git add lib/matplotlib/conflicted_file2.py
git cherry-pick --continue
```

Use your discretion to push directly to upstream or to open a PR; be sure to push or PR against the v2.2.x upstream branch, not master!
This document is only relevant for matplotlib release managers.
A guide for developers who are doing a matplotlib release.

Note: This assumes that a read-only remote for the canonical repository is remote and a read/write remote is DANGER

34.1 All Releases

34.1.1 Testing

We use travis-ci for continuous integration. When preparing for a release, the final tagged commit should be tested locally before it is uploaded:

```
pytest -n 8 .
```

In addition the following test should be run and manually inspected:

```
python unit/memleak.py agg agg.pdf
```

In addition the following should be run and manually inspected, but is currently broken:

```
pushd examples/tests/
python backend_driver_sgskip.py
popd
```

34.1.2 GitHub Stats

We automatically extract GitHub issue, PRs, and authors from GitHub via the API. copy the current github_stats.rst to github_stats_X.Y.Z.rst.

To re-generate the updated

```
python tools/github_stats.py --since-tag v2.2.0 --milestone=v3.0 --project 'matplotlib/matplotlib' --links > doc/users/github_stats.rst
```
Review and commit changes. Some issue/PR titles may not be valid rst (the most common issue is * which is interpreted as unclosed markup).

### 34.1.3 Update and Validate the Docs

Merge the most recent `doc` branch (v3.0.2-doc) into the branch you are going to tag on and delete the doc branch on GitHub.

Before tagging, update the “what’s new” and “API changes” listings.

for the “what’s new”

1. copy the current content to a file in doc/users/prev_whats_new
2. merge all of the files in doc/users/next_whats_new/ into doc/users/whats_new.rst and delete the individual files
3. comment out the next whats new glob at the top

Similarly for the “API changes”

1. copy the current api changes to a file is doc/api/prev_api_changes
2. merge all of the files in doc/api/next_api_changes/ into doc/api/whats_new.rst
3. comment out the next API changes at the top.

In both cases step 3 will have to be un-done right after the release.

Finally, make sure that the docs build cleanly

```
make -Cdoc O=-j$(nproc) html latexpdf
```

After the docs are built, check that all of the links, internal and external, are still valid. We use linkchecker for this, which has not been ported to python3 yet. You will need to create a python2 environment with requests==2.9.0 and linkchecker

```
conda create -p /tmp/lnkchk python=2 requests==2.9.0
source activate /tmp/lnkchk
pip install linkchecker
pushd doc/build/html
linkchecker index.html --check-extern
popd
```

Address any issues which may arise. The internal links are checked on travis, this should only flag failed external links.

### 34.1.4 Create release commit and tag

To create the tag, first create an empty commit with a very terse set of the release notes in the commit message

```
git commit --allow-empty
```

and then create a signed, annotated tag with the same text in the body message

```
git tag -a -s v2.0.0
```
which will prompt you for your gpg key password and an annotation. For pre releases it is important to follow PEP 440 so that the build artifacts will sort correctly in pypi. Finally, push the tag to GitHub

```
git push -t DANGER v2.0.0
```

Congratulations, the scariest part is done!

To prevent issues with any down-stream builders which download the tarball from GitHub it is important to move all branches away from the commit with the tag¹:

```
git commit --allow-empty
git push DANGER master
```

If this is a final release, also create a ‘doc’ branch (this is not done for pre-releases):

```
git branch v2.0.0-doc
git push DANGER v2.0.0-doc
```

and if this is a major or minor release, also create a bug-fix branch (a micro release will be cut off of this branch):

```
git branch v2.0.x
```

On this branch un-comment the globs from Update and Validate the Docs. And then

```
git push DANGER v2.0.x
```

### 34.1.5 Release Management / DOI

Via the GitHub UI, turn the newly pushed tag into a release. If this is a pre-release remember to mark it as such.

For final releases also get a DOI from zenodo and edit doc/citing.rst with DOI link and commit to the VER-doc branch and push to GitHub

```
git checkout v2.0.0-doc
eemacs doc/_templates/citing.html
git push DANGER v2.0.0-doc:v2.0.0-doc
```

### 34.1.6 Building binaries

We distribute mac, windows, and many linux wheels as well as a source tarball via pypi. Before uploading anything, contact the various builders. Mac and manylinux wheels are built

¹ The tarball that is provided by GitHub is produced using `git archive`. We use `versioneer` which uses a format string in `lib/matplotlib/_version.py` to have `git` insert a list of references to exported commit (see `.gitattributes` for the configuration). This string is then used by `versioneer` to produce the correct version, based on the git tag, when users install from the tarball. However, if there is a branch pointed at the tagged commit, then the branch name will also be included in the tarball. When the branch eventually moves, anyone how checked the hash of the tarball before the branch moved will have an incorrect hash.

To generate the file that GitHub does use

```
git archive v2.0.0 -o matplotlib-2.0.0.tar.gz --prefix=matplotlib-2.0.0/
```
on travis. You need to edit the `.travis.yml` file and push to the correct branch of the build project. For new minor versions create a new branch, for bug-fixes continue to use the current release branch.

The auto-tick bot should open a pull request into the conda-forge feedstock. Review and merge (if you have the power to).

**Warning:** Because this is automated, it is extremely important to bump all branches away from the tag as discussed in *Create release commit and tag*.

If this is a final release the following downstream packagers should be contacted:

- Debian
- Fedora
- Arch
- Gentoo
- Macports
- Homebrew
- Christoph Gohlke
- Continuum
- Enthought

This can be done ahead of collecting all of the binaries and uploading to pypi.

### 34.1.7 make distribution and upload to pypi / SF

Once you have collected all of the wheels (expect this to take about a day), generate the tarball

```
    git checkout v2.0.0
    git clean -xfd
    python setup.py sdist
```

and copy all of the wheels into `dist` directory. You should use `twine` to upload all of the files to pypi

```
    twine upload -s dist/matplotlib*tar.gz
    twine upload dist/*whl
```

Congratulations, you have now done the second scariest part!

Additionally, for a final release, upload all of the files to sourceforge.

### 34.1.8 Build and Deploy Documentation

To build the documentation you must have the tagged version installed, but build the docs from the `ver-doc` branch. An easy way to arrange this is:
which will build both the html and pdf version of the documentation.

The built documentation exists in the matplotlib.github.com repository. Pushing changes to master automatically updates the website.

The documentation is organized by version. At the root of the tree is always the documentation for the latest stable release. Under that, there are directories containing the documentation for older versions. The documentation for current master are built on travis and push to the devdocs repository. These are available at matplotlib.org/devdocs.

Assuming you have this repository checked out in the same directory as matplotlib

which will copy the built docs over. If this is a final release, also replace the top-level docs

You will need to manually edit versions.html to show the last 3 tagged versions. Now commit and push everything to GitHub

Congratulations you have now done the third scariest part!

If you have access, clear the cloudflare caches.

It typically takes about 5-10 minutes for GitHub to process the push and update the live web page (remember to clear your browser cache).

### 34.1.9 Announcing

The final step is to announce the release to the world. A short version of the release notes along with acknowledgments should be sent to

- matplotlib-user@python.org
- matplotlib-devel@python.org
- matplotlib-announce@python.org

For final releases announcements should also be sent to the numpy/scipy/scikit-image mailing lists.
In addition, announcements should be made on social networks (twitter via the @matplotlib account, any other via personal accounts). NumFOCUS should be contacted for inclusion in their newsletter.
MINIMUM VERSION OF DEPENDENCIES POLICY

For the purpose of this document, 'minor version' is in the sense of SemVer (major, minor, patch) and includes both major and minor releases. For projects that use date-based versioning, every release is a 'minor version'.

35.1 Python and numpy

- support minor versions of Python initially released 36 months prior to our planned release date.
- support minor versions of numpy initially released in the 36 months prior to our planned release date or oldest that supports the minimum python version (which ever is higher)

We will bump the minimum python and numpy versions as we can every minor and major release, but never on a patch release.

35.2 Python Dependencies

For python dependencies we should support at least:

with compiled extensions minor versions initially released in the 36 months prior to our planned release date or the oldest that support our minimum python + numpy

without compiled extensions minor versions initially released in the 24 months prior to our planned release date or the oldest that supports our minimum python.

We will only bump these dependencies as we need new features or the old versions no longer support our minimum numpy or python.

35.3 Test and Documentation Dependencies

As these packages are only needed for testing or building the docs and not needed by end-users, we can be more aggressive about dropping support for old versions. However, we need to be careful to not over-run what down-stream packagers support (as most of the run the tests and build the documentation as part of the packaging process).

We will support at least minor versions of the development dependencies released in the 12 months prior to our planned release.
We will only bump these as needed or versions no longer support our minimum Python and numpy.

35.4 System and C-dependencies

For system or c-dependencies (libpng, freetype, GUI frameworks, latex, gs, ffmpeg) support as old as practical. These can be difficult to install for end-users and we want to be usable on as many systems as possible. We will bump these on a case-by-case basis.
Matplotlib Enhancement Proposals (MEP), inspired by cpython’s PEP’s but less formal, are design documents for large or controversial changes to Matplotlib. These documents should provide a discussion of both why and how the changes should be made.

To create a new MEP open a pull request (PR) adding a file based on the template to this the MEP directory. For the initial PR only a rough description is required and it should be merged quickly. Further detailed discussion can happen in follow on PRs.

36.1 MEP Template

- Status
- Branches and Pull requests
- Abstract
- Detailed description
- Implementation
- Backward compatibility
- Alternatives

This MEP template is a guideline of the sections that a MEP should contain. Extra sections may be added if appropriate, and unnecessary sections may be noted as such.

36.1.1 Status

MEPs go through a number of phases in their lifetime:

- **Discussion**: The MEP is being actively discussed on the mailing list and it is being improved by its author. The mailing list discussion of the MEP should include the MEP number (MEPxxx) in the subject line so they can be easily related to the MEP.
- **Progress**: Consensus was reached and implementation work has begun.
- **Completed**: The implementation has been merged into master.
- **Superseded**: This MEP has been abandoned in favor of another approach.
- **Rejected**: There are currently no plans to implement the proposal.
36.1.2 Branches and Pull requests

All development branches containing work on this MEP should be linked to from here.
All pull requests submitted relating to this MEP should be linked to from here. (A MEP does
not need to be implemented in a single pull request if it makes sense to implement it in discrete
phases).

36.1.3 Abstract

The abstract should be a short description of what the MEP will achieve.

36.1.4 Detailed description

This section describes the need for the MEP. It should describe the existing problem that it
is trying to solve and why this MEP makes the situation better. It should include examples of
how the new functionality would be used and perhaps some use cases.

36.1.5 Implementation

This section lists the major steps required to implement the MEP. Where possible, it should
be noted where one step is dependent on another, and which steps may be optionally omitted.
Where it makes sense, each step should include a link related pull requests as the implemen-
tation progresses.

36.1.6 Backward compatibility

This section describes the ways in which the MEP breaks backward incompatibility.

36.1.7 Alternatives

If there were any alternative solutions to solving the same problem, they should be discussed
here, along with a justification for the chosen approach.

36.2 MEP8: PEP8

- Status
- Branches and Pull requests
- Abstract
- Detailed description
- Implementation

Chapter 36. Matplotlib Enhancement Proposals
36.2.1 Status

Completed
We are currently enforcing a sub-set of pep8 on new code contributions.

36.2.2 Branches and Pull requests
None so far.

36.2.3 Abstract
The matplotlib codebase predates PEP8, and therefore is less than consistent style-wise in some areas. Bringing the codebase into compliance with PEP8 would go a long way to improving its legibility.

36.2.4 Detailed description
Some files use four space indentation, some use three. Some use different levels in the same file.
For the most part, class/function/variable naming follows PEP8, but it wouldn’t hurt to fix where necessary.

36.2.5 Implementation
The implementation should be fairly mechanical: running the pep8 tool over the code and fixing where appropriate.
This should be merged in after the 2.0 release, since the changes will likely make merging any pending pull requests more difficult.
Additionally, and optionally, PEP8 compliance could be tracked by an automated build system.

36.2.6 Backward compatibility
Public names of classes and functions that require change (there shouldn’t be many of these) should first be deprecated and then removed in the next release cycle.

36.2.7 Alternatives
PEP8 is a popular standard for Python code style, blessed by the Python core developers, making any alternatives less desirable.
36.3 MEP9: Global interaction manager

- Status
- Branches and Pull requests
- Abstract
- Detailed description
- Implementation
- Current summary of the mixin
- Backward compatibility
- Alternatives

Add a global manager for all user interactivity with artists; make any artist resizeable, moveable, highlightable, and selectable as desired by the user.

36.3.1 Status

Discussion

36.3.2 Branches and Pull requests

https://github.com/dhyams/matplotlib/tree/MEP9

36.3.3 Abstract

The goal is to be able to interact with matplotlib artists in a very similar way as drawing programs do. When appropriate, the user should be able to move, resize, or select an artist that is already on the canvas. Of course, the script writer is ultimately in control of whether an artist is able to be interacted with, or whether it is static.

This code to do this has already been privately implemented and tested, and would need to be migrated from its current “mixin” implementation, to a bona-fide part of matplotlib.

The end result would be to have four new keywords available to matplotlib.artist.Artist: _moveable_, _resizeable_, _selectable_, and _highlightable_. Setting any one of these keywords to True would activate interactivity for that artist.

In effect, this MEP is a logical extension of event handling in matplotlib; matplotlib already supports “low level” interactions like left mouse presses, a key press, or similar. The MEP extends the support to the logical level, where callbacks are performed on the artists when certain interactive gestures from the user are detected.

36.3.4 Detailed description

This new functionality would be used to allow the end-user to better interact with the graph. Many times, a graph is almost what the user wants, but a small repositioning and/or resizing
of components is necessary. Rather than force the user to go back to the script to trial-and-error the location, and simple drag and drop would be appropriate.

Also, this would better support applications that use matplotlib; here, the end-user has no reasonable access or desire to edit the underlying source in order to fine-tune a plot. Here, if matplotlib offered the capability, one could move or resize artists on the canvas to suit their needs. Also, the user should be able to highlight (with a mouse over) an artist, and select it with a double-click, if the application supports that sort of thing. In this MEP, we also want to support the highlighting and selection natively; it is up to application to handle what happens when the artist is selected. A typical handling would be to display a dialog to edit the properties of the artist.

In the future, as well (this is not part of this MEP), matplotlib could offer backend-specific property dialogs for each artist, which are raised on artist selection. This MEP would be a necessary stepping stone for that sort of capability.

There are currently a few interactive capabilities in matplotlib (e.g. legend.draggable()), but they tend to be scattered and are not available for all artists. This MEP seeks to unify the interactive interface and make it work for all artists.

The current MEP also includes grab handles for resizing artists, and appropriate boxes drawn when artists are moved or resized.

### 36.3.5 Implementation

- Add appropriate methods to the “tree” of artists so that the interactivity manager has a consistent interface for the interactivity manager to deal with. The proposed methods to add to the artists, if they are to support interactivity, are:
  - get_pixel_position_ll(self): get the pixel position of the lower left corner of the artist’s bounding box
  - get_pixel_size(self): get the size of the artist’s bounding box, in pixels
  - set_pixel_position_and_size(self, x, y, dx, dy): set the new size of the artist, such that it fits within the specified bounding box.

- add capability to the backends to 1) provide cursors, since these are needed for visual indication of moving/resizing, and 2) provide a function that gets the current mouse position

- Implement the manager. This has already been done privately (by dhyams) as a mixin, and has been tested quite a bit. The goal would be to move the functionality of the manager into the artists so that it is in matplotlib properly, and not as a “monkey patch” as I currently have it coded.

### 36.3.6 Current summary of the mixin

(Note that this mixin is for now just private code, but can be added to a branch obviously)

InteractiveArtistMixin:

Mixin class to make any generic object that is drawn on a matplotlib canvas moveable and possibly resizeable. The Powerpoint model is followed as closely as possible; not because I’m enamoured with Powerpoint, but because that’s what most people understand. An artist can also be selectable, which means that the artist will receive the on_activated() callback when double clicked. Finally, an artist can be highlightable, which means that a highlight is drawn
on the artist whenever the mouse passes over. Typically, highlightable artists will also be
selectable, but that is left up to the user. So, basically there are four attributes that can be
set by the user on a per-artist basis:

- highlightable
- selectable
- moveable
- resizeable

To be moveable (draggable) or resizeable, the object that is the target of the mixin must
support the following protocols:

- get_pixel_position_ll(self)
- get_pixel_size(self)
- set_pixel_position_and_size(self, x, y, sx, sy)

Note that nonresizeable objects are free to ignore the sx and sy parameters. To be high-
lightable, the object that is the target of the mixin must also support the following protocol:

- get_highlight(self)

Which returns a list of artists that will be used to draw the highlight.

If the object that is the target of the mixin is not an matplotlib artist, the following protocols
must also be implemented. Doing so is usually fairly trivial, as there has to be an artist
somewhere that is being drawn. Typically your object would just route these calls to that
artist.

- get_figure(self)
- get_axes(self)
- contains(self, event)
- set_animated(self, flag)
- draw(self, renderer)
- get_visible(self)

The following notifications are called on the artist, and the artist can optionally implement
these.

- on_select_begin(self)
- on_select_end(self)
- on_drag_begin(self)
- on_drag_end(self)
- on_activated(self)
- on_highlight(self)
- on_right_click(self, event)
- on_left_click(self, event)
- on_middle_click(self, event)
- on_context_click(self, event)
- on_key_up(self, event)
• on_key_down(self, event)

The following notifications are called on the canvas, if no interactive artist handles the event:

• on_press(self, event)
• on_left_click(self, event)
• on_middle_click(self, event)
• on_right_click(self, event)
• on_context_click(self, event)
• on_key_up(self, event)
• on_key_down(self, event)

The following functions, if present, can be used to modify the behavior of the interactive object:

• press_filter(self, event)  # determines if the object wants to have the press event routed to it
• handle_unpicked_cursor()  # can be used by the object to set a cursor as the cursor passes over the object when it is unpicked.

Supports multiple canvases, maintaining a drag lock, motion notifier, and a global “enabled” flag per canvas. Supports fixed aspect ratio resizings by holding the shift key during the resize.

Known problems:

• Zorder is not obeyed during the selection/drag operations. Because of the blit technique used, I do not believe this can be fixed. The only way I can think of is to search for all artists that have a zorder greater then me, set them all to animated, and then redraw them all on top during each drag refresh. This might be very slow; need to try.

• the mixin only works for wx backends because of two things: 1) the cursors are hard-coded, and 2) there is a call to wx.GetMousePosition() Both of these shortcomings are reasonably fixed by having each backend supply these things.

36.3.7 Backward compatibility

No problems with backward compatibility, although once this is in place, it would be appropriate to obsolete some of the existing interactive functions (like legend.draggable())

36.3.8 Alternatives

None that I know of.

36.4 MEP10: Docstring consistency

• Status
• Branches and Pull requests
• Abstract
• Detailed description
  - Numpy docstring format
  - Cross references
  - Overriding signatures
  - Linking rather than duplicating
  - autosummary extension
  - Examples linking to relevant documentation
  - Documentation using help() vs a browser
• Implementation
• Backward compatibility
• Alternatives

36.4.1 Status

Progress
This is still an on-going effort

36.4.2 Branches and Pull requests

36.4.3 Abstract

matplotlib has a great deal of inconsistency between docstrings. This not only makes the docs harder to read, but it is harder on contributors, because they don’t know which specifications to follow. There should be a clear docstring convention that is followed consistently.

The organization of the API documentation is difficult to follow. Some pages, such as pyplot and axes, are enormous and hard to browse. There should instead be short summary tables that link to detailed documentation. In addition, some of the docstrings themselves are quite long and contain redundant information.

Building the documentation takes a long time and uses a make.py script rather than a Makefile.

36.4.4 Detailed description

There are number of new tools and conventions available since matplotlib started using Sphinx that make life easier. The following is a list of proposed changes to docstrings, most of which involve these new features.
Numpy docstring format

**Numpy docstring format:** This format divides the docstring into clear sections, each having different parsing rules that make the docstring easy to read both as raw text and as HTML. We could consider alternatives, or invent our own, but this is a strong choice, as it’s well used and understood in the Numpy/Scipy community.

Cross references

Most of the docstrings in matplotlib use explicit “roles” when linking to other items, for example: :func:`myfunction`. As of Sphinx 0.4, there is a “default_role” that can be set to “obj”, which will polymorphically link to a Python object of any type. This allows one to write `myfunction` instead. This makes docstrings much easier to read and edit as raw text. Additionally, Sphinx allows for setting a current module, so links like `~matplotlib.axes.Axes.set_xlim` could be written as `~axes.Axes.set_xlim`.

Overriding signatures

Many methods in matplotlib use the *args and **kwargs syntax to dynamically handle the keyword arguments that are accepted by the function, or to delegate on to another function. This, however, is often not useful as a signature in the documentation. For this reason, many matplotlib methods include something like:

```python
def annotate(self, *args, **kwargs):
    """
    Create an annotation: a piece of text referring to a data point.

    Call signature:

    annotate(s, xy, xytext=None, xycoords='data',
             textcoords='data', arrowprops=None, **kwargs)
    """
```

This can’t be parsed by Sphinx, and is rather verbose in raw text. As of Sphinx 1.1, if the autodoc_docstring_signature config value is set to True, Sphinx will extract a replacement signature from the first line of the docstring, allowing this:

```python
def annotate(self, *args, **kwargs):
    """
    annotate(s, xy, xytext=None, xycoords='data',
             textcoords='data', arrowprops=None, **kwargs)
    Create an annotation: a piece of text referring to a data point.
    """
```

The explicit signature will replace the actual Python one in the generated documentation.
Linking rather than duplicating

Many of the docstrings include long lists of accepted keywords by interpolating things into the docstring at load time. This makes the docstrings very long. Also, since these tables are the same across many docstrings, it inserts a lot of redundant information in the docs - particularly a problem in the printed version.

These tables should be moved to docstrings on functions whose only purpose is for help. The docstrings that refer to these tables should link to them, rather than including them verbatim.

autosummary extension

The Sphinx autosummary extension should be used to generate summary tables, that link to separate pages of documentation. Some classes that have many methods (e.g. `Axes.axes`) should be documented with one method per page, whereas smaller classes should have all of their methods together.

Examples linking to relevant documentation

The examples, while helpful at illustrating how to use a feature, do not link back to the relevant docstrings. This could be addressed by adding module-level docstrings to the examples, and then including that docstring in the parsed content on the example page. These docstrings could easily include references to any other part of the documentation.

Documentation using help() vs a browser

Using Sphinx markup in the source allows for good-looking docs in your browser, but the markup also makes the raw text returned using help() look terrible. One of the aims of improving the docstrings should be to make both methods of accessing the docs look good.

36.4.5 Implementation

1. The numpydoc extensions should be turned on for matplotlib. There is an important question as to whether these should be included in the matplotlib source tree, or used as a dependency. Installing Numpy is not sufficient to get the numpydoc extensions - it's a separate install procedure. In any case, to the extent that they require customization for our needs, we should endeavor to submit those changes upstream and not fork them.

2. Manually go through all of the docstrings and update them to the new format and conventions. Updating the cross references (from `:func:`myfunc` to `func`) may be able to be semi-automated. This is a lot of busy work, and perhaps this labor should be divided on a per-module basis so no single developer is over-burdened by it.

3. Reorganize the API docs using autosummary and sphinx-autogen. This should hopefully have minimal impact on the narrative documentation.

4. Modify the example page generator (`gen_rst.py`) so that it extracts the module docstring from the example and includes it in a non-literal part of the example page.

5. Use sphinx-quickstart to generate a new-style Sphinx Makefile. The following features in the current make.py will have to be addressed in some other way:
• Copying of some static content
• Specifying a “small” build (only low-resolution PNG files for examples)

Steps 1, 2, and 3 are interdependent. 4 and 5 may be done independently, though 5 has some dependency on 3.

### 36.4.6 Backward compatibility

As this mainly involves docstrings, there should be minimal impact on backward compatibility.

### 36.4.7 Alternatives

None yet discussed.

### 36.5 MEP11: Third-party dependencies

This MEP attempts to improve the way in which third-party dependencies in matplotlib are handled.

#### 36.5.1 Status

**Completed** – needs to be merged

#### 36.5.2 Branches and Pull requests

#1157: Use automatic dependency resolution
#1290: Debundle pyparsing
#1261: Update six to 1.2
36.5.3 Abstract

One of the goals of matplotlib has been to keep it as easy to install as possible. To that end, some third-party dependencies are included in the source tree and, under certain circumstances, installed alongside matplotlib. This MEP aims to resolve some problems with that approach, bring some consistency, while continuing to make installation convenient.

At the time that was initially done, setuptools, easy_install and PyPI were not mature enough to be relied on. However, at present, we should be able to safely leverage the “modern” versions of those tools, distribute and pip.

While matplotlib has dependencies on both Python libraries and C/C++ libraries, this MEP addresses only the Python libraries so as to not confuse the issue. C libraries represent a larger and mostly orthogonal set of problems.

36.5.4 Detailed description

matplotlib depends on the following third-party Python libraries:

• Numpy
• dateutil (pure Python)
• pytz (pure Python)
• six – required by dateutil (pure Python)
• pyparsing (pure Python)
• PIL (optional)
• GUI frameworks: pygtk, gobject, tkinter, PySide, PyQt4, wx (all optional, but one is required for an interactive GUI)

Current behavior

When installing from source, a git checkout or pip:

• setup.py attempts to import numpy. If this fails, the installation fails.
• For each of dateutil, pytz and six, setup.py attempts to import them (from the top-level namespace). If that fails, matplotlib installs its local copy of the library into the top-level namespace.
• pyparsing is always installed inside of the matplotlib namespace.

This behavior is most surprising when used with pip, because no pip dependency resolution is performed, even though it is likely to work for all of these packages.

The fact that pyparsing is installed in the matplotlib namespace has reportedly (#1290) confused some users into thinking it is a matplotlib-related module and import it from there rather than the top-level.

When installing using the Windows installer, dateutil, pytz and six are installed at the top-level always, potentially overwriting already installed copies of those libraries.

TODO: Describe behavior with the OS-X installer.

When installing using a package manager (Debian, RedHat, MacPorts etc.), this behavior actually does the right thing, and there are no special patches in the matplotlib packages to...
deal with the fact that we handle dateutil, pytz and six in this way. However, care should be taken that whatever approach we move to continues to work in that context.

Maintaining these packages in the matplotlib tree and making sure they are up-to-date is a maintenance burden. Advanced new features that may require a third-party pure Python library have a higher barrier to inclusion because of this burden.

Desired behavior

Third-party dependencies are downloaded and installed from their canonical locations by leveraging pip, distribute and PyPI.

dateutil, pytz, and pyparsing should be made into optional dependencies – though obviously some features would fail if they aren’t installed. This will allow the user to decide whether they want to bother installing a particular feature.

36.5.5 Implementation

For installing from source, and assuming the user has all of the C-level compilers and dependencies, this can be accomplished fairly easily using distribute and following the instructions here. The only anticipated change to the matplotlib library code will be to import pyparsing from the top-level namespace rather than from within matplotlib. Note that distribute will also allow us to remove the direct dependency on six, since it is, strictly speaking, only a direct dependency of dateutil.

For binary installations, there are a number of alternatives (here ordered from best/hardest to worst/easiest):

1. The distutils wininst installer allows a post-install script to run. It might be possible to get this script to run pip to install the other dependencies. (See this thread for someone who has trod that ground before).

2. Continue to ship dateutil, pytz, six and pyparsing in our installer, but use the post-install-script to install them only if they can not already be found.

3. Move all of these packages inside a (new) matplotlib.extern namespace so it is clear for outside users that these are external packages. Add some conditional imports in the core matplotlib codebase so dateutil (at the top-level) is tried first, and failing that matplotlib.extern.dateutil is used.

2 and 3 are undesirable as they still require maintaining copies of these packages in our tree – and this is exacerbated by the fact that they are used less – only in the binary installers. None of these 3 approaches address Numpy, which will still have to be manually installed using an installer.

TODO: How does this relate to the Mac OS-X installer?

36.5.6 Backward compatibility

At present, matplotlib can be installed from source on a machine without the third party dependencies and without an internet connection. After this change, an internet connection (and a working PyPI) will be required to install matplotlib for the first time. (Subsequent matplotlib updates or development work will run without accessing the network).
36.5.7 Alternatives

Distributing binary eggs doesn’t feel like a usable solution. That requires getting easy_install installed first, and Windows users generally prefer the well known exe or msi installer that works out of the box.

36.6 MEP12: Improve Gallery and Examples

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
  - Gallery sections
  - Clean up guidelines
    * Additional suggestions
- **Backward compatibility**
- **Alternatives**
  - Tags

36.6.1 Status

**Progress**

Initial changes added in 1.3. Conversion of the gallery is on-going. 29 September 2015 - The last pylab_examples where pylab is imported has been converted over to use matplotlib pyplot and numpy.

36.6.2 Branches and Pull requests

#1623, #1924, #2181

PR #2474 <https://github.com/matplotlib/matplotlib/pull/2474> _ demonstrates a single example being cleaned up and moved to the appropriate section.

36.6.3 Abstract

Reorganizing the matplotlib plot gallery would greatly simplify navigation of the gallery. In addition, examples should be cleaned-up and simplified for clarity.
36.6.4 Detailed description

The matplotlib gallery was recently set up to split examples up into sections. As discussed in that PR\(^1\), the current example sections (api, pylab_examples) aren’t terribly useful to users: New sections in the gallery would help users find relevant examples.

These sections would also guide a cleanup of the examples: Initially, all the current examples would remain and be listed under their current directories. Over time, these examples could be cleaned up and moved into one of the new sections.

This process allows users to easily identify examples that need to be cleaned up; i.e. anything in the api and pylab_examples directories.

36.6.5 Implementation

1. Create new gallery sections. [Done]
2. Clean up examples and move them to the new gallery sections (over the course of many PRs and with the help of many users/developers). [In progress]

Gallery sections

The naming of sections is critical and will guide the clean-up effort. The current sections are:

- Lines, bars, and markers (more-or-less 1D data)
- Shapes and collections
- Statistical plots
- Images, contours, and fields
- Pie and polar charts: Round things
- Color
- Text, labels, and annotations
- Ticks and spines
- Subplots, axes, and figures
- Specialty plots (e.g., sankey, radar, tornado)
- Showcase (plots with tweaks to make them publication-quality)

These names are certainly up for debate. As these sections grow, we should reevaluate them and split them up as necessary.

Clean up guidelines

The current examples in the api and pylab_examples sections of the gallery would remain in those directories until they are cleaned up. After clean-up, they would be moved to one of the new gallery sections described above. “Clean-up” should involve:

\(^1\) [https://github.com/matplotlib/matplotlib/pull/714](https://github.com/matplotlib/matplotlib/pull/714)
• **sphinx-gallery docstrings**: a title and a description of the example formatted as follows, at the top of the example:

```""
===============
Colormaps alter your perception
===============

Here I plot the function

.. math:: f(x, y) = \sin(x) + \cos(y)

with different colormaps. Look at how colormaps alter your perception!
""
```

• **PEP8** clean-ups (running **flake8**, or a similar checker, is highly recommended)

• Commented-out code should be removed.

• Replace uses of **pylab** interface with **pyplot** (+ **numpy**, etc.). See **c25ef1e**

• Remove shebang line, e.g.:

  ```
  #!/usr/bin/env python
  ```

• Use consistent imports. In particular:

  ```python
  import numpy as np
  import matplotlib.pyplot as plt
  ```

  Avoid importing specific functions from these modules (e.g. **from numpy import sin**)

• Each example should focus on a specific feature (excluding **showcase** examples, which will show more “polished” plots). Tweaking unrelated to that feature should be removed. See **f7b2217**, **e57b5fc**, and **1458aa8**

Use of **pylab** should be demonstrated/discussed on a dedicated help page instead of the gallery examples.

**Note**: When moving an existing example, you should search for references to that example. For example, the API documentation for **axes.py** and **pyplot.py** may use these examples to generate plots. Use your favorite search tool (e.g., grep, ack, **grin**, **pss**) to search the matplotlib package. See **2dc9a46** and **aa6b410**

**Additional suggestions**

• Provide links (both ways) between examples and API docs for the methods/objects used. (issue **#2222**)

• Use **plt.subplots** (note trailing “s”) in preference over **plt.subplot**.

• Rename the example to clarify it’s purpose. For example, the most basic demo of **imshow** might be **imshow_demo.py**, and one demonstrating different interpolation settings would be **imshow_demo_interpolation.py** (**not imshow_demo2.py**).

• Split up examples that try to do too much. See **5099675** and **fc2ab07**

• Delete examples that don’t show anything new.
• Some examples exercise esoteric features for unit testing. These tweaks should be moved out of the gallery to an example in the unit directory located in the root directory of the package.

• Add plot titles to clarify intent of the example. See bd2b13c

36.6.6 Backward compatibility

The website for each Matplotlib version is readily accessible, so users who want to refer to old examples can still do so.

36.6.7 Alternatives

Tags

Tagging examples will also help users search the example gallery. Although tags would be a big win for users with specific goals, the plot gallery will remain the entry point to these examples, and sections could really help users navigate the gallery. Thus, tags are complementary to this reorganization.

36.7.3 Abstract

Wrap all of the matplotlib getter and setter methods with python properties, allowing them to be read and written like class attributes.

36.7.4 Detailed description

Currently matplotlib uses getter and setter functions (usually prefixed with get_ and set_, respectively) for reading and writing data related to classes. However, since 2.6 python supports properties, which allow such setter and getter functions to be accessed as though they were attributes. This proposal would implement all existing setter and getter methods as properties.

36.7.5 Implementation

1. All existing getter and setter methods will need to have two aliases, one with the get_ or set_ prefix and one without. Getter methods that currently lack prefixes should be recording in a text file.
2. Classes should be reorganized so setter and getter methods are sequential in the code, with getter methods first.
3. Getter and setter methods the provide additional optional optional arguments should have those arguments accessible in another manner, either as additional getter or setter methods or attributes of other classes. If those classes are not accessible, getters for them should be added.
4. Property decorators will be added to the setter and getter methods without the prefix. Those with the prefix will be marked as deprecated.
5. Docstrings will need to be rewritten so the getter with the prefix has the current docstring and the getter without the prefix has a generic docstring appropriate for an attribute.
6. Automatic alias generation will need to be modified so it will also create aliases for the properties.
7. All instances of getter and setter method calls will need to be changed to attribute access.
8. All setter and getter aliases with prefixes will be removed

The following steps can be done simultaneously: 1, 2, and 3; 4 and 5; 6 and 7. Only the following steps must be done in the same release: 4, 5, and 6. All other changes can be done in separate releases. 8 should be done several major releases after everything else.
36.7.6 Backward compatibility

All existing getter methods that do not have a prefix (such as get_) will need to be changed from function calls to attribute access. In most cases this will only require removing the parenthesis.

setter and getter methods that have additional optional arguments will need to have those arguments implemented in another way, either as a separate property in the same class or as attributes or properties of another class.

Cases where the setter returns a value will need to be changed to using the setter followed by the getter.

Cases where there are set_ATTR_on() and set_ATTR_off() methods will be changed to ATTR_on properties.

36.7.7 Examples

axes.Axes.set_axis_off/set_axis_on

Current implementation:

axes.Axes.set_axis_off()
axes.Axes.set_axis_on()

New implementation:

True = axes.Axes.axis_on
False = axes.Axes.axis_on
axes.Axes.axis_on = True
axes.Axes.axis_on = False

axes.Axes.get_xlim/set_xlim and get_autoscalex_on/set_autoscalex_on

Current implementation:

[left, right] = axes.Axes.get_xlim()
auto = axes.Axes.get_autoscalex_on()

[left, right] = axes.Axes.set_xlim(left=left, right=right, emit=emit, auto=auto)
[left, right] = axes.Axes.set_xlim(left=left, right=None, emit=emit, auto=auto)
[left, right] = axes.Axes.set_xlim(left=None, right=right, emit=emit, auto=auto)
[left, right] = axes.Axes.set_xlim(left=left, emit=emit, auto=auto)
[left, right] = axes.Axes.set_xlim(right=right, emit=emit, auto=auto)

axes.Axes.set_autoscalex_on(auto)

New implementation:

[left, right] = axes.Axes.axes_xlim
auto = axes.Axes.autoscalex_on
**axes.Axes.axes_xlim**

- `axes.Axes.axes_xlim = [left, right]`
- `axes.Axes.axes_xlim = [left, None]`
- `axes.Axes.axes_xlim = [None, right]`
- `axes.Axes.axes_xlim[0] = left`

- `axes.Axes.autoscalex_on = auto`
- `axes.Axes.emit_xlim = emit`

**axes.Axes.get_title/set_title**

Current implementation:

```python
string = axes.Axes.get_title()
axes.Axes.set_title(string, fontdict=fontdict, **kwargs)
```

New implementation:

```python
string = axes.Axes.title
string = axes.Axes.title_text.text

text.Text = axes.Axes.title_text
text.Text.<attribute> = attribute
text.Text.fontdict = fontdict

axes.Axes.title = string
axes.Axes.title = text.Text
axes.Axes.title_text = string
axes.Axes.title_text = text.Text
```

**axes.Axes.get_ticklabels/set_ticklabels**

Current implementation:

```python
[text.Text] = axes.Axes.get_ticklabels()
[text.Text] = axes.Axes.get_ticklabels(minor=False)
[text.Text] = axes.Axes.get_ticklabels(minor=True)
[text.Text] = axes.Axes([string], fontdict=None, **kwargs)
[text.Text] = axes.Axes([string], fontdict=None, minor=False, **kwargs)
[text.Text] = axes.Axes([string], fontdict=None, minor=True, **kwargs)
```

New implementation:

```python
[text.Text] = axes.Axes.ticklabels
[text.Text] = axes.Axes.xminorticklabels
axes.ticklabels = [string]
axes.Axes.xminorticklabels = [string]
axes.Axes.ticklabels = [text.Text]
```
36.7.8 Alternatives

Instead of using decorators, it is also possible to use the property function. This would change the procedure so that all getter methods that lack a prefix will need to be renamed or removed. This makes handling docstrings more difficult and harder to read.

It is not necessary to deprecate the setter and getter methods, but leaving them in will complicate the code.

This could also serve as an opportunity to rewrite or even remove automatic alias generation.

Another alternate proposal:

Convert `set_xlim, set_xlabel, set_title, etc. to xlim, xlabel, title,...` to make the transition from `plt` functions to `axes` methods significantly simpler. These would still be methods, not properties, but it’s still a great usability enhancement while retaining the interface.

36.8 MEP14: Text handling

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
- **Backward compatibility**
- **Alternatives**

36.8.1 Status

- **Discussion**

36.8.2 Branches and Pull requests

Issue #253 demonstrates a bug where using the bounding box rather than the advance width of text results in misaligned text. This is a minor point in the grand scheme of things, but it should be addressed as part of this MEP.

36.8.3 Abstract

By reorganizing how text is handled, this MEP aims to:

- improve support for Unicode and non-ltr languages
- improve text layout (especially multi-line text)
• allow support for more fonts, especially non-Apple-format TrueType fonts and OpenType fonts.
• make the font configuration easier and more transparent

36.8.4 Detailed description

Text layout
At present, matplotlib has two different ways to render text: “built-in” (based on FreeType and our own Python code), and “usetex” (based on calling out to a TeX installation). Adjunct to the “built-in” renderer there is also the Python-based “mathtext” system for rendering mathematical equations using a subset of the TeX language without having a TeX installation available. Support for these two engines is strewn about many source files, including every backend, where one finds clauses like

```
if rcParams['text.usetex']:
    # do one thing
else:
    # do another
```

Adding a third text rendering approach (more on that later) would require editing all of these places as well, and therefore doesn’t scale.

Instead, this MEP proposes adding a concept of “text engines”, where the user could select one of many different approaches for rendering text. The implementations of each of these would be localized to their own set of modules, and not have little pieces around the whole source tree.

Why add more text rendering engines? The “built-in” text rendering has a number of shortcomings.

• It only handles right-to-left languages, and doesn’t handle many special features of Unicode, such as combining diacriticals.
• The multiline support is imperfect and only supports manual line-breaking – it can not break up a paragraph into lines of a certain length.
• It also does not handle inline formatting changes in order to support something like Markdown, reStructuredText or HTML. (Though rich-text formatting is contemplated in this MEP, since we want to make sure this design allows it, the specifics of a rich-text formatting implementation is outside of the scope of this MEP.)

Supporting these things is difficult, and is the “full-time job” of a number of other projects:

• pango/harfbuzz
• QtTextLayout
• Microsoft DirectWrite
• Apple Core Text

Of the above options, it should be noted that harfbuzz is designed from the start as a cross platform option with minimal dependencies, so therefore is a good candidate for a single option to support.

Additionally, for supporting rich text, we could consider using WebKit, and possibly whether than represents a good single cross-platform option. Again, however, rich text formatting is outside of the scope of this project.

Rather than trying to reinvent the wheel and add these features to matplotlib’s “built-in” text renderer, we should provide a way to leverage these projects to get more powerful text
layout. The “built-in” renderer will still need to exist for reasons of ease of installation, but its feature set will be more limited compared to the others. [TODO: This MEP should clearly decide what those limited features are, and fix any bugs to bring the implementation into a state of working correctly in all cases that we want it to work. I know @leejjoon has some thoughts on this.]

**Font selection**

Going from an abstract description of a font to a file on disk is the task of the font selection algorithm – it turns out to be much more complicated than it seems at first.

The “built-in” and “usetex” renderers have very different ways of handling font selection, given their different technologies. TeX requires the installation of TeX-specific font packages, for example, and can not use TrueType fonts directly. Unfortunately, despite the different semantics for font selection, the same set of font properties are used for each. This is true of both the `FontProperties` class and the font-related `rcParams` (which basically share the same code underneath). Instead, we should define a core set of font selection parameters that will work across all text engines, and have engine-specific configuration to allow the user to do engine-specific things when required. For example, it is possible to directly select a font by name in the “built-in” using `font.family`, but the same is not possible with “usetex”. It may be possible to make it easier to use TrueType fonts by using XeTeX, but users will still want to use the traditional metafonts through TeX font packages. So the issue still stands that different text engines will need engine-specific configuration, and it should be more obvious to the user which configuration will work across text engines and which are engine-specific.

Note that even excluding “usetex”, there are different ways to find fonts. The default is to use the font list cache in `font_manager.py` which matches fonts using our own algorithm based on the CSS font matching algorithm. It doesn’t always do the same thing as the native font selection algorithms on Linux (`fontconfig`), Mac and Windows, and it doesn’t always find all of the fonts on the system that the OS would normally pick up. However, it is cross-platform, and always finds the fonts that ship with matplotlib. The Cairo and MacOSX backends (and presumably a future HTML5-based backend) currently bypass this mechanism and use the OS-native ones. The same is true when not embedding fonts in SVG, PS or PDF files and opening them in a third-party viewer. A downside there is that (at least with Cairo, need to confirm with MacOSX) they don’t always find the fonts we ship with matplotlib. (It may be possible to add the fonts to their search path, though, or we may need to find a way to install our fonts to a location the OS expects to find them).

There are also special modes in the PS and PDF to only use the core fonts that are always available to those formats. There, the font lookup mechanism must only match against those fonts. It is unclear whether the OS-native font lookup systems can handle this case.

There is also experimental support for using `fontconfig` for font selection in matplotlib, turned off by default. `fontconfig` is the native font selection algorithm on Linux, but is also cross-platform and works well on the other platforms (though obviously is an additional dependency there).

Many of the text layout libraries proposed above (pango, QtTextLayout, DirectWrite and CoreText etc.) insist on using the font selection library from their own ecosystem.

All of the above seems to suggest that we should move away from our self-written font selection algorithm and use the native APIs where possible. That’s what Cairo and MacOSX backends already want to use, and it will be a requirement of any complex text layout library. On Linux, we already have the bones of a `fontconfig` implementation (which could also be accessed through pango). On Windows and Mac we may need to write custom wrappers. The nice thing is that the API for font lookup is relatively small, and essentially consist of “given a dictionary of font properties, give me a matching font file”.

36.8. MEP14: Text handling
Font subsetting

Font subsetting is currently handled using ttconv. ttconv was a standalone commandline utility for converting TrueType fonts to subsetted Type 3 fonts (among other features) written in 1995, which matplotlib (well, I) forked in order to make it work as a library. It only handles Apple-style TrueType fonts, not ones with the Microsoft (or other vendor) encodings. It doesn’t handle OpenType fonts at all. This means that even though the STIX fonts come as .otf files, we have to convert them to .ttf files to ship them with matplotlib. The Linux packagers hate this – they’d rather just depend on the upstream STIX fonts. ttconv has also been shown to have a few bugs that have been difficult to fix over time.

Instead, we should be able to use FreeType to get the font outlines and write our own code (probably in Python) to output subsetted fonts (Type 3 on PS and PDF and paths on SVG). Freetype, as a popular and well-maintained project, handles a wide variety of fonts in the wild. This would remove a lot of custom C code, and remove some code duplication between backends.

Note that subsetting fonts this way, while the easiest route, does lose the hinting in the font, so we will need to continue, as we do now, provide a way to embed the entire font in the file where possible.

Alternative font subsetting options include using the subsetting built-in to Cairo (not clear if it can be used without the rest of Cairo), or using fontforge (which is a heavy and not terribly cross-platform dependency).

Freetype wrappers

Our FreeType wrapper could really use a reworking. It defines its own image buffer class (when a Numpy array would be easier). While FreeType can handle a huge diversity of font files, there are limitations to our wrapper that make it much harder to support non-Apple-vendor TrueType files, and certain features of OpenType files. (See #2088 for a terrible result of this, just to support the fonts that ship with Windows 7 and 8). I think a fresh rewrite of this wrapper would go a long way.

Text anchoring and alignment and rotation

The handling of baselines was changed in 1.3.0 such that the backends are now given the location of the baseline of the text, not the bottom of the text. This is probably the correct behavior, and the MEP refactoring should also follow this convention.

In order to support alignment on multi-line text, it should be the responsibility of the (proposed) text engine to handle text alignment. For a given chunk of text, each engine calculates a bounding box for that text and the offset of the anchor point within that box. Therefore, if the va of a block was “top”, the anchor point would be at the top of the box.

Rotating of text should always be around the anchor point. I’m not sure that lines up with current behavior in matplotlib, but it seems like the sanest/least surprising choice. [This could be revisited once we have something working]. Rotation of text should not be handled by the text engine – that should be handled by a layer between the text engine and the rendering backend so it can be handled in a uniform way. [I don’t see any advantage to rotation being handled by the text engines individually...]

There are other problems with text alignment and anchoring that should be resolved as part of this work. [TODO: enumerate these].

Other minor problems to fix

The mathtext code has backend-specific code – it should instead provide its output as just another text engine. However, it’s still desirable to have mathtext layout inserted as part of a larger layout performed by another text engine, so it should be possible to do this. It’s
an open question whether embedding the text layout of an arbitrary text engine in another
should be possible.

The text mode is currently set by a global rcParam ("text.usetex") so it’s either all on or all off.
We should continue to have a global rcParam to choose the text engine ("text.layout_engine"),
but it should under the hood be an overridable property on the Text object, so the same figure
can combine the results of multiple text layout engines if necessary.

36.8.5 Implementation

A concept of a “text engine” will be introduced. Each text engine will implement a number of
abstract classes. The TextFont interface will represent text for a given set of font properties.
It isn’t necessarily limited to a single font file – if the layout engine supports rich text, it
may handle a number of font files in a family. Given a TextFont instance, the user can get a
TextLayout instance, which represents the layout for a given string of text in a given font. From
a TextLayout, an iterator over TextSpans is returned so the engine can output raw editable text
using as few spans as possible. If the engine would rather get individual characters, they can
be obtained from the TextSpan instance:

class TextFont(TextFontBase):
    def __init__(self, font_properties):
        """
        Create a new object for rendering text using the given font properties.
        """
        pass

    def get_layout(self, s, ha, va):
        """
        Get the TextLayout for the given string in the given font and
        the horizontal (left, center, right) and verticalalignment (top,
        center, baseline, bottom)
        """
        pass

class TextLayout(TextLayoutBase):
    def get_metrics(self):
        """
        Return the bounding box of the layout, anchored at (0, 0).
        """
        pass

    def get_spans(self):
        """
        Returns an iterator over the spans of different in the layout.
        This is useful for backends that want to editable raw text as
        individual lines. For rich text where the font may change,
        each span of different font type will have its own span.
        """
        pass

    def get_image(self):
        """
        Returns a rasterized image of the text. Useful for raster backends,
        (continues on next page)
like Agg.

In all likelihood, this will be overridden in the backend, as it can be created from get_layout(), but certain backends may want to override it if their library provides it (as freetype does).

```python
pass
```

```python
def get_rectangles(self):
    ""
    Returns an iterator over the filled black rectangles in the layout. Used by TeX and mathtext for drawing, for example, fraction lines.
    ""
    pass
```

```python
def get_path(self):
    ""
    Returns a single Path object of the entire laid out text.

    [Not strictly necessary, but might be useful for textpath functionality]
    ""
    pass
```

```python
class TextSpan(TextSpanBase):
    x, y  # Position of the span -- relative to the text layout as a whole
    # where (0, 0) is the anchor. y is the baseline of the span.
    fontfile  # The font file to use for the span
    text  # The text content of the span

    def get_path(self):
        pass  # See TextLayout.get_path

    def get_chars(self):
        ""
        Returns an iterator over the characters in the span.
        ""
        pass
```

```python
class TextChar(TextCharBase):
    x, y  # Position of the character -- relative to the text layout as
    # a whole, where (0, 0) is the anchor. y is in the baseline
    # of the character.
    codepoint  # The unicode code point of the character -- only for informational
    # purposes, since the mapping of codepoint to glyph_id may have been
    # handled in a complex way by the layout engine. This is an int
    # to avoid problems on narrow Unicode builds.
    glyph_id  # The index of the glyph within the font
    fontfile  # The font file to use for the char

    def get_path(self):
        ""
```

(continues on next page)
Get the path for the character.

pass

Graphic backends that want to output subset of fonts would likely build up a file-global dictionary of characters where the keys are (fontname, glyph_id) and the values are the paths so that only one copy of the path for each character will be stored in the file.

Special casing: The “usetex” functionality currently is able to get Postscript directly from TeX to insert directly in a Postscript file, but for other backends, parses a DVI file and generates something more abstract. For a case like this, TextLayout would implement get_spans for most backends, but add get_ps for the Postscript backend, which would look for the presence of this method and use it if available, or fall back to get_spans. This kind of special casing may also be necessary, for example, when the graphics backend and text engine belong to the same ecosystem, e.g. Cairo and Pango, or MacOSX and CoreText.

There are three main pieces to the implementation:

1) Rewriting the freetype wrapper, and removing ttconv.
   a) Once (1) is done, as a proof of concept, we can move to the upstream STIX .otf fonts
   b) Add support for web fonts loaded from a remote URL. (Enabled by using freetype for font subsetting).

2) Refactoring the existing “builtin” and “usetex” code into separate text engines and to follow the API outlined above.

3) Implementing support for advanced text layout libraries.

(1) and (2) are fairly independent, though having (1) done first will allow (2) to be simpler. (3) is dependent on (1) and (2), but even if it doesn’t get done (or is postponed), completing (1) and (2) will make it easier to move forward with improving the “builtin” text engine.

36.8.6 Backward compatibility

The layout of text with respect to its anchor and rotation will change in hopefully small, but improved, ways. The layout of multiline text will be much better, as it will respect horizontal alignment. The layout of bidirectional text or other advanced Unicode features will now work inherently, which may break some things if users are currently using their own workarounds.

Fonts will be selected differently. Hacks that used to sort of work between the “builtin” and “usetex” text rendering engines may no longer work. Fonts found by the OS that weren’t previously found by matplotlib may be selected.

36.8.7 Alternatives

TBD
36.9 MEP15 - Fix axis autoscaling when limits are specified for one axis only

- Status
- Branches and Pull requests
- Abstract
- Detailed description
- Implementation
- Backward compatibility
- Alternatives

36.9.1 Status

Discussion

36.9.2 Branches and Pull requests

None so far.

36.9.3 Abstract

When one axis of a 2-dimensional plot if overridden via $\texttt{xlim}$ or $\texttt{ylim}$, automatic scaling of the remaining axis should be based on the data that falls within the specified limits of the first axis.

36.9.4 Detailed description

When axis limits for a 2-D plot are specified for one axis only (via $\texttt{xlim}$ or $\texttt{ylim}$), matplotlib currently does not currently rescale the other axis. The result is that the displayed curves or symbols may be compressed into a tiny portion of the available area, so that the final plot conveys much less information than it would with appropriate axis scaling.

The proposed change of behavior would make matplotlib choose the scale for the remaining axis using only the data that falls within the limits for the axis where limits were specified.

36.9.5 Implementation

I don't know enough about the internals of matplotlib to be able to suggest an implementation.
36.9.6 Backward compatibility

From the standpoint of software interfaces, there would be no break in backward compatibility. Some outputs would be different, but if the user truly desires the previous behavior, he/she can achieve this by overriding the axis scaling for both axes.

36.9.7 Alternatives

The only alternative that I can see is to maintain the status quo.

36.10 MEP19: Continuous Integration

36.10.1 Status

Completed

36.10.2 Branches and Pull requests

36.10.3 Abstract

matplotlib could benefit from better and more reliable continuous integration, both for testing and building installers and documentation.

36.10.4 Detailed description

Current state-of-the-art

Testing

matplotlib currently uses Travis-CI for automated tests. While Travis-CI should be praised for how much it does as a free service, it has a number of shortcomings:

• It often fails due to network timeouts when installing dependencies.
• It often fails for inexplicable reasons.
• build or test products can only be saved from build off of branches on the main repo, not pull requests, so it is often difficult to “post mortem” analyse what went wrong. This is particularly frustrating when the failure can not be subsequently reproduced locally.
• It is not extremely fast. matplotlib’s cpu and memory requirements for testing are much higher than the average Python project.
• It only tests on Ubuntu Linux, and we have only minimal control over the specifics of the platform. It can be upgraded at any time outside of our control, causing unexpected delays at times that may not be convenient in our release schedule.

On the plus side, Travis-CI’s integration with github – automatically testing all pending pull requests – is exceptional.

Builds
There is no centralized effort for automated binary builds for matplotlib. However, the following disparate things are being done [If the authors mentioned here could fill in detail, that would be great!]:

- @sandrotosi: builds Debian packages
- @takluyver: Has automated Ubuntu builds on Launchpad
- @cgohlke: Makes Windows builds (don’t know how automated that is)
- @r-owen: Makes OS-X builds (don’t know how automated that is)

Documentation

Documentation of master is now built by travis and uploaded to http://matplotlib.org/devdocs/index.html

@NelleV, I believe, generates the docs automatically and posts them on the web to chart MEP10 progress.

Peculiarities of matplotlib

matplotlib has complex requirements that make testing and building more taxing than many other Python projects.

- The CPU time to run the tests is quite high. It puts us beyond the free accounts of many CI services (e.g. ShiningPanda)
- It has a large number of dependencies, and testing the full matrix of all combinations is impractical. We need to be clever about what space we test and guarantee to support.

Requirements

This section outlines the requirements that we would like to have.

1. Testing all pull requests by hooking into the Github API, as Travis-CI does
2. Testing on all major platforms: Linux, Mac OS-X, MS Windows (in that order of priority, based on user survey)
3. Retain the last n days worth of build and test products, to aid in post-mortem debugging.
4. Automated nightly binary builds, so that users can test the bleeding edge without installing a complete compilation environment.
5. Automated benchmarking. It would be nice to have a standard benchmark suite (separate from the tests) whose performance could be tracked over time, in different backends and platforms. While this is separate from building and testing, ideally it would run on the same infrastructure.
6. Automated nightly building and publishing of documentation (or as part of testing, to ensure PRs don’t introduce documentation bugs). (This would not replace the static documentation for stable releases as a default).
7. The test systems should be manageable by multiple developers, so that no single person becomes a bottleneck. (Travis-CI’s design does this well – storing build configuration in the git repository, rather than elsewhere, is a very good design.)
8. Make it easy to test a large but sparse matrix of different versions of matplotlib's dependencies. The matplotlib user survey provides some good data as to where to focus our efforts: https://docs.google.com/spreadsheet/ccc?key=0AjrPjTMRTwTdHpQS25pcTZIRWdqX0pNckNSU01sMHc#gid=0

9. Nice to have: A decentralized design so that those with more obscure platforms can publish build results to a central dashboard.

36.10.5 Implementation

This part is yet-to-be-written. However, ideally, the implementation would be a third-party service, to avoid adding system administration to our already stretched time. As we have some donated funds, this service may be a paid one if it offers significant time-saving advantages over free offerings.

36.10.6 Backward compatibility

Backward compatibility is not a major concern for this MEP. We will replace current tools and procedures with something better and throw out the old.

36.10.7 Alternatives

36.10.8 Hangout Notes

CI Infrastructure

- We like Travis and it will probably remain part of our arsenal in any event. The reliability issues are being looked into.
- Enable Amazon S3 uploads of testing products on Travis. This will help with post-mortem of failures (@mdboom is looking into this now).
- We want Mac coverage. The best bet is probably to push Travis to enable it for our project by paying them for a Pro account (since they don’t otherwise allow testing on both Linux and Mac).
- We want Windows coverage. Shining Panda is an option there.
- Investigate finding or building a tool that would collect and synthesize test results from a number of sources and post it to Github using the Github API. This may be of general use to the Scipy community.
- For both Windows and Mac, we should document (or better yet, script) the process of setting up the machine for a build, and how to build binaries and installers. This may require getting information from Russel Owen and Christoph Gohlke. This is a necessary step for doing automated builds, but would also be valuable for a number of other reasons.
The test framework itself

- We should investigate ways to make it take less time
  - Eliminating redundant tests, if possible
  - General performance improvements to matplotlib will help
- We should be covering more things, particularly more backends
- We should have more unit tests, fewer integration tests, if possible

36.11 MEP21: color and cm refactor

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
- **Backward compatibility**
- **Alternatives**

36.11.1 Status

- **Discussion**: This MEP has not commenced yet, but here are some ongoing ideas which may become a part of this MEP:

36.11.2 Branches and Pull requests

36.11.3 Abstract

- **color**
  - tidy up the namespace
  - Define a "Color" class
  - make it easy to convert from one color type to another `hex -> RGB`, `RGB -> hex`, `HSV -> RGB` etc.
  - improve the construction of a colormap - the dictionary approach is archaic and overly complex (though incredibly powerful)
  - make it possible to interpolate between two or more color types in different modes, especially useful for construction of colormaps in HSV space for instance
- **cm**
  - rename the module to something more descriptive - mappables?
Overall, there are a lot of improvements that can be made with matplotlib color handling - managing backwards compatibility will be difficult as there are some badly named variables/modules which really shouldn’t exist - but a clear path and message for migration should be available, with a large amount of focus on this in the API changes documentation.

Progress

36.12.2 Branches and Pull requests

Previous work
- https://github.com/matplotlib/matplotlib/pull/1849
- https://github.com/matplotlib/matplotlib/pull/2557
- https://github.com/matplotlib/matplotlib/pull/2465

Pull Requests:
- Removing the NavigationToolbar classes https://github.com/matplotlib/matplotlib/pull/2740 CLOSED
• Keeping the NavigationToolBar classes https://github.com/matplotlib/matplotlib/pull/2759 CLOSED
• Navigation by events: https://github.com/matplotlib/matplotlib/pull/3652

36.12.3 Abstract

The main goal of this MEP is to make it easier to modify (add, change, remove) the way the user interacts with the figures.

The user interaction with the figure is deeply integrated within the Canvas and Toolbar. Making extremely difficult to do any modification.

This MEP proposes the separation of this interaction into Toolbar, Navigation and Tools to provide independent access and reconfiguration.

This approach will make easier to create and share tools among users. In the far future, we can even foresee a kind of Marketplace for Tools where the most popular can be added into the main distribution.

36.12.4 Detailed description

The reconfiguration of the Toolbar is complex, most of the time it requires a custom backend.

The creation of custom Tools sometimes interferes with the Toolbar, as example see https://github.com/matplotlib/matplotlib/issues/2694 also the shortcuts are hardcoded and again not easily modifiable https://github.com/matplotlib/matplotlib/issues/2699

The proposed solution is to take the actions out of the Toolbar and the shortcuts out of the Canvas. This actions and shortcuts will be in the form of Tools.

A new class Navigation will be the bridge between the events from the Canvas and Toolbar and redirect them to the appropriate Tool.

At the end the user interaction will be divided into three classes:

• NavigationBase: This class is instantiated for each FigureManager and connect the all user interactions with the Tools
• ToolbarBase: This existing class is relegated only as a GUI access to Tools.
• ToolBase: Is the basic definition of Tools.

36.12.5 Implementation

ToolBase(object)

Tools can have a graphical representation as the SubplotTool or not even be present in the Toolbar as Quit

The ToolBase has the following class attributes for configuration at definition time

• keymap = None: Key(s) to be used to trigger the tool
• description = “”: Small description of the tool
• image = None: Image that is used in the toolbar
The following instance attributes are set at instantiation:

- name
- navigation

Methods

- trigger(self, event): This is the main method of the Tool, it is called when the Tool is triggered by:
  * Toolbar button click
  * keypress associated with the Tool Keymap
  * Call to navigation.trigger_tool(name)
- set_figure(self, figure): Set the figure and navigation attributes
- destroy(self, *args): Destroy the Tool graphical interface (if exists)

Available Tools

- ToolQuit
- ToolEnableAllNavigation
- ToolEnableNavigation
- ToolToggleGrid
- ToolToggleFullScreen
- ToolToggleYScale
- ToolToggleXScale
- ToolHome
- ToolBack
- ToolForward
- SaveFigureBase
- ConfigureSubplotsBase

ToolToggleBase(ToolBase)

The ToolToggleBase has the following class attributes for configuration at definition time

- radio_group = None: Attribute to group ‘radio’ like tools (mutually exclusive)
- cursor = None: Cursor to use when the tool is active

The Toggleable Tools, can capture keypress, mouse moves, and mouse button press

It defines the following methods

- enable(self, event): Called by ToolToggleBase.trigger method
- disable(self, event): Called when the tool is untoggled
- toggled : Property True or False

Available Tools

- ToolZoom
- ToolPan
NavigationBase

Defines the following attributes

- canvas:
- keypresslock: Lock to know if the canvas key_press_event is available and process it
- messagemock: Lock to know if the message is available to write

Public methods for User use:

- nav_connect(self, s, func): Connect to to navigation for events
- nav_disconnect(self, cid): Disconnect from navigation event
- message_event(self, message, sender=None): Emit a tool_message_event event
- active_toggle(self): Property The currently toggled tools or None
- get_tool_keymap(self, name): Return a list of keys that are associated with the tool
- set_tool_keymap(self, name, *keys): Set the keys for the given tool
- remove_tool(self, name): Removes tool from the navigation control.
- add_tools(self, tools): Add multiple tools to Navigation
- add_tool(self, name, tool, group=None, position=None): Add a tool to the Navigation
- tool_trigger_event(self, name, sender=None, canvasevent=None, data=None): Trigger a tool and fire the event
- tools(self) Property: Return a dict with available tools with corresponding keymaps, descriptions and objects
- get_tool(self, name): Return the tool object

ToolbarBase

Methods for Backend implementation

- add_toolitem(self, name, group, position, image, description, toggle): Add a toolitem to the toolbar. This method is a callback from tool_added_event (emitted by navigation)
- set_message(self, s): Display a message on toolbar or in status bar
- toggle_toolitem(self, name): Toggle the toolitem without firing event.
- remove_toolitem(self, name): Remove a toolitem from the Toolbar

36.12.6 Backward compatibility

For backward compatibility added a ‘navigation’ key to rcsetup.validate_toolbar, that is used for Navigation classes instantiation instead of the NavigationToolbar classes

With this parameter, it makes it transparent to anyone using the existing backends.
[@pelson comment: This also gives us an opportunity to avoid needing to implement all of this in the same PR - some backends can potentially exist without the new functionality for a short while (but it must be done at some point).]

36.13 MEP23: Multiple Figures per GUI window

- Implementation
  - FigureManagerBase
  - new_figure_manager
  - new_figure_manager_given_figure
  - NavigationBase
- Backward compatibility
- Alternatives

36.13.1 Status

Discussion

36.13.2 Branches and Pull requests

Previous work - https://github.com/matplotlib/matplotlib/pull/2465 To-delete

36.13.3 Abstract

Add the possibility to have multiple figures grouped under the same FigureManager

36.13.4 Detailed description

Under the current structure, every canvas has its own window.

This is and may continue to be the desired method of operation for most use cases.

Sometimes when there are too many figures open at the same time, it is desirable to be able to group these under the same window [see](https://github.com/matplotlib/matplotlib/issues/2194).
The proposed solution modifies FigureManagerBase to contain and manage more than one canvas. The settings parameter `rcParams["backend.multifigure"]` control when the Multifigure behaviour is desired.

**Note**

It is important to note, that the proposed solution, assumes that the [MEP22](https://github.com/matplotlib/matplotlib/wiki/Mep22) is already in place. This is simply because the actual implementation of the Toolbar makes it pretty hard to switch between canvases.

### 36.13.5 Implementation

The first implementation will be done in GTK3 using a Notebook as canvas container.

**FigureManagerBase**

will add the following new methods

- **add_canvas**: To add a canvas to an existing FigureManager object
- **remove_canvas**: To remove a canvas from a FigureManager object, if it is the last one, it will be destroyed
- **move_canvas**: To move a canvas from one FigureManager to another.
- **set_canvas_title**: To change the title associated with a specific canvas container
- **get_canvas_title**: To get the title associated with a specific canvas container
- **get_active_canvas**: To get the canvas that is in the foreground and is subject to the gui events. There is no `set_active_canvas` because the active canvas, is defined when `show` is called on a Canvas object.

**new_figure_manager**

To control which FigureManager will contain the new figures, an extra optional parameter `figuremanager` will be added, this parameter value will be passed to `new_figure_manager_given_figure`

**new_figure_manager_given_figure**

- If `figuremanager` parameter is give, this FigureManager object will be used instead of creating a new one.
- If `rcParams['backend.multifigure']` == True: The last FigureManager object will be used instead of creating a new one.

**NavigationBase**

Modifies the NavigationBase to keep a list of canvases, directing the actions to the active one
36.13.6 Backward compatibility

For the **MultiFigure** properties to be visible, the user has to activate them directly setting
\[ \text{rcParams['backend.multifigure']} = \text{True} \]

It should be backwards compatible for backends that adhere to the current `FigureManagerBase` structure even if they have not implemented the **MultiFigure** magic yet.

36.13.7 Alternatives

Instead of modifying the `FigureManagerBase` it could be possible to add a parallel class, that handles the cases where \[ \text{rcParams['backend.multifigure']} = \text{True} \]. This will warranty that there won’t be any problems with custom made backends, but also makes bigger the code, and more things to maintain.

36.14 MEP24: negative radius in polar plots

None

36.14.3 Abstract

It is clear that polar plots need to be able to gracefully handle negative r values (not by clipping or reflection).
36.14.4 Detailed description

One obvious application that we should support is bB plots (see https://github.com/matplotlib/matplotlib/issues/1730#issuecomment-40815837), but this seems more generally useful (for example growth rate as a function of angle). The assumption in the current code (as I understand it) is that the center of the graph is \( r=0 \), however it would be good to be able to set the center to be at any \( r \) (with any value less than the offset clipped).

36.15.2 Branches and Pull requests

- development branches:
- related pull requests:
36.15.3 Abstract

This MEP aims at adding a serializable Controller objects to act as an Artist managers. Users would then communicate changes to an Artist via a Controller. In this way, functionality of the Controller objects may be added incrementally since each Artist is still responsible for drawing everything. The goal is to create an API that is usable both by graphing libraries requiring high-level descriptions of figures and libraries requiring low-level interpretations.

36.15.4 Detailed description

Matplotlib is a core plotting engine with an API that many users already understand. It’s difficult/impossible for other graphing libraries to (1) get a complete figure description, (2) output raw data from the figure object as the user has provided it, (3) understand the semantics of the figure objects without heuristics, and (4) give matplotlib a complete figure description to visualize. In addition, because an Artist has no conception of its own semantics within the figure, it’s difficult to interact with them in a natural way.

In this sense, matplotlib will adopt a standard Model-View-Controller (MVC) framework. The Model will be the user defined data, style, and semantics. The Views are the ensemble of each individual Artist, which are responsible for producing the final image based on the model. The Controller will be the Controller object managing its set of Artist objects.

The Controller must be able to export the information that it’s carrying about the figure on command, perhaps via a to_json method or similar. Because it would be extremely extraneous to duplicate all of the information in the model with the controller, only user-specified information (data + style) are explicitly kept. If a user wants more information (defaults) from the view/model, it should be able to query for it.

- This might be annoying to do, non-specified kwargs are pulled from the rcParams object which is in turn created from reading a user specified file and can be dynamically changed at run time. I suppose we could keep a dict of default defaults and compare against that. Not clear how this will interact with the style sheet [MEP26] - @tacaswell

Additional Notes:

- The raw data does not necessarily need to be a list, ndarray, etc. Rather, it can more abstractly just have a method to yield data when needed.
- Because the Controller will contain extra information that users may not want to keep around, it should not be created by default. You should be able to both (a) instantiate a Controller with a figure and (b) build a figure with a Controller.

Use Cases:

- Export all necessary informat
- Serializing a matplotlib figure, saving it, and being able to rerun later.
- Any other source sending an appropriately formatted representation to matplotlib to open

36.15.5 Examples

Here are some examples of what the controllers should be able to do.

1. Instantiate a matplotlib figure from a serialized representation (e.g., JSON):
import json
from matplotlib.controllers import Controller
with open('my_figure') as f:
    o = json.load(f)
    c = Controller(o)
    fig = c.figure

2. Manage artists from the controller (e.g., Line2D):

```python
# not really sure how this should look
fig.axes[0].lines[0].color = 'b'
```

3. Export serializable figure representation:

```python
o = c.to_json()
# or... we should be able to throw a figure object in there too
o = controller.to_json(mpl_fig)
```

### 36.15.6 Implementation

1. Create base `Controller` objects that are able to manage `Artist` objects (e.g., `Hist`)

   **Comments:**
   - initialization should happen via unpacking `**`, so we need a copy of call signature parameter for the `Artist` we’re ultimately trying to control. Unfortunate hard-coded repetition...
   - should the additional `**kwargs` accepted by each `Artist` be tracked at the `Controller`
   - how does a `Controller` know which artist belongs where? E.g., do we need to pass `axes` references?

   **Progress:**
   - A simple NB demonstrating some functionality for `Line2DController` objects: https://nbviewer.jupyter.org/gist/theengineear/f0aa8d79f64325e767c0

2. Write in protocols for the `Controller` to update the model.

   **Comments:**
   - how should containers be dealt with? E.g., what happens to old patches when we re-bin a histogram?
   - in the link from (1), the old line is completely destroyed and redrawn, what if something is referencing it?

3. Create method by which a json object can be assembled from the `Controllers`

4. Deal with serializing the unserializable aspects of a figure (e.g., non-affine transforms?)

5. Be able to instantiate from a serialized representation

6. Reimplement the existing `pyplot.hist` and `Axes.hist` in terms of the new controller class.
> @theengineer: in #2 above, what do you mean by *get updates* from each *Artist*?

^ Yup. The *Controller* shouldn’t need to get updated. This just happens in #3. Delete comments when you see this.

### 36.15.7 Backward compatibility

- pickling will change
- non-affine transformations will require a defined pickling method

### 36.15.8 Alternatives

PR #3150 suggested adding semantics by parasitically attaching extra containers to axes objects. This is a more complete solution with what should be a more developed/flexible/powerful framework.

#### 36.16.1 Status

Rejected
36.16.2 Branches and Pull requests

36.16.3 Abstract

This MEP proposes a new stylesheet implementation to allow more comprehensive and dynamic styling of artists.

The current version of matplotlib (1.4.0) allows stylesheets based on the rcParams syntax to be applied before creation of a plot. The methodology below proposes a new syntax, based on CSS, which would allow styling of individual artists and properties, which can be applied dynamically to existing objects.

This is related to (and makes steps toward) the overall goal of moving to a DOM/tree-like architecture.

36.16.4 Detailed description

Currently, the look and appearance of existing artist objects (figure, axes, Line2D etc...) can only be updated via set_ and get_ methods on the artist object, which is quite laborious, especially if no reference to the artist(s) has been stored. The new style sheets introduced in 1.4 allow styling before a plot is created, but do not offer any means to dynamically update plots or distinguish between artists of the same type (i.e. to specify the line color and line style separately for differing Line2D objects).

The initial development should concentrate on allowing styling of artist primitives (those artists that do not contain other artists), and further development could expand the CSS syntax rules and parser to allow more complex styling. See the appendix for a list of primitives.

The new methodology would require development of a number of steps:

- A new stylesheet syntax (likely based on CSS) to allow selection of artists by type, class, id etc...
- A mechanism by which to parse a stylesheet into a tree
- A mechanism by which to translate the parse-tree into something which can be used to update the properties of relevant artists. Ideally this would implement a method by which to traverse the artists in a tree-like structure.
- A mechanism by which to generate a stylesheet from existing artist properties. This would be useful to allow a user to export a stylesheet from an existing figure (where the appearance may have been set using the matplotlib API)...

36.16.5 Implementation

It will be easiest to allow a '3rd party' to modify/set the style of an artist if the 'style' is created as a separate class and store against the artist as a property. The GraphicsContext class already provides a the basis of a Style class and an artists draw method can be refactored to use the Style class rather than setting up it’s own GraphicsContext and transferring it’s style-related properties to it. A minimal example of how this could be implemented is shown here: https://github.com/JamesRamm/mpl_experiment

IMO, this will also make the API and code base much neater as individual get/set methods for artist style properties are now redundant... Indirectly related would be a general drive to
replace get/set methods with properties. Implementing the style class with properties would be a big stride toward this...

For initial development, I suggest developing a syntax based on a much (much much) simplified version of CSS. I am in favour of dubbing this Artist Style Sheets :+1: :

**BNF Grammar**

I propose a very simple syntax to implement initially (like a proof of concept), which can be expanded upon in the future. The BNF form of the syntax is given below and then explained

```
RuleSet ::= SelectorSequence "{"Declaration"}"
SelectorSequence ::= = Selector {"," Selector}
Declaration ::= propName":" propValue":"
Selector ::= ArtistIdent"#"Ident
propName ::= Ident
propValue ::= Ident | Number | Colour | "None"
```

ArtistIdent, Ident, Number and Colour are tokens (the basic building blocks of the expression) which are defined by regular expressions.

**Syntax**

A CSS stylesheet consists of a series of **rule sets** in hierarchical order (rules are applied from top to bottom). Each rule follows the syntax

```
selector {attribute: value;}
```

Each rule can have any number of attribute: value pairs, and a stylesheet can have any number of rules.

The initial syntax is designed only for artist primitives. It does not address the question of how to set properties on container types (whose properties may themselves be artists with settable properties), however, a future solution to this could simply be nested RuleSet s

**Selectors**

Selectors define the object to which the attribute updates should be applied. As a starting point, I propose just 2 selectors to use in initial development:

**Artist Type Selector**

Select an artist by it’s type. E.g Line2D or Text:

```
Line2D {attribute: value}
```

The regex for matching the artist type selector (ArtistIdent in the BNF grammar) would be:
ArtistIdent = r'(?P<ArtistIdent>\bLine2D|\bText|\bAxesImage|\bFigureImage|\bPatch)'

GID selector

Select an artist by its gid:

Line2D#myGID {attribute: value}

A gid can be any string, so the regex could be as follows:

Ident = r'(?P<Ident>[a-zA-Z_][a-zA-Z_0-9]*)'

The above selectors roughly correspond to their CSS counterparts (http://www.w3.org/TR/CSS21/selector.html)

Attributes and values

- Attributes are any valid (settable) property for the artist in question.
- Values are any valid value for the property (Usually a string, or number).

Parsing

Parsing would consist of breaking the stylesheet into tokens (the python cookbook gives a nice tokenizing recipe on page 66), applying the syntax rules and constructing a Tree. This requires defining the grammar of the stylesheet (again, we can borrow from CSS) and writing a parser. Happily, there is a recipe for this in the python cookbook aswell.

Visitor pattern for matplotlib figure

In order to apply the stylesheet rules to the relevant artists, we need to ‘visit’ each artist in a figure and apply the relevant rule. Here is a visitor class (again, thanks to python cookbook), where each node would be an artist in the figure. A visit_ method would need to be implemented for each mpl artist, to handle the different properties for each

```python
class Visitor:
    def visit(self, node):
        name = 'visit_' + type(node).__name__
        meth = getattr(self, name, None)
        if meth is None:
            raise NotImplementedError
        return meth(node)
```

An evaluator class would then take the stylesheet rules and implement the visitor on each one of them.
36.16.6 Backward compatibility

Implementing a separate `Style` class would break backward compatibility as many get/set methods on an artist would become redundant. While it would be possible to alter these methods to hook into the `Style` class (stored as a property against the artist), I would be in favor of simply removing them to both neaten/simplify the codebase and to provide a simple, uncluttered API...

36.16.7 Alternatives

No alternatives, but some of the ground covered here overlaps with MEP25, which may assist in this development

36.16.8 Appendix

Matplotlib primitives

This will form the initial selectors which stylesheets can use.

36.17 MEP27: decouple pyplot from backends

- Status
- Branches and Pull requests
- Abstract
- Detailed description
- Implementation
- Future compatibility
- Backward compatibility
- Alternatives
- Questions

36.17.1 Status

Progress
36.17.2 Branches and Pull requests

Main PR (including GTK3): + https://github.com/matplotlib/matplotlib/pull/4143

36.17.3 Abstract

This MEP refactors the backends to give a more structured and consistent API, removing generic code and consolidate existing code. To do this we propose splitting:

1. `FigureManagerBase` and its derived classes into the core functionality class `FigureManager` and a backend specific class `WindowBase` and
2. `ShowBase` and its derived classes into `Gcf.show_all` and `MainLoopBase`.

36.17.4 Detailed description

This MEP aims to consolidate the backends API into one single uniform API, removing generic code out of the backend (which includes `_pylab_helpers` and `Gcf`), and push code to a more appropriate level in matplotlib. With this we automatically remove inconsistencies that appear in the backends, such as `FigureManagerBase.resize(w, h)` which sometimes sets the canvas, and other times set the entire window to the dimensions given, depending on the backend.

Two main places for generic code appear in the classes derived from `FigureManagerBase` and `ShowBase`.

1. `FigureManagerBase` has three jobs at the moment:
   1. The documentation describes it as a “Helper class for pyplot mode, wraps everything up into a neat bundle”
   2. But it doesn’t just wrap the canvas and toolbar, it also does all of the windowing tasks itself. The conflation of these two tasks gets seen the best in the following line: `python self.set_window_title("Figure %d" % num)` `This combines backend specific code self.set_window_title(title) with matplotlib generic code title = "Figure %d" % num."
   3. Currently the backend specific subclass of `FigureManager` decides when to end the mainloop. This also seems very wrong as the figure should have no control over the other figures.

2. `ShowBase` has two jobs:
   1. It has the job of going through all figure managers registered in `_pylab_helpers.Gcf` and telling them to show themselves.
   2. And secondly it has the job of performing the backend specific mainloop to block the main programme and thus keep the figures from dying.
36.17.5 Implementation

The description of this MEP gives us most of the solution:

1. To remove the windowing aspect out of FigureManagerBase letting it simply wrap this new class along with the other backend classes. Create a new WindowBase class that can handle this functionality, with pass-through methods (:arrow_right:) to WindowBase. Classes that subclass WindowBase should also subclass the GUI specific window class to ensure backward compatibility (manager.window == manager.window).

2. Refactor the mainloop of ShowBase into MainLoopBase, which encapsulates the end of the loop as well. We give an instance of MainLoop to FigureManager as a key unlock the exit method (requiring all keys returned before the loop can die). Note this opens the possibility for multiple backends to run concurrently.

3. Now that FigureManagerBase has no backend specifics in it, to rename it to FigureManager, and move to a new file backend_managers.py noting that:

   1. This allows us to break up the conversion of backends into separate PRs as we can keep the existing FigureManagerBase class and its dependencies intact.

   2. and this also anticipates MEP22 where the new NavigationBase has morphed into a backend independent ToolManager.

36.17.6 Future compatibility

As eluded to above when discussing MEP 22, this refactor makes it easy to add in new generic features. At the moment, MEP 22 has to make ugly hacks to each class extending from FigureManagerBase. With this code, this only needs to get made in the single FigureManager
class. This also makes the later deprecation of `NavigationToolbar2` very straightforward, only needing to touch the single `FigureManager` class.

MEP 23 makes for another use case where this refactored code will come in very handy.

### 36.17.7 Backward compatibility

As we leave all backend code intact, only adding missing methods to existing classes, this should work seamlessly for all use cases. The only difference will lie for backends that used `FigureManager.resize` to resize the canvas and not the window, due to the standardisation of the API.

I would envision that the classes made obsolete by this refactor get deprecated and removed on the same timetable as `NavigationToolbar2`, also note that the change in call signature to the `FigureCanvasWx` constructor, while backward compatible, I think the old (imho ugly style) signature should get deprecated and removed in the same manner as everything else.

<table>
<thead>
<tr>
<th>backend</th>
<th>manager.resize(w, h)</th>

</tbody>
</table>

### 36.17.8 Alternatives

If there were any alternative solutions to solving the same problem, they should be discussed here, along with a justification for the chosen approach.

### 36.17.9 Questions

Mdehoon: Can you elaborate on how to run multiple backends concurrently?

OceanWolf: @mdehoon, as I say, not for this MEP, but I see this MEP opens it up as a future possibility. Basically the `MainLoopBase` class acts a per backend Gcf, in this MEP it tracks the number of figures open per backend, and manages the mainloops for those backends. It closes the backend specific mainloop when it detects that no figures remain open for that backend. Because of this I imagine that with only a small amount of tweaking that we can do full-multi-backend matplotlib. No idea yet why one would want to, but I leave the possibility there in `MainLoopBase`. With all the backend-code specifics refactored out of `FigureManager` also aids in this, one manager to rule them (the backends) all.

Mdehoon: @OceanWolf, OK, thanks for the explanation. Having a uniform API for the backends is very important for the maintainability of matplotlib. I think this MEP is a step in the right direction.

36.18.1 Status

Discussion

36.18.2 Branches and Pull requests

The following lists any open PRs or branches related to this MEP:

3. Deprecate passings 2D numpy arrays as input: None
5. Exposing `cbook.boxplot_stats` through `Axes.boxplot` kwargs: None
6. Remove redundant statistical kwargs in `Axes.boxplot`: None
7. Remove redundant style options in `Axes.boxplot`: None
8. Remaining items that arise through discussion: None

36.18. MEP28: Remove Complexity from `Axes.boxplot`
Abstract

Over the past few releases, the `Axes.boxplot` method has grown in complexity to support fully customizable artist styling and statistical computation. This lead to `Axes.boxplot` being split off into multiple parts. The statistics needed to draw a boxplot are computed in `cbook.boxplot_stats`, while the actual artists are drawn by `Axes.bxp`. The original method, `Axes.boxplot` remains as the most public API that handles passing the user-supplied data to `cbook.boxplot_stats`, feeding the results to `Axes.bxp`, and pre-processing style information for each facet of the boxplot plots.

This MEP will outline a path forward to rollback the added complexity and simplify the API while maintaining reasonable backwards compatibility.

Detailed description

Currently, the `Axes.boxplot` method accepts parameters that allow the users to specify medians and confidence intervals for each box that will be drawn in the plot. These were provided so that advanced users could provide statistics computed in a different fashion than the simple method provided by matplotlib. However, handling this input requires complex logic to make sure that the forms of the data structure match what needs to be drawn. At the moment, that logic contains 9 separate if/else statements nested up to 5 levels deep with a for loop, and may raise up to 2 errors. These parameters were added prior to the creation of the `Axes.bxp` method, which draws boxplots from a list of dictionaries containing the relevant statistics. Matplotlib also provides a function that computes these statistics via `cbook.boxplot_stats`. Note that advanced users can now either a) write their own function to compute the stats required by `Axes.bxp`, or b) modify the output returned by `cbook.boxplot_stats` to fully customize the position of the artists of the plots. With this flexibility, the parameters to manually specify only the medians and their confidence intervals remain for backwards compatibility.

Around the same time that the two roles of `Axes.boxplot` were split into `cbook.boxplot_stats` for computation and `Axes.bxp` for drawing, both `Axes.boxplot` and `Axes.bxp` were written to accept parameters that individually toggle the drawing of all components of the boxplots, and parameters that individually configure the style of those artists. However, to maintain backwards compatibility, the `sym` parameter (previously used to specify the symbol of the fliers) was retained. This parameter itself requires fairly complex logic to reconcile the `sym` parameters with the newer `flierprops` parameter at the default style specified by `matplotlibrc`.

This MEP seeks to dramatically simplify the creation of boxplots for novice and advanced users alike. Importantly, the changes proposed here will also be available to downstream packages like seaborn, as seaborn smartly allows users to pass arbitrary dictionaries of parameters through the seaborn API to the underlying matplotlib functions.

This will be achieved in the following way:

1. `cbook.boxplot_stats` will be modified to allow pre- and post- computation transformation functions to be passed in (e.g., `np.log` and `np.exp` for lognormally distributed data)

2. `Axes.boxplot` will be modified to also accept and naively pass them to `cbook.boxplot_stats` (Alt: pass the stat function and a dict of its optional parameters).

3. Outdated parameters from `Axes.boxplot` will be deprecated and later removed.
Importance

Since the limits of the whiskers are computed arithmetically, there is an implicit assumption of normality in box and whisker plots. This primarily affects which data points are classified as outliers.

Allowing transformations to the data and the results used to draw boxplots will allow users to opt-out of that assumption if the data are known to not fit a normal distribution.

Below is an example of how `Axes.boxplot` classifies outliers of lognormal data differently depending one these types of transforms.

```python
import numpy as np
import matplotlib.pyplot as plt
from matplotlib import cbook

np.random.seed(0)

fig, ax = plt.subplots(figsize=(4, 6))
ax.set_yscale('log')
data = np.random.lognormal(-1.75, 2.75, size=37)

stats = cbook.boxplot_stats(data, labels=['arithmetic'])
logstats = cbook.boxplot_stats(np.log(data), labels=['log-transformed'])

for lsdict in logstats:
    for key, value in lsdict.items():
        if key != 'label':
            lsdict[key] = np.exp(value)

stats.extend(logstats)
ax.bxp(stats)
fig.show()
```

36.18.5 Implementation

Passing transform functions to `cbook.boxplots_stats`

This MEP proposes that two parameters (e.g., `transform_in` and `transform_out` be added to the cookbook function that computes the statistics for the boxplot function. These will be optional keyword-only arguments and can easily be set to `lambda x: x` as a no-op when omitted by the user. The `transform_in` function will be applied to the data as the `boxplot_stats` function loops through each subset of the data passed to it. After the list of statistics dictionaries are computed the `transform_out` function is applied to each value in the dictionaries.

These transformations can then be added to the call signature of `Axes.boxplot` with little impact to that method’s complexity. This is because they can be directly passed to `cbook.boxplot_stats`. Alternatively, `Axes.boxplot` could be modified to accept an optional statistical function kwarg and a dictionary of parameters to be directly passed to it.

At this point in the implementation users and external libraries like seaborn would have complete control via the `Axes.boxplot` method. More importantly, at the very least, seaborn would require no changes to its API to allow users to take advantage of these new options.
Matplotlib, Release 3.1.1

Chapter 36. Matplotlib Enhancement Proposals
Simplifications to the `Axes.boxplot` API and other functions

Simplifying the boxplot method consists primarily of deprecating and then removing the redundant parameters. Optionally, a next step would include rectifying minor terminological inconsistencies between `Axes.boxplot` and `Axes.bxp`.

The parameters to be deprecated and removed include:

1. `usermedians` - processed by 10 SLOC, 3 if blocks, a for loop
2. `conf_intervals` - handled by 15 SLOC, 6 if blocks, a for loop
3. `sym` - processed by 12 SLOC, 4 if blocks

Removing the `sym` option allows all code in handling the remaining styling parameters to be moved to `Axes.bxp`. This doesn’t remove any complexity, but does reinforce the single responsibility principle among `Axes.bxp`, `cbook.boxplot_stats`, and `Axes.boxplot`.

Additionally, the `notch` parameter could be renamed `shownotches` to be consistent with `Axes.bxp`. This kind of cleanup could be taken a step further and the `whis`, `bootstrap`, `autorange` could be rolled into the kwargs passed to the new `statfxn` parameter.

36.18.6 Backward compatibility

Implementation of this MEP would eventually result in the backwards incompatible deprecation and then removal of the keyword parameters `usermedians`, `conf_intervals`, and `sym`. Cursory searches on GitHub indicated that `usermedians`, `conf_intervals` are used by few users, who all seem to have a very strong knowledge of matplotlib. A robust deprecation cycle should provide sufficient time for these users to migrate to a new API.

Deprecation of `sym` however, may have a much broader reach into the matplotlib userbase.

Schedule

An accelerated timeline could look like the following:

1. v2.0.1 add transforms to `cbook.boxplots_stats`, expose in `Axes.boxplot`
2. v2.1.0 Initial Deprecations, and using 2D numpy arrays as input
   a. Using 2D numpy arrays as input. The semantics around 2D arrays are generally confusing.
   b. `usermedians`, `conf_intervals`, `sym` parameters
3. v2.2.0
   a. remove `usermedians`, `conf_intervals`, `sym` parameters
   b. deprecate `notch` in favor of `shownotches` to be consistent with other parameters and `Axes.bxp`
4. v2.3.0
   a. remove `notch` parameter
   b. move all style and artist toggling logic to `Axes.bxp` such `Axes.boxplot` is little more than a broker between `Axes.bxp` and `cbook.boxplots_stats`
Anticipated Impacts to Users

As described above deprecating `usermedians` and `conf_intervals` will likely impact few users. Those who will be impacted are almost certainly advanced users who will be able to adapt to the change.

Deprecating the `sym` option may import more users and effort should be taken to collect community feedback on this.

Anticipated Impacts to Downstream Libraries

The source code (GitHub master as of 2016-10-17) was inspected for seaborn and python-ggplot to see if these changes would impact their use. None of the parameters nominated for removal in this MEP are used by seaborn. The seaborn APIs that use matplotlib’s boxplot function allow user’s to pass arbitrary `**kwargs` through to matplotlib’s API. Thus seaborn users with modern matplotlib installations will be able to take full advantage of any new features added as a result of this MEP.

Python-ggplot has implemented its own function to draw boxplots. Therefore, no impact can come to it as a result of implementing this MEP.

36.18.7 Alternatives

Variations on the theme

This MEP can be divided into a few loosely coupled components:

1. Allowing pre- and post-computation transformation function in `cbook.boxplot_stats`
2. Exposing that transformation in the `Axes.boxplot` API
3. Removing redundant statistical options in `Axes.boxplot`
4. Shifting all styling parameter processing from `Axes.boxplot` to `Axes.bxp`.

With this approach, #2 depends and #1, and #4 depends on #3.

There are two possible approaches to #2. The first and most direct would be to mirror the new `transform_in` and `transform_out` parameters of `cbook.boxplot_stats` in `Axes.boxplot` and pass them directly.

The second approach would be to add `statfxn` and `statfxn_args` parameters to `Axes.boxplot`. Under this implementation, the default value of `statfxn` would be `cbook.boxplot_stats`, but users could pass their own function. Then `transform_in` and `transform_out` would then be passed as elements of the `statfxn_args` parameter.

```python
def boxplot_stats(data, ..., transform_in=None, transform_out=None):
    if transform_in is None:
        transform_in = lambda x: x

    if transform_out is None:
        transform_out = lambda x: x

    output = []
    for _d in data:
        (continues on next page)```
d = transform_in(d)
stat_dict = do_stats(d)
for key, value in stat_dict.items():
    if key != 'label':
        stat_dict[key] = transform_out(value)
output.append(d)
return output

class Axes(...):
    def boxplot_option1(data, ..., transform_in=None, transform_out=None):
        stats = cbook.boxplot_stats(data, ...,
                                   transform_in=transform_in,
                                   transform_out=transform_out)
        return self.bxp(stats, ...)
    def boxplot_option2(data, ..., statfxn=None, **statopts):
        if statfxn is None:
            statfxn = boxplot_stats
        stats = statfxn(data, **statopts)
        return self.bxp(stats, ...)

Both cases would allow users to do the following:

```python
fig, ax1 = plt.subplots()
artists1 = ax1.boxplot_optionX(data, transform_in=np.log,
                                transform_out=np.exp)
```

But Option Two lets a user write a completely custom stat function (e.g., `my_box_stats`) with fancy BCA confidence intervals and the whiskers set differently depending on some attribute of the data.

This is available under the current API:

```python
fig, ax1 = plt.subplots()
my_stats = my_box_stats(data, bootstrap_method='BCA',
                        whisker_method='dynamic')
ax1.bxp(my_stats)
```

And would be more concise with Option Two

```python
fig, ax = plt.subplots()
statopts = dict(transform_in=np.log, transform_out=np.exp)
ax.boxplot(data, ..., **statopts)
```

Users could also pass their own function to compute the stats:

```python
fig, ax1 = plt.subplots()
ax1.boxplot(data, statfxn=my_box_stats, bootstrap_method='BCA',
            whisker_method='dynamic')
```

From the examples above, Option Two seems to have only marginal benefit, but in the context of downstream libraries like seaborn, its advantage is more apparent as the following would be possible without any patches to seaborn:
```python
import seaborn
tips = seaborn.load_data('tips')
g = seaborn.factorplot(x="day", y="total_bill", hue="sex", data=tips,
    kind='box', palette="PRGn", shownotches=True,
    statfn=my_box_stats, bootstrap_method='BCA',
    whisker_method='dynamic')
```

This type of flexibility was the intention behind splitting the overall boxplot API in the current three functions. In practice however, downstream libraries like seaborn support versions of matplotlib dating back well before the split. Thus, adding just a bit more flexibility to the `Axes.boxplot` could expose all the functionality to users of the downstream libraries with modern matplotlib installation without intervention from the downstream library maintainers.

**Doing less**

Another obvious alternative would be to omit the added pre- and post- computation transform functionality in `cbook.boxplot_stats` and `Axes.boxplot`, and simply remove the redundant statistical and style parameters as described above.

**Doing nothing**

As with many things in life, doing nothing is an option here. This means we simply advocate for users and downstream libraries to take advantage of the split between `cbook.boxplot_stats` and `Axes.boxplot` and let them decide how to provide an interface to that.

### 36.19 MEP29: Text light markup

- **Status**
- **Branches and Pull requests**
- **Abstract**
- **Detailed description**
- **Implementation**
  - **Improvements**
  - **Problems**
- **Backward compatibility**
- **Alternatives**

#### 36.19.1 Status

Discussion
36.19.2 Branches and Pull requests

None at the moment, proof of concept only.

36.19.3 Abstract

This MEP proposes to add lightweight markup to the text artist.

36.19.4 Detailed description

Using different size/color/family in a text annotation is difficult because the `text` method accepts argument for size/color/family/weight/etc. that are used for the whole text. But, if one wants, for example, to have different colors, one has to look at the gallery where one such example is provided: http://matplotlib.org/examples/text_labels_and_annotations/rainbow_text.html

This example takes a list of strings as well as a list of colors which makes it cumbersome to use. An alternative would be to use a restricted set of pango-like markup (see https://developer.gnome.org/pango/stable/PangoMarkupFormat.html) and to interpret this markup.

Some markup examples:

```markdown
Hello <b>world!</b>
Hello <span color="blue">world!</span>
```

36.19.5 Implementation

A proof of concept is provided in `markup_example.py` but it currently only handles the horizontal direction.

Improvements

- This proof of concept uses regex to parse the text but it may be better to use the `html.parser` from the standard library.
- Computation of text fragment positions could benefit from the OffsetFrom class. See for example item 5 in Using Complex Coordinates with Annotations

Problems

- One serious problem is how to deal with text having both latex and html-like tags. For example, consider the following:

```latex
$<$b>Bold$</b>
```

Recommendation would be to have mutual exclusion.
36.19.6 Backward compatibility

None at the moment since it is only a proof of concept

36.19.7 Alternatives

As proposed by @anntzer, this could be also implemented as improvements to mathtext. For example:

\textbf{world}
\textcolor{blue}{world}
{textsf{\small world}}
Matplotlib only uses BSD compatible code. If you bring in code from another project make sure it has a PSF, BSD, MIT or compatible license (see the Open Source Initiative licenses page for details on individual licenses). If it doesn’t, you may consider contacting the author and asking them to relicense it. GPL and LGPL code are not acceptable in the main code base, though we are considering an alternative way of distributing L/GPL code through an separate channel, possibly a toolkit. If you include code, make sure you include a copy of that code’s license in the license directory if the code’s license requires you to distribute the license with it. Non-BSD compatible licenses are acceptable in matplotlib toolkits (e.g., basemap), but make sure you clearly state the licenses you are using.

37.1 Why BSD compatible?

The two dominant license variants in the wild are GPL-style and BSD-style. There are countless other licenses that place specific restrictions on code reuse, but there is an important difference to be considered in the GPL and BSD variants. The best known and perhaps most widely used license is the GPL, which in addition to granting you full rights to the source code including redistribution, carries with it an extra obligation. If you use GPL code in your own code, or link with it, your product must be released under a GPL compatible license. i.e., you are required to give the source code to other people and give them the right to redistribute it as well. Many of the most famous and widely used open source projects are released under the GPL, including linux, gcc, emacs and sage.

The second major class are the BSD-style licenses (which includes MIT and the python PSF license). These basically allow you to do whatever you want with the code: ignore it, include it in your own open source project, include it in your proprietary product, sell it, whatever. python itself is released under a BSD compatible license, in the sense that, quoting from the PSF license page:

There is no GPL-like "copyleft" restriction. Distributing binary-only versions of Python, modified or not, is allowed. There is no requirement to release any of your source code. You can also write extension modules for Python and provide them only in binary form.

Famous projects released under a BSD-style license in the permissive sense of the last paragraph are the BSD operating system, python and TeX.

There are several reasons why early matplotlib developers selected a BSD compatible license. matplotlib is a python extension, and we choose a license that was based on the python license (BSD compatible). Also, we wanted to attract as many users and developers as possible, and
many software companies will not use GPL code in software they plan to distribute, even those that are highly committed to open source development, such as enthought, out of legitimate concern that use of the GPL will “infect” their code base by its viral nature. In effect, they want to retain the right to release some proprietary code. Companies and institutions who use matplotlib often make significant contributions, because they have the resources to get a job done, even a boring one. Two of the matplotlib backends (FLTK and WX) were contributed by private companies. The final reason behind the licensing choice is compatibility with the other python extensions for scientific computing: ipython, numpy, scipy, the enthought tool suite and python itself are all distributed under BSD compatible licenses.
As discussed at length elsewhere, \texttt{jet} is an empirically bad color map and should not be the default color map. Due to the position that changing the appearance of the plot breaks backward compatibility, this change has been put off for far longer than it should have been. In addition to changing the default color map we plan to take the chance to change the default color-cycle on plots and to adopt a different color map for filled plots (\texttt{imshow}, \texttt{pcolor}, \texttt{contourf}, etc) and for scatter like plots.

38.1 Default Heat Map Colormap

The choice of a new color map is fertile ground to bike-shedding (“No, it should be \_this\_ color”) so we have a proposed set criteria (via Nathaniel Smith) to evaluate proposed color maps.

- it should be a sequential colormap, because diverging colormaps are really misleading unless you know where the “center” of the data is, and for a default colormap we generally won’t.
- it should be perceptually uniform, i.e., human subjective judgments of how far apart nearby colors are should correspond as linearly as possible to the difference between the numerical values they represent, at least locally.
- it should have a perceptually uniform luminance ramp, i.e. if you convert to greyscale it should still be uniform. This is useful both in practical terms (greyscale printers are still a thing!) and because luminance is a very strong and natural cue to magnitude.
- it should also have some kind of variation in hue, because hue variation is a really helpful additional cue to perception, having two cues is better than one, and there’s no reason not to do it.
- the hue variation should be chosen to produce reasonable results even for viewers with the more common types of colorblindness. (Which rules out things like red-to-green.)
- For bonus points, it would be nice to choose a hue ramp that still works if you throw away the luminance variation, because then we could use the version with varying luminance for 2d plots, and the version with just hue variation for 3d plots. (In 3d plots you really want to reserve the luminance channel for lighting/shading, because your brain is really good at extracting 3d shape from luminance variation. If the 3d surface itself has massively varying luminance then this screws up the ability to see shape.)
- Not infringe any existing IP
38.1.1 Example script

38.1.2 Proposed Colormaps

38.2 Default Scatter Colormap

For heat-map like applications it can be desirable to cover as much of the luminence scale as possible, however when color mapping markers, having markers too close to white can be a problem. For that reason we propose using a different (but maybe related) color map to the heat map for marker-based. The design parameters are the same as above, only with a more limited luminence variation.

38.2.1 Example script

```python
import numpy as np
import matplotlib.pyplot as plt

np.random.seed(1234)

fig, (ax1, ax2) = plt.subplots(1, 2)

N = 50
x = np.random.rand(N)
y = np.random.rand(N)
colors = np.random.rand(N)
area = np.pi * (15 * np.random.rand(N))**2  # 0 to 15 point radiuses

ax1.scatter(x, y, s=area, c=colors, alpha=0.5)

X,Y = np.meshgrid(np.arange(0, 2*np.pi, .2),
                   np.arange(0, 2*np.pi, .2))
U = np.cos(X)
V = np.sin(Y)
Q = ax2.quiver(X, Y, U, V, units='width')
qd = np.random.rand(np.prod(X.shape))
Q.set_array(qd)
```

38.2.2 Proposed Colormaps

38.3 Color Cycle / Qualitative color map

When plotting lines it is frequently desirable to plot multiple lines or artists which need to be distinguishable, but there is no inherent ordering.
38.3.1 Example script

```python
import numpy as np
import matplotlib.pyplot as plt

fig, (ax1, ax2) = plt.subplots(1, 2)

x = np.linspace(0, 1, 10)

for j in range(10):
    ax1.plot(x, x * j)

th = np.linspace(0, 2*np.pi, 1024)
for j in np.linspace(0, np.pi, 10):
    ax2.plot(th, np.sin(th + j))

ax2.set_xlim(0, 2*np.pi)
```

38.3.2 Proposed Color cycle
Part VII

Glossary
AGG The Anti-Grain Geometry (Agg) rendering engine, capable of rendering high-quality images

Cairo The Cairo graphics engine

dateutil The dateutil library provides extensions to the standard datetime module

EPS Encapsulated Postscript (EPS)

FreeType FreeType is a font rasterization library used by matplotlib which supports TrueType, Type 1, and OpenType fonts.

GDK The Gimp Drawing Kit for GTK+

GTK The GIMP Toolkit (GTK) graphical user interface library

JPg The Joint Photographic Experts Group (JPEG) compression method and file format for photographic images

numpy numpy is the standard numerical array library for python, the successor to Numeric and numarray. numpy provides fast operations for homogeneous data sets and common mathematical operations like correlations, standard deviation, fourier transforms, and convolutions.

PDF Adobe’s Portable Document Format (PDF)

PNG Portable Network Graphics (PNG), a raster graphics format that employs lossless data compression which is more suitable for line art than the lossy jpg format. Unlike the gif format, png is not encumbered by requirements for a patent license.

PS Postscript (PS) is a vector graphics ASCII text language widely used in printers and publishing. Postscript was developed by adobe systems and is starting to show its age: for example is does not have an alpha channel. PDF was designed in part as a next-generation document format to replace postscript.

PyGObject PyGObject provides Python wrappers for the GTK widgets library

pyqt pyqt provides python wrappers for the Qt widgets library and is required by the matplotlib Qt5Agg and Qt4Agg backends. Widely used on linux and windows; many linux distributions package this as ‘python-qt5’ or ‘python-qt4’.

python python is an object oriented interpreted language widely used for scripting, application development, web application servers, scientific computing and more.

Qt Qt is a cross-platform application framework for desktop and embedded development.

Qt4 Qt4 is the previous, but most widely used, version of Qt cross-platform application framework for desktop and embedded development.

Qt5 Qt5 is the current version of Qt cross-platform application framework for desktop and embedded development.

Raster graphics Raster graphics, or bitmaps, represent an image as an array of pixels which is resolution dependent. Raster graphics are generally most practical for photo-realistic images, but do not scale easily without loss of quality.

SVG The Scalable Vector Graphics format (SVG). An XML based vector graphics format supported by many web browsers.

TIFF Tagged Image File Format (TIFF) is a file format for storing images, including photographs and line art.

Tk Tk is a graphical user interface for Tcl and many other dynamic languages. It can produce rich, native applications that run unchanged across Windows, Mac OS X, Linux and more.
**vector graphics** vector graphics use geometrical primitives based upon mathematical equations to represent images in computer graphics. Primitives can include points, lines, curves, and shapes or polygons. Vector graphics are scalable, which means that they can be resized without suffering from issues related to inherent resolution like are seen in raster graphics. Vector graphics are generally most practical for typesetting and graphic design applications.

**wxpython** wxpython provides python wrappers for the wxWidgets library for use with the WX and WXAgg backends. Widely used on linux, OS-X and windows, it is often packaged by linux distributions as ‘python-wxgtk’

**wxWidgets** WX is cross-platform GUI and tools library for GTK, MS Windows, and MacOS. It uses native widgets for each operating system, so applications will have the look-and-feel that users on that operating system expect.
